Syntax Conventions

These are the syntax conventions used throughout the Vertica documentation.

Syntax Convention	Description
Text without brackets or braces	Content that you type as shown, such as CREATE TABLE.
<i>table name</i>	Italics: Descriptive placeholder text that you replace with an appropriate identifier or expression.
{ param1, param2 }	Curly braces: Required parameters or arguments. For example: LIGHT_STATUS { ON OFF DIMMED} indicates that the syntax requires you to specify one value (ON, OFF, or DIMMED).
{ this that }	Vertical bar: A separator for two or more mutually exclusive items. Such items can be optional (in square brackets), or required (in curly braces). You must enter one of the given values: { ASC DESC } With square brackets, you can choose one, or neither.
[<i>param1</i>]	Square brackets: Optional statement items. For example, CREATE TABLE [<i>schema_name.</i>] <i>table_name</i> indicates that <i>schema_name.</i> is optional.
<i>column_def</i> [, ...]	Square brackets with comma and ellipses (,...): A parameter option that you can repeat. For example, <i>column_def</i> [, ...] means you can specify one or more comma-separated <i>column_def</i> options.
<i>start_json_display</i> . . . <i>end_display</i>	Vertical ellipses: Indicate text intentionally omitted for readability, such as in an example of multi-row result sets.
Indentation	Indented text: Formatting to maximize readability for

Syntax Convention	Description
	syntax sub-options. Indentation is never required, since SQL is a free-form language.

Vertica 8.1.x Supported Platforms

Welcome to Vertica Analytics Platform Supported Platforms. This document details platform support for the various components of Vertica 8.1.x.

Vertica Server and Vertica Management Console

Supported Operating Systems and Operating System Versions

Micro Focus International plc supports Vertica Analytics Platform 8.1.x running on the following 64-bit operating systems and versions on x86_x64 architecture.

Important: This document reflects what has been tested with Vertica Analytics Platform 8.1.x. Be aware that operating system vendors and communities release updates and patches for all versions of their operating systems on their own schedules. Such updates to these operating systems may or may not coincide with the release schedule for Vertica. While other versions of the operating systems listed may have been successfully deployed by customers in their environments, stability and performance of these configurations may vary. If you choose to run Vertica on an operating system version not listed in this document and experience an issue, the Vertica Support team may ask you to reproduce the issue using one of the configurations described in this document to aid in troubleshooting. Depending on the details of the case, the Support team may also ask you to enter a support ticket with your operating system vendor.

When there are multiple minor versions supported for a major operating system release, Micro Focus recommends that you run Vertica on the latest minor version listed in the supported versions list. For example, if you run Vertica on a Red Hat Enterprise Linux 7.x release, Micro Focus International plc recommends you upgrade to or be running the latest supported RHEL 7.x release, which is 7.4.

Red Hat Enterprise Linux

- Versions 6.6, 6.7, 6.8, 6.9*, 7.0, 7.3, 7.4*

*Vertica 8.1.1-7 and later 8.1.1 hotfixes support Red Hat Enterprise Linux 6.9 and 7.4.

Important: You cannot perform an in-place upgrade of your current Vertica Analytics Platform from Red Hat Enterprise Linux 6.6–6.9 to Red Hat Enterprise Linux 7.0/7.3/7.4. For

information on how to upgrade to Red Hat Enterprise Linux 7, see the [Upgrading Your Operating System on Nodes in Your Vertica Cluster](#). For information on changes to the operating system for Red Hat Enterprise Linux 7, see the [Red Hat Enterprise Linux 7 documentation](#).

CentOS

- Versions 6.6, 6.7, 6.8, 6.9*, 7.0, 7.3, 7.4*

*Vertica 8.1.1-7 and later 8.1.1 hotfixes support CentOS 6.9 and 7.4.

Important: You cannot perform an in-place upgrade of your current Vertica Analytics Platform from CentOS 6.6–6.9 to CentOS 7.0/7.3/7.4. For information on how to upgrade to CentOS 7.0/7.3/7.4, see the [Upgrading Your Operating System on Nodes in Your Vertica Cluster](#).

SUSE Linux Enterprise Server

- Version 11.0 SP3*

*Vertica 8.1.1 supports SUSE V11SP3. In the upcoming releases, Vertica will phase out support for SUSE V11SP3 and replace it with support for SUSE 12SP2. See [End-of-Support and Deprecation Notices](#) for more information.

Note: SUSE Linux Enterprise Server (SLES) 11.0 Service Pack 3 (SP3) supports the ext3 file system.

Oracle Enterprise Linux

Vertica supports the following Oracle Enterprise Linux (OEL) versions. Vertica only supports Red Hat Compatible Kernels. Vertica is not supported on unbreakable kernels (kernels with a *uel* suffix).

- Versions 6.7, 6.8, 7.3, 7.4*

*Vertica 8.1.1-7 and later 8.1.1 hotfixes support Red Hat Enterprise Linux 6.9 and 7.4.

Debian Linux

- Versions 7.6, 7.7, 8.5, 8.9*

*Vertica 8.1.1-7 and later 8.1.1 hotfixes support Debian Linux 8.9.

Ubuntu

- Version 12.04 LTS*
- Version 14.04 LTS

*Micro Focus is phasing out support for Vertica on Ubuntu 12.04 LTS. See [End-of-Support and Deprecation Notices](#) for more information.

Supported File Systems

Vertica Analytics Platform Enterprise Edition has been tested on all supported Linux platforms running the ext4 file system. For the Vertica Analytics Platform I/O profile, the ext4 file system is considerably faster than ext3.

While other file systems have been successfully deployed by some customers, Vertica Analytics Platform cannot guarantee performance or stability of the product on these file systems. In certain support situations, you may be asked to migrate off of these unsupported file systems to help you troubleshoot or fix an issue. In particular, several file corruption issues have been linked to the use of XFS with Vertica; Micro Focus strongly recommends not using it in production.

Vertica Analytics Platform supports Linux Volume Manager (LVM) on all supported operating systems. Your LVM version must be 2.02.66 or later, and must include device-mapper version 1.02.48 or later. For information on requirements and restrictions, see the section, [Vertica Support for LVM](#).

Supported Browsers for Vertica Management Console

Vertica Analytics Platform 8.1.x Management Console is supported on the following web browsers:

- Internet Explorer 10 and later
- Firefox 31 and later
- Google Chrome 38 and later

Vertica Server and Management Console Compatibility

Management Console (MC) 8.1.x is compatible with the latest hotfix version of Vertica server 7.2.3 and above.

Vertica 8.1.x Client Drivers

Vertica provides JDBC, ODBC, OLE DB, Python, vsql, and ADO.NET client drivers. Download the latest drivers from: [Vertica Client Drivers](#). Choose from these drivers:

- Linux and UNIX-like platforms: ODBC, JDBC, Python, and vsql clients. See [Installing the Client Drivers on Linux and UNIX-Like Platforms](#).
- Windows platforms: ODBC, ADO.NET, and OLE DB client drivers, the vsql client, the Microsoft Connectivity Pack, and the Visual Studio plug-in. See [Installing the Client Drivers and Tools on Windows](#).
- Mac OS X platforms: ODBC and vsql clients. See [Installing the Client Drivers on Mac OS X](#).
- The cross-platform JDBC client driver .jar file available for installation on all platforms.

To view a list of driver and server version compatibility, see [Vertica Analytics Platform Driver/Server Compatibility](#).

ADO.NET and OLE DB Drivers

The ADO.NET and OLE DB drivers are supported on the following platforms:

Platform	Processor	Supported Versions	.NET Requirements
Microsoft Windows	x86 (32-bit)	Windows 7 Windows 8 Windows 10	Microsoft .NET Framework 3.5 SP1 or later
Microsoft Windows	x64 (64-bit)	Windows 7 Windows 8 Windows 10	
Microsoft Windows Server	x64 (64-bit)	2012 2012 R2 2016	

JDBC Driver

All non-FIPS JDBC drivers are supported on any Java 5-compliant platform. (Java 5 is the minimum.)

The Vertica 8.1.x FIPS-enabled JDBC driver requires RHEL 6.6.

Python Driver

The Python driver requires Python version 2.7.x, and is supported on the following platforms:

Platform	Processor	Supported Versions
Red Hat Enterprise Linux	x86_64	6.6, 6.7, 6.8, 6.9*, 7.0, 7.3, 7.4*
CentOS	x86_64	6.6, 6.7, 6.8, 6.9*, 7.0, 7.3, 7.4*
SUSE Linux Enterprise	x86_64	11.0 SP3**, 12 SP2
Oracle Enterprise Linux (Red Hat Compatible Kernel only)	x86_64	6.7, 6.8, 7.3, 7.4*
Debian Linux	x86_64	7.6, 7.7, 8.5, 8.9*
Ubuntu	x86_64	12.04 LTS** 14.04 LTS

*Vertica 8.1.1-7 and later 8.1.1 hotfixes support Red Hat Enterprise Linux 6.9, 7.4, CentOS 6.9, 7.4, Oracle Enterprise Linux 7.4, and Debian Linux 8.9.

**Micro Focus is phasing out support for this operating system. See [End-of-Support and Deprecation Notices](#) for more information.

ODBC Driver

Vertica Analytics Platform provides both 32-bit and 64-bit ODBC drivers. Vertica 8.1.x ODBC drivers are supported on the following platforms:

Platform	Processor	Supported Versions	Driver Manager
Microsoft Windows	x86 (32-bit)	Windows 7 Windows 8 Windows 10	Microsoft ODBC MDAC 2.8
Microsoft Windows	x64 (64-bit)	Windows 7 Windows 8 Windows 10	
Microsoft Windows Server	x64 (64-bit)	2012 2012 R2 2016	
Red Hat Enterprise Linux	x86_64	6.6, 6.7, 6.8, 6.9*, 7.0, 7.3, 7.4*	iODBC 3.52.6 and higher unixODBC 2.3.0 and higher DataDirect 5.3 and 6.1 and higher
CentOS	x86_64	6.6, 6.7, 6.8, 6.9*, 7.0, 7.3, 7.4*	
FIPS-compliant Red Hat Enterprise Linux	x86_64	6.6	
SUSE Linux Enterprise	x86_64	11.0 SP3*, 12 SP2	
Oracle Enterprise Linux (Red Hat Compatible Kernel only)	x86_64	6.7, 6.8, 7.3, 7.4*	
Ubuntu	x86_64	12.04 LTS**	

Platform	Processor	Supported Versions	Driver Manager
		14.04 LTS	
Debian Linux	x86_64	7.6, 7.7, 8.5, 8.9*	
AIX	PowerPC-64	7.1	
HP-UX	IA-64	11i V3**	
Solaris	SPARC-64	10	
Mac OS X	x86_64	10.10, 10.11, 10.12	

*Vertica 8.1.1-7 and later 8.1.1 hotfixes support Red Hat Enterprise Linux 6.9, 7.4, CentOS 6.9, 7.4, Oracle Enterprise Linux 7.4, and Debian Linux 8.9.

** Micro Focus is phasing out support on this operating system. See [End-of-Support and Deprecation Notices](#) for more information.

Vertica Analytics Platform Driver/Server Compatibility

This section provides information on compatibility for the Vertica Analytics Platform driver and server versions.

Note: SHA password security is supported on client driver and server versions 7.1.x and later.

The following table indicates that, in general, all clients are forward compatible.

Client	Client Driver Version	Compatible Server Versions
All Clients	6.1.x	6.1.x, 7.0.x, 7.1.x, 7.2.x, 8.0.x, 8.1.x
	7.0.x	7.0.x, 7.1.x, 7.2.x, 8.0.x, 8.1.x
	7.1.x	7.1.x, 7.2.x, 8.0.x, 8.1.x
	7.2.x	7.2.x, 8.0.x, 8.1.x
	8.0.x	8.0.x, 8.1.x
	8.1.x	8.1.x

The following table lists FIPS 140-2 compatible clients.

Client	Client Driver Version	Compatible Server Versions
FIPS-enabled ODBC	8.0.x	8.0.x, 8.1.x
FIPS-enabled ODBC	8.1.x	8.0.x, 8.1.x
FIPS-enabled JDBC	8.1.x	8.1.x

The following table indicates that the 8.1.x ODBC client is backward compatible.

Client	Client Driver Version	Compatible Server Versions
ODBC (backwards compatibility)	8.1.x	7.1.x, 7.2.x, 8.0.x, 8.1.x

Note: Vertica Release 8.1.x and later adds backwards compatibility for the ODBC client driver. The 8.1.x ODBC client driver is backwards compatible to Vertica server version 7.1. For full compatibility with the previous server version, specify the Protocol property in your connection string. For more information about the Protocol property, see [Data Source Name \(DSN\) Connection Properties](#).

vsqI Client

The Vertica vsqI client is included in all client packages; it is not available for download separately. The vsqI client is supported on the following platforms:

Operating System	Processor
Microsoft Windows <ul style="list-style-type: none">Windows 2012, 2012 R2, 2016, all variantsWindows 7, all variantsWindows 8, all variantsWindows 10	x86, x64
Red Hat Enterprise Linux 6.6, 6.7, 6.8, 6.9*, 7.0, 7.3, 7.4*	x86, x64
CentOS 6.6, 6.7, 6.8, 6.9*, 7.0, 7.3, 7.4*	x86, x64
FIPS-compliant Red Hat Enterprise Linux 6.6	x64
Oracle Enterprise Linux 6.7, 6.8, 7.3, 7.4* (Red Hat Compatible Kernels only)	x86, x64
Ubuntu 12.04LTS**, 14.04 LTS	x86, x64
Debian Linux 7.6, 7.7, 8.5, 8.9*	x86, x64
Solaris 10	SPARC-64
AIX 7.1	PowerPC-64
HP-UX 11i V3	IA64
Mac OS X 10.10, 10.11, 10.12	x86, x64

*Vertica 8.1.1-7 and later 8.1.1 hotfixes support Red Hat Enterprise Linux 6.9, 7.4, CentOS 6.9, 7.4, Oracle Enterprise Linux 7.4, and Debian Linux 8.9.

**Micro Focus is phasing out support for these operating systems. See [End-of-Support and Deprecation Notices](#) for more information.

Perl and Python Requirements

You can use Vertica's ODBC driver to connect applications written in Perl or Python to the Vertica Analytics Platform.

Perl

To use Perl with Vertica, you must install the Perl driver modules (DBI and DBD::ODBC) and a Vertica ODBC driver on the machine where Perl is installed. The following table lists the Perl versions supported with Vertica 8.1.x.

Perl Version	Perl Driver Modules	ODBC Requirements
<ul style="list-style-type: none">• 5.8• 5.10	<ul style="list-style-type: none">• DBI driver version 1.609• DBD::ODBC version 1.22	See Vertica 8.1.x Client Drivers .

Python

To use Python with Vertica, you must install the Vertica Python Client or the pyodbc module and a Vertica ODBC driver on the machine where Python is installed. The following table lists the Python versions supported with Vertica 8.1.x:

Python Version	Python Driver Module	ODBC Requirements
2.4.6	pyodbc 2.1.6	See Vertica 8.1.x Client Drivers .
2.7.x	Vertica Python Client (Linux only)	
2.7.3	pyodbc 3.0.6	
3.3.4	pyodbc 3.0.7	

Vertica SDKs

This section details software requirements for running User Defined Extensions (UDxs) developed using the Vertica SDKs.

C++ SDK

The Vertica cluster does not have any special requirements for running UDxs written in C++.

Java SDK

Your Vertica cluster must have a Java runtime installed to run UDxs developed using the Vertica Java SDK. Micro Focus has tested the following Java Runtime Environments (JREs) with this version of the Vertica Java SDK:

- Oracle Java Platform Standard Edition 6 (version number 1.6)
- Oracle Java Platform Standard Edition 7 (version number 1.7)
- Oracle Java Platform Standard Edition 8 (version number 1.8)
- OpenJDK 6 (version number 1.6)
- OpenJDK 7 (version number 1.7)
- OpenJDK 8 (version number 1.8)

Python SDK

The Vertica Python SDK does not require any additional configuration or header files.

R Language Pack

The Vertica R Language Pack provides version 3.2.5 of the R runtime and associated libraries for interfacing with Vertica. You install the R Language Pack on the Vertica server.

FIPS 140-2 Supported Platforms

Micro Focus Vertica uses a certified OpenSSL FIPS 140-2 cryptographic module to meet the security standards set by the National Institute of Standards and Technology (NIST) for Federal Agencies in the United States or other countries.

FIPS-enabled Vertica requires the following:

- Red Hat Linux 6.6, a FIPS compliant operating system
- OpenSSL 1.0.1e
- A user-generated certificate signed by an approved Certificate Authority
- TLS 1.2 to support the server-client connection for a FIPS-enabled system

Supported Drivers

Vertica supports the following client drivers for FIPS-compliance:

- vsql
- ODBC
- JDBC

Important: FIPS-enablement is not supported in the Management Console.

For more information see [Federal Information Processing Standard](#).

Vertica Integrations for Hadoop

Micro Focus has tested Vertica 8.1.x with the following Hadoop distributions. Micro Focus expects Vertica to work with subsequent Hadoop distributions, and tests such later distributions as soon as practical.

Distribution	Versions Tested with Vertica Server 7.0.x
Cloudera (CDH)	<ul style="list-style-type: none">• 5.7• 5.8
HortonWorks Data Platform (HDP)	<ul style="list-style-type: none">• 2.4• 2.5
MapR	<ul style="list-style-type: none">• 5.1• 5.2

You must apply patches for the following issues: HDFS-8855, HDFS-8696, HDFS-7280, HDFS-7279, HDFS-7270, and HDFS-7945. See your Hadoop vendor documentation for further instructions.

Packs, Plug-Ins, and Connectors for Partner Products

Micro Focus provides the following optional module for Vertica client machines.

Informatica PowerCenter Plug-In

The Vertica plug-in for Informatica PowerCenter is supported on the following platforms:

Plug-in Version	Informatica PowerCenter Versions	Vertica Versions
1.1	9.x	6.x (limited functionality) 7.x (all enhancements) 8.x (all enhancements)

For a complete list of supported client drivers, see [Vertica 8.1.x Client Drivers](#).

For more information about the Informatica PowerCenter Plug-in, see [Introduction to Using Informatica PowerCenter with Vertica](#).

Vertica on Amazon Web Services

Micro Focus provides a preconfigured AMI for users who want to run Vertica Analytics Platform on Amazon Web Services (AWS). This AMI allows users to configure their own storage and has been configured for and tested on AWS. This AMI is the officially supported version of Vertica Analytics Platform for AWS.

Note that Micro Focus develops AMIs for Vertica on a slightly different schedule than our product release schedule. Therefore, AMIs will be available for Vertica releases sometime following the initial release of Vertica software.

Vertica in a Virtualized Environment

Vertica runs in the following virtualization environment:

Important: Vertica does not support suspending a virtual machine while Vertica is running on it.

Host

- VMware version 5.5
- The number of virtual machines per host did not exceed the number of physical processors
- CPU frequency scaling turned off at the host level and for each virtual machine
- VMware parameters for hugepages set at version. 5.5 defaults

Input/Output

- Measured by [vioperf](#) concurrently on all Vertica nodes When running vioperf, provide the `–duration=2min` option and start on all nodes concurrently
- 25 megabytes per second per core of write
- 20+20 megabytes per second per core of rewrite
- 40 megabytes per second per core of read
- 150 seeks per second of latency (SkipRead)
- Thick provisioned disk, or pass-through-storage

Network

- Dedicated 10G NIC for each Virtual Machine
- No oversubscription at the switch layer, verified with [vnetperf](#)

Processor

- Architecture of Sandy Bridge (HP Gen8 or higher)
- 8 or more virtual cores per virtual machine
- No oversubscription
- [vcupperf](#) time of no more than 12 seconds (\approx 2.2 GHz clock speed)

Memory

- Pre-allocate and reserve memory for the VM
- 4G per virtual core of the virtual machines

HP has tested the configuration above. While other virtualization configurations may have been successfully deployed by customers in development environments, performance of these configurations may vary. If you choose to run Vertica on a different virtualization configuration and experience an issue, the Vertica Support team may ask you to reproduce the issue using the configuration described above, or in a bare-metal environment, to aid in troubleshooting. Depending on the details of the case, the Support team may also ask you to enter a support ticket with your virtualization vendor.

Vertica Integration for Apache Kafka

You can use Vertica with the Apache Kafka message broker. For more information on Kafka integration, refer to [How Vertica and Apache Kafka Work Together](#).

Kafka Versions

Vertica supports the following Kafka distributions:

Apache Kafka Versions	Vertica Versions
0.9.0	7.2 SP2 and later
0.10	8.1 and later

Java Versions

The data streaming job scheduler needs to make a JDBC connection to the target database, and requires Java 7.0 or later to run.

Vertica Support for LVM

Vertica Analytics Platform 8.1.x supports Linux Volume Manager (LVM) on all supported operating systems.

LVM Version Supported

Vertica Analytics Platform supports LVM version 2.02.66 or later, and must include device-mapper version 1.02.48 or later.

LVM Configuration Notes

In configuring LVM:

- When you create logical volumes with the `lvcreate` command, use the `readahead` option to set the read ahead sector count to greater than 2048 KB.
- You can use the default settings for all other LVM options.

LVM Restrictions

The following limitations apply to LVM support:

- Your logical volume file system type must be ext4.

Note: SUSE Linux Enterprise Server (SLES) 11.0 Service Pack 3 (SP3) supports the ext3 file system. However, Vertica is phasing out support for this operating system. See [End-of-Support and Deprecation Notices](#) for more information.

- You cannot have physical drives shared across several nodes.
- Vertica supports linear logical volumes only. Vertica does not support striped or mirrored logical volumes.

- Vertica supports extending logical volumes (`lvextend`), but not reducing the size of a logical volume.
- Vertica recommends frequent backups.
- Vertica does not support LVM backup and restore, such as LVM snapshot and merge. Use the Vertica backup file `vbr.py`.
- Vertica does not support LVM space reclamation. Space reclamation is duplicated with reducing the size of a logical volume.
- Vertica does not support LVM migration. Use Vertica Copy operations.
- Vertica does not support LVM high availability. Use Vertica high availability capabilities.
- Vertica does not support LVM RAID .Configure RAID at the disk controller level.

Vertica Integration for Apache Spark

You can use the Vertica Connector for Apache Spark to transfer data between Vertica and Apache Spark. Vertica supports the following Apache Spark versions:

Apache Spark Version	Scala Version	Vertica Versions
1.6	2.10	8.0.x, 8.1.x
2.0	2.10, 2.11	8.0.x, 8.1.x
2.1	2.10, 2.11	8.0.x, 8.1.x

Note: Vertica 8.0.x is compatible with Spark versions 2.0 and 2.1 and Scala versions 2.10 and 2.11 when you use the Spark connector distributed with Vertica version 8.1.x.

For more information on Apache Spark integration, refer to [Integrating with Apache Spark](#).

End-of-Support and Deprecation Notices

These end-of-support notices apply to specific client, Linux, Hadoop, and Kafka distributions.

End-of-Support Notices

There are no new supported platforms end of support notices in this release of Vertica. However, Vertica is phasing out support for certain client platforms and server distributions. See [Deprecation Notices](#).

Deprecation Notices

Vertica is phasing out support for the following clients on the listed platforms.

Client	End of Support for Platform
All Client Drivers	Ubuntu 12.04 LTS
	SUSE 11 SP3

For a list of supported platforms for Vertica clients, see [Vertica 8.1.x Client Drivers](#).

Vertica is phasing out support for the following Linux distributions.

Distribution	End of Support for Version
Ubuntu	12.04 LTS
SUSE	11 SP3

For a list of supported server operating systems, see [Vertica Server and Vertica Management Console](#).

Vertica 8.1.x New Features

Welcome to Vertica Analytics Platform New Features. This guide briefly describes the new features introduced in the most recent releases of Vertica and provides references to detailed information in the documentation set.

To see a list of known and fixed issues in the most current release, see the Vertica Release Notes, which you can find at https://my.vertica.com/docs/ReleaseNotes/8.0.x/Vertica_8.1.x_Release_Notes.htm.

Vertica 8.1.1 New Features and Changes

Read the topics in this section for information about new and changed functionality in Vertica 8.1.x.

Supported Platforms

This section contains information on updates to supported platforms for Vertica Analytics Platform 8.1.x.

- [Changes for Operating System Support](#)
- [Changes for Vertica Integration with Apache Spark](#)

Changes for Operating System Support

Vertica operating system support changes follow.

Server

Vertica has added support for Oracle Enterprise Linux (OEL) 6.8. For a list of all supported operating systems, see [Vertica Server and Vertica Management Console](#).

Vertica has added support for Linux Volume Manager on all supported operating systems. For information on supported file systems, See [Vertica Server and Vertica Management Console](#). For information on requirements and restrictions, see the section, [Vertica Support for LVM](#).

Vertica has deprecated support for Ubuntu 12.04 LTS and SUSE 11 SP3. For more information, refer to [End-of-Support and Deprecation Notices](#).

Client

For all client drivers, Vertica has added support for OEL 6.8 and SUSE 12 SP2.

For a complete list of client drivers, see [Vertica 8.1.x Client Drivers](#).

Vertica has deprecated support for Ubuntu 12.04 LTS and SUSE 11 SP3 for all client drivers. For more information, refer to [End-of-Support and Deprecation Notices](#).

Changes for Vertica Integration with Apache Spark

Vertica has added support for Apache Spark version 2.1.

For a list of supported Spark versions, see [Vertica Integration for Apache Spark](#).

For More Information

See [Vertica 8.1.x Supported Platforms](#)

Upgrade and Installation

Model Schema Restrictions

As of this release, you can create models only in `public` and user-created schemas (excluding `HCatalog`). Attempts to create models elsewhere return an error. If the upgrade finds a model that was created in a schema that does not conform with this restriction, it moves the model to the `public` schema. If another object of the same name already exists in `public`, the upgrade renames the moved model as follows:

```
model-name >> model-name_vN
```

where N is an integer ≥ 0 . If *model-name_vN* identifies an object that already exists in the schema, Vertica increments N until it finds a name that is unique in the schema. After the upgrade is complete, check the Vertica log for all changes of this type.

Database Management

This section contains information on updates to database operations for Vertica Analytics Platform 8.1.x.

Map New IP Addresses

Vertica provides an easy way to apply new IP addresses to nodes in a cluster in cases where old IP addresses are no longer valid. For example, if you are running Vertica in a cloud environment and the cloud vendor reassigns IP addresses.

Mapping new IP addresses involves creating a mapping file and running commands in admintools. For more information see [Mapping New IP Addresses](#).

For More Information

See [Managing the Database](#).

Data Analysis

This section contains information on updates to data analysis for Vertica Analytics Platform 8.1.x.

Machine Learning for Predictive Analytics

Machine Learning for Predictive Analytics new features include:

- In-database predictive modeling for classification problems using random forest
- In-database predictive modeling for regression problems using SVM (support vector machine)
- Support for the ability to detect outliers by group
- Support for the ability to extract model attributes
- Support for imbalanced data process using a hybrid method of under-sampling and over-sampling

For More Information

See [Machine Learning for Predictive Analytics](#).

Client Connectivity

This section contains information on updates to connection information for Vertica Analytics Platform 8.1.x.

Direct ODBC or OLE DB Log Entries to ETW

You can now have Vertica send ODBC or OLE DB log entries to Event Tracing for Windows (ETW).

To enable this feature, you add a new string to your Windows Registry, LogType, and you set the string value to ETW. Once set, ODBC or OLE DB log entries appear in the Windows Event Viewer.

When you turn this feature on, be aware of the differences between the LogLevel parameter settings and how those settings are compressed for the Windows Event Viewer. LogLevel settings are 0 through 6 (described in [Additional Parameter Settings](#)). Entries are sent to the Windows Event Viewer as four levels rather than six.

For more detailed information about this feature for ODBC, see [Register the ODBC Driver as a Windows Event Log Provider, and Enable the Logs](#)

For more detailed information about this feature for OLE DB, see [Register the OLE DB Driver as a Windows Event Log Provider, and Enable the Logs](#).

Disable Local Copying in JDBC Connections

The JDBC connector now has the setting DisableCopyLocal. When set to true, it disables file-based COPY LOCAL operations, including copying data from local files and using local files to store data and exceptions. For more information, refer to [JDBC Connection Properties](#).

For More Information

See [Connecting to Vertica](#).

Workload Management

This section contains information on updates to workload management for Vertica Analytics Platform 8.1.x.

Configuring a Grace Period to Handle Session Socket Blocking

A session socket can occasionally be blocked indefinitely while awaiting client input or output for a given query. You can now set a grace period to handle session socket blocking, at the session, user, node, and database levels. If a socket is blocked for a continuous period that exceeds the grace period setting, the server shuts down the socket and throws a fatal error. The session is then terminated.

For details, see [Handling Session Socket Blocking](#) in the Administrator's Guide.

For More Information

See [Managing Workloads](#).

Geospatial Analytics

This section contains information on updates to Vertica Geospatial Analytics for Vertica Analytics Platform 8.1.x.

Improved STV_NN Analytic Performance

The Geospatial Analytic function [STV_NN](#) is now at least twice as fast when performing point-to-point calculations.

For More Information

See [Geospatial Analytics](#).

Backup, Restore, Recovery, and Replication

This section contains information on updates to backup and restore operations for Vertica Analytics Platform 8.1.x.

Backup and Restore to Amazon S3

Vertica now has the ability to backup and restore to Amazon S3 Standard for Vertica instances hosted locally and on Amazon Web Services. For more information, refer to [Creating Backups on Amazon S3](#).

Sample VBR Configuration Files

Vertica now includes sample configuration files that you can copy, edit, and deploy for your various vbr tasks. Vertica automatically installs these files at `/opt/vertica/share/vbr/example_configs`. For more information, refer to [Sample VBR .ini Files](#).

Ability to View All Backups in a Location

The Vertica backup and restore utility now has the following additional parameters for the `listbackup` task:

- `--list-all` - Lists all backups store on the hosts and paths listed in the specified configuration file.
- `--json` - Displays a JSON delimited list of all backups stored on the hosts and paths listed in the specified configuration file.
- `--list-output-file` - Outputs a file containing a JSON delimited list of all backups stored on the hosts and paths listed in the specified configuration file.

For more information, refer to [Viewing Backups](#).

For More Information

See [Backing Up and Restoring the Database](#).

Table Data Management

This section summarizes new options and changes in Vertica Analytics Platform 8.1.x, for managing table data in a Vertica database.

Projections and Anchor Tables Required to Share Same Schema

As of release 8.1.1, Vertica requires that all projections of a given table must share the same schema. On upgrade to this version, Vertica checks whether all projections are in the same schema as their respective anchor tables. If not, Vertica moves the projections to the appropriate schema, resolving name conflicts as needed.

Support will continue for specifying schemas in statements and functions, to ensure backward compatibility with existing scripts.

New Header_Names Parameter for fcsvparser

The fcsvparser has a new `HEADER_NAMES= ' '` parameter. Use this optional parameter to override existing column names, or to add column names where they are missing. For example, to add four column headings when loading a CSV file that has none, use a definition such as this with the new parameter:

```
HEADING_NAMES= 'NAME , CITY , STATE , ZIP '
```

For more information and examples, see [Loading CSV Data](#) and [FCSVPARSER](#)

For More Information

See [Managing Tables](#), [Creating Flex Tables](#), and [Understanding Flex Tables](#)

Management Console

This section contains information on updates to the Management Console for Vertica Analytics Platform 8.1.x.

Run Queries Through MC

You can now use MC to run SQL queries on your database. Enter ad hoc queries, upload a SQL script, or select previously run queries using the MC Query Runner to get query results through your browser.

To reach the Query Runner, select your database from the Home page or the Databases and Clusters page to view your database's Overview page. Select **Query Execution** at the bottom of the Overview page.

For more about the Query Runner, see [Running Queries in Management Console](#)

The screenshot shows the Management Console interface for the Query Runner. The breadcrumb navigation is "Databases and Clusters > VMart > Query Runner". On the left, there is a "Query History" panel with a "Clear all" button and a "Filter previous queries" input. Below this, several query snippets are listed. The main area contains a SQL query editor with the following code:

```
1 SELECT sales_quantity, sales_dollar_amount, transaction_type, cc_name
2 FROM online_sales.online_sales_fact
3 INNER JOIN online_sales.call_center_dimension
4 ON (online_sales.online_sales_fact.call_center_key
5     = online_sales.call_center_dimension.call_center_key
6     AND sale_date_key = 156)
7 ORDER BY sales_dollar_amount DESC;
8 SELECT order_number, date_ordered
9 FROM store.store_orders_fact orders
10 WHERE orders.store_key IN (
11   SELECT store_key
12   FROM store.store_dimension
13   WHERE store_state = 'MA')
14   AND orders.vendor_key NOT IN (
15     SELECT vendor_key
16     FROM public.vendor_dimension
17     WHERE vendor_state = 'MA')
18   AND date_ordered < '2012-03-01';
19 SELECT store_key, order_number, date_ordered
```

Below the query editor is a green "Execute Queries" button. Underneath, there are tabs for "Query Results", "Query Plan", and "Query Profile". The "Query Results" tab is active, showing a table with the following data:

sales_quantity	sales_dollar_amount	transaction_type	cc_name
7	589	purchase	Central Midwest
8	589	purchase	South Midwest
8	589	purchase	California

At the bottom of the results table, it says "2514 rows | Execution time: 0.113s". The bottom navigation bar includes "Overview", "Activity", "Manage", "Design", "Load", "Query Execution" (highlighted), "Query Plan", "License", and "Settings".

Explore New Features After Upgrade

MC displays a new "Explore New Features in Vertica" notification after upgrade. Through this you can explore the features in the newest version of Vertica, the Vertica YouTube channel for new features highlights and video tutorials, and the deprecated functionality list.

You will see this notification upon first upgrading and logging into MC.

Improved Contextual Help

The contextual help in MC now has a new look and feel, and provides a new menu you can use to navigate to online documentation, Vertica video tutorials, and the Vertica forum.

Click the question mark icon at the top right of any page in MC to view contextual help.

For More Information

See [Using Management Console](#) .

SQL Functions and Statements

This section contains information on updates to SQL functions and statements for Vertica Analytics Platform 8.1.x:

MERGE Support for Subqueries and Views as Source Data

MERGE functionality has been extended to support specifying views and subqueries as merge source data. The MERGE statement 's USING clause can now:

- Specify a view in the same way as a table. Vertica expands the view name to the query that it encapsulates, and uses the result set as the merge source data.
- Specify a subquery. Vertica executes the query and uses the result set as the merge source data.

For details, see [MERGE Source Options](#) in the Administrator's Guide.

Shortcut Constraint DEFAULT USING

Before this release, a column was required to specify separate subqueries for DEFAULT and SET USING constraints, even if both constraints specified the same subquery. Now, you can combine the two constraints and specify their subquery once, as follows:

```
column-name data-type DEFAULT USING (subquery)
```

For example, the following two statements are equivalent:

```
=> ALTER TABLE T1 ADD yy varchar(20)  
    DEFAULT (SELECT y FROM T2 WHERE (T1.c1 = T2.c1))  
    SET USING (SELECT y FROM T2 WHERE (T1.c1 = T2.c1));
```

```
=> ALTER TABLE T1 ADD yy varchar(20) DEFAULT USING (SELECT y FROM T2 WHERE (T1.c1 = T2.c1));
```

Note: When you use DEFAULT USING, the DDL that Vertica generates for the table specifies separate DEFAULT and SET USING constraints.

Forcing Early Materialization

You can qualify one or more tables in a query with the hint [EARLY_MATERIALIZATION](#). This hint can be useful in cases where late materialization of join inputs precludes other optimizations—for example, pushing aggregation down the joins or using live aggregate projections.

For More Information

See [SQL Reference Manual](#).

System Table Updates

This section contains information on system tables updates for Vertica Analytics Platform 8.1.x.

GRACE_PERIOD Column

System tables [SESSIONS](#) and [USERS](#) now include a GRACE_PERIOD column that is set by [SET SESSION GRACEPERIOD](#) and [CREATE USER/ALTER USER](#), respectively. For general information, see [Handling Session Socket Blocking](#) in the Administrator's Guide.

Table for Auditing External Tables

System table [EXTERNAL_TABLE_DETAILS](#) records information about external tables. You can use this table to audit the amount of ORC and Parquet data you are using, which might be limited by your license.

Table for Monitoring Memory Pool Allocations

System table [ALLOCATOR_USAGE](#) provides information on memory pool allocation and usage for each Vertica node. You can use the information presented in the table to help diagnose memory pool issues.

Table for Monitoring Notifier Errors

The system table [NOTIFIER_ERRORS](#) now provides information on errors encountered by [notifiers](#).

For More Information

See [Vertica System Tables](#).

Apache Hadoop Integration

This section contains information on updates to Hadoop-integration information for Vertica Analytics Platform 8.1.x.

Exporting Parquet Data

You can export data from Vertica, either to share it with other Hadoop-based applications or to move lower-priority data from ROS to less-expensive storage. The [EXPORT TO PARQUET](#) statement exports a result set as Parquet data. After exporting ROS data, you can drop affected ROS partitions to reclaim storage space. If you need to access the data in Vertica again, you can create external tables from the exported data.

For more information, see [Exporting Data](#)

HCatalog Connector Uses HiveServer2

Previously the HCatalog Connector read Hive metadata using the WebHCat web service, which has poor performance. The HCatalog Connector now supports HiveServer2, which has a faster JDBC interface, and uses it by default. (You can still use WebHCat if you prefer it.)

When using [CREATE HCATALOG SCHEMA](#) to create a schema in Vertica to mirror a Hive schema, you can now specify an additional parameter, `HIVESERVER2_HOSTNAME`. This statement has an additional (optional) parameter, `WEBHDFS_ADDRESS`. The `WEBHDFS_PORT` parameter has been removed.

For more information, see [Using the HCatalog Connector](#).

Cloudera Manager Integration

The Cloudera distribution of Hadoop includes Cloudera Manager, a web-based tool for managing a Hadoop cluster. Cloudera Manager can manage any service for which a service description is available. This release includes a service description for Vertica. After installing this service description, you can manage your Vertica cluster from the Cloudera Manager console. You can start, stop, and add nodes and manage memory pools.

For more information, see [Integrating With Cloudera Manager](#).

hdfs Scheme Fully Supports High Availability Name Node

Previous versions of Vertica added support for using the `hdfs` URL scheme in HDFS clusters with High Availability Name Node (HA NN). Reads and writes using the `hdfs` scheme can sometimes fall back to using `webhdfs`, which does not support HA NN. Vertica now supports

HA NN when falling back to webhdfs from hdfs. For more information, see the description of the LibHDFS++ FAILOVER RETRY event in [Check Query Events](#) in Analyzing Data.

For More Information

See [Integrating with Apache Hadoop](#)

Apache Kafka Integration

Vertica version 8.1.1 includes the following changes to its integration with Apache Kafka.

Setting a Starting Offset for a Microbatch

Previously, a microbatch always started loading data from the start of a stream. You can now use the `--offset` parameter to set an offset in the stream where the microbatch will start loading data. This new parameter lets you have the microbatch skip older data in a stream or to force it reload old data. See [Microbatch Utility Options](#) for details.

Setting an Ending Offset for KafkaSource

Previously, KafkaSource could end streaming either after a timeout or on reaching the end of a stream. You can now have it end streaming when it reaches a specific offset in the stream. See [Using COPY with Data Streaming](#) for more information.

For More Information

See [Integrating with Apache Kafka](#)

Apache Spark Integration

This section contains updates to the Apache Spark integration for Vertica Analytics Platform version 8.1.x.

Support for Spark 2.1

The Vertica Connector for Apache Spark now supports Spark 2.1. The connector's JAR file is compatible with a specific combination of Spark and Scala versions. Micro Focus supplies multiple JAR files, one for each supported version combination. See [Getting the Spark Connector](#) in [Integrating with Apache Spark](#) for more information.

For More Information

See [Integrating with Apache Spark](#) .

Performance Improvements

This section summarizes performance improvements in Vertica Analytics Platform 8.1.x.

Common Subexpression Elimination

Queries with complex expressions are routinely generated by business intelligence tools, and can occasionally be slow to execute. Query execution can be optimized by identifying and reusing common subexpressions (*common subexpression elimination*, or CSE). With this release, Vertica provides its own CSE implementation, so evaluation results between expressions can be shared within a single query.

All subexpressions in an expression are candidates for substitution. Substitution does not apply to trivial substitutions—for example, variables and constants—and to expressions that occur only once. Substitution can be recursive—that is, substitution can be applied to substituted expressions.

Better Handling of Concurrent Queries

Vertica now handles throughput of concurrent queries much more efficiently, yielding significant improvements in execution time.

Execution of Queries on Tables with Many Projections

With this release, the number of projections anchored to a table has significantly less impact on the execution time of queries on that table.

Vertica Community Edition VM

This section contains information on updates to the Vertica Community Edition VM for Vertica Analytics Platform 8.1.x.

VM Enhancements

The Vertica Community Edition VM, previously called the Vertica Virtual Machine, is significantly enhanced for usability in 8.1 SP1. Vertica Community Edition is provided in a VM so that users can quickly gain hands-on experience with Vertica.

Prior to 8.1 SP1, the VM came with Vertica Community Edition installed, but setting up a learning environment was left to the user. For example, the user had to create a database, generate and load VMart example data, and then learn how to use Vertica Administration Tools and vsql.

With 8.1. SP1, the Vertica Community Edition VM (Vertica CE VM) is a live, pre-configured environment. The Vertica client tools, including Management Console, are connected to the VMart example database, and a user guide provides step-by-step exercises for using the tools. Many of the exercises introduce the user to Vertica Management Console, a user-friendly tool that runs in a browser. The Vertica CE VM also includes the complete Vertica documentation set.

For More Information

See [Downloading and Starting the Vertica Community Edition VM](#)

Vertica 8.1 New Features and Changes

Read the topics in this section for information about new and changed functionality in Vertica 8.1.x.

Supported Platforms

This section contains information on updates to supported platforms for Vertica Analytics Platform 8.1.x. Administrator's Guide

- [Changes for Operating System Support](#)
- [Changes for Hadoop and Kafka Distribution Support](#)

Changes for Operating System Support

Vertica operating system support changes follow.

Server

Vertica has added support for these operating systems:

- Red Hat Enterprise Linux (RHEL) 7.3
- CentOS 7.3
- Oracle Enterprise Linux (OEL) 7.3

For a list of all supported operating systems, see [Vertica Server and Vertica Management Console](#).

Vertica has added support for Linux Volume Manager on RHEL 6.8. For information on supported file systems, See [Vertica Server and Vertica Management Console](#). For information on requirements and restrictions, see the section, [Vertica Support for LVM](#).

Vertica has ended support for RHEL 6.5 and CentOS 6.5. For more information, refer to [End-of-Support and Deprecation Notices](#).

Client

Vertica has added support for the following:

- For the ADO.NET, OLE DB, and ODBC clients, Vertica now supports Windows Server 2016.
- For the ODBC and vsql clients, Vertica now supports AIX 7.1 and Mac OS X 10.12.
- Vertica has added a FIPS-compliant (FIPS 140-2) JDBC client driver.

For a complete list of client drivers, see [Vertica 8.1.x Client Drivers](#).

For information on FIPS 140-2 prerequisites, see [FIPS 140-2 Supported Platforms](#).

Vertica has ended support for AIX 5.3, AIX 5.6, and Mac OS X 10.9. For more information, refer to [End-of-Support and Deprecation Notices](#).

ODBC Client Driver Backwards Compatibility

In general, all Vertica clients are forward compatible with later Vertica server versions. For Release 8.1.x, Vertica has added backwards compatibility for the ODBC client driver.

- The 8.1.x ODBC client driver is backwards compatible to Vertica server version 7.1.
- For full compatibility between the 8.1.x ODBC client driver and a previous Vertica server version, Vertica has added a connection string property named Protocol. The Protocol connection string option specifies the front-end protocol that the client and server use to communicate. For more information about the Protocol connection string property, see [Data Source Name \(DSN\) Connection Properties](#).

Changes for Hadoop and Kafka Distribution Support

Vertica has added support for the following:

- Hortonworks Data Platform (HDP) 2.5
- MapR 5.2
- Apache Kafka 0.10

For a list of supported Hadoop distributions, see [Vertica Integrations for Hadoop](#).

For a list of supported Apache Kafka distributions, see [Vertica Integration for Apache Kafka](#).

Vertica has ended support for Cloudera CDH 5.6, Hortonworks HDP 2.3, MapR 4.1 and 5.0, and Apache Kafka 0.8. For more information, refer to [End-of-Support and Deprecation Notices](#).

More Details

For complete information on platform support see [Vertica 8.1.x Supported Platforms](#)

Performance Improvements

This section summarizes performance improvements in Vertica Analytics Platform 8.1.0.

Queries with Multiple Distinct Aggregates

Queries that include multiple distinct aggregates now execute more efficiently. The scale of this improvement is especially significant for queries where all distinct aggregate columns have a similar number of distinct values.

Query Optimization

This section contains information on query execution improvements for Vertica Analytics Platform 8.1.x.

Flattened Tables

Before release 8.1., Vertica users could denormalize their data by combining all fact and dimension table columns in a single 'fat' table. However, this approach required them to maintain redundant sets of normalized and denormalized data.

Release 8.1. addresses this issue with flattened tables, which include columns that get their values by querying other tables. Operations on the source tables and flattened table are decoupled: changes in one are not automatically propagated to the other. This minimizes the overhead that is otherwise typical of conventional denormalized tables.

For details, see [Flattened Tables](#) in Analyzing Data.

Wide Column Data Queried for Insertion into Another Table

Query execution is significantly improved in two cases where a table is populated with variable length columns (VARCHAR/LONG VARCHAR and VARBINARY/LONG VARBINARY) from another table:

- [CREATE TABLE...AS SELECT](#)
- [INSERT...SELECT](#)

If the source and target tables share the same sort order but are segmented differently, Vertica buffers the query results. With release 8.1.x, Vertica optimizes buffering for wide columns, so overall query execution now incurs much less overhead than before.

Note: Performance improvements can vary, depending on the width of the source column data.

Queries with Multiple Distinct Aggregates

Vertica has improved the performance of queries that include multiple distinct aggregates. While all queries that include multiple distinct aggregates experience this improvement, the scale of the performance improvement depends upon your data and how your queries are structured. Queries where all the distinct aggregate columns have a similar number of distinct values experience the greatest performance improvement. Queries where the distinct aggregate columns have a vastly different number of distinct values experience a performance improvement to a lesser extent.

Security and Authentication

This section contains information on updates to security and authentication features for Vertica Analytics Platform 8.1.x.

Encrypting Passwords on ODBC DSN

You can encrypt the database password and store it in registry. This prevents illicit access to the database.

For more information see [Encrypting Passwords on ODBC DSN](#).

More Details

For more information see [Security and Authentication](#) .

Data Analysis

This section contains information on updates to data analysis for Vertica Analytics Platform 8.1.x.

Machine Learning for Predictive Analytics

Machine Learning for Predictive Analytics new features include:

- In-database predictive modeling for classification problems, using support vector machine (SVM)
- New normalization functions to save transformation parameters
- An impute function to impute missing values in your data
- Support for [ALTER MODEL](#) and [DROP MODEL](#) for machine learning models

More Details

For more information see [Analyzing Data](#)

Client Connectivity

This section contains information on updates to connection information for Vertica Analytics Platform 8.1.x.

\timing Meta-command

You can toggle the `\timing` command from Vsql as follows:

```
=> \timing on  
Timing is on
```

```
=> \timing off  
Timing is off
```

You can also enable `/timing` from the command line with the `-i` command:

```
$VSQL -h host1 -U user1 -d VMart -p 15 -w ***** -i -f transactions.sql
```

For more information see [\timing](#) and [Command-Line Options](#).

More Details

For more information see [Connecting to Vertica](#).

Query Management

This section contains information on updates to Query Management for Vertica Analytics Platform 8.1.x.

New Semantics for Complex Joins

With this release, Vertica introduces new semantics that allow directed queries to support complex half joins and cross joins. These semantics can also be used to construct queries that filter the results of half-join subqueries.

More Details

See [Half Join and Cross Join Semantics](#) in the Administrator's Guide.

Tables

This section summarizes the Vertica Analytics Platform 8.1.x updates to regular and flex tables.

Creating a Flex Table from Query Results

The CREATE FLEX TABLE AS statement allows a user to create a flex table from the results of a query. This statement was already functional for regular tables--this feature enables it for flex tables as well.

More Details

For more information see [Managing Tables](#), [Creating Flex Tables](#), and [Understanding Flex Tables](#)

Geospatial Analytics

This section contains information on updates to Vertica Geospatial Analytics for Vertica Analytics Platform 8.1.x.

GeoHash Support

Vertica supports GeoHashes. A GeoHash is a geocoding system for hierarchically encoding increasingly granular spatial references. Vertica supports the following functions for use with GeoHashes:

- [ST_GeoHash](#) - Returns a GeoHash in the shape of the specified geometry.
- [ST_GeomFromGeoHash](#)- Returns a polygon in the shape of the specified GeoHash.

- [ST_PointFromGeoHash](#) - Returns the center point of the specified GeoHash.

More Details

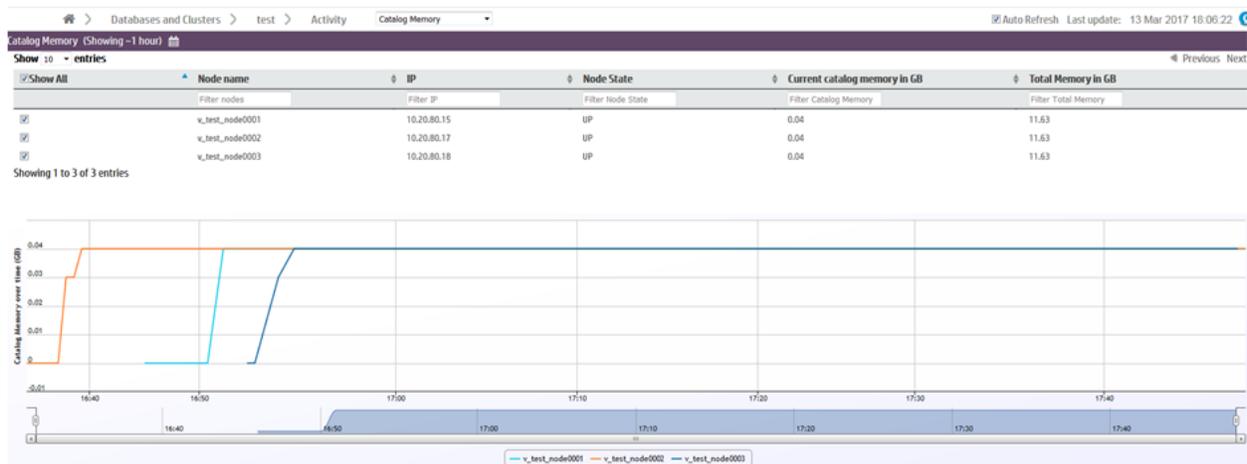

For more information see [Geospatial Analytics](#).

Management Console

This section contains information on updates to the Management Console for Vertica Analytics Platform 8.1.x.

Catalog Memory Activity Page

The new Catalog Memory activity page displays the catalog memory for each node in your database. Use this page to check for sudden changes in catalog memory, or discrepancies in memory distribution across your nodes.

For more about monitoring catalog memory in MC, see [Monitoring Catalog Memory](#).

Configure JVM Settings in MC

Management Console (MC) introduces the ability to configure application server JVM settings on the MC Settings page.

Enabling Extended Monitoring in MC allows you to view more historical monitoring data. For MC to handle larger amounts of monitoring data, Micro Focus recommends increasing JVM initial heap size and maximum heap size. You can now do so on the Configuration tab in MC settings.

Configure WLA Settings in MC

If queries perform sub-optimally, you can get tuning recommendations for them, as well as for hints about optimizing database objects, by using the Workload Analyzer (WLA).

To optimize when WLA uses resources, you can now set WLA to run at a different time for any or all databases that MC monitors. You can also set MC to never run WLA automatically. This setting is available on the Monitoring tab on the MC Settings page.

New Create Cluster Wizard

Vertica 8.1 improves the look and feel of the Create Cluster wizard in MC.

More Details

For more information see [Using Management Console](#) .

SQL Functions and Statements

This section contains information on updates to SQL Functions and Statements for Vertica Analytics Platform 8.1.x:

- [MERGE Support for Update and Insert Filters](#)
- [Adding New Columns to Existing Projections](#)
- [Function to Verify Kerberos Configuration](#)

MERGE Support for Update and Insert Filters

Each `WHEN MATCHED` and `WHEN NOT MATCHED` clause in a `MERGE` statement can now optionally specify an update filter and insert filter, respectively:

```
WHEN MATCHED AND update-filter THEN UPDATE ...  
WHEN NOT MATCHED AND insert-filter THEN INSERT ...
```

Each filter can specify multiple conditions. For details on using these filters, see [Update and Insert Filters](#) in the Administrator's Guide.

Adding New Columns to Existing Projections

Previously, when you added a new column to a table using `ALTER TABLE ADD COLUMN`, existing projections (non-superprojections) did not include the new column. If you wanted to include the new column in your projection, you needed to drop and recreate it. Vertica has added the option `PROJECTIONS` to `ALTER TABLE ADD COLUMN`. When you add a new column to a table, use the `PROJECTIONS` option to simultaneously add the column to one or more existing projections.

For the statement syntax for adding columns to tables, see [ALTER TABLE](#). For an example of adding a new column to an existing projection, see [Adding Table Columns](#).

Function to Verify Kerberos Configuration

You can use the `KERBEROS_CONFIG_CHECK` metafunction to verify your Kerberos configuration. The function tests each element of Kerberos configuration and reports specific errors if it finds any.

More Details

For more information see the [SQL Reference Manual](#).

SDK Updates

This section contains information on updates to the SDK for Vertica Analytics Platform 8.1.x.

Support for C++ 11

The Vertica SDK now supports writing both fenced and unfenced UDxs in C++ 11.

Improvements to Cooperative Parse and Apportioned Load

You can now write UDL functions that support both cooperative parse and apportioned load. Previously a UDL could support only one. Using the C++ API you can now write chunkers that support apportioned load even if the parsers that use them do not. For more information, see [Load Parallelism](#) in Extending Vertica.

More Details

For more information see [Extending Vertica](#).

Apache Kafka Integration

This section contains information on updates to Kafka-integration information for Vertica Analytics Platform 8.1.x.

Execution Parallelism

You can specify the `executionparallelism` parameter in the `KafkaSource` UDL. By default, Vertica automatically creates a thread for every partition. You can use this parameter to throttle the number of threads used to process any `COPY` statement.

Schema Registry Support

Vertica supports the use of a Confluent schema registry with the KafkaAVROParser. By using a schema registry, you enable the Avro parser to parse and decode messages written by the registry and to retrieve schemas stored in the registry. In addition, a schema registry enables Vertica to process streamed data without sending a copy of the schema with each record.

SSL Support

Vertica supports SSL connections between the scheduler, Vertica and Kafka.

More Details

For more information see [Integrating with Apache Kafka](#) .

Apache Spark Integration

This section contains updates to the Apache Spark integration for Vertica Analytics Platform version 8.1.0.

Support for Spark 2.0 and Scala 2.11

The Vertica Connector for Apache Spark now supports Spark 2.0 and Scala 2.11. The connector's JAR file is compatible with a specific version of Spark and Scala. Micro Focus supplies multiple JAR files for download, each of which is compatible with a specific combination of Spark and Scala versions. See [Getting the Spark Connector](#) in [Integrating with Apache Spark](#) for more information.

SaveMode.Append Behavior Change

Previously, the connector returned an error when moving data from Spark to Vertica if you specified SaveMode.Append and the target table did not already exist in Vertica. In version 8.1.0, Vertica creates the table if it does not exist and loads data into it.

Hadoop Integration

This section contains information on updates to Hadoop-integration information for Vertica Analytics Platform 8.1.x.

Rack Locality

When database nodes are co-located on Hadoop nodes, Vertica can take advantage of the Hadoop rack configuration to execute queries. Moving query execution closer to the data reduces network latency and can improve performance.

Vertica automatically uses database nodes that are co-located with the HDFS nodes that contain the data. This behavior, called node locality, requires no additional configuration. In this release, if no database node has local data, Vertica uses a database node in the same rack as the data. Rack locality must be configured. See [Configuring Rack Locality](#) in *Integrating with Apache Hadoop*.

Rack locality is available for reading ORC and Parquet data on co-located clusters.

Function to Verify Kerberos Configuration

You can use the [KERBEROS_HDFS_CONFIG_CHECK](#) metafunction to verify that Vertica can use Kerberos authentication with HDFS. You can have the function test all Hadoop integrations that it finds, or you can test specific clusters or services. The function tests each element of Kerberos configuration and reports specific errors if it finds any.

More Details

For more information see [Integrating with Apache Hadoop](#).

Documentation Changes

The following changes are effective for Vertica 8.1.0.

Document Additions and Revisions

The following additions and revisions have been made to the Vertica product documentation:

- The section Developing UDSFs and UDTFs in R has been re-organized to align with the other SDKs in Extending Vertica. The content can now be found in [Developing with the R SDK](#). This re-organization also includes the creation of the [R SDK API Documentation](#).

Deprecated and Retired Functionality

This section describes the two phases Micro Focus follows to retire Vertica functionality:

- **Deprecated.** Vertica announces deprecated features and functionality in a major or minor release. Deprecated features remain in the product and are functional. Documentation is included in the published release documentation. Accessing the feature can result in informational messages noting that the feature will be removed in the following major or minor release. Vertica identifies deprecated features in this document.
- **Removed.** Micro Focus removes a feature in the major or minor release immediately following the deprecation announcement. Users can no longer access the functionality. Vertica announces all feature removal in this document. Documentation describing the retired functionality is removed, but remains in previous documentation versions.

Deprecated Functionality in This Release

In version 7.0.x the following Vertica functionality was deprecated:

- The `owner` parameter used by the Machine Learning for Predictive Analytics package
- The `key_columns` parameter used by the Machine Learning for Predictive Analytics package
- `vbr --setupconfig` command

See Also

For a description of how Vertica deprecates features and functionality, see [Deprecated and Retired Functionality](#).

Retired Functionality History

The following functionality has been deprecated or removed in the indicated versions:

Functionality	Component	Deprecated Version	Removed Version
Machine Learning for Predictive Analytics package parameter owner.	Server	8.1.1	
Backup and restore --setupconfig command	Server	8.1.1	
vbr --setupconfig command	Server	8.1	
RENAME_MODEL()	Server	8.1	8.1.1
DELETE_MODEL()	Server	8.1	8.1.1
Ability to create a projection in a schema different from its anchor table	Server	8.0.1	8.1.1
PreExcavatorReplicatedProjection()	Server		8.0.1
SET_RECOVER_BY_TABLE(). Do <i>not</i> disable recovery by table.	Server	8.0.1	
Prejoin projections	Server	8.0	
PROJECTIONS_USED column in system table V_MONITOR.QUERY_PROFILES	Optimizer	7.2.2	7.2.3
Administration Tools option --compat21	Server	7.2.1	
ext3 file system SUSE Linux Enterprise Server (SLES) 11.0 Service Pack 3 (SP3) continues to support the ext3 file system.	Server	7.2	8.0
Backup and restore overwrite configuration parameter	Server	7.2	7.2
Buddy projections with different sort order	Server	7.2	
verticaConfig vbr configuration option	Server	7.1	7.2
JavaClassPathForUDx configuration parameter	Server	7.1	

Functionality	Component	Deprecated Version	Removed Version
ADD_LOCATION()	Server	7.1	
bwlimit	Server	7.1	
EXECUTION_ENGINE_PROFILES counters: file handles, memory allocated, and memory reserved	Server	7.0	
MERGE_PARTITIONS()	Server	7.0

Administration Tools option check_spread	Server, clients	7.0	
krb5 client authentication method Use the Kerberos gss method for client authentication, instead of krb5. See Configuring Kerberos Authentication .	All clients	7.0	
Pload library	Server	7.0	8.1.1
range-segmentation-clause	Server	6.1.1	
scope parameter of CLEAR_PROFILING()	Server	6.1	
IMPLEMENT_TEMP_DESIGN()	Server, clients	6.1	

Vertica Concepts

This guide introduces the basic concepts to get you started in effectively designing, building, operating, and maintaining a Vertica database. This document assumes that you are familiar with the basic concepts and terminology of relational database management systems and SQL.

The Vertica Approach

The Vertica Analytics Platform consists of the following key features:

Columnar Storage and Execution - column stores offer significant gains in performance, I/O, storage footprint, and efficiency when it comes to analytic workloads. With columnar storage the query only reads the columns needed to answer the query.

Real-time loading and querying - with high query concurrency and the ability to simultaneously load new data into the system, Vertica can load data up to 10X faster than traditional row-store databases.

Advanced Database Analytics - a set of Advanced In-Database Analytics allows you to conduct the analytics computations closer to the data. This provides immediate results from a single place without having to extract data from a separate environment.

Database Designer and Administration Tools - these features allow you to tune and control Vertica with minimal administration effort. For more information see [About Database Designer](#) and [Using the Administration Tools](#).

Advanced Compression - aggressive encoding and compression allows Vertica to dramatically improve analytic performance by reducing CPU, memory, and disk I/O at processing time. Vertica can reduce the original data size to up to 1/10th its original size.

Massively Parallel Processing - a robust and scalable parallel processing solution provides active redundancy, automatic replication, failover, and recovery.

Use Case

A mobile gaming company used to rely on a patchwork of technologies for data warehousing and business intelligence reporting. It took two to four hours to run a query on each game server. The search for a solution led the company to evaluate different companies for expanding its analytic capabilities. The Vertica implementation accomplished the following for the company:

- Queries were reduced from two to four hours to minutes or seconds
- Solution successfully met cloud deployment requirement
- Expanded data capacity from a few months to whole lifetime of data

This has led to better customer support by shortening response time to customer issues, as well as providing the ability to answer many more questions than before the Vertica implementation.

Getting Started

See [Getting Started Overview](#) in the online product documentation and [Get Started With Vertica](#) on our Community site for information on Vertica Analytics Platform implementation.

Vertica Platform

The Vertica Platform provides a unique architecture that allows for efficient processing of custom SQL queries. The architecture also provides a quick return of data. Vertica accomplishes this using the following components:

- Columnar data storage
- Advanced compression
- High Availability
- Automatic Database Design
- Massive Parallel Processing
- Application Integration

Vertica Cluster Architecture

In Vertica, the physical architecture is designed to distribute physical storage and to allow parallel query execution over a potentially large collection of computing resources.

Hybrid Data Store

Vertica stores data on the database in two containers:

- Write Optimized Store (WOS) - stores data in memory without compression or indexing. You can use [INSERT](#), [UPDATE](#), and [COPY](#) to load data into WOS.
- Read Optimized Store (ROS) - stores data on disk. The data is segmented, sorted, and compressed for high optimization. You can load data directly into the ROS using the [COPY](#) statement.

The Tuple Mover moves data from the WOS (memory) to the ROS (disk) using the following processes:

- **Moveout** copies data from the WOS to the Tuple Mover and then to the ROS; data is sorted, encoded, and compressed into column files.
- **Mergeout** combines smaller ROS containers into larger ones to reduce fragmentation.

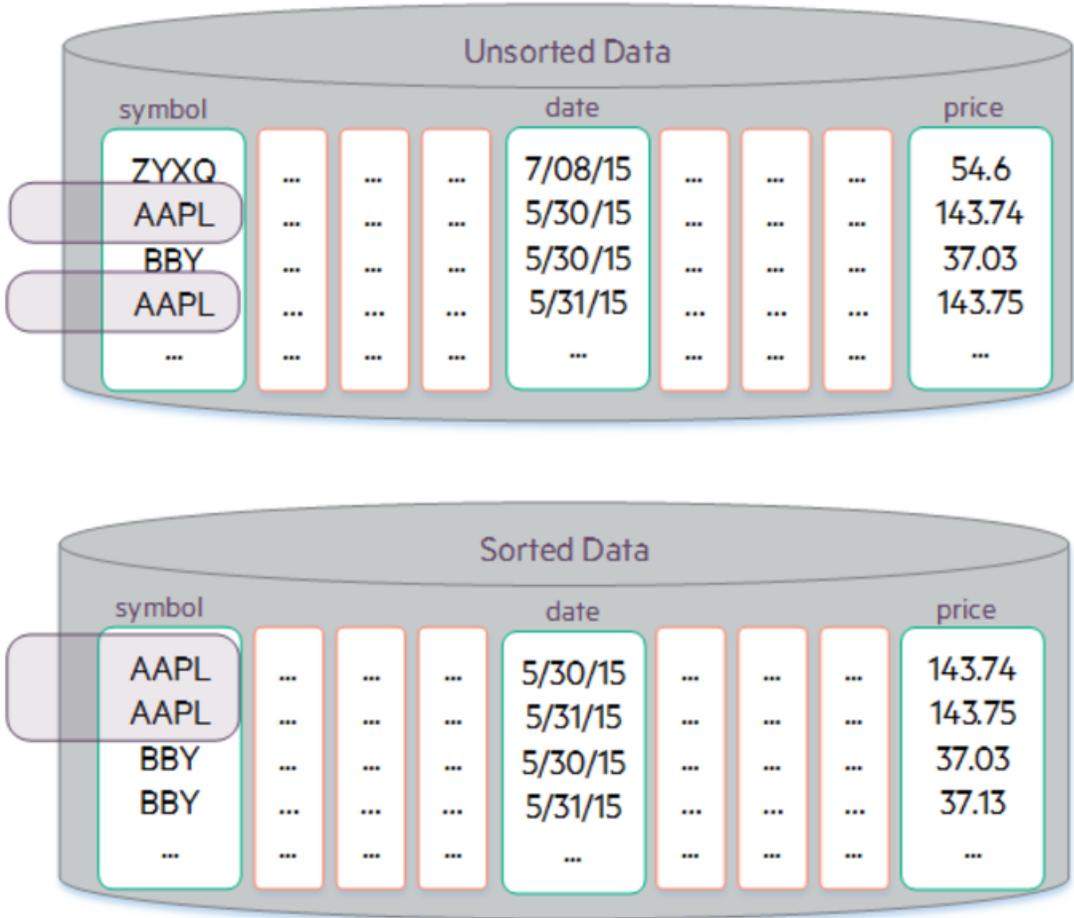

COPY can load data into WOS, where the Tuple Mover moves it to ROS. COPY can also specify loading data directly into the ROS. For more on load options, see [Choosing a Load Method](#).

Column Storage

Vertica stores data in a column format so it can be queried for best performance. Compared to row-based storage, column storage reduces disk I/O making it ideal for read-intensive workloads. Vertica reads only the columns needed to answer the query. For example:

```
=> SELECT avg(price) FROM tickstore WHERE symbol = 'AAPL' and date = '5/31/13';
```

For this example query, a column store reads only three columns while a row store reads all columns:

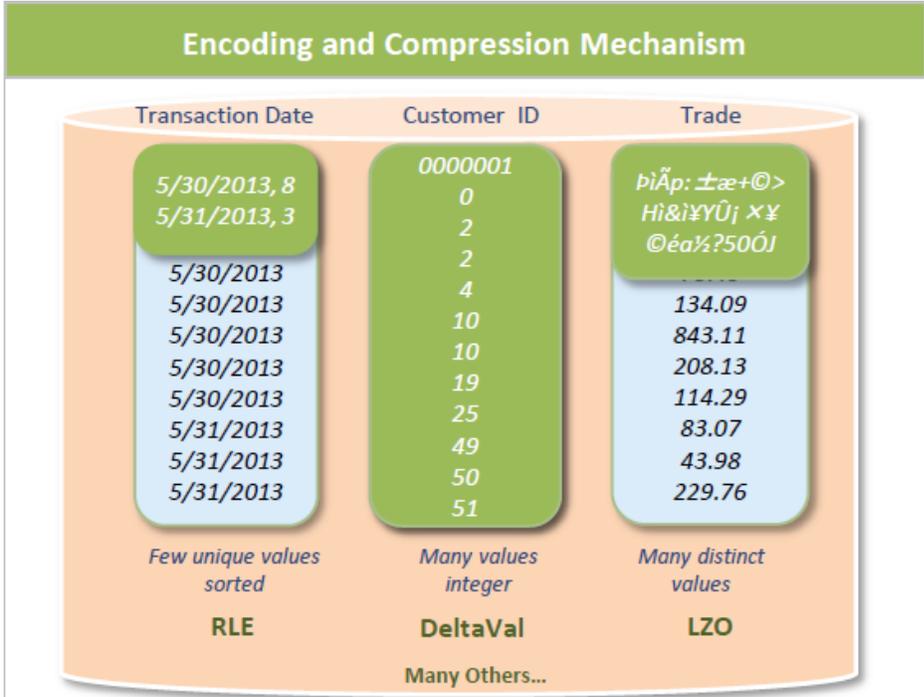

Data Encoding and Compression

Vertica uses encoding and compression to optimize query performance and save storage space.

Encoding converts data into a standard format. Vertica uses a number of different encoding strategies, depending on column data type, table cardinality, and sort order. Encoding increases performance because there is less disk I/O during query execution. In addition, you can store more data in less space.

Compression transforms data into a compact format. Vertica uses several different compression methods and automatically chooses the best one for the data being compressed. Using compression, Vertica stores more data, provides more views, and uses less hardware than other databases. Using compression lets you keep much more historical data in physical storage.

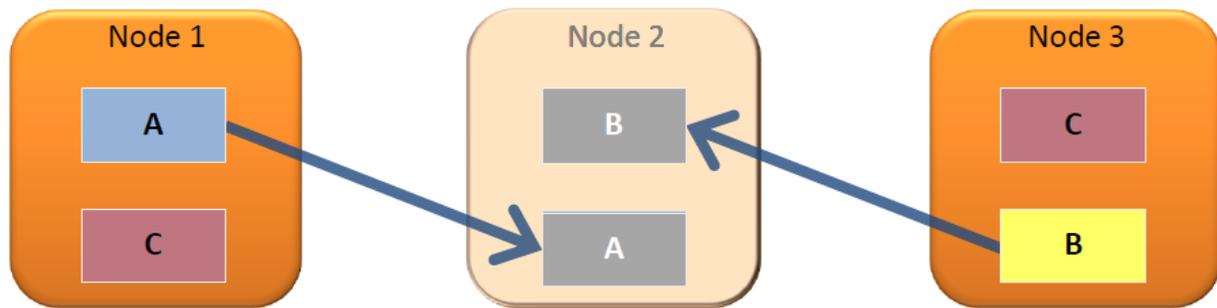

The following shows compression using sorting and cardinality:

For more information, see [Data Encoding and Compression](#).

Clustering

Clustering supports scaling and redundancy. You can scale your database cluster by adding more hardware, and you can improve reliability by distributing and replicating data across your cluster.

Column data gets distributed across nodes in a cluster, so if one node becomes unavailable the database continues to operate. When a node is added to the cluster, or comes back online after being unavailable, it automatically queries other nodes to update its local data.

Projections

A *projection* consists of a set of columns with the same sort order, defined by a column to sort by or a sequence of columns by which to sort. Like an index or materialized view in a traditional database, a projection accelerates query processing. When you write queries in terms of the original tables, the query uses the projections to return query results.

Projections are distributed and replicated across nodes in your cluster, ensuring that if one node becomes unavailable, another copy of the data remains available. For more information, see [K-Safety](#).

Automatic data replication, failover, and recovery provide for *active* redundancy, which increases performance. Nodes recover automatically by querying the system.

Logical and Physical Schema

Vertica stores information about database objects in the logical schema and the physical schema. The difference between the two schemas and how they relate to data storage is an important and unique aspect of the VERTICA architecture.

A *logical* schema consists of objects such as tables, constraints, and views. VERTICA supports any relational schema design that you choose. A *physical* schema consists of collections of table columns called projections. A projection can contain some or all of the columns of a table.

Continuous Performance

Vertica queries and loads data continuously 24x7.

Concurrent loading and querying provides real-time views and eliminates the need for nightly load windows. On-the-fly schema changes allow you to add columns and projections without shutting down your database; Vertica manages updates while keeping the database available.

Terminology

It is helpful to understand the following terms when using Vertica:

Host

A computer system with a 32-bit (non-production use only) or 64-bit Intel or AMD processor, RAM, hard disk, and TCP/IP network interface (IP address and hostname). Hosts share neither disk space nor main memory with each other.

Instance

An instance of Vertica consists of the running Vertica process and disk storage (catalog and data) on a host. Only one instance of Vertica can be running on a host at any time.

Node

A host configured to run an instance of Vertica. It is a member of the database cluster. For a database to have the ability to recover from the failure of a node requires a database K-safety value of at least 1 (3+ nodes).

Cluster

The concept of Cluster in the Vertica Analytics Platform is a collection of hosts with the Vertica software packages (RPM or DEB) that are in one admin tools domain. You can access and manage a cluster from one admintools initiator host.

Database

A cluster of nodes that, when active, can perform distributed data storage and SQL statement execution through administrative, interactive, and programmatic user interfaces.

Note: Although you can define more than one database on a cluster, Vertica supports running only one database per cluster at a time.

Data Encoding and Compression

Vertica uses encoding and compression to optimize query performance and save storage space.

Encoding

Encoding converts data into a standard format and increases performance because there is less disk I/O during query execution. It also passes encoded values to other operations, saving memory bandwidth. Vertica uses several encoding strategies, depending on data type, table cardinality, and sort order. Vertica can directly process encoded data.

Run the Database Designer for optimal encoding in your physical schema. The Database Designer analyzes the data in each column and recommends encoding types for each column in the proposed projections, depending on your design optimization objective. For flex tables, Database Designer recommends the best encoding types for any materialized flex table columns, but not for `__raw__` column projections.

Compression

Compression transforms data into a compact format. Vertica uses integer packing for unencoded integers and LZ0 for compressed data. Before Vertica can process compressed data it must be decompressed.

Compression allows a column store to occupy substantially less storage than a row store. In a column store, every value stored in a column of a projection has the same data type. This greatly facilitates compression, particularly in sorted columns. In a row store, each value of a row can have a different data type, resulting in a much less effective use of compression. Vertica compresses flex table `__raw__` column data by about one half (1/2).

The efficient storage methods that Vertica uses for your database allows you to you maintain more historical data in physical storage.

High Availability

Vertica provides high availability of the database using a RAID-like functionality. This provides the following mechanisms to ensure little to no downtime:

- Multiple copies of the same data on different nodes.
- Vertica continues to load and query data if a node is down.
- Vertica automatically recovers missing data by querying other nodes.

K-Safety

K-safety sets the fault tolerance in the database cluster. The value K represents the number of replicated data in the database cluster. These replicas allow other nodes to take over query processing for any failed nodes.

In Vertica, the value of K can be zero (0), one (1), or two (2). If a database with a K-safety of one (K=1) loses a node, the database continues to run normally. Potentially, the database could continue running if additional nodes fail, as long as at least one other node in the cluster has a copy of the failed node's data. Increasing K-safety to 2 ensures that Vertica can run normally if any two nodes fail. When the failed node or nodes return and successfully recover, they can participate in database operations again.

Note: If the number of failed nodes exceeds the K value, some the data may become unavailable. In this case, the database is considered unsafe and automatically shuts down. However, if every data segment is available on at least one functioning cluster node Vertica continues to run safely.

Potentially, up to half the nodes in a database with a K-safety of 1 could fail without causing the database to shut down. As long as the data on each failed node is available from another active node, the database continues to run.

Note: If half or more of the nodes in the database cluster fail, the database automatically shuts down even if all of the data in the database is available from replicas. This behavior prevents issues due to network partitioning.

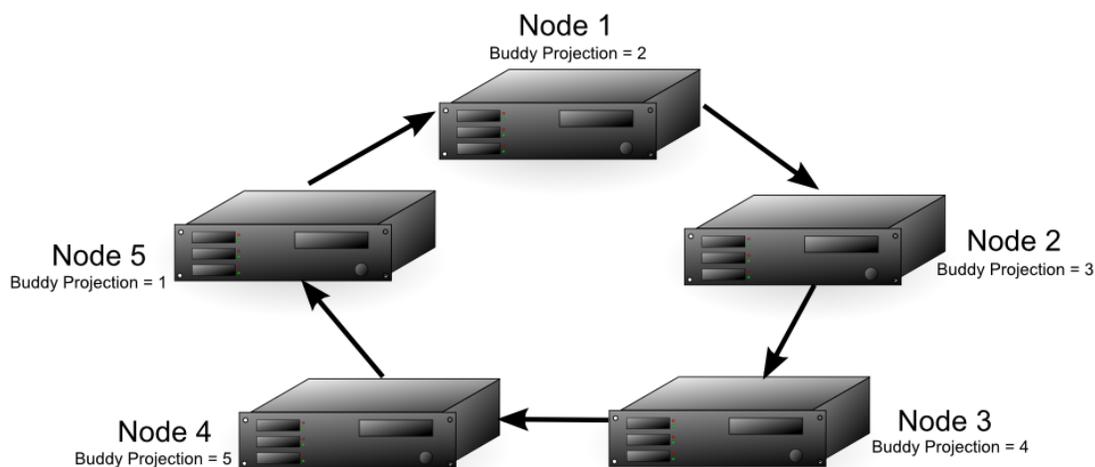

Note: The physical schema design must meet certain requirements. To create designs that are K-safe, Vertica recommends using the Database Designer,.

Buddy Projections

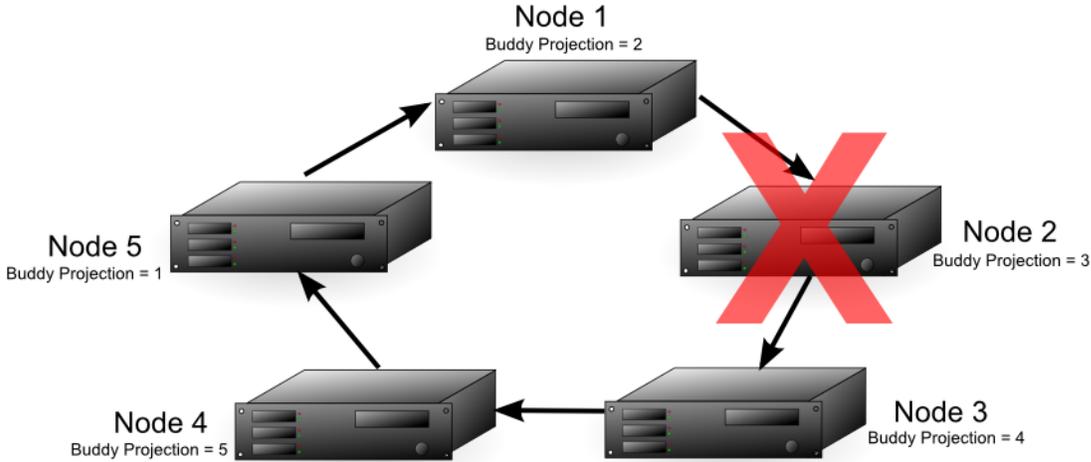

In order to determine the value of k-safety, Vertica creates [buddy projections](#), which are copies of segmented projections distributed across database nodes. (See [Projection Segmentation](#).) Vertica distributes segments that contain the same data to different nodes. This ensures that if a node goes down, all the data is available on the remaining nodes.

K-Safety Example

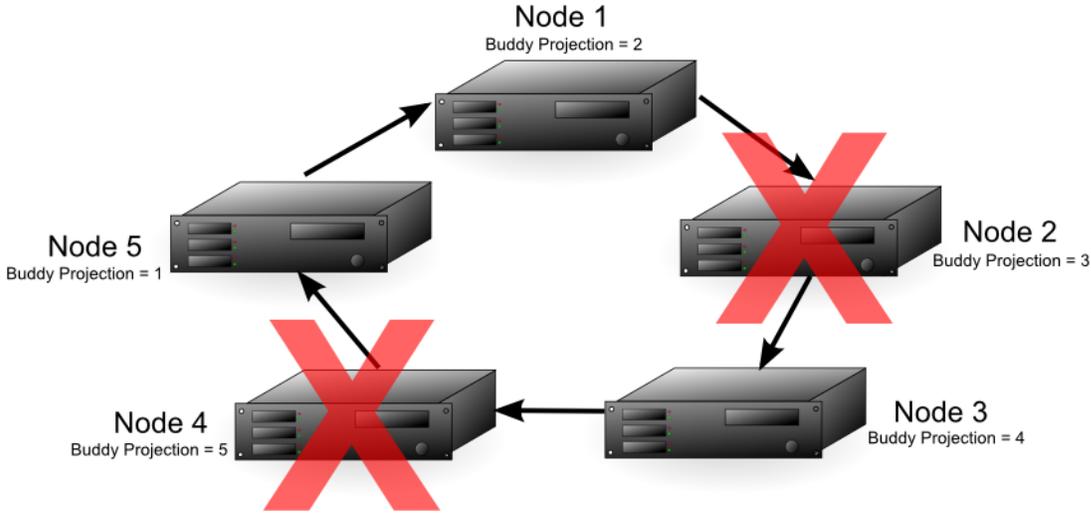

This diagram above shows a 5-node cluster with a K-safety level of 1. Each node contains buddy projections for the data stored in the next higher node (node 1 has buddy projections for node 2, node 2 has buddy projections for node 3, and so on). If any of the nodes fails the database continues to run, though with lower performance, since one of the nodes must handle its own workload and the workload of the failed node.

The diagram below shows a failure of Node 2. In this case, Node 1 handles processing for Node 2 since it contains a replica of node 2's data. Node 1 also continues to perform its own processing. The fault tolerance of the database falls from 1 to 0, since a single node failure could cause the database to become unsafe. In this example, if either Node 1 or Node 3 fails, the database becomes unsafe because not all of its data is available. If Node 1 fails, Node 2's data is no longer available. If Node 3 fails, its data is no longer available, because node 2 is down and could not use the buddy projection. In this case, nodes 1 and 3 are considered critical nodes. In a database with a K-safety level of 1, the node that contains the buddy projection of a failed node, and the node whose buddy projections are on the failed node, always become critical nodes.

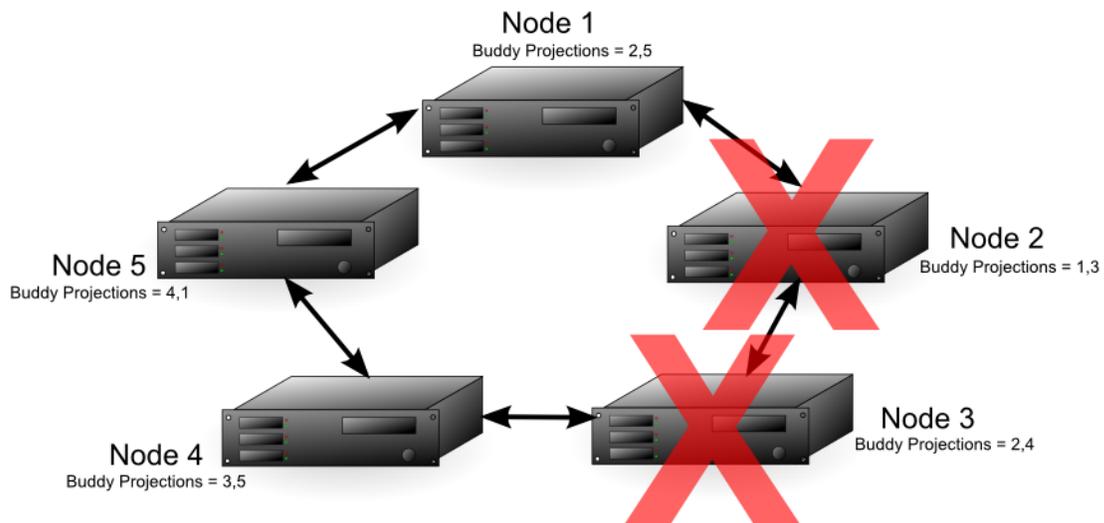

With Node 2 down, either node 4 or 5 could fail and the database still has all of its data available. The diagram below shows that if node 4 fails, node 3 can use its buddy projections to fill in for it. In this case, any further loss of nodes results in a database shutdown, since all the nodes in the cluster are now critical nodes. In addition, if one more node were to fail, half or more of the nodes would be down, requiring Vertica to automatically shut down, no matter if all of the data were available or not.

In a database with a K-safety level of 2, Node 2 and any other node in the cluster could fail and the database continues running. The diagram below shows that each node in the cluster contains buddy projections for both of its neighbors (for example, Node 1 contains buddy projections for Node 5 and Node 2). In this case, nodes 2 and 3 could fail and the database continues running. Node 1 could fill in for Node 2 and Node 4 could fill in for Node 3. Due to the requirement that half or more nodes in the cluster be available in order for the database to

continue running, the cluster could not continue running if node 5 failed, even though nodes 1 and 4 both have buddy projections for its data.

Note: Vertica requires that more than half of all nodes in a cluster must always be available; otherwise, it views the database as being in an unsafe state and shuts it down. Thus, in the previous example, the cluster cannot continue running if Node 5 fails, even though nodes 1 and 4 have buddy projections for its data.

Monitoring K-safety

Use the [SYSTEM](#) table to monitor information related to K-safety, such as:

- `NODE_COUNT`: Number of nodes in the cluster
- `NODE_DOWN_COUNT`: Number of nodes in the cluster that are currently down
- `CURRENT_FAULT_TOLERANCE`: System K-safety level

High Availability With Projections

To ensure high availability and recovery for database clusters of three or more nodes, Vertica:

- Replicates small, unsegmented projections
- Creates buddy projections for large, segmented projections.

Replication (Unsegmented Projections)

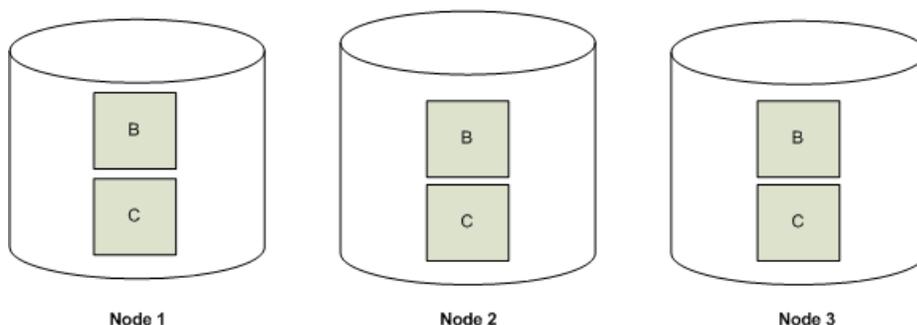

When it creates projections, Database Designer replicates them, creating and storing duplicates of these projections on all nodes in the database.

Replication ensures:

- Distributed query execution across multiple nodes.
- High availability and recovery. In a K-safe database, replicated projections serve as buddy projections. This means that you can use a replicated projection on any node for recovery.

Note: We recommend you use Database Designer to create your physical schema. If you choose not to, be sure to segment all large tables across all database nodes, and replicate small, unsegmented table projections on all database nodes.

The following illustration shows two projections, B and C, replicated across a three node cluster.

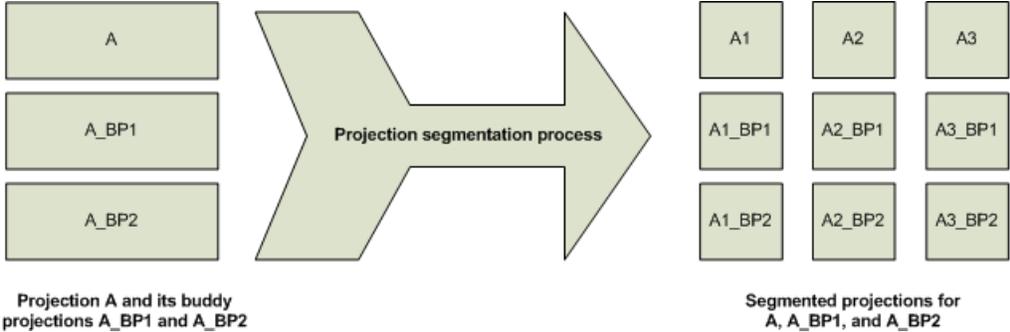

Buddy Projections (Segmented Projections)

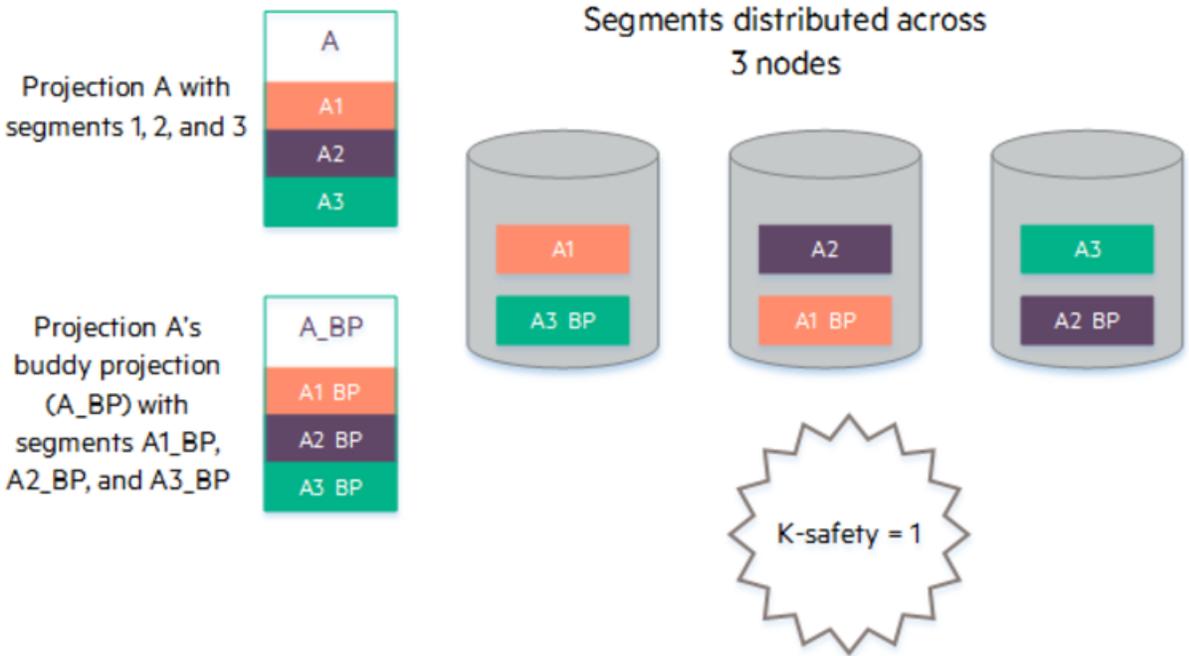

Vertica creates *buddy projections* which are copies of segmented projections that are distributed across database nodes (see [Projection Segmentation](#).) Vertica distributes segments

that contain the same data to different nodes. This ensures that if a node goes down, all the data is available on the remaining nodes. Vertica distributes segments to different nodes by using offsets. For example, segments that comprise the first buddy projection (A_BP1) are offset from projection A by one node, and segments from the second buddy projection (A_BP2) are offset from projection A by two nodes.

The following diagram shows the segmentation for a projection called A and its buddy projections, A_BP1 and A_BP2, for a three node cluster.

The following diagram shows how Vertica uses offsets to ensure that every node has a full set of data for the projection.

How Result Sets Are Stored

Vertica duplicates table columns on all nodes in the cluster to ensure high availability and recovery. Thus, if one node goes down in a K-Safe environment, the database continues to

operate using duplicate data on the remaining nodes. Once the failed node resumes its normal operation, it automatically recovers its lost objects and data by querying other nodes.

Vertica compresses and encodes data to greatly reduce the storage space. It also operates on the encoded data whenever possible to avoid the cost of decoding. This combination of compression and encoding optimizes disk space while maximizing query performance.

Vertica stores table columns as projections. This enables you to optimize the stored data for specific queries and query sets. Vertica provides two methods for storing data:

- Projection segmentation is recommended for large tables (fact and large dimension tables)
- Replication is recommended for the rest of the tables.

High Availability with Fault Groups

Use fault groups to reduce the risk of correlated failures inherent in your physical environment. Correlated failures occur when two or more nodes fail as a result of a single failure. For example, such failures can occur due to problems with shared resources such as power loss, networking issues, or storage.

Vertica minimizes the risk of correlated failures by letting you define fault groups on your cluster. Vertica then uses the fault groups to distribute data segments across the cluster, so the database continues running if a single failure event occurs.

Note: If your cluster layout is managed by a single network switch, a switch failure would cause a single point of failure. Fault groups cannot help with single-point failures.

Vertica supports complex, hierarchical fault groups of different shapes and sizes. You can integrate fault groups with [elastic cluster](#) and [large cluster](#) arrangements to add cluster flexibility and reliability.

Making Vertica Aware of Cluster Topology with Fault Groups

You can also use fault groups to make Vertica aware of the topology of the cluster on which your Vertica database is running. Making Vertica aware of your cluster's topology is required when using Terrace Routing.

Terrace routing is a feature that can reduce the buffer requirements of large queries. Use terrace routing in situations where you have large queries and clusters with a large number of nodes. Without terrace routing, these situations would otherwise require excessive buffer space.

For more information about Terrace Routing, see [Terrace Routing](#).

Automatic Fault Groups

When you configure a cluster of 120 nodes or more, Vertica automatically creates fault groups around control nodes. *Control nodes* are a subset of cluster nodes that manage spread (control messaging). Vertica places nodes that share a control node in the same fault group. See [Large Cluster](#) in the Administrator's Guide for details.

User-Defined Fault Groups

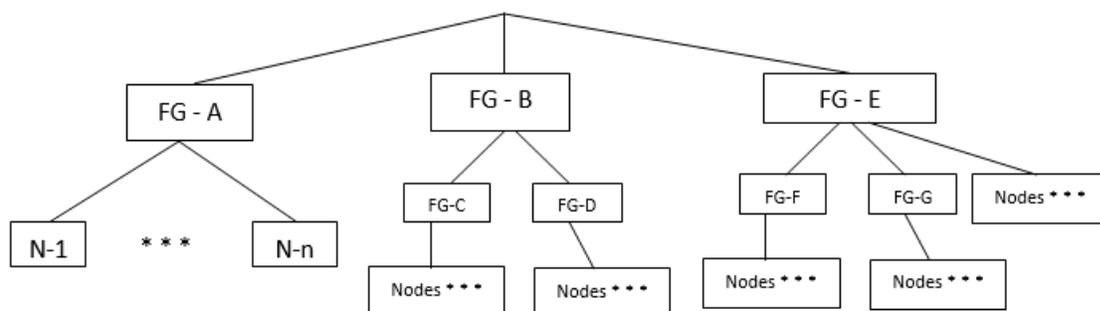

Define your own default groups if:

- Your cluster layout has the potential for correlated failures.
- You want to influence which cluster hosts manage control messaging.

Example Cluster Topology

The following diagram provides an example of hierarchical fault groups configured on a single cluster:

- Fault group FG-A contains nodes only.
- Fault group FG-B (parent) contains child fault groups FG-C and FG-D. Each child fault group also contain nodes.
- Fault group FG-E (parent) contains child fault groups FG-F and FG-G. The parent fault group FG-E also contains nodes.

How to Create Fault Groups

Before you define fault groups, you must have a thorough knowledge of your physical cluster layout. Fault groups require careful planning.

To define fault groups, create an input file of your cluster arrangement. Then, pass the file to a script supplied by Vertica, and the script returns the SQL statements you need to run. See [Fault Groups](#) in the Administrator's Guide for details.

Vertica Components

This section provides an overview of the components that make up Vertica:

- [Logical Schema](#)
- [Physical Schema](#)
- [Database](#)
- [Management Console](#)
- [Administration Tools](#)

These components allow you to tune and control your Vertica Analytics Platform with minimal effort. This eliminates the time and effort a database administrator of a typical database spends identifying issues.

Logical Schema

Design a logical schema for a Vertica database as you would for any SQL database. A logical schema consist of objects such as:

- [Schema](#)
- [Table](#)
- [View](#)
- [Referential Integrity](#)

Vertica supports any relational schema design that you choose.

For more information, see [Designing a Logical Schema](#) in the Administrator's Guide.

Physical Schema

Unlike traditional databases that store data in tables, Vertica physically stores table data in projections, which are collections of table columns.

Projections store data in a format that optimizes query execution. Similar to materialized views, they store result sets on disk rather than compute them each time they are used in a query. Vertica automatically refreshes these result sets with updated or new data.

Projections provide the following benefits:

- Compress and encode data to reduce storage space. Additionally, Vertica operates on the encoded data representation whenever possible to avoid the cost of decoding. This combination of compression and encoding optimizes disk space while maximizing query performance.
- Facilitate distribution across the database cluster. Depending on their size, projections can be segmented or replicated across cluster nodes. For instance, projections for large tables can be segmented and distributed across all nodes. Unsegmented projections for small tables can be replicated across all nodes.
- Transparent to end-users. The Vertica query optimizer automatically picks the best projection to execute a given query.
- Provide high availability and recovery. Vertica duplicates table columns on at least K+1 nodes in the cluster. If one machine fails in a K-Safe environment, the database continues to operate using replicated data on the remaining nodes. When the node resumes normal operation, it automatically queries other nodes to recovers data and lost objects. For more information, see [High Availability with Fault Groups](#) and [High Availability With Projections](#).

Projection Types

A Vertica table typically has multiple projections, each defined to contain different content. Content for the projections of a given table can differ in scope and how it is organized. These differences can generally be divided into the following projection types:

Superprojections

A superprojection contains all the columns of a table. For each table in the database, Vertica requires a minimum of one superprojection.

Under certain conditions, Vertica [automatically creates a table's superprojection](#) immediately on table creation. Vertica also creates a superprojection when you first load data into that table, if none already exists. `CREATE PROJECTION` can create a superprojection if it specifies to include all table columns. A table can have multiple superprojections.

Query-Specific Projections

A query-specific projection is a projection that contains only the subset of table columns to process a given query. Query-specific projections significantly improve the performance of those queries for which they are optimized.

Aggregate Projections

Queries that include expressions or aggregate functions such as [SUM](#) and [COUNT](#) can perform more efficiently when they use projections that already contain the aggregated data. This is especially true for queries on large quantities of data.

Vertica provides three types of projections for storing data that is returned from aggregate functions or expressions:

- [Projection that contains expressions](#): Projection with columns whose values are calculated from anchor table columns.
- [Live aggregate projection](#): Projection that contains columns with values that are aggregated from columns in its anchor table. You can also define live aggregate projections that include [user-defined transform functions](#).
- [Top-K projection](#): Type of live aggregate projection that returns the top k rows from a partition of selected rows. Create a Top-K projection that satisfies the criteria for a Top-K query.

For more information, see [Pre-Aggregating Data in Projections](#).

Projection Segmentation

You can define a projection to maintain its data on the cluster in two ways:

- Divided into multiple segments, or *segmented projections*
- Undivided storage units, or *unsegmented projections*

Segmented Projections

You typically create segmented projections for large fact tables. Vertica splits segmented projections into chunks (segments) of similar size and distributes these segments evenly across the cluster. System K-safety determines how many duplicates (*buddies*) of each segment are created and maintained on different nodes.

You create segmented projections with a `CREATE PROJECTION` statement that includes a `SEGMENTED BY` clause.

Projection segmentation achieves the following goals:

- Ensures high availability and recovery.
- Spreads the query execution workload across multiple nodes.
- Allows each node to be optimized for different query workloads.

Hash Segmentation

Vertica uses hash segmentation to segment large projections. Hash segmentation allows you to segment a projection based on a built-in hash function that provides even distribution of data across multiple nodes, resulting in optimal query execution. In a projection, the data to be hashed consists of one or more column values, each having a large number of unique values and an acceptable amount of skew in the value distribution. Primary key columns typically meet these criteria, so they are often used as hash function arguments.

Unsegmented Projections

In many cases, dimension tables are relatively small, so you do not need to segment them. Accordingly, you should design a K-safe database so projections for its dimension tables are replicated without segmentation on all cluster nodes. You create unsegmented projections with a `CREATE PROJECTION` statement that includes the clause `UNSEGMENTED ALL NODES`. This clause specifies to create identical instances of the projection on all cluster nodes.

How Projections are Created

For each table in the database, Vertica requires a minimum of one projection, called a superprojection. A superprojection contains all columns in a given table. Vertica uses superprojections to ensure support for all queries and other DML operations.

Under certain conditions, Vertica [automatically creates a table's superprojection](#) immediately on table creation. Vertica also creates a superprojection when you first load data into that table, if none already exists. [CREATE PROJECTION](#) can create a superprojection if it specifies to include all table columns. A table can have multiple superprojections.

While superprojections can support all queries on any table, they do not facilitate optimal execution of specific queries. To optimize query execution, you should run Database Designer on a representative sample of your data. Database Designer creates projections that optimize your database based on its data statistics and the queries you use, as follows:

1. Analyzes your logical schema, sample data, and (optionally) sample queries.
2. Creates a physical schema, design (projections) in the form of a SQL script that can be deployed automatically or manually.

Database Designer creates designs that provide excellent query performance within physical constraints. Database Designer uses sophisticated strategies to provide excellent ad-hoc query performance while using disk space efficiently. If desired, you can also design [custom projections](#).

Projection Definition Components

[CREATE PROJECTION](#) defines a projection, as in the following example:

```
=> CREATE PROJECTION retail_sales_fact_p (  
    store_key ENCODING RLE,  
    pos_transaction_number ENCODING RLE,  
    sales_dollar_amount,  
    cost_dollar_amount )  
AS SELECT  
    store_key,  
    pos_transaction_number,  
    sales_dollar_amount,  
    cost_dollar_amount  
FROM store.store_sales_fact  
ORDER BY store_key  
SEGMENTED BY HASH(pos_transaction_number) ALL NODES;
```

A projection definition includes the following components:

- [Column List and Encoding](#)
- [Base Query](#)
- [Sort Order](#)
- [Segmentation](#)

Column List and Encoding

This portion of the SQL statement lists every column in the projection and defines the encoding for each column. Vertica supports encoded data, which helps query execution to incur less disk I/O.

```
CREATE PROJECTION retail_sales_fact_P (  
  store_key ENCODING RLE,  
  pos_transaction_number ENCODING RLE,  
  sales_dollar_amount,  
  cost_dollar_amount )
```

Base Query

A projection's base query clause identifies which columns to include in the projection.

```
AS SELECT  
  store_key,  
  pos_transaction_number,  
  sales_dollar_amount,  
  cost_dollar_amount
```

Sort Order

A projection's `ORDER BY` clause determines how to sort projection data. The sort order localizes logically grouped values so a disk read can identify many results at once. For maximum performance, do not sort projections on `LONG VARBINARY` and `LONG VARCHAR` columns. For more information see [ORDER BY Clause](#)

```
ORDER BY store_key
```

Segmentation

A projection's segmentation clause specifies how to distribute projection data across all nodes in the database. Even load distribution helps maximize access to projection data. For large tables, distribute projection data in segments with `SEGMENTED BY HASH`. For example:

```
SEGMENTED BY HASH(pos_transaction_number) ALL NODES;
```

For small tables, use the UNSEGMENTED keyword to replicate table data. Vertica creates identical copies of an unsegmented projection on all cluster nodes. Replication ensures high availability and recovery.

For maximum performance, do not segment projections on LONG VARBINARY and LONG VARCHAR columns.

For more information see [Projection Segmentation](#).

Database

This section covers the following database elements:

- [Database Setup](#)
- [Database Connections](#)
- [Database Security](#)
- [Database Designer](#)
- [Data Loading](#)
- [Workload Management](#)
- [Database Locks](#)

Database Setup

This page provides an overview on setting up a Vertica database . For complete details see [Configuring the Database](#).

Prepare SQL Scripts and Data Files

Prepare the following files before installing Vertica:

- [Logical schema script](#)
- Loadable [data files](#)
- [Load scripts](#)
- [Sample query script](#) (training set)

Create the Database

Create the database after installing Vertica on at least one host:

- Use the Administration Tools to:
 - Create a database
 - Connect to the database
- Use the Database Designer to design the physical schema.
- Use the vsql interactive interface to run SQL scripts that:
 - Create tables and constraints
 - Create projections

Test the Empty Database

- Test for sufficient projections using the sample query script
- Test the projections for K-safety

Test the Partially-Loaded Database

- Load the dimension tables
- Partially load the fact table
- Check system resource usage

- Check query execution times
- Check projection usage

Complete the Fact Table Load

- Monitor system usage
- Complete the fact table load

Set up Security

For security-related tasks, see [Security and Authentication](#) .

- [Optional] Set up SSL
- [Optional] Set up client authentication
- Set up database users and privileges

Set up Incremental Loads

Set up periodic (trickle) loads, see [Trickle Loading](#)

Database Connections

You can connect to a Vertica database in the following ways:

- Interactively using the `vsql` client, as described in [Using vsql](#) in the Administrator's Guide.

`vsql` is a character-based, interactive, front-end utility that lets you type SQL statements and see the results. It also provides a number of meta-commands and various shell-like features that facilitate writing scripts and automating a variety of tasks.

You can run `vsql` on any node within a database. To start `vsql`, use the Administration Tools or the shell command described in [Using vsql](#).

- Programmatically using the **JDBC** driver provided by Vertica, as described in [Programming JDBC Client Applications](#) in Connecting to Vertica.

An abbreviation for Java Database Connectivity, JDBC is a call-level application programming interface (API) that provides connectivity between Java programs and data sources (SQL databases and other non-relational data sources, such as spreadsheets or flat files). JDBC is included in the Java 2 Standard and Enterprise editions.

- Programmatically using the **ODBC** driver provided by Vertica, as described in [Programming ODBC Client Applications](#) in Connecting to Vertica.

An abbreviation for Open DataBase Connectivity, ODBC is a standard application programming interface (API) for access to database management systems.

- Programmatically using the **ADO.NET** driver provided by Vertica, as described in [Programming ADO.NET Applications](#) in Connecting to Vertica.

The Vertica driver for ADO.NET allows applications written in C# and Visual Studio to read data from, update, and load data into Vertica databases. It provides a data adapter that facilitates reading data from a database into a data set, and then writing changed data from the data set back to the database. It also provides a data reader ([VerticaDataReader](#)) for reading data and [autocommit](#) functionality for committing transactions automatically.

- Programmatically using **Perl** and the DBI driver, as described in [Programming Perl Client Applications](#) in Connecting to Vertica.

Perl is a free, stable, open source, cross-platform programming language licensed under its Artistic License, or the GNU General Public License (GPL).

- Programmatically using **Python** and the Vertica Python Client or the pyodbc driver, as described in [Programming Python Client Applications](#) in Connecting to Vertica.

Python is a free, agile, object-oriented, cross-platform programming language designed to emphasize rapid development and code readability.

Micro Focus recommends that you deploy Vertica as the only active process on each machine in the cluster and connect to it from applications on different machines. Vertica expects to use all available resources on the machine, and to the extent that other applications are also using these resources, suboptimal performance could result.

Database Security

Vertica secures access to the database and its resources by enabling you to control user access to the database and which tasks users are authorized to perform. See [Security and Authentication](#) .

Database Designer

Vertica's Database Designer is a tool that:

- Analyzes your logical schema, sample data, and, optionally, your sample queries.
- Creates a [Physical Schema](#) design that can be deployed automatically or manually.
- Can be used by anyone without specialized database knowledge. Even business users can run Database Designer.
- Can be run and re-run any time for additional optimization without stopping the database.

Run the DBD

Run the Database Designer in one of the following ways:

- With the Management Console, as described in [Using Management Console to Create a Design](#)
- Programmatically, using the steps described in [About Running Vertica Programmatically](#).
- With the Administration Tools by selecting **Configuration Menu > Run Database Designer**. For details, see [Using the Administration Tools to Create a Design](#)

Use the Database Designer to create one of the following types of designs:

- A [comprehensive design](#) that allows you to create new projections for all tables in your database.
- An [incremental design](#) that creates projections for all tables referenced in the queries you supply.

Database Designer benefits include:

- Accepting up to 100 queries in the query input file for an incremental design.
- Accepting unlimited queries for a comprehensive design.
- Producing higher quality designs by considering UPDATE and DELETE statements.

In most cases, the designs created by Database Designer provide optimal query performance within physical constraints. Database Designer uses sophisticated strategies to provide optimal query performance and data compression.

See Also

- [Physical Schema](#)
- [Creating a Database Design](#)

Data Loading

The SQL Data Manipulation Language (DML) commands INSERT, UPDATE, and DELETE perform the same functions in Vertica as they do in row-oriented databases. These commands follow the SQL-92 transaction model and can be intermixed.

Use the [COPY](#) statement for bulk loading data. COPY reads data from text files or data pipes and inserts it into WOS (memory) or directly into the ROS (disk). COPY can load compressed formats such as GZIP and LZO. COPY automatically commits itself and any current transaction but is not atomic; some rows could be rejected. Note that COPY does not automatically commit when copying data into temporary tables.

You can use the COPY statement's NO COMMIT option to prevent COPY from committing a transaction when it finishes copying data. This allows you to ensure the data in the bulk load is either committed or rolled back at the same time. Also, combining multiple smaller data loads into a single transaction allows Vertica to load the data more efficiently. See the [COPY statement](#) in the SQL Reference Manual for more information.

You can use multiple, simultaneous database connections to load and/or modify data.

For more information about bulk loading, see [Bulk Loading Data](#).

Workload Management

Vertica's resource management scheme allows diverse, concurrent workloads to run efficiently on the database. For basic operations, Vertica pre-configures the built-in [GENERAL pool](#) based on RAM and machine cores. You can customize the General pool to handle specific concurrency requirements.

You can also define new resource pools that you configure to limit memory usage, concurrency, and query priority. You can then optionally assign each database user to use a specific resource pool, which controls memory resources used by their requests.

User-defined pools are useful if you have competing resource requirements across different classes of workloads. Example scenarios include:

- A large batch job takes up all server resources, leaving small jobs that update a web page without enough resources. This can degrade user experience.

In this scenario, create a resource pool to handle web page requests and ensure users get resources they need. Another option is to create a limited resource pool for the batch job, so the job cannot use up all system resources.

- An application has lower priority than other applications and you want to limit the amount of memory and number of concurrent users for the low-priority application.

In this scenario, create a resource pool with an upper limit on the query's memory and associate the pool with users of the low-priority application.

For more information, see [Managing Workload Resources](#) in the Administrator's Guide.

Vertica Database Locks

When multiple users concurrently access the same database information, data manipulation can cause conflicts and threaten data integrity. Conflicts occur because some transactions block other operations until the transaction completes. Because transactions committed at the same time should produce consistent results, Vertica uses locks to maintain data concurrency and consistency. Vertica automatically controls locking by limiting the actions a user can take on an object, depending on the state of that object.

Vertica uses object locks and system locks. *Object locks* are used on objects, such as tables and projections. *System locks* include global catalog locks, local catalog locks, and elastic cluster

locks. Vertica supports a full range of standard SQL [lock modes](#), such as shared (S) and exclusive (X).

For related information about lock usage in different transaction isolation levels, see [READ COMMITTED Isolation](#) and [SERIALIZABLE Isolation](#).

Lock Modes

Vertica has different lock modes that determine how a lock acts on an object. Each lock mode has a lock compatibility and lock strength that reflect how it interacts with other locks in the same environment.

Lock Mode	Description
S - Shared	<p>Use a Shared lock for SELECT queries that run at the serialized transaction isolation level. This allows queries to run concurrently, but the S lock creates the effect that transactions are running in serial order. The S lock ensures that one transaction does not affect another transaction until one transaction completes and its S lock is released.</p> <p>Select operations in READ COMMITTED transaction mode do not require S table locks. See Transactions in Vertica Concepts for more information.</p>
I - Insert	<p>Vertica requires an Insert lock to insert data into a table. Multiple transactions can lock an object in Insert mode simultaneously, enabling multiple inserts and bulk loads to occur at the same time. This behavior is critical for parallel loads and high ingestion rates.</p>
SI - Shared Insert	<p>Vertica requires a Shared Insert lock when both a read and an insert occur in a transaction. Shared Insert mode prohibits delete/update operations. An SI lock also results from lock promotion.</p>
X - Exclusive	<p>Vertica uses Exclusive locks when performing deletes and updates. Only mergeout and moveout operations (U locks) can run concurrently on objects with X locks.</p>
T - Tuple Mover	<p>The Tuple Mover uses T locks for operations on delete vectors. Tuple Mover operations upgrade the table lock mode</p>

	from U to T when work on delete vectors starts so that no other updates or deletes can happen concurrently.
U - Usage	Vertica uses Usage locks for moveout and mergeout Tuple Mover operations. These Tuple Mover operations run automatically in the background, therefore, most other operations (except those requiring an O lock) can run when the object is locked in U mode.
O - Owner	An O lock is the strongest Vertica lock mode. An object acquires an Owner lock when it undergoes changes in both data and structure. Such changes can occur in some DDL operations, such as DROP_PARTITION, TRUNCATE TABLE, and ADD COLUMN. When an object is locked in O mode, it cannot be locked simultaneously by another transaction in any mode.
IV - Insert-Validate	An Insert Validate lock is needed for insert operations where the system performs constraint validation for enabled PRIMARY or UNIQUE key constraints.

Lock Compatibility

Lock compatibility refers to having two locks in effect on the same object at the same time.

Lock Compatibility Matrix

This matrix shows which locks can be used on the same object simultaneously.

When two lock modes intersect in a Yes cell, those modes are compatible. If two requested modes intersect in a No cell, the second request is not granted until the first request releases its lock.

	Granted Mode							
Requested Mode	S	I	IV	SI	X	T	U	O
S	Yes	No	No	No	No	Yes	Yes	No
I	No	Yes	Yes	No	No	Yes	Yes	No

IV	No	Yes	No	No	No	Yes	Yes	No
SI	No	No	No	No	No	Yes	Yes	No
X	No	No	No	No	No	No	Yes	No
T	Yes	Yes	Yes	Yes	No	Yes	Yes	No
U	Yes	No						
O	No	No						

Lock Upgrade Matrix

This matrix shows how your object lock responds to an INSERT request.

If an object has an S lock and you want to do an INSERT, your transaction requests an SI lock. However, if an object has an S lock and you want to perform an operation that requires an S lock, no lock request is issued.

	Granted Mode							
Requested Mode	S	I	IV	SI	X	T	U	O
S	S	SI	SI	SI	X	S	S	O
I	SI	I	IV	SI	X	I	I	O
IV	SI	IV	IV	SI	X	IV	IV	O
SI	SI	SI	SI	SI	X	SI	SI	O
X	X	X	X	X	X	X	X	O
T	S	I	IV	SI	X	T	T	O

U	S	I	IV	SI	X	T	U	O
O	O	O	O	O	O	O	O	O

Lock Strength

Lock strength refers to the ability of a lock mode to interact with another lock mode. O locks are strongest and are incompatible with all other locks. Conversely, U locks are weakest and can run concurrently with all other locks except an O lock.

This figure depicts lock mode strength:

Troubleshooting Locks

The [LOCKS](#) and [LOCK_USAGE](#) system tables can help identify problems you may encounter with Vertica database locks.

This example shows one row from the LOCKS system table. From this table you can see what types of locks are active on specific objects and nodes.

```

=> SELECT node_names, object_name, lock_mode, lock_scope FROM LOCKS;
node_names      | object_name      | lock_mode | lock_scope
-----+-----+-----+-----
v_vmart_node001 | Table:public.customer_dimension | X          | TRANSACTION
  
```

This example shows two rows from the LOCKS_USAGE system table. You can also use this table to see what locks are in use on specific objects and nodes.

```

=> SELECT node_name, object_name, mode FROM LOCK_USAGE;
node_name      | object_name      | mode
-----+-----+-----
  
```

```
-----+-----+-----  
v_vmart_node0001 | Cluster Topology | S  
v_vmart_node0001 | Global Catalog | X
```

Management Console

Management Console (MC) is a user-friendly performance monitoring and management tool that provides a unified view of your Vertica database operations. Using a browser, you can create, import, manage, and monitor one or more databases and their associated clusters. You can also create and manage MC users. You can then map the MC users to a Vertica database and manage them through the MC interface.

What You Can Do with Management Console

Create...
A database cluster on hosts that do not have Vertica installed
Multiple Vertica databases on one or more clusters from a single point of control
MC users and grant them access to MC and databases managed by MC
Configure...
Database parameters and user settings dynamically
Resource pools
Monitor...
License usage and conformance
Dynamic metrics about your database cluster
Resource pools
User information and activity on MC
Alerts by accessing a single message box of alerts for all managed databases
Recent databases and clusters through a quick link
Import or Export...
Troubleshoot...

Create...
Configure...
Monitor...
Multiple Vertica databases on one or more clusters from a single point of control
Import or Export...
Export all database messages or log/query details to a file
Import multiple Vertica databases on one or more clusters from a single point of control
Troubleshoot...
MC-related issues through a browser

Management Console provides some, but not all, the functionality that Administration Tools provides. Management Console also includes extended functionality not available in admintools. This additional functionality includes a graphical view of your Vertica database and detailed monitoring charts and graphs. See [Administration Tools and Management Console](#) in the Administrator's Guide for more information.

Getting MC

Download the Vertica server RPM and the MC package from [myVertica Portal](#). You then have two options:

- Install Vertica and MC at the command line and import one or more Vertica database clusters into the MC interface
- Install Vertica directly through MC

See the [Installation Guide](#) for details.

What You Need to Know

If you plan to use MC, review the following topics in the Administrator's Guide:

If you want to ...	See ...
Create a new, empty Vertica database	Create a Database on a Cluster
Import an existing Vertica database cluster into MC	Managing Database Clusters
Understand how MC users differ from database users	About MC Users
Read about the MC privilege model	About MC Privileges and Roles
Create new MC users	Creating an MC User
Grant MC users privileges on one or more Vertica databases managed by MC	Granting Database Access to MC Users
Use Vertica functionality through the MC interface	Using Management Console
Monitor MC and Vertica databases managed by MC	Monitoring Vertica Using Management Console
Monitor and configure Resource Pools	Monitoring Resource Pools

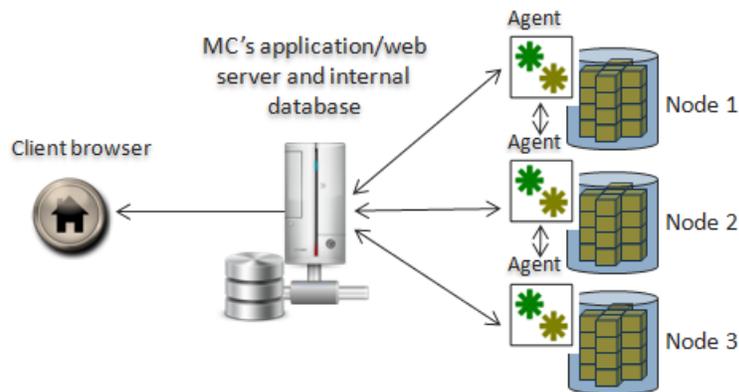

Management Console Architecture

MC accepts HTTP requests from a client web browser, gathers information from the Vertica database cluster, and returns that information to the browser for monitoring.

MC Components

The primary components that drive Management Console are an application/web server and agents that get installed on each node in the Vertica cluster.

The following diagram is a logical representation of MC, the MC user's interface, and the database cluster nodes.

Application/web Server

The application server hosts MC's web application and uses port 5450 for node-to-MC communication and to perform the following:

- Manage one or more Vertica database clusters
- Send rapid updates from MC to the web browser
- Store and report MC metadata, such as alerts and events, current node state, and MC users, on a lightweight, embedded (Derby) database
- Retain workload history

MC Agents

MC agents are internal daemon process that run on each Vertica cluster node. The default agent port, 5444, must be available for MC-to-node and node-to-node communications. Agents monitor MC-managed Vertica database clusters and communicate with MC to provide the following functionality:

- Provide local access, command, and control over database instances on a given node, using functionality similar to Administration Tools.
- Report log-level data from the Administration Tools and Vertica log files.
- Cache details from long-running jobs—such as create/start/stop database operations—that you can view through your browser.
- Track changes to data-collection and monitoring utilities and communicate updates to MC .

- Communicate between all cluster nodes and MC through a webhook subscription, which automates information sharing and reports on cluster-specific issues like node state, alerts, and events.

See Also

- [Monitoring Using MC](#)

Management Console Security

The Management Console (MC) manages multiple Vertica clusters, all which might have different levels and types of security, such as user names and passwords and LDAP authentication. You can also manage MC users who have varying levels of access across these components.

Open Authorization and SSL

Management Console (MC) uses a combination of OAuth (Open Authorization), Secure Socket Layer (SSL), and locally-encrypted passwords to secure HTTPS requests between a user's browser and MC, and between MC and the agents. Authentication occurs through MC and between agents within the cluster. Agents also authenticate and authorize jobs.

The MC configuration process sets up SSL automatically, but you must have the `openssl` package installed on your Linux environment first.

See the following topics in the in the Administrator's Guide for more information:

- [SSL Overview](#)
- [TLS/SSL Server Authentication](#)
- [Generating Certificates and Keys for MC](#)
- [Importing a New Certificate to MC](#)

User Authentication and Access

MC provides two user authentication methods, LDAP or MC. You can use only one method at a time. For example, if you chose LDAP, all MC users will be authenticated against your organization's LDAP server.

You set LDAP authentication up through MC Settings > Authentication on the MC interface.

Note: MC uses LDAP data for authentication purposes only. It does not modify user information in the LDAP repository.

The MC authentication method stores MC user information internally and encrypts passwords. These MC users are not system (Linux) users. They are accounts that have access to MC and, optionally, to one or more MC-managed Vertica databases through the MC interface.

Management Console also has rules for what users can see when they sign in to MC from a client browser. These rules are governed by access levels, each of which is made up of a set of roles.

See Also

- [About MC Users](#)
- [About MC Privileges and Roles](#)
- [Creating an MC User](#)

Management Console Home Page

The MC Home page is the entry point to all MC-managed Vertica database clusters and MC users. User [access levels](#) determine what a user can see on the MC Home page. Layout and navigation are described in [Using Management Console](#) .

Administration Tools

The Vertica Administration tools allow you to easily perform administrative tasks. You can perform most Vertica database administration tasks with Administration Tools.

Run Administration Tools using the Database Administrator account on the Administration host, if possible. Make sure that no other Administration Tools processes are running.

If the Administration host is unresponsive, run Administration Tools on a different node in the cluster. That node permanently takes over the role of Administration host.

Any user can view the man page available for admintools. Enter the following:

```
man admintools
```

Running Administration Tools

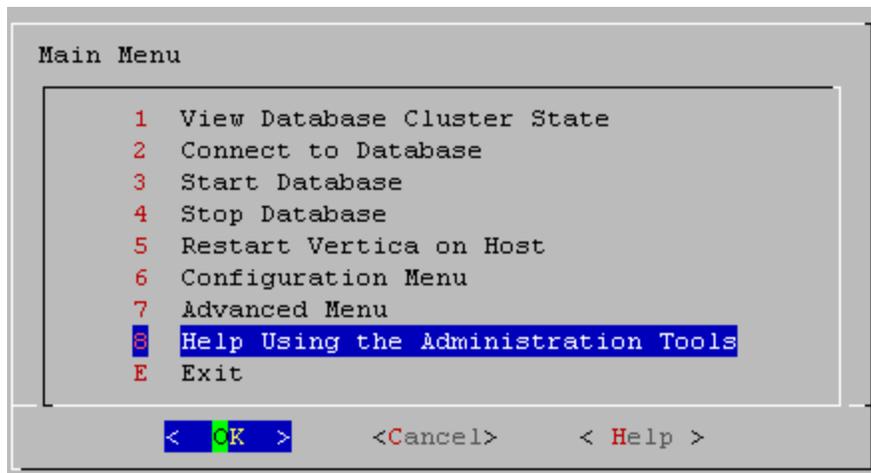

As dbadmin user, you can run administration tools. The syntax follows:

```
/opt/vertica/bin/admintools [--debug ][  
  { -h | --help }  
  | { -a | --help_all }  
  | { -t | --tool } name_of_tool[ options]  
]
```

Options

<code>--debug</code>	If you include the debug option, Vertica logs debug information. Note: You can specify the debug option with or without naming a specific tool. If you specify debug with a specific tool, Vertica logs debug information during tool execution. If you do not specify a tool, Vertica logs debug information when you run tools through the admintools user interface.
<code>-h</code> <code>--help</code>	Outputs abbreviated help.
<code>-a</code> <code>--help_all</code>	Outputs verbose help, which lists all command-line sub-commands and options.
<code>{ -t --tool } <i>name_of_tool</i> [<i>options</i>]</code>	Specifies the tool to run, where <i>name_of_tool</i> is one of the tools described in the help output, and <i>options</i> are one or more comma-delimited tool arguments. Note: Enter <code>admintools -h</code> to see the list of tools available. Enter <code>admintools -t <i>name_of_tool</i> --help</code> to review a specific tool's options.

An unqualified `admintools` command displays the Main Menu dialog box.

If you are unfamiliar with this type of interface, read [Using the Administration Tools Interface](#)

First Login as Database Administrator

The first time you log in as the Database Administrator and run the Administration Tools, the user interface displays.

1. In the end-user license agreement (EULA) window, type `accept` to proceed.

A window displays, requesting the location of the license key file you downloaded from the Micro Focus Web site. The default path is `/tmp/vlicense.dat`.

2. Type the absolute path to your license key (for example, `/tmp/vlicense.dat`) and click **OK**.

Between Dialogs

While the Administration Tools are working, you see the command line processing in a window similar to the one shown below. Do not interrupt the processing.

```
*** Creating database: Stock_Multi ***
Running integrity check
Thread: changing permissions of /opt/vertica/config/share/partinfo.dat: Operation not permitted
Will create database on port 5635
Checking that nodes are defined and installed
stock_multi_node_0 OK [vertica11.2.011288736238288801]
stock_multi_node_1 OK [vertica11.2.011288736238288801]
stock_multi_node_2 OK [vertica11.2.011288736238288801]
Checking full connectivity
Checking/updating multicasting layer
Spread daemon processing
Verifying zspread has been enabled on all nodes
Nominated initiator node stock_multi_node_0
Creating catalog and data directories
Starting DB in multi-node mode
Creating database Stock_Multi

  qa0
  qa1
  qa2
processing host qa0
processing host qa1
processing host qa2
Node Status: stock_multi_node_0: (UP)
Creating database nodes
Node Status: stock_multi_node_0: (UP) stock_multi_node_1: (UP) stock_multi_node_2: (UP)
Multi-node start returns: 1
Multi-node DB create completed
Replicating configuration to all nodes
```

SQL in Vertica

Vertica offers a robust set of SQL elements that allow you to manage and analyze massive volumes of data quickly and reliably. Vertica uses the following:

[SQL language elements](#), including:

- Keywords and Reserved Words
- Identifiers
- Literals
- Operators
- Expressions
- Predicates
- Hints

[SQL data types](#), including:

- Binary
- Boolean
- Character
- Date/Time
- Long
- Numeric

[SQL functions](#) including Vertica-specific functions that take advantage of Vertica's unique column-store architecture. For example, call [ANALYZE_STATISTICS](#) to collect and aggregate a variable amount of sample data for statistical analysis.

[SQL statements](#) that let you write robust queries to quickly return large volumes of data.

About Query Execution

When you submit a query, the initiator quickly chooses the projections to use, optimizes and plans the query execution, and logs the SQL statement to its log. This planning results in an Explain Plan. The Explain Plan maps out the steps the query performs. You can view it in the Management Console.

The optimizer breaks down the Explain Plan into smaller plans distributed to [Executor Node](#)

In the final stages of query plan execution, the initiator node does the following:

- Combines results in a grouping operation
- Merges multiple sorted partial result sets from all the executors
- Formats the results to return to the client

For detailed information about writing and executing queries, see [Queries](#) in Analyzing Data.

Backup Isolation Mode

Vertica can run any SQL query in snapshot isolation mode in order to obtain the fastest possible execution. To be precise, snapshot isolation mode is actually a form of a historical query. The syntax is:

```
AT EPOCH LATEST SELECT...
```

The command queries all data in the database up to but not including the current epoch without holding a lock or blocking write operations, which could cause the query to miss rows loaded by other users up to (but no more than) a specific number of minutes before execution.

Historical Queries

Vertica can run a query from a snapshot of the database taken at a specific date and time or at a specific epoch. The syntax is:

```
AT TIME 'timestamp' SELECT...  
AT EPOCH epoch_number SELECT...  
AT EPOCH LATEST SELECT...
```

The command queries all data in the database up to and including the specified epoch or the epoch representing the specified date and time, without holding a lock or blocking write operations. The specified `TIMESTAMP` and `epoch_number` values must be greater than or equal to the Ancient History Mark epoch.

Historical queries are useful because they access data in past epochs only. Historical queries do not need to hold table locks or block write operations because they do not return the absolute latest data. Their content is private to the transaction and valid only for the length of the transaction.

Historical queries behave in the same manner regardless of transaction isolation level. Historical queries observe only committed data, even excluding updates made by the current transaction, unless those updates are to a temporary table.

Be aware that there is only one backup of the logical schema. This means that any changes you make to the schema are reflected across all epochs. If, for example, you add a new column to a table and you specify a default value for the column, all historical epochs display the new column and its default value.

The `DELETE` command in Vertica does not actually delete data; it marks records as deleted. (The `UPDATE` command is actually a combined `INSERT` and a `DELETE`.) Thus, you can control how much deleted data is stored on disk. For more information, see [Managing Disk Space](#) in the Administrator's Guide.

Transactions

When transactions in multiple user sessions concurrently access the same data, session-scoped isolation levels determine what data each transaction can access.

A transaction retains its isolation level until it completes, even if the session's isolation level changes during the transaction. Vertica internal processes (such as the Tuple Mover and refresh operations) and DDL operations always run at the `SERIALIZABLE` isolation level to ensure consistency.

The Vertica query parser supports standard ANSI SQL-92 isolation levels as follows:

- `READ COMMITTED` (default)
- `READ UNCOMMITTED` : Automatically interpreted as `READ COMMITTED`.
- `REPEATABLE READ`: Automatically interpreted as `SERIALIZABLE`
- `SERIALIZABLE`

Transaction isolation levels `READ COMMITTED` and `SERIALIZABLE` differ as follows:

Isolation level	Dirty read	Non-repeatable read	Phantom read
<code>READ COMMITTED</code>	Not Possible	Possible	Possible
<code>SERIALIZABLE</code>	Not Possible	Not Possible	Not Possible

You can [set separate isolation levels](#) for the database and individual transactions.

Implementation Details

Vertica supports conventional SQL transactions with standard ACID properties:

- ANSI SQL 92 style-implicit transactions. You do not need to run a `BEGIN` or `START TRANSACTION` command.
- No redo/undo log or two-phase commits.
- The `COPY` command automatically commits itself and any current transaction (except when loading temporary tables). It is generally good practice to commit or roll back the current

transaction before you use COPY. This step is optional for DDL statements, which are auto-committed.

Rollback

Transaction rollbacks restore a database to an earlier state by discarding changes made by that transaction. Statement-level rollbacks discard only the changes initiated by the reverted statements. Transaction-level rollbacks discard all changes made by the transaction.

With a ROLLBACK statement, you can explicitly roll back to a named savepoint within the transaction, or discard the entire transaction. Vertica can also initiate automatic rollbacks in two cases:

- An individual statement returns an ERROR message. In this case, Vertica rolls back the statement.
- DDL errors, systemic failures, dead locks, and resource constraints return a ROLLBACK message. In this case, Vertica rolls back the entire transaction.

Explicit and automatic rollbacks always release any locks that the transaction holds.

Savepoints

A *savepoint* is a special marker inside a transaction that allows commands that execute after the savepoint to be rolled back. The transaction is restored to the state that preceded the savepoint.

Vertica supports two types of savepoints:

- An *implicit savepoint* is automatically established after each successful command within a transaction. This savepoint is used to roll back the next statement if it returns an error. A transaction maintains one implicit savepoint, which it rolls forward with each successful command. Implicit savepoints are available to Vertica only and cannot be referenced directly.
- *Named savepoints* are labeled markers within a transaction that you set through [SAVEPOINT](#) statements. A named savepoint can later be referenced in the same transaction through [RELEASE SAVEPOINT](#), which destroys it, and [ROLLBACK TO SAVEPOINT](#), which rolls back all operations that followed the savepoint. Named savepoints can be especially useful

in nested transactions: a nested transaction that begins with a savepoint can be rolled back entirely, if necessary.

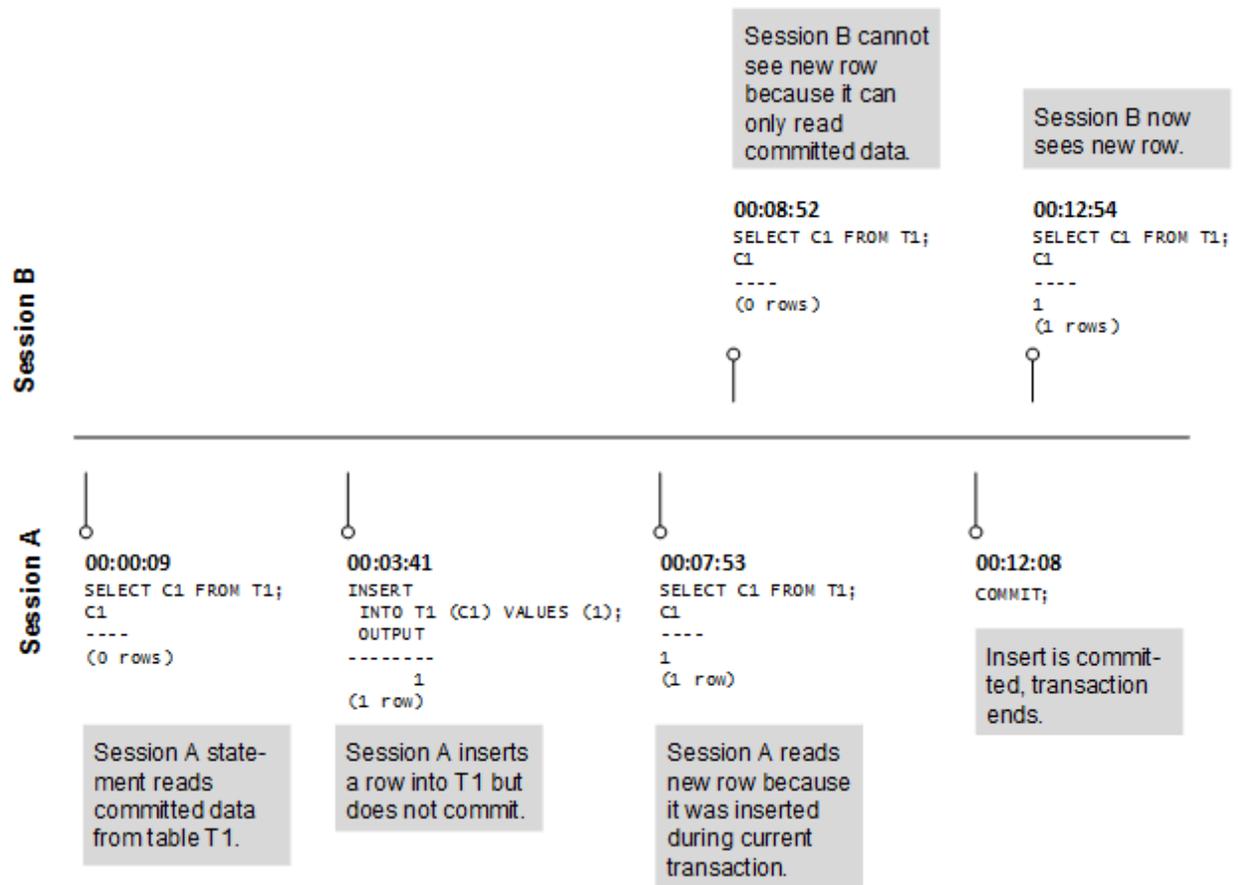

READ COMMITTED Isolation

When you use the isolation level `READ COMMITTED`, a `SELECT` query obtains a backup of committed data at the transaction's start. Subsequent queries during the current transaction also see the results of uncommitted updates that already executed in the same transaction.

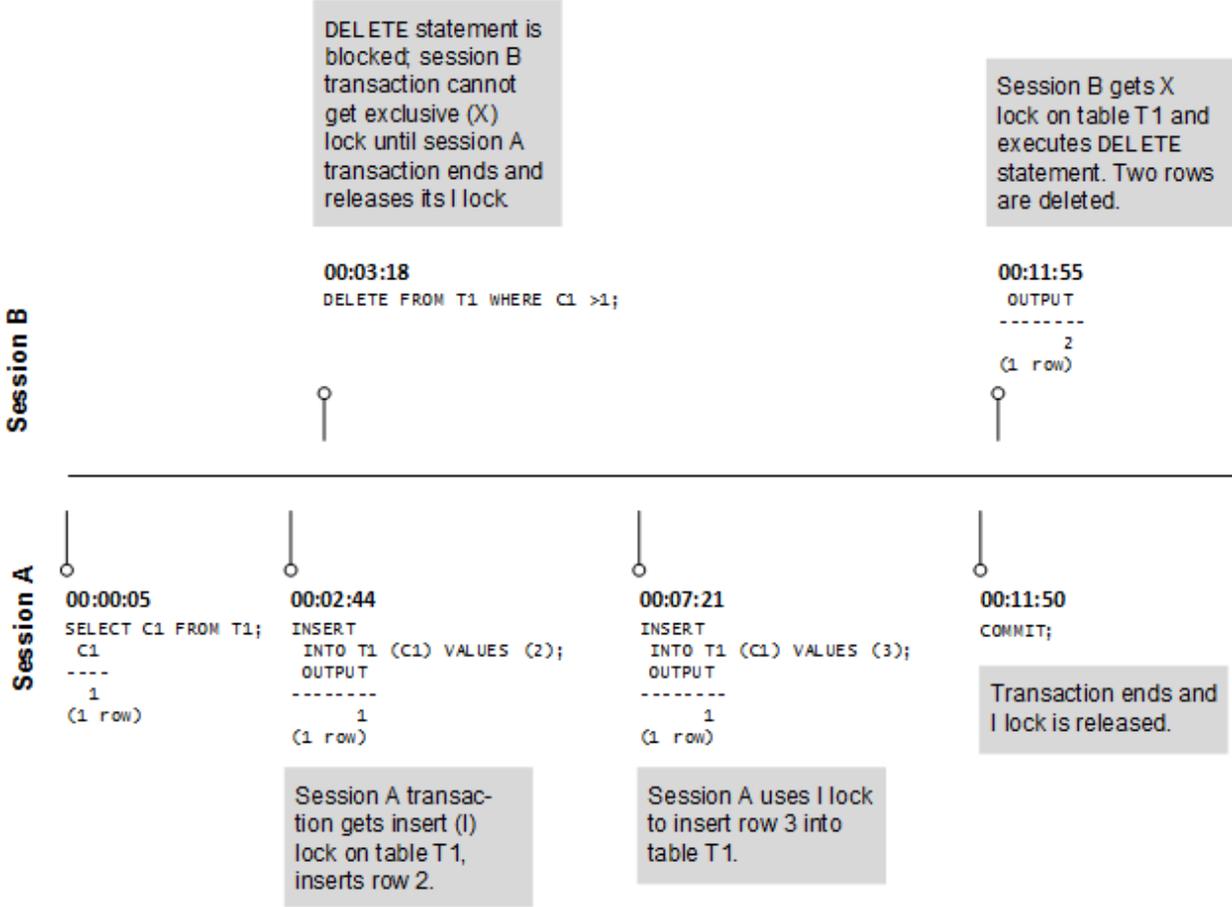

When you use DML statements, your query acquires write locks to prevent other `READ COMMITTED` transactions from modifying the same data. However, be aware that `SELECT` statements do not acquire locks, so concurrent transactions can obtain read and write access to the same selection.

`READ COMMITTED` is the default isolation level. For most queries, this isolation level balances database consistency and concurrency. However, this isolation level can allow one transaction to change the data that another transaction is in the process of accessing. Such changes can yield nonrepeatable and phantom reads. You may have applications with complex queries and updates that require a more consistent view of the database. If so, use [SERIALIZABLE Isolation](#) instead.

The following figure shows how `READ COMMITTED` isolation might control how concurrent transactions read and write the same data:

READ COMMITTED isolation maintains exclusive write locks until a transaction ends, as shown in the following graphic:

- [Vertica Database Locks](#)
- [LOCKS](#)
- [SET SESSION CHARACTERISTICS AS TRANSACTION](#)
- [Configuration Parameters](#)

SERIALIZABLE Isolation

SERIALIZABLE is the strictest SQL transaction isolation level. While this isolation level permits transactions to run concurrently, it creates the effect that transactions are running in serial order. Transactions acquire locks for read and write operations. Thus, successive SELECT

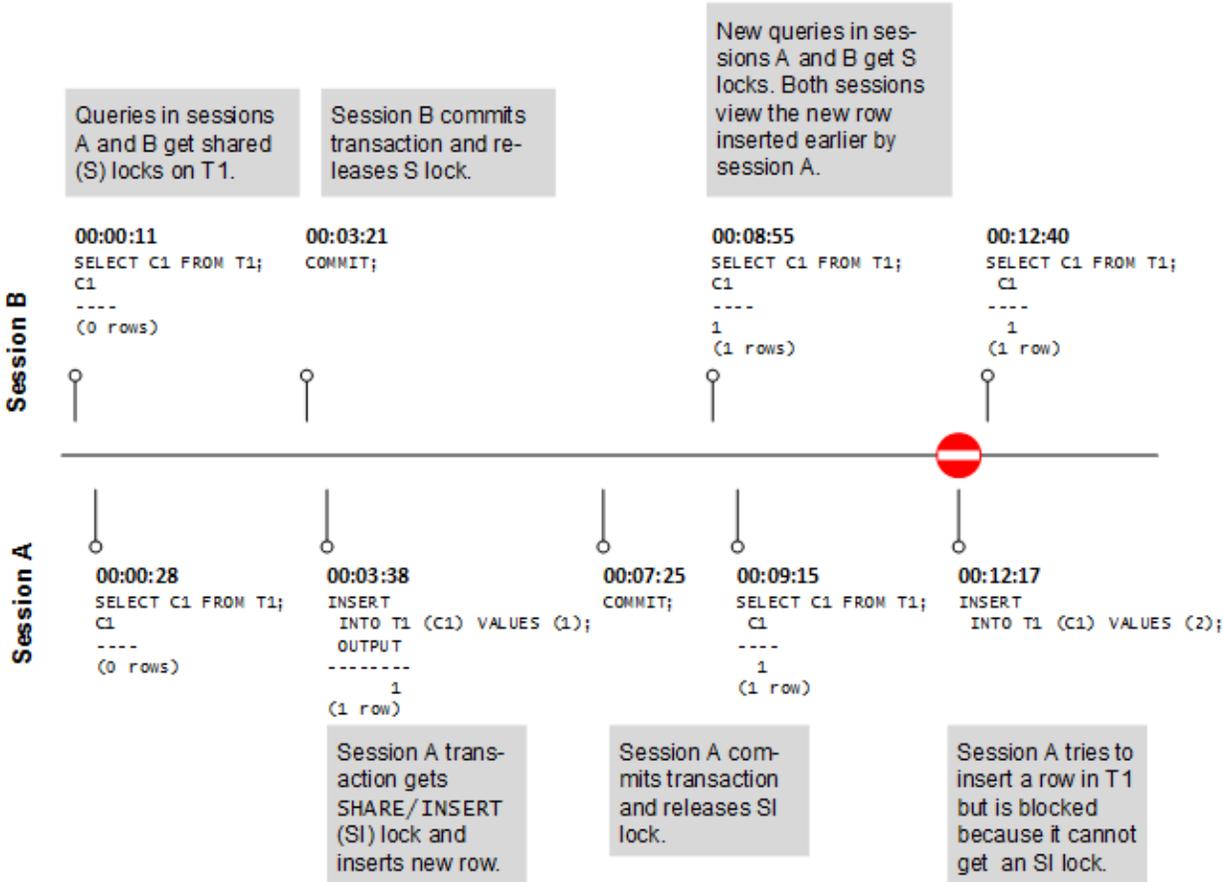

commands within a single transaction always produce the same results. Because SERIALIZABLE isolation provides a consistent view of data, it is useful for applications that require complex queries and updates. However, serializable isolation reduces concurrency. For example, it blocks queries during a bulk load.

SERIALIZABLE isolation establishes the following locks:

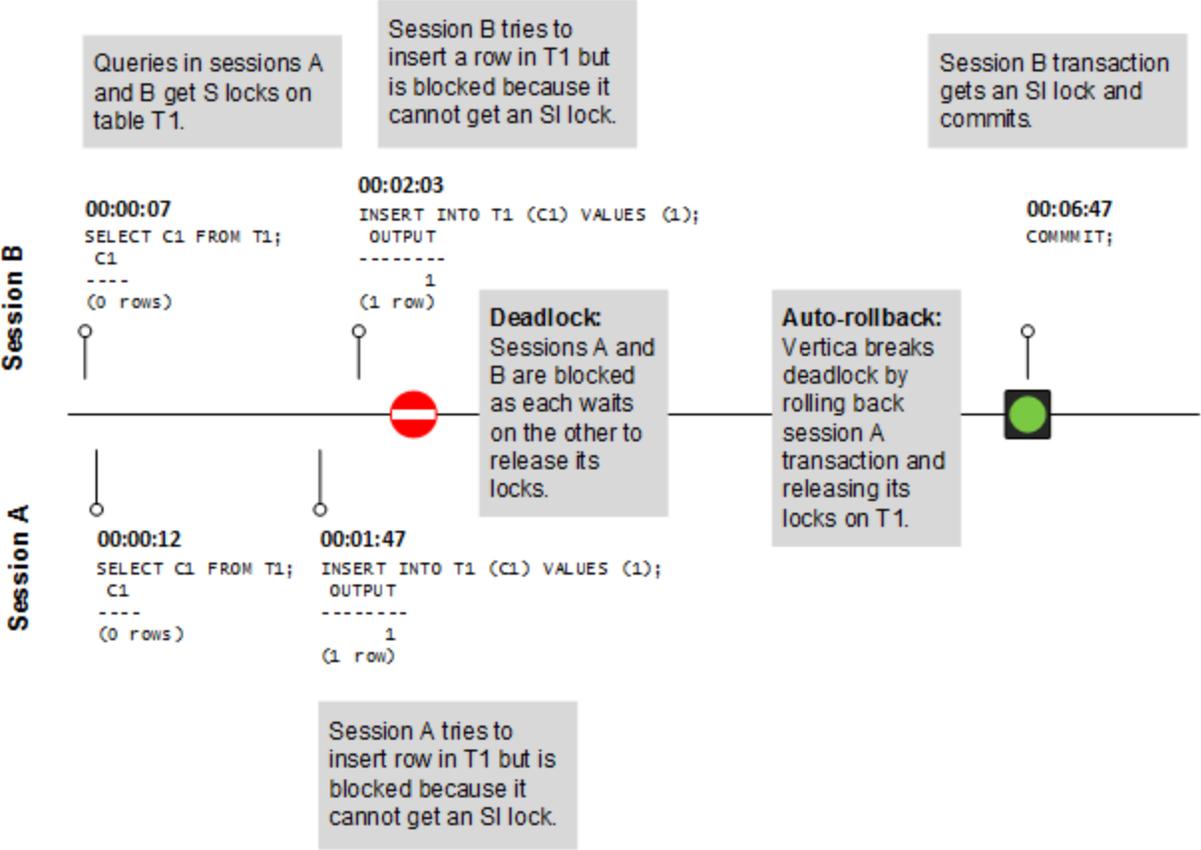

- Table-level read locks: Vertica acquires table-level read locks on selected tables and releases them when the transaction ends. This behavior prevents one transaction from modifying rows while they are being read by another transaction.
- Table-level write lock: Vertica acquires table-level write locks on update and releases them when the transaction ends. This behavior prevents one transaction from reading another transaction's changes to rows before those changes are committed.

At the start of a transaction, a SELECT statement obtains a backup of the selection's committed data. The transaction also sees the results of updates that are run within the transaction before they are committed.

The following figure shows how concurrent transactions that both have SERIALIZABLE isolation levels handle locking:

Applications that use SERIALIZABLE must be prepared to retry transactions due to serialization failures. Such failures often result from deadlocks. When a deadlock occurs, any transaction awaiting a lock automatically times out after 5 minutes. The following figure shows how deadlock might occur and how Vertica handles it:

Note: SERIALIZABLE isolation does not apply to temporary tables. No locks are required for these tables because they are isolated by their transaction scope.

- [Vertica Database Locks](#)
- [LOCKS](#)

Extending Vertica

Vertica lets you extend its capabilities to perform new operations or handle new data types, using the following:

- [User-Defined SQL Function](#) allows you to store frequently-used SQL statements.
- [User-Defined Extensions and User-Defined Functions](#) allows you to develop analytic or data-loading tools using programming languages C++, Java, and R.
- [External Procedures](#) allows you to run external scripts installed in your database cluster.

User-Defined SQL Functions

User-defined SQL functions allow you to create and store commonly-used SQL statements. You can use a user-defined SQL function anywhere in a query where an ordinary SQL statement can be used. You need USAGE privileges on the schema and EXECUTE privileges on the function to run a user-defined SQL function.

For information on creating and managing user-defined SQL functions see [Using User-Defined SQL Functions](#).

User-Defined Extensions and User-Defined Functions

User-Defined Extension (UDx) refers to all extensions to Vertica developed using the APIs in the Vertica SDK. UDxs encompass functions such as User-Defined Scalar Functions (UDSFs), and utilities such as the User-Defined Load (UDL) feature that let you create custom data load routines.

Thanks to their tight integration with Vertica, UDxs usually have better performance than User-defined SQL functions or External Procedures.

User-Defined Functions (UDFs) are a specific type of UDx. You use them in SQL statements to process data similarly to Vertica's own built-in functions. They give you the power of creating your own functions that run just slightly slower than Vertica's own function.

The Vertica SDK uses the term UDx extensively, even for APIs that deal exclusively with developing UDFs.

External Procedures

External procedures allow you to call a script or executable program stored in your database cluster. You can pass literal values to this external procedure as arguments. The external procedure cannot communicate back to Vertica.

For information on creating and using external procedures see [Using External Procedures](#).

International Languages and Character Sets

This section describes how Vertica handles internationalization and character sets.

Unicode Character Encoding

Vertica supports Unicode Transformation Format-8, or UTF8, where 8 equals 8-bit. UTF-8 is a variable-length character encoding for Unicode created by Ken Thompson and Rob Pike. UTF-8 can represent any universal character in the Unicode standard. Initial encoding of byte codes and character assignments for UTF-8 coincides with ASCII. Thus, UTF8 requires little or no change for software that handles ASCII but preserves other values.

Vertica database servers expect to receive all data in UTF-8, and Vertica outputs all data in UTF-8. The ODBC API operates on data in UCS-2 on Windows systems, and normally UTF-8 on Linux systems. JDBC and ADO.NET APIs operate on data in UTF-16. Client drivers automatically convert data to and from UTF-8 when sending to and receiving data from Vertica using API calls. The drivers do not transform data loaded by executing a [COPY](#) or [COPY LOCAL](#) statement.

See [Implement Locales for International Data Sets](#) in the Administrator's Guide for details.

Locales

Locale specifies the user's language, country, and any special variant preferences, such as collation. Vertica uses locale to determine the behavior of certain string functions. Locale also determines the collation for various SQL commands that require ordering and comparison, such as aggregate `GROUP BY` and `ORDER BY` clauses, joins, and the analytic `ORDER BY` clause.

The default locale for a Vertica database is `en_US@collation=binary` (English US). You can define a new default locale that is used for all sessions on the database. You can also override the locale for individual sessions. However, projections are always collated using the default `en_US@collation=binary` collation, regardless of the session collation. Any locale-specific collation is applied at query time.

If you set the locale to null, Vertica sets the locale to `en_US_POSIX`. You can set the locale back to the default locale and collation by issuing the `vsq` meta-command `\locale`. For example:

```
=> set locale to '';  
INFO 2567: Canonical locale: 'en_US_POSIX'  
Standard collation: 'LEN'  
English (United States, Computer)  
SET  
=> \locale en_US@collation=binary;  
INFO 2567: Canonical locale: 'en_US'  
Standard collation: 'LEN_KBINARY'  
English (United States)  
=> \locale  
en_US@collation=binary;
```

You can set locale through [ODBC](#), [JDBC](#), and [ADO.net](#).

See the following topics in the Administrator's Guide for details:

- [Implement Locales for International Data Sets](#)
- [Supported Locales](#) in the [Appendix](#)

String Functions

Vertica provides string functions to support internationalization. Unless otherwise specified, these string functions can optionally specify whether VARCHAR arguments should be interpreted as octet (byte) sequences, or as (locale-aware) sequences of characters. This is accomplished by adding "USING OCTETS" and "USING CHARACTERS" (default) as a parameter to the function.

See [String Functions](#) for details.

Character String Literals

By default, string literals (' . . . ') treat back slashes literally, as specified in the SQL standard.

Tip: If you have used previous releases of Vertica and you do not want string literals to treat back slashes literally (for example, you are using a back slash as part of an escape sequence), you can turn off the `StandardConformingStrings` configuration parameter. See [Internationalization Parameters](#) in the Administrator's Guide. You can also use the `EscapeStringWarning` parameter to locate back slashes which have been incorporated into string literals, in order to remove them.

See [Character String Literals](#) for details.

Installing Vertica

Welcome to Installing Vertica. Read this guide to learn how to prepare for and install the Vertica server. This guide also provides instructions for installing the Vertica Management Console.

For information about installing client drivers, see [Client Drivers](#).

Prerequisites

- This document assumes that you have become familiar with the concepts discussed in Vertica Concepts.
- To perform the procedures described in this document, you must have root password or sudo access (for all commands) for all nodes in your cluster.

Installation Overview and Checklist

This page provides an overview of installation tasks. Carefully review and follow the instructions in all sections in this topic.

Important Notes

- Vertica supports only one running database per cluster.
- Vertica supports installation on one, two, or multiple nodes. The steps for [Installing Vertica](#) are the same, no matter how many nodes are in the cluster.
- Prerequisites listed in [Before You Install Vertica](#) are required for all Vertica configurations.
- Only one instance of Vertica can be running on a host at any time.
- To run the `install_vertica` script, as well as adding, updating, or deleting nodes, you must be logged in as root, or sudo as a user with all privileges. You must run the script for all installations, including upgrades and single-node installations.

Installation Scenarios

The four main scenarios for installing Vertica on hosts are:

- A single node install, where Vertica is installed on a single host as a *localhost* process. This form of install cannot be expanded to more hosts later on and is typically used for development or evaluation purposes.
- Installing to a cluster of physical host hardware. This is the most common scenario when deploying Vertica in a testing or production environment.
- Installing on Amazon Web Services (AWS). When you choose the recommended Amazon Machine Image (AMI), Vertica is installed when you create your instances. For the AWS specific installation procedure, see [Installing and Running Vertica on AWS: The Detailed Procedure](#) rather than the using the steps for installation and upgrade that appear in this guide.

- Installing to a local cluster of virtual host hardware. Also similar to installing on physical hosts, but with network configuration differences.

Before You Install

[Before You Install Vertica](#) describes how to construct a hardware platform and prepare Linux for Vertica installation.

These preliminary steps are broken into two categories:

- Configuring Hardware and Installing Linux
- Configuring the Network

Install or Upgrade Vertica

Once you have completed the steps in the [Before You Install Vertica](#) section, you are ready to run the install script.

[Installing Vertica](#) describes how to:

- Back up any existing databases.
- Download and install the Vertica RPM package.
- Install a cluster using the `install_vertica` script.
- [Optional] [Create a properties file](#) that lets you install Vertica silently.

Note: This guide provides additional [manual procedures](#) in case you encounter installation problems.

- [Upgrading Vertica](#) describes how to upgrade to a more recent version of the software.

Note: If you are upgrading your Vertica license, refer to [Managing Licenses](#) in the Administrator's Guide.

Post-Installation Tasks

[After You Install Vertica](#) describes subsequent steps to take after you've run the installation script. Some of the steps can be skipped based on your needs:

- Install the license key.
- Verify that kernel and user parameters are correctly set.
- Install the vsql client application on non-cluster hosts.
- Resolve any SLES 11.3 issues during spread configuration.
- Use the Vertica documentation online, or download and install Vertica documentation. Find the online documentation and documentation packages to download at <http://my.vertica.com/docs>.
- Install client drivers.
- Extend your installation with Vertica packages.
- [Install](#) or [upgrade](#) the Management Console.

Get started!

- Read the [Concepts Guide](#) for a high-level overview of the Vertica Analytics Platform.
- Proceed to the [Installing and Connecting to the VMart Example Database](#) in Getting Started, where you will be guided through setting up a database, loading sample data, and running sample queries.

About Linux Users Created by Vertica and Their Privileges

This topic describes the Linux accounts that the installer creates and configures so Vertica can run. When you install Vertica, the installation script optionally creates the following Linux user and group:

- dbadmin—Administrative user
- verticadba—Group for DBA users

dbadmin and verticadba are the default names. If you want to change what these Linux accounts are called, you can do so using the installation script. See [Installing Vertica with the Installation Script](#) for details.

Before You Install Vertica

See the following topics for more information:

- [Installation Overview and Checklist](#)
- [General Hardware and OS Requirements and Recommendations](#)

When You Install Vertica

The Linux dbadmin user owns the database catalog and data storage on disk. When you run the install script, Vertica creates this user on each node in the database cluster. It also adds dbadmin to the Linux dbadmin and verticadba groups, and configures the account as follows:

- Configures and authorizes dbadmin for passwordless SSH between all cluster nodes. SSH must be installed and configured to allow passwordless logins. See [Enable Secure Shell \(SSH\) Logins](#).
- Sets the dbadmin user's BASH shell to `/bin/bash`, required to run scripts, such as `install_vertica` and the Administration Tools.
- Provides read-write-execute permissions on the following directories:

- `/opt/vertica/*`
- `/home/dbadmin`—the default directory for database data and catalog files (configurable through the install script)

Note: The Vertica installation script also creates a Vertica database superuser named `dbadmin`. They share the same name, but they are not the same; one is a Linux user and the other is a Vertica user. See [Database Administration User](#) in the Administrator's Guide for information about the database superuser.

After You Install Vertica

Root or sudo privileges are not required to start or run Vertica after the installation process completes.

The `dbadmin` user can log in and perform Vertica tasks, such as creating a database, installing/changing the license key, or installing drivers. If `dbadmin` wants database directories in a location that differs from the default, the root user (or a user with sudo privileges) must create the requested directories and change ownership to the `dbadmin` user.

Vertica prevents administration from users other than the `dbadmin` user (or the user name you specified during the installation process if not `dbadmin`). Only this user can run Administration Tools.

See Also

- [Installation Overview and Checklist](#)
- [Before You Install Vertica](#)
- [Platform Requirements and Recommendations](#)
- [Enable Secure Shell \(SSH\) Logins](#)

Before You Install Vertica

Complete all of the tasks in this section before you install Vertica. When you have completed this section, proceed to [Installing Vertica](#).

Platform Requirements and Recommendations

You must verify that your servers meet the platform requirements described in [Supported Platforms](#). The Supported Platforms topics detail supported versions for the following:

- OS for Server and Management Console (MC)
- Supported Browsers for MC
- Vertica driver compatibility
- R
- Hadoop
- Various plug-ins

BASH Shell

All shell scripts included in Vertica must run under the BASH shell. If you are on a Debian system, then the default shell can be DASH. DASH is not supported. Change the shell for root and for the dbadmin user to BASH with the chsh command.

For example:

```
# getent passwd | grep root
root:x:0:0:root:/root:/bin/dash

# chsh
Changing shell for root.
New shell [/bin/dash]: /bin/bash
Shell changed.
```

Then, as root, change the symbolic link for `/bin/sh` from `/bin/dash` to `/bin/bash`:

```
# rm /bin/sh
# ln -s /bin/bash /bin/sh
```

Log out and back in for the change to take effect.

Install the Latest Vendor Specific System Software

Install the latest vendor drivers for your hardware. For Micro Focus Servers, update to the latest versions for:

- HP ProLiant Smart Array Controller Driver (cciss)
- Smart Array Controller Firmware
- HP Array Configuration Utility (HP ACU CLI)

Data Storage Recommendations

- All internal drives connect to a single RAID controller.
- The RAID array should form one hardware RAID device as a contiguous /data volume.

Validation Utilities

Vertica provides several validation utilities that validate the performance on prospective hosts. The utilities are installed when you install the Vertica RPM, but you can use them before you run the `install_vertica` script. See [Validation Scripts](#) for more details on running the utilities and verifying that your hosts meet the recommended requirements.

General Hardware and OS Requirements and Recommendations

Hardware Recommendations

The Vertica Analytics Platform is based on a massively parallel processing (MPP), shared-nothing architecture, in which the query processing workload is divided among all nodes of the Vertica database. Micro Focus highly recommends using a homogeneous hardware configuration for your Vertica cluster; that is, each node of the cluster should be similar in CPU, clock speed, number of cores, memory, and operating system version.

Note that Micro Focus has not tested Vertica on clusters made up of nodes with disparate hardware specifications. While it is expected that a Vertica database would functionally work in a mixed hardware configuration, performance will most certainly be limited to that of the slowest node in the cluster.

Detailed hardware recommendations are available in [Recommendations for Sizing Vertica Nodes and Clusters](#) (formerly the Vertica Hardware Planning Guide).

Platform OS Requirements

Important: Deploy Vertica as the only active process on each host—other than Linux processes or software explicitly approved by Vertica. Vertica cannot be colocated with other software. Remove or disable all non-essential applications from cluster hosts.

You must verify that your servers meet the platform requirements described in [Vertica Server and Vertica Management Console](#).

Verify Sudo

Vertica uses the sudo command during installation and some administrative tasks. Ensure that sudo is available on all hosts with the following command:

```
# which sudo
/usr/bin/sudo
```

If sudo is not installed, browse to the [Sudo Main Page](#) and install sudo on all hosts.

When you use sudo to install Vertica, the user that performs the installation must have privileges on all nodes in the cluster.

Configuring sudo with privileges for the individual commands can be a tedious and error-prone process; thus, the Vertica documentation does not include every possible sudo command that you can include in the sudoers file. Instead, Micro Focus recommends that you temporarily elevate the sudo user to have all privileges for the duration of the install.

Note: See the sudoers and visudo man pages for the details on how to write/modify a sudoers file.

To allow root sudo access on all commands as any user on any machine, use visudo as root to edit the /etc/sudoers file and add this line:

```
## Allow root to run any commands anywhere
root    ALL=(ALL) ALL
```

After the installation completes, remove (or reset) sudo privileges to the pre-installation settings.

Prepare Disk Storage Locations

You must create and specify directories in which to store your catalog and data files (physical schema). You can specify these locations when you install or configure the database, or later during database operations. Both the catalog and data directories must be owned by the database administrator.

The directory you specify for database catalog files (the catalog path) is used across all nodes in the cluster. For example, if you specify `/home/catalog` as the catalog directory, Vertica uses that catalog path on all nodes. The catalog directory should always be separate from any data file directories.

Note: Do not use a shared directory for more than one node. Data and catalog directories must be distinct for each node. Multiple nodes must not be allowed to write to the same data or catalog directory.

The data path you designate is also used across all nodes in the cluster. Specifying that data should be stored in `/home/data`, Vertica uses this path on all database nodes.

Do not use a single directory to contain both catalog and data files. You can store the catalog and data directories on different drives, which can be either on drives local to the host (recommended for the catalog directory) or on a shared storage location, such as an external disk enclosure or a SAN.

Before you specify a catalog or data path, be sure the parent directory exists on all nodes of your database. Creating a database in `admintools` also creates the catalog and data directories, but the parent directory must exist on each node.

You do not need to specify a disk storage location during installation. However, you can do so by using the `--data-dir` parameter to the `install_vertica` script. See [Specifying Disk Storage Location During Installation](#)

See Also

- [Specifying Disk Storage Location on MC](#)
- [Specifying Disk Storage Location During Database Creation](#)
- [Configuring Disk Usage to Optimize Performance](#)
- [Using Shared Storage With Vertica](#)

Disk Space Requirements for Vertica

In addition to actual data stored in the database, Vertica requires disk space for several data reorganization operations, such as mergeout and [managing nodes](#) in the cluster. For best results, Micro Focus recommends that disk utilization per node be no more than sixty percent (60%) for a K-Safe=1 database to allow such operations to proceed.

In addition, disk space is temporarily required by certain query execution operators, such as hash joins and sorts, in the case when they cannot be completed in memory (RAM). Such operators might be encountered during queries, recovery, refreshing projections, and so on. The amount of disk space needed (known as temp space) depends on the nature of the queries, amount of data on the node and number of concurrent users on the system. By default, any unused disk space on the data disk can be used as temp space. However, Micro Focus recommends provisioning temp space separate from data disk space. See [Configuring Disk Usage to Optimize Performance](#).

Configuring the Network

This group of steps involve configuring the network. These steps differ depending on your installation scenario. A single node installation requires little network configuration, since the single instance of the Vertica server does not need to communication with other nodes in a cluster. For cluster and cloud install scenarios, you must make several decisions regarding your configuration.

Vertica supports server configuration with multiple network interfaces. For example, you might want to use one as a private network interface for internal communication among cluster hosts (the ones supplied via the `--hosts` option to `install_vertica`) and a separate one for client connections.

Important: Vertica performs best when all nodes are on the same subnet and have the same broadcast address for one or more interfaces. A cluster that has nodes on more than one subnet can experience lower performance due to the network latency associated with a multi-subnet system at high network utilization levels.

Important Notes

- Network configuration is exactly the same for single nodes as for multi-node clusters, with one special exception. If you install Vertica on a single host machine that is to remain a permanent single-node configuration (such as for development or Proof of Concept), you can install Vertica using `localhost` or the loopback IP (typically `127.0.0.1`) as the value for `--hosts`. Do not use the hostname `localhost` in a node definition if you are likely to add nodes to the configuration later.
- If you are using a host with multiple network interfaces, configure Vertica to use the address which is assigned to the NIC that is connected to the other cluster hosts.
- Use a dedicated gigabit switch. If you do not performance could be severely affected.
- Do not use DHCP dynamically-assigned IP addresses for the private network. Use only static addresses or permanently-leased DHCP addresses.

Optionally Run Spread on Separate Control Network

If your query workloads are network intensive, you can use the `--control-network` parameter with the `install_vertica` script (see [Installing Vertica with the Installation Script](#)) to allow spread communications to be configured on a subnet that is different from other Vertica data communications.

The `--control-network` parameter accepts either the default value or a broadcast network IP address (for example, `192.168.10.255`).

Configure SSH

- Verify that root can use Secure Shell (SSH) to log in (`ssh`) to all hosts that are included in the cluster. SSH (SSH client) is a program for logging into a remote machine and for running commands on a remote machine.
- If you do not already have SSH installed on all hosts, log in as root on each host and install it before installing Vertica. You can download a free version of the SSH connectivity tools from [OpenSSH](#).
- Make sure that `/dev/pts` is mounted. Installing Vertica on a host that is missing the mount point `/dev/pts` could result in the following error when you create a database:

```
TIMEOUT ERROR: Could not login with SSH. Here is what SSH said:Last login: Sat Dec 15 18:05:35 2007  
from v_vmart_node0001
```

Allow Passwordless SSH Access for the Dbadmin User

The `dbadmin` user must be authorized for passwordless `ssh`. In typical installs, you won't need to change anything; however, if you set up your system to disallow passwordless login, you'll need to enable it for the `dbadmin` user. See [Enable Secure Shell \(SSH\) Logins](#).

Ensure Ports Are Available

Verify that ports required by Vertica are not in use by running the following command as the root user and comparing it with the ports required in **Firewall Considerations** below:

```
netstat -atupn
```

If you are using a Red Hat 7/CentOS 7 system, use the following command instead:

```
ss -atupn
```

Firewall Considerations

Vertica requires several ports to be open on the local network. Vertica does not recommend placing a firewall between nodes (all nodes should be behind a firewall), but if you must use a firewall between nodes, ensure the following ports are available:

Port	Protocol	Service	Notes
7	TCP	Management Console	Required by Management Console to discover Vertica nodes.
22	TCP	sshd	Required by Administration Tools and the Management Console Cluster Installation wizard.
5433	TCP	Vertica	Vertica client (vsq, ODBC, JDBC, etc) port.
5434	TCP	Vertica	Intra- and inter-cluster communication. Vertica opens the Vertica client port +1 (5434 by default) for intra-cluster communication, such as during a plan. If the port +1 from the default client port is not available, then Vertica opens a random port for intra-cluster communication.
5433	UDP	Vertica	Vertica spread monitoring.
5444	TCP	Vertica Management Console	MC-to-node and node-to-node (agent) communications port. See Changing MC or Agent Ports .
5450	TCP	Vertica Management Console	Port used to connect to MC from a web browser and allows

Port	Protocol	Service	Notes
			communication from nodes to the MC application/web server. See Connecting to Management Console .
4803	TCP	Spread	Client connections.
4803	UDP	Spread	Daemon to Daemon connections.
4804	UDP	Spread	Daemon to Daemon connections.
6543	UDP	Spread	Monitor to Daemon connection.

Operating System Configuration Task Overview

This topic provides a high-level overview of the OS settings required for Vertica. Each item provides a link to additional details about the setting and detailed steps on making the configuration change. The installer tests for all of these settings and provides hints, warnings, and failures if the current configuration does not meet Vertica requirements.

Before You Install the Operating System

Configuration	Description
Supported Platforms	Verify that your servers meet the platform requirements described in Supported Platforms . Unsupported operating systems are detected by the installer.
LVM	Vertica Analytics Platform supports Linux Volume Manager (LVM) on all supported operating systems. For information on LVM requirements and restrictions, see the section, Vertica Support for LVM .
Filesystem	The filesystem for the Vertica data and catalog directories must be formatted as ext4.
Swap Space	A 2GB swap partition is required. Partition the remaining disk space in a single partition under "/".
Disk Block Size	The disk block size for the Vertica data and catalog directories should be 4096 bytes, the default for ext4 filesystems.
Memory	For more information on sizing your hardware, see the Vertica Hardware Planning Guide .

Firewall Considerations

Configuration	Description
Firewall/Ports	Firewalls, if present, must be configured so as not to interfere with Vertica.

General Operating System Configuration - Automatically Configured by Installer

These general OS settings are automatically made by the installer if they do not meet Vertica requirements. You can prevent the installer from automatically making these configuration changes by using the `--no-system-configuration` parameter for the `install_vertica` script.

Configuration	Description
Nice Limits	The database administration user must be able to <i>nice</i> processes back to the default level of 0.
min_free_kbytes	The <code>vm.min_free_kbytes</code> setting in <code>/etc/sysctl.conf</code> must be configured sufficiently high. The specific value depends on your hardware configuration.
User Open Files Limit	The open file limit for the <code>dbadmin</code> user should be at least 1 file open per MB of RAM, 65536, or the amount of RAM in MB; whichever is greater.
System Open File Limits	The maximum number of files open on the system must not be less than at least the amount of memory in MB, but not less than 65536.
Pam Limits	<code>/etc/pam.d/su</code> must contain the line: <code>session required pam_limits.so</code> This allows for the conveying of limits to commands run with the <code>su</code> - command.
Address Space Limits	The address space limits (<code>as</code> setting) defined in <code>/etc/security/limits.conf</code> must be unlimited for the database administrator.
File Size Limits	The file size limits (<code>fsize</code> setting) defined in <code>/etc/security/limits.conf</code> must

Configuration	Description
	be unlimited for the database administrator.
User Process Limits	The nproc setting defined in /etc/security/limits.conf must be 1024 or the amount of memory in MB, whichever is greater.
Maximum Memory Maps	The vm.max_map_count in /etc/sysctl.conf must be 65536 or the amount of memory in KB / 16, whichever is greater.

General Operating System Configuration - Manual Configuration

The following general OS settings must be done manually.

Configuration	Description
Disk Readahead	This disk readahead must be at least 2048, with a high of 8192. Set this high limit only with the help of Vertica support. The specific value depends on your hardware configuration.
NTP Services	The NTP daemon must be enabled and running, with the exception of Red Hat 7 and CentOS 7 systems.
chrony	For Red Hat 7 and CentOS 7 systems, chrony must be enabled and running.
SELinux	SELinux must be disabled or run in permissive mode.
CPU Frequency Scaling	Vertica recommends that you disable CPU Frequency Scaling. Important: Your systems may use significantly more energy when CPU frequency scaling is disabled.
Transparent Hugepages	For Red Hat 7 and CentOS 7 systems, Transparent Hugepages must be set to <i>always</i> . For all other operating systems, Transparent Hugepages must be disabled or set to <i>advise</i> .
I/O Scheduler	The I/O Scheduler for disks used by Vertica must be set to <i>deadline</i> or <i>noop</i> .

Configuration	Description
Support Tools	Several optional packages can be installed to assist Vertica support when troubleshooting your system.

System User Requirements

The following tasks pertain to the configuration of the system user required by Vertica.

Configuration	Required Setting(s)
System User Requirements	The installer automatically creates a user with the correct settings. If you specify a user with <code>--dba-user</code> , then the user must conform to the requirements for the Vertica system user.
LANG Environment Settings	The LANG environment variable must be set and valid for the database administration user.
TZ Environment Settings	The TZ environment variable must be set and valid for the database administration user.

Before You Install The Operating System

The topics in this section detail system settings that must be configured when you install the operating system. These settings cannot be easily changed after the operating system is installed.

Supported Platforms

The Vertica installer checks the type of operating system that is installed. If the operating system does not meet one of the supported operating systems (See [Vertica Server and Vertica Management Console](#)), or the operating system cannot be determined, then the installer halts.

The installer generates one of the following issue identifiers if it detects an unsupported operating system:

- [S0320] - Fedora OS is not supported.
- [S0321] - The version of Red Hat/CentOS is not supported.
- [S0322] - The version of Ubuntu/Debian is not supported.
- [S0323] - The operating system could not be determined. The unknown operating system is not supported because it does not match the list of supported operating systems.
- [S0324] - The version of Red Hat is not supported.

Filesystem Requirement

Vertica requires that your Linux filesystem be ext4. All other filesystem types are unsupported. The installer reports this issue with the identifier **S0160**.

Swap Space Requirements

Vertica requires at least 2 GB swap partition regardless of the amount of RAM installed on your system. The installer reports this issue with identifier **S0180**.

For typical installations Vertica recommends that you partition your system with a 2GB primary partition for swap regardless of the amount of installed RAM. Larger swap space is acceptable, but unnecessary.

Note: Do not place a swap file on a disk containing the Vertica data files. If a host has only two disks (boot and data), put the swap file on the boot disk.

If you do not have at least a 2 GB swap partition then you may experience performance issues when running Vertica.

You typically define the swap partition when you install Linux. See your platform's documentation for details on configuring the swap partition.

Disk Block Size Requirements

Vertica recommends that the disk block size be 4096 bytes, the default on ext4 filesystems. The installer reports this issue with the identifier **S0165**.

The disk block size is set when you format your file system. Changing the block size requires a re-format.

Memory Requirements

Vertica requires, at a minimum, 1GB of RAM per logical processor. The installer reports this issue with the identifier **S0190**.

However, for performance reasons, you typically require more RAM than the minimum. For more information on sizing your hardware, see the [Vertica Hardware Planning Guide](#).

Firewall Considerations

Vertica requires multiple ports be open between nodes. You may use a firewall (IP Tables) on Redhat/CentOS and Ubuntu/Debian based systems. Note that firewall use is not supported on SuSE systems and that SuSE systems must disable the firewall. The installer reports issues found with your IP tables configuration with the identifiers **N0010** for (systems that use IP Tables) and **N011** (for SuSE systems).

The installer checks the IP tables configuration and issues a warning if there are any configured rules or chains. The installer does not detect if the configuration may conflict with Vertica. It is your responsibility to verify that your firewall allows traffic for Vertica as described in [Ensure Ports Are Available](#).

Note: The installer does not check NAT entries in iptables.

You can modify your firewall to allow for Vertica network traffic, or you can disable the firewall if your network is secure. Note that firewalls are not supported for Vertica systems running on SuSE.

Important: You may encounter the **N0010** issue even when the firewall is disabled. If this occurs, you can work around this issue and install Vertica by ignoring installer WARN messages. To do this, install (or update) with a failure threshold of FAIL. For example, `/opt/vertica/sbin/install_vertica --failure-threshold FAIL <other install options...>`.

Red Hat 6 and CentOS 6 Systems

For details on how to configure iptables and allow specific ports to be open, see the platform-specific documentation for your platform:

- RedHat: https://access.redhat.com/site/documentation/en-US/Red_Hat_Enterprise_Linux/6/html/Security_Guide/sect-Security_Guide-IPTables.html
- CentOS: <http://wiki.centos.org/HowTos/Network/IPTables>

To disable iptables, run the following command as root or sudo:

```
# service iptables save
# service iptables stop
# chkconfig iptables off
```

To disable iptables if you are using the ipv6 versions of iptables, run the following command as root or sudo:

```
# service ip6tables save
# service ip6tables stop
# chkconfig ip6tables off
```

Red Hat 7 and CentOS 7 Systems:

To disable the system firewall, run the following command as root or sudo:

```
# systemctl mask firewalld
# systemctl disable firewalld
# systemctl stop firewalld
```

Ubuntu and Debian Systems

For details on how to configure iptables and allow specific ports to be open, see the platform-specific documentation for your platform:

- Debian: <https://wiki.debian.org/iptables>
- Ubuntu: <https://help.ubuntu.com/12.04/serverguide/firewall.html>.

Note: Ubuntu uses the ufw program to manage iptables.

To disable iptables on Debian, run the following command as root or sudo:

```
/etc/init.d/iptables stop

update-rc.d -f iptables remove
```

To disable iptables on Ubuntu, run the following command:

```
sudo ufw disable
```

SuSE Systems

The firewall must be disabled on SUSE systems. To disable the firewall on SuSE systems, run the following command:

```
/sbin/SuSEfirewall12 off
```

Port Availability

The `install_vertica` script checks that required ports are open and available to Vertica. The installer reports any issues with the identifier: **N0020**.

Port Requirements

The following table lists the ports required by Vertica.

Port	Protocol	Service	Notes
7	TCP	Management Console	Required by Management Console to discover Vertica nodes.
22	TCP	sshd	Required by Administration Tools and the Management Console Cluster Installation wizard.
5433	TCP	Vertica	Vertica client (vsq , ODBC, JDBC, etc) port.
5434	TCP	Vertica	Intra- and inter-cluster communication. Vertica opens the Vertica client port +1 (5434 by default) for intra-cluster communication, such as during a plan. If the port +1 from the default client port is not available, then Vertica opens a random port for intra-cluster communication.

Port	Protocol	Service	Notes
5433	UDP	Vertica	Vertica spread monitoring.
5444	TCP	Vertica Management Console	MC-to-node and node-to-node (agent) communications port. See Changing MC or Agent Ports .
5450	TCP	Vertica Management Console	Port used to connect to MC from a web browser and allows communication from nodes to the MC application/web server. See Connecting to Management Console .
4803	TCP	Spread	Client connections.
4803	UDP	Spread	Daemon to Daemon connections.
4804	UDP	Spread	Daemon to Daemon connections.
6543	UDP	Spread	Monitor to Daemon connection.

General Operating System Configuration - Automatically Configured by the Installer

These general Operating System settings are automatically made by the installer if they do not meet Vertica requirements. You can prevent the installer from automatically making these configuration changes by using the `--no-system-configuration` parameter for the `install_vertica` script.

sysctl

During installation, Vertica attempts to automatically change various OS level settings. The installer may not change values on your system if they exceed the threshold required by the installer. You can prevent the installer from automatically making these configuration changes by using the `--no-system-configuration` parameter for the `install_vertica` script.

To permanently edit certain settings and prevent them from reverting on reboot, use `sysctl`.

The `sysctl` settings relevant to the installation of Vertica include:

- [min_free_kbytes](#)
- [fs.file_max](#)
- [vm.max_map_count](#)

Permanently Changing Settings with sysctl:

1. As the root user, open the `/etc/sysctl.conf` file:

```
# vi /etc/sysctl.conf
```

2. Enter a parameter and value:

```
parameter = value
```

For example, to set the parameter and value for `fs.file-max` to meet Vertica requirements, enter:

```
fs.file-max = 65536
```

3. Save your changes, and close the `/etc/sysctl.conf` file.
4. As the root user, reload the config file:

```
# sysctl -p
```

Identifying Settings Added by the Installer

You can see whether the installer has added a setting by opening the `/etc/sysctl.conf` file:

```
# vi /etc/sysctl.conf
```

If the installer has added a setting, the following line appears:

```
# The following 1 line added by Vertica tools. 2015-02-23 13:20:29  
parameter = value
```

Nice Limits Configuration

The Vertica system user (`dbadmin` by default) must be able to raise and lower the priority of Vertica processes. To do this, the `nice` option in the `/etc/security/limits.conf` file must

include an entry for the dbadmin user. The installer reports this issue with the identifier: **S0010**.

The installer automatically configures the correct setting if the default value does not meet system requirements. If there is an issue setting this value, or you have used the `--no-system-configuration` argument to the installer and the current setting is incorrect, then the installer reports this as an issue.

Note: Vertica never raises priority above the default level of 0. However, Vertica does lower the priority of certain Vertica threads and needs to be able to raise the priority of these threads back up to the default level. This setting allows Vertica to raise the priorities back to the default level.

All Systems

To set the Nice Limit configuration for the dbadmin user, edit `/etc/security/limits.conf` and add the following line. Replace *dbadmin* with the name of your system user.

```
dbadmin - nice 0
```

min_free_kbytes Setting

This topic details how to update the `min_free_kbytes` setting so that it is within the range supported by Vertica. The installer reports this issue with the identifier: **S0050** if the setting is too low, or **S0051** if the setting is too high.

The `vm.min_free_kbytes` setting configures the page reclaim thresholds. When this number is increased the system starts reclaiming memory earlier, when its lowered it starts reclaiming memory later. The default `min_free_kbytes` is calculated at boot time based on the number of pages of physical RAM available on the system.

The setting must be the greater of:

- The default value configured by the system, or
- 4096, or
- determine the value from running the command below.

The installer automatically configures the correct setting if the default value does not meet system requirements. If there is an issue setting this value, or you have used the `--no-`

`system-configuration` argument to the installer and the current setting is incorrect, then the installer reports this as an issue.

All Systems

To manually set `min_free_kbytes`:

1. Determine the current/default setting with the following command:

```
/sbin/sysctl vm.min_free_kbytes
```

2. If the result of the previous command is `No such file or directory` or the default value is less than 4096, then run the command below:

```
memtot=`grep MemTotal /proc/meminfo | awk '{printf "%.0f", $2}'`  
echo "scale=0;sqrt ($memtot*16)" | bc
```

3. Edit or add the current value of `vm.min_free_kbytes` in `/sbin/sysctl.conf` with the value from the output of the previous command.

```
# The min_free_kbytes setting  
  
vm.min_free_kbytes=5572
```

4. Run `sysctl -p` to apply the changes in `sysctl.conf` immediately.

Note: These steps will need to be replicated for each node in the cluster.

User Max Open Files Limit

This topic details how to change the user max open-files limit setting to meet Vertica requirements. The installer reports this issue with the identifier: **S0060**.

The installer automatically configures the correct setting if the default value does not meet system requirements. If there is an issue setting this value, or you have used the `--no-system-configuration` argument to the installer and the current setting is incorrect, then the installer reports this as an issue.

Vertica requires that the `dbadmin` user not be limited when opening files. The open file limit should be at least 1 file open per MB of RAM, 65536, or the amount of RAM in MB; whichever is greater. Vertica sets this to the minimum recommended value of 65536 or the amount of RAM in MB.

All Systems

The open file limit can be determined by running `ulimit -n` as the `dbadmin` user. For example:

```
dbadmin@localhost:$ ulimit -n
65536
```

To manually set the limit, edit `/etc/security/limits.conf` and edit/add the line for the `nofile` setting for the user you configured as the database admin (default `dbadmin`). The setting must be at least 65536.

```
dbadmin -          nofile 65536
```

Note: There is also an open file limit on the system. See [System Max Open Files Limit](#).

System Max Open Files Limit

This topic details how to modify the limit for the number of open files on your system so that it meets Vertica requirements. The installer reports this issue with the identifier: **S0120**.

Vertica opens many files. Some platforms have global limits on the number of open files. The open file limit must be set sufficiently high so as not to interfere with database operations.

The recommended value is at least the amount of memory in MB, but not less than 65536.

The installer automatically configures the correct setting if the default value does not meet system requirements. If there is an issue setting this value, or you have used the `--no-system-configuration` argument to the installer and the current setting is incorrect, then the installer reports this as an issue.

All Systems

To manually set the open file limit:

1. Run `/sbin/sysctl fs.file-max` to determine the current limit.
2. If the limit is not **65536** or the amount of system memory in MB (whichever is higher), then edit or add `fs.file-max=max number of files` to `/etc/sysctl.conf`.

```
# Controls the maximum number of open files
fs.file-max=65536
```

3. Run `sysctl -p` to apply the changes in `sysctl.conf` immediately.

Note: These steps will need to be replicated for each node in the cluster.

Pam Limits

This topic details how to enable the "su" `pam_limits.so` module required by Vertica. The installer reports issues with the setting with the identifier: **S0070**.

On some systems the pam module called `pam_limits.so` is not set in the file `/etc/pam.d/su`. When it is not set, it prevents the conveying of limits (such as open file descriptors) to any command started with `su -`.

In particular, the Vertica init script would fail to start Vertica because it calls the Administration Tools to start a database with the `su -` command. This problem was first noticed on Debian systems, but the configuration could be missing on other Linux distributions. See the [pam_limits](#) man page for more details.

The installer automatically configures the correct setting if the default value does not meet system requirements. If there is an issue setting this value, or you have used the `--no-system-configuration` argument to the installer and the current setting is incorrect, then the installer reports this as an issue.

All Systems

To manually configure this setting, append the following line to the `/etc/pam.d/su` file:

```
session required pam_limits.so
```

See the `pam_limits` man page for more details: `man pam_limits`.

pid_max Setting

This topic explains how to change `pid_max` to a supported value. The value of `pid_max` should be

```
pid_max = num_user_proc + 2**15 = num_user_proc + 32768
```

where `num_user_proc` is the size of memory in megabytes.

The minimum value for `pid_max` is 524288.

If your `pid_max` value is too low, the installer reports this problem and indicates the minimum value.

The installer automatically configures the correct setting if the default value does not meet system requirements. If there is an issue setting this value, or you have used the `--no-system-configuration` argument to the installer and the current setting is incorrect, then the installer reports this as an issue.

All Systems

To change the `pid_max` value:

```
# sysctl -w kernel.pid_max=524288
```

User Address Space Limits

This topic details how to modify the Linux address space limit for the `dbadmin` user so that it meets Vertica requirements. The address space setting controls the maximum number of threads and processes for each user. If this setting does not meet the requirements then the installer reports this issue with the identifier: **S0090**.

The installer automatically configures the correct setting if the default value does not meet system requirements. If there is an issue setting this value, or you have used the `--no-system-configuration` argument to the installer and the current setting is incorrect, then the installer reports this as an issue.

The address space available to the `dbadmin` user must not be reduced via user limits and must be set to **unlimited**.

All Systems

To manually set the address space limit:

1. Run `ulimit -v` as the `dbadmin` user to determine the current limit.
2. If the limit is not **unlimited**, then add the following line to `/etc/security/limits.conf`. Replace `dbadmin` with your database admin user

```
dbadmin - as unlimited
```

User File Size Limit

This topic details how to modify the file size limit for files on your system so that it meets Vertica requirements. The installer reports this issue with the identifier: **S0100**.

The installer automatically configures the correct setting if the default value does not meet system requirements. If there is an issue setting this value, or you have used the `--no-system-configuration` argument to the installer and the current setting is incorrect, then the installer reports this as an issue.

The file size limit for the `dbadmin` user must not be reduced via user limits and must be set to **unlimited**.

All Systems

To manually set the file size limit:

1. Run `ulimit -f` as the `dbadmin` user to determine the current limit.
2. If the limit is not **unlimited**, then edit/add the following line to `/etc/security/limits.conf`. Replace `dbadmin` with your database admin user.

```
dbadmin -      fsize      unlimited
```

User Process Limit

This topic details how to change the user process limit so that it meets Vertica requirements. The installer reports this issue with the identifier: **S0110**.

The installer automatically configures the correct setting if the default value does not meet system requirements. If there is an issue setting this value, or you have used the `--no-system-configuration` argument to the installer and the current setting is incorrect, then the installer reports this as an issue.

The user process limit must be high enough to allow for the many threads opened by Vertica. The recommended limit is the amount of RAM in MB and must be at least 1024.

All Systems

To manually set the user process limit:

1. Run `ulimit -u` as the `dbadmin` user to determine the current limit.
2. If the limit is not the amount of memory in MB on the server, then edit/add the following line to `/etc/security/limits.conf`. Replace `4096` with the amount of system memory, in MB, on the server.

```
dbadmin - nproc 4096
```

Maximum Memory Maps Configuration

This topic details how to modify the limit for the number memory maps a process can have on your system so that it meets Vertica requirements. The installer reports this issue with the identifier: **S0130**.

The installer automatically configures the correct setting if the default value does not meet system requirements. If there is an issue setting this value, or you have used the `--no-system-configuration` argument to the installer and the current setting is incorrect, then the installer reports this as an issue.

Vertica uses a lot of memory while processing and can approach the default limit for memory maps per process.

The recommended value is at least the amount of memory on the system in KB / 16, but not less than 65536.

All Systems

To manually set the memory map limit:

1. Run `/sbin/sysctl vm.max_map_count` to determine the current limit.
2. If the limit is not **65536** or the amount of system memory in KB / 16 (whichever is higher), then edit/add the following line to `/etc/sysctl.conf`. Replace `65536` with the value for your system.

```
# The following 1 line added by Vertica tools. 2014-03-07 13:20:31  
vm.max_map_count=65536
```

3. Run `sysctl -p` to apply the changes in `sysctl.conf` immediately.

Note: These steps will need to be replicated for each node in the cluster.

General Operating System Configuration - Manual Configuration

The following general Operating System settings must be done manually.

Manually Configuring Operating System Settings

Vertica requires that you manually configure some general operating system settings. Vertica recommends that you configure these settings in the `/etc/rc.local` script to prevent them from reverting on reboot. The `/etc/rc.local` startup script contains scripts and commands that run each time the system is booted.

If you are using Red Hat 7.0 or CentOS 7.0 or higher, you must make sure the tuning system service will not start upon reboot. Run the following command as `sudo` or `root`:

```
$ chkconfig tuned off
```

Turning off tuning prevents monitoring of your OS and any tuning of your OS based on this monitoring. Tuning also enables THP silently which may cause issues in other areas, for example read ahead.

Note: SUSE systems use the `/etc/init.d/after.local` file rather than the `etc/rc.local` file. For purposes of using Vertica, the functionality of both files is the same.

Settings to Configure Manually

The `/etc/rc.local` settings relevant to the installation of Vertica include:

- [Disk Readahead](#)
- [I/O Scheduling](#)
- [Enabling or Disabling Transparent Hugepages](#)

Permanently Changing Settings with /etc/rc.local

1. As the root user, open the /etc/rc.local file:

```
# vi /etc/rc.local
```

2. Enter a script or command. For example, to set the transparent hugepages setting to meet Vertica requirements, enter:

```
echo never > /sys/kernel/mm/redhat_transparent_hugepage/enabled
```

Important: On some Ubuntu/Debian systems, the last line in /etc/rc.local must be "exit 0". Any additions to /etc/rc.local must come before "exit 0".

3. Save your changes, and close the /etc/rc.local file.
4. If you are using Red Hat 7.0 or CentOS 7.0 or higher, run the following command as root or sudo:

```
$ chmod +x /etc/rc.d/rc.local
```

On the next reboot, the command runs during startup. You can also run the command manually, as the root user, if you want it to take effect immediately.

Check for Swappiness

The swappiness kernel parameter defines the amount, and how often, the kernel copies RAM contents to a swap space. Vertica recommends a value of 1. The installer reports any swappiness issues with identifier **S0112**.

To set the swappiness value add or update the following in /etc/sysctl.conf:

```
vm.swappiness = 1
```

This also ensures that the value persists after a reboot.

You can check the swappiness value as follows:

```
cat /proc/sys/vm/swappiness
```

If necessary, you change the swappiness value at runtime by logging in as root and running the following:

```
echo 1 > /proc/sys/vm/swappiness
```

Disk Readahead

This topic details how to change [Disk Readahead](#) to a supported value. Vertica requires that Disk Readahead be set to at least 2048. The installer reports this issue with the identifier: **S0020**.

Note:

- These commands must be executed with root privileges and assumes the blockdev program is in `/sbin`.
- The blockdev program operates on whole devices, and not individual partitions. You cannot set the readahead value to different settings on the same device. If you run blockdev against a partition, for example: `/dev/sda1`, then the setting is still applied to the entire `/dev/sda` device. For instance, running `/sbin/blockdev --setra 2048 /dev/sda1` also causes `/dev/sda2 through /dev/sdaN` to use a readahead value of 2048.

RedHat/CentOS and SuSE Based Systems

For each drive in the Vertica system, Vertica recommends that you set the readahead value to at least 2048 for most deployments. The command immediately changes the readahead value for the specified disk. The second line adds the command to `/etc/rc.local` so that the setting is applied each time the system is booted. Note that some deployments may require a higher value and the setting can be set as high as 8192, under guidance of support.

Note: For systems that do not support `/etc/rc.local`, use the equivalent startup script that is run after the destination runlevel has been reached. For example SuSE uses `/etc/init.d/after.local`.

```
/sbin/blockdev --setra 2048 /dev/sda  
echo '/sbin/blockdev --setra 2048 /dev/sda' >> /etc/rc.local
```

If you are using Red Hat 7.0 or CentOS 7.0 or higher, run the following command as root or sudo:

```
$ chmod +x /etc/rc.d/rc.local
```

Ubuntu and Debian Systems

For each drive in the Vertica system, set the readahead value to 2048. Run the command once in your shell, then add the command to `/etc/rc.local` so that the setting is applied each time the system is booted. Note that on Ubuntu systems, the last line in `rc.local` must be `exit 0`. So you must manually add the following line to `etc/rc.local` before the last line with `exit 0`.

Note: For systems that do not support `/etc/rc.local`, use the equivalent startup script that is run after the destination runlevel has been reached. For example SuSE uses `/etc/init.d/after.local`.

```
/sbin/blockdev --setra 2048 /dev/sda
```

Enabling Network Time Protocol (NTP)

The network time protocol (NTP) daemon must be running on all of the hosts in the cluster so that their clocks are synchronized. The spread daemon relies on all of the nodes to have their clocks synchronized for timing purposes. If your nodes do not have NTP running, the installation can fail with a spread configuration error or other errors.

Note: Different Linux distributions refer to the NTP daemon in different ways. For example, SUSE and Debian/Ubuntu refer to it as `ntp`, while CentOS and Red Hat refer to it as `ntpd`. If the following commands produce errors, try using `ntp` in place of `ntpd`.

Verify That NTP Is Running

To verify that your hosts are configured to run the NTP daemon on startup, enter the following command:

```
$ chkconfig --list ntpd
```

Debian and Ubuntu do not support `chkconfig`, but they do offer an optional package. You can install this package with the command `sudo apt-get install sysv-rc-conf`. To verify that your hosts are configured to run the NTP daemon on startup with the `sysv-rc-conf` utility, enter the following command:

```
$ sysv-rc-conf --list ntpd
```

The `chkconfig` command can produce an error similar to `ntpd: unknown service`. If you get this error, verify that your Linux distribution refers to the NTP daemon as `ntpd` rather than `ntp`. If it does not, you need to install the NTP daemon package before you can configure it. Consult your Linux documentation for instructions on how to locate and install packages.

If the NTP daemon is installed, your output should resemble the following:

```
ntp 0:off 1:off 2:on 3:on 4:off 5:on 6:off
```

The output indicates the runlevels where the daemon runs. Verify that the current runlevel of the system (usually 3 or 5) has the NTP daemon set to `on`. If you do not know the current runlevel, you can find it using the `runlevel` command:

```
$ runlevel
N 3
```

Configure NTP for Red Hat 6/CentOS 6 and SLES

If your system is based on Red Hat 6/CentOS 6 or SUSE Linux Enterprise Server, use the `service` and `chkconfig` utilities to start NTP and have it start at startup.

```
/sbin/service ntpd restart
/sbin/chkconfig ntpd on
```

- **Red Hat 6/CentOS 6**—NTP uses the default time servers at `ntp.org`. You can change the default NTP servers by editing `/etc/ntp.conf`.
- **SLES**—By default, no time servers are configured. You must edit `/etc/ntp.conf` after the install completes and add time servers.

Configure NTP for Ubuntu and Debian

By default, the [NTP daemon](#) is not installed on some Ubuntu and Debian systems. First, install NTP, and then start the NTP process. You can change the default NTP servers by editing `/etc/ntp.conf` as shown:

```
sudo apt-get install ntp
sudo /etc/init.d/ntp reload
```

Verify That NTP Is Operating Correctly

To verify that the Network Time Protocol Daemon (NTPD) is operating correctly, issue the following command on all nodes in the cluster.

For Red Hat 6/CentOS 6 and SLES:

```
/usr/sbin/ntpq -c rv | grep stratum
```

For Ubuntu and Debian:

```
ntpq -c rv | grep stratum
```

A stratum level of 16 indicates that NTP is not synchronizing correctly.

If a stratum level of 16 is detected, wait 15 minutes and issue the command again. It may take this long for the NTP server to stabilize.

If NTP continues to detect a stratum level of 16, verify that the NTP port (UDP Port 123) is open on all firewalls between the cluster and the remote machine to which you are attempting to synchronize.

Red Hat Documentation Related to NTP

The preceding links were current as of the last publication of the Vertica documentation and could change between releases.

- <http://kbase.redhat.com/faq/docs/DOC-6731>
- <http://kbase.redhat.com/faq/docs/DOC-6902>
- <http://kbase.redhat.com/faq/docs/DOC-6991>

Enabling chrony or ntpd for Red Hat 7/CentOS 7 Systems

Before you can install Vertica, you must enable one of the following on your system for clock synchronization:

- chrony
- NTPD

You must enable and activate the Network Time Protocol (NTP) before installation. Otherwise, the installer reports this issue with the identifier **S0030**.

For information on installing and using chrony, see the information below. For information on NTPD see [Enabling Network Time Protocol \(NTP\)](#).

Install chrony

The chrony suite consists of:

- `chronyd` - the daemon for clock synchronization.
- `chronyc` - the command-line utility for configuring `chronyd` .

`chrony` is installed by default on some versions of Red Hat/CentOS 7. However, if `chrony` is not installed on your system, you must download it. To download `chrony`, run the following command as `sudo` or `root`:

```
# yum install chrony
```

Verify That `chrony` Is Running

To view the status of the `chronyd` daemon, run the following command:

```
$ systemctl status chronyd
```

If `chrony` is running, an output similar to the following appears:

```
chronyd.service - NTP client/server
  Loaded: loaded (/usr/lib/systemd/system/chronyd.service; enabled)
  Active: active (running) since Mon 2015-07-06 16:29:54 EDT; 15s ago
  Main PID: 2530 (chronyd)
  CGroup: /system.slice/chronyd.service
          ┆â2530 /usr/sbin/chronyd -u chrony
```

If `chrony` is not running, execute the following command as `sudo` or `root`. This command also causes `chrony` to run at boot time:

```
# systemctl enable chronyd
```

Verify That `chrony` Is Operating Correctly

To verify that the `chrony` daemon is operating correctly, issue the following command on all nodes in the cluster:

```
$ chronyc tracking
```

An output similar to the following appears:

```
Reference ID      : 198.247.63.98 (time01.website.org)

A stratum level of 16 indicates that chrony is not synchronizing correctly. If chrony continues to detect a stratum level of 16, verify that the UDP port 323 is open. This port must be open on all firewalls between the cluster and the remote machine to which you are attempting to synchronize.

Red Hat Documentation Related to chrony

These links to Red Hat documentation were current as of the last publication of the Vertica documentation. Be aware that they could change between releases:

- [Configuring NTP Using the chrony Suite](#)
- [Using chrony](#)

SELinux Configuration

Vertica does not support SELinux except when SELinux is running in permissive mode. If it detects that SELinux is installed and the mode cannot be determined the installer reports this issue with the identifier: **S0080**. If the mode can be determined, and the mode is not permissive, then the issue is reported with the identifier: **S0081**.

Red Hat and SUSE Systems

You can either disable SELinux or change it to use permissive mode.

To disable SELinux:

1. Edit `/etc/selinux/config` and change setting for SELinux to disabled (`SELINUX=disabled`). This disables SELinux at boot time.
2. As root/sudo, type `setenforce 0` to disable SELinux immediately.

To change SELinux to use permissive mode:

1. Edit `/etc/selinux/config` and change setting for SELINUX to permissive (`SELINUX=Permissive`).

2. As root/sudo, type `setenforce Permissive` to switch to permissive mode immediately.

Ubuntu and Debian Systems

You can either disable SELinux or change it to use permissive mode.

To disable SELinux:

1. Edit `/selinux/config` and change setting for SELinux to disabled (`SELINUX=disabled`). This disables SELinux at boot time.
2. As root/sudo, type `setenforce 0` to disable SELinux immediately.

To change SELinux to use permissive mode:

1. Edit `/selinux/config` and change setting for SELinux to permissive (`SELINUX=Permissive`).
2. As root/sudo, type `setenforce Permissive` to switch to permissive mode immediately.

CPU Frequency Scaling

This topic details the various CPU frequency scaling methods supported by Vertica. In general, if you do not require CPU frequency scaling, then disable it so as not to impact system performance.

Important: Your systems may use significantly more energy when frequency scaling is disabled.

The installer allows CPU frequency scaling to be enabled when the `cpufreq` scaling governor is set to `performance`. If the `cpu` scaling governor is set to `ondemand`, and `ignore_nice_load` is 1 (true), then the installer **fails** with the error **S0140**. If the `cpu` scaling governor is set to `ondemand` and `ignore_nice_load` is 0 (false), then the installer **warns** with the identifier **S0141**.

CPU frequency scaling is a hardware and software feature that helps computers conserve energy by slowing the processor when the system load is low, and speeding it up again when the system load increases. This feature can impact system performance, since raising the CPU frequency in response to higher system load does not occur instantly. Always disable this feature on the Vertica database hosts to prevent it from interfering with performance.

You disable CPU scaling in your host's system BIOS. There may be multiple settings in your host's BIOS that you need to adjust in order to completely disable CPU frequency scaling. Consult your host hardware's documentation for details on entering the system BIOS and disabling CPU frequency scaling.

If you cannot disable CPU scaling through the system BIOS, you can limit the impact of CPU scaling by disabling the scaling through the Linux kernel or setting the CPU frequency governor to always run the CPU at full speed.

Caution: This method is not reliable, as some hardware platforms may ignore the kernel settings. **The only reliable method is to disable CPU scaling in BIOS.**

The method you use to disable frequency depends on the CPU scaling method being used in the Linux kernel. See your Linux distribution's documentation for instructions on disabling scaling in the kernel or changing the CPU governor.

Enabling or Disabling Transparent Hugepages

You can modify transparent hugepages so that the configuration meets Vertica requirements.

- For Red Hat 7/CentOS 7 systems, you must enable transparent hugepages. The installer reports this issue with the identifier: **S0312**.
- For all other systems, you must disable transparent hugepages or set them to `madvise`. The installer reports this issue with the identifier: **S0310**.

Disable Transparent Hugepages on Red Hat 6/CentOS 6 Systems

Important: If you are using Red Hat 7/CentOS 7, you must enable, rather than disable transparent hugepages. See: [Enable Transparent Hugepages on Red Hat 7/CentOS 7 Systems](#).

Determine if transparent hugepages is enabled. To do so, run the following command.

```
cat /sys/kernel/mm/redhat_transparent_hugepage/enabled  
[always] madvise never
```

The setting returned in brackets is your current setting.

If you are not using `madvise` or `never` as your transparent hugepage setting, then you can disable transparent hugepages in one of two ways:

- Edit your boot loader (for example `/etc/grub.conf`). Typically, you add the following to the end of the kernel line. However, consult the documentation for your system before editing your boot loader configuration.

```
transparent_hugepage=never
```

- Edit `/etc/rc.local` and add the following script.

```
if test -f /sys/kernel/mm/redhat_transparent_hugepage/enabled; then
  echo never > /sys/kernel/mm/redhat_transparent_hugepage/enabled
fi
```

For systems that do not support `/etc/rc.local`, use the equivalent startup script that is run after the destination runlevel has been reached. For example SuSE uses `/etc/init.d/after.local`.

Regardless of which approach you choose, you must reboot your system for the setting to take effect, or run the following echo line to proceed with the install without rebooting:

```
echo never > /sys/kernel/mm/redhat_transparent_hugepage/enabled
```

Enable Transparent Hugepages on Red Hat 7/CentOS 7 Systems

Determine if transparent hugepages is enabled. To do so, run the following command.

```
cat /sys/kernel/mm/transparent_hugepage/enabled
[always] madvise never
```

The setting returned in brackets is your current setting.

For systems that do not support `/etc/rc.local`, use the equivalent startup script that is run after the destination runlevel has been reached. For example SuSE uses `/etc/init.d/after.local`.

You can enable transparent hugepages by editing `/etc/rc.local` and adding the following script:

```
if test -f /sys/kernel/mm/transparent_hugepage/enabled; then
  echo always > /sys/kernel/mm/transparent_hugepage/enabled
fi
```

You must reboot your system for the setting to take effect, or, as root, run the following echo line to proceed with the install without rebooting:

```
# echo always > /sys/kernel/mm/transparent_hugepage/enabled
```

If you are using Red Hat 7.0 or CentOS 7.0 or higher, run the following command as root or sudo:

```
$ chmod +x /etc/rc.d/rc.local
```

Disable Transparent Hugepages on Other Systems

Note: SuSE did not offer transparent hugepage support in its initial 11.0 release. However, subsequent SuSE service packs do include support for transparent hugepages.

To determine if transparent hugepages is enabled, run the following command.

```
cat /sys/kernel/mm/transparent_hugepage/enabled  
[always] madvise never
```

The setting returned in brackets is your current setting. Depending on your platform OS, the `madvise` setting may not be displayed.

You can disable transparent hugepages one of two ways:

- Edit your boot loader (for example `/etc/grub.conf`). Typically, you add the following to the end of the kernel line. However, consult the documentation for your system before editing your bootloader configuration.

```
transparent_hugepage=never
```

- Edit `/etc/rc.local` (on systems that support `rc.local`) and add the following script.

```
if test -f /sys/kernel/mm/transparent_hugepage/enabled; then  
    echo never > /sys/kernel/mm/transparent_hugepage/enabled  
fi
```

For systems that do not support `/etc/rc.local`, use the equivalent startup script that is run after the destination runlevel has been reached. For example SuSE uses `/etc/init.d/after.local`.

Regardless of which approach you choose, you must reboot your system for the setting to take effect, or run the following two echo lines to proceed with the install without rebooting:

```
echo never > /sys/kernel/mm/transparent_hugepage/enabled
```

Disabling Defrag for Red Hat and CentOS Systems

On all Red Hat and CentOS systems, you must disable the defrag utility to meet Vertica configuration requirements. The steps necessary to disable defrag on Red Hat 6/CentOS 6 systems differ from those used to disable defrag on Red Hat 7/CentOS 7 systems.

Disable Defrag on Red Hat 6/CentOS 6 Systems

1. Determine if defrag is enabled by running the following command:

```
cat /sys/kernel/mm/redhat_transparent_hugepage/defrag  
[always] madvise never
```

The setting returned in brackets is your current setting. If you are not using `madvise` or `never` as your defrag setting, then you must disable defrag.

2. Edit `/etc/rc.local`, and add the following script:

```
if test -f /sys/kernel/mm/redhat_transparent_hugepage/enabled; then  
    echo never > /sys/kernel/mm/redhat_transparent_hugepage/defrag  
fi
```

You must reboot your system for the setting to take effect, or run the following echo line to proceed with the install without rebooting:

```
# echo never > /sys/kernel/mm/redhat_transparent_hugepage/defrag
```

Disable Defrag on Red Hat 7/CentOS 7 Systems

1. Determine if defrag is enabled by running the following command:

```
cat /sys/kernel/mm/transparent_hugepage/defrag  
[always] madvise never
```

The setting returned in brackets is your current setting. If you are not using `madvise` or `never` as your defrag setting, then you must disable defrag.

2. Edit `/etc/rc.local`, and add the following script:

```
if test -f /sys/kernel/mm/transparent_hugepage/enabled; then  
    echo never > /sys/kernel/mm/transparent_hugepage/defrag  
fi
```

You must reboot your system for the setting to take effect, or run the following echo line to proceed with the install without rebooting:

```
# echo never > /sys/kernel/mm/transparent_hugepage/defrag
```

3. If you are using Red Hat 7.0 or CentOS 7.0 or higher, run the following command as root or sudo:

```
$ chmod +x /etc/rc.d/rc.local
```

I/O Scheduling

This topic details how to change [I/O Scheduling](#) to a supported scheduler. Vertica requires that I/O Scheduling be set to [deadline](#) or [noop](#). The installer checks what scheduler the system is using, reporting an unsupported scheduler issue with identifier: **S0150**. If the installer cannot detect the type of scheduler in use (typically if your system is using a RAID array), it reports that issue with identifier: **S0151**.

If your system is not using a RAID array, then complete the following steps to change your system to a supported I/O Scheduler. If you are using a RAID array, then consult your RAID vendor documentation for the best performing scheduler for your hardware.

Configure the I/O Scheduler

The Linux kernel can use several different I/O schedulers to prioritize disk input and output. Most Linux distributions use the Completely Fair Queuing (CFQ) scheme by default, which gives input and output requests equal priority. This scheduler is efficient on systems running multiple tasks that need equal access to I/O resources. However, it can create a bottleneck when used on Vertica drives containing the catalog and data directories, because it gives write requests equal priority to read requests, and its per-process I/O queues can penalize processes making more requests than other processes.

Instead of the CFQ scheduler, configure your hosts to use either the Deadline or NOOP I/O scheduler for the drives containing the catalog and data directories:

- The Deadline scheduler gives priority to read requests over write requests. It also imposes a deadline on all requests. After reaching the deadline, such requests gain priority over all other requests. This scheduling method helps prevent processes from becoming starved for

I/O access. The Deadline scheduler is best used on physical media drives (disks using spinning platters), since it attempts to group requests for adjacent sectors on a disk, lowering the time the drive spends seeking.

- The NOOP scheduler uses a simple FIFO approach, placing all input and output requests into a single queue. This scheduler is best used on solid state drives (SSDs). Because SSDs do not have a physical read head, no performance penalty exists when accessing non-adjacent sectors.

Failure to use one of these schedulers for the Vertica drives containing the catalog and data directories can result in slower database performance. Other drives on the system (such as the drive containing swap space, log files, or the Linux system files) can still use the default CFQ scheduler (although you should always use the NOOP scheduler for SSDs).

There are two ways for you to set the scheduler used by your disk devices:

1. Write the name of the scheduler to a file in the `/sys` directory.

--or--

2. Use a kernel boot parameter.

Configure the I/O Scheduler - Changing the Scheduler Through the `/sys` Directory

You can view and change the scheduler Linux uses for I/O requests to a single drive using a virtual file under the `/sys` directory. The name of the file that controls the scheduler a block device uses is:

```
/sys/block/deviceName/queue/scheduler
```

Where *deviceName* is the name of the disk device, such as `sda` or `cciss\!c0d1` (the first disk on an Micro Focus RAID array). Viewing the contents of this file shows you all of the possible settings for the scheduler. The currently-selected scheduler is surrounded by square brackets:

```
# cat /sys/block/sda/queue/scheduler  
noop deadline [cfq]
```

To change the scheduler, write the name of the scheduler you want the device to use to its scheduler file. You must have root privileges to write to this file. For example, to set the `sda` drive to use the deadline scheduler, run the following command as root:

```
# echo deadline > /sys/block/sda/queue/scheduler  
# cat /sys/block/sda/queue/scheduler
```

```
noop [deadline] cfq
```

Changing the scheduler immediately affects the I/O requests for the device. The Linux kernel starts using the new scheduler for all of the drive's input and output requests.

Note: While tests show that changing the scheduler settings while Vertica is running does not cause problems, Vertica recommends shutting down. Before changing the I/O schedule, or making any other changes to the system configuration, consider shutting down any running database.

Changes to the I/O scheduler made through the `/sys` directory only last until the system is rebooted, so you need to add the commands that change the I/O scheduler to a startup script (such as those stored in `/etc/init.d`, or through a command in `/etc/rc.local`). You also need to use a separate command for each drive on the system whose scheduler you want to change.

For example, to make the configuration take effect immediately and add it to `rc.local` so it is used on subsequent reboots.

Note: For systems that do not support `/etc/rc.local`, use the equivalent startup script that is run after the destination runlevel has been reached. For example SuSE uses `/etc/init.d/after.local`.

```
echo deadline > /sys/block/sda/queue/scheduler  
echo 'echo deadline > /sys/block/sda/queue/scheduler' >> /etc/rc.local
```

Note: On some Ubuntu/Debian systems, the last line in `rc.local` must be `exit 0`. So you must manually add the following line to `etc/rc.local` before the last line with `exit 0`.

You may prefer to use this method of setting the I/O scheduler over using a boot parameter if your system has a mix of solid-state and physical media drives, or has many drives that do not store Vertica catalog and data directories.

If you are using Red Hat 7.0 or CentOS 7.0 or higher, run the following command as root or sudo:

```
$ chmod +x /etc/rc.d/rc.local
```

Configure the I/O Scheduler - Changing the Scheduler with a Boot Parameter

Use the `elevator` kernel boot parameter to change the default scheduler used by all disks on your system. This is the best method to use if most or all of the drives on your hosts are of the same type (physical media or SSD) and will contain catalog or data files. You can also use the

boot parameter to change the default to the scheduler the majority of the drives on the system need, then use the `/sys` files to change individual drives to another I/O scheduler. The format of the elevator boot parameter is:

```
elevator=schedulerName
```

Where *schedulerName* is `deadline`, `noop`, or `cfq`. You set the boot parameter using your bootloader (`grub` or `grub2` on most recent Linux distributions). See your distribution's documentation for details on how to add a kernel boot parameter.

Support Tools

Vertica suggests that the following tools are installed so support can assist in troubleshooting your system if any issues arise:

- `pstack` (or `gstack`) package. Identified by issue **S0040** when not installed.
 - On Red Hat 7 and CentOS 7 systems, the `pstack` package is installed as part of the `gdb` package.
- `mcelog` package. Identified by issue **S0041** when not installed.
- `sysstat` package. Identified by issue **S0045** when not installed.

Red Hat 6 and CentOS 6 Systems

To install the required tools on Red Hat 6 and CentOS 6 systems, run the following commands as `sudo` or `root`:

```
yum install pstack  
yum install mcelog  
yum install sysstat
```

Red Hat 7 and CentOS 7 Systems

To install the required tools on Red Hat 7/CentOS 7 systems, run the following commands as `sudo` or `root`:

```
yum install gdb  
yum install mcelog  
yum install sysstat
```

Ubuntu and Debian Systems

To install the required tools on Ubuntu and Debian systems, run the following commands as `sudo` or `root`:

```
apt-get install pstack  
apt-get install mcelog  
apt-get install sysstat
```

SuSE Systems

To install the required tools on SuSE systems, run the following commands as `sudo` or `root`.

```
zypper install sysstat  
zypper install mcelog
```

There is no individual SuSE package for `pstack/gstack`. However, the `gdb` package contains `gstack`, so you could optionally install `gdb` instead, or build `pstack/gstack` from source. To install the `gdb` package:

```
zypper install gdb
```

System User Configuration

The following tasks pertain to the configuration of the system user required by Vertica.

System User Requirements

Vertica has specific requirements for the system user that runs and manages Vertica. If you specify a user during install, but the user does not exist, then the installer reports this issue with the identifier: **S0200**.

System User Requirement Details

Vertica requires a system user to own database files and run database processes and administration scripts. By default, the install script automatically configures and creates this user for you with the username `dbadmin`. See [About Linux Users Created by Vertica and Their Privileges](#) for details on the default user created by the install script. If you decide to manually

create your own system user, then you must create the user **before** you run the install script. If you manually create the user:

Note: Instances of `dbadmin` and `verticadba` are placeholders for the names you choose if you do not use the default values.

- the user must have the same username and password on all nodes
- the user must use the BASH shell as the user's default shell. If not, then the installer reports this issue with identifier **[S0240]**.
- the user must be in the `verticadba` group (for example: `usermod -a -G verticadba userNameHere`). If not, the installer reports this issue with identifier **[S0220]**.

Note: You must create a `verticadba` group on all nodes. If you do not, then the installer reports the issue with identifier **[S0210]**.

- the user's login group must be either `verticadba` or a group with the same name as the user (for example, the home group for `dbadmin` is `dbadmin`). You can check the groups for a user with the `id` command. For example: `id dbadmin`. The "gid" group is the user's primary group. If this is not configured correctly then the installer reports this issue with the identifier **[S0230]**. Vertica recommends that you use `verticadba` as the user's primary login group. For example: `usermod -g verticadba userNameHere`. If the user's primary group is not `verticadba` as suggested, then the installer reports this with HINT **[S0231]**.
- the user must have a home directory. If not, then the installer reports this issue with identifier **[S0260]**.
- the user's home directory must be owned by the user. If not, then the installer reports the issue with identifier **[S0270]**.
- the system must be aware of the user's home directory (you can set it with the `usermod` command: `usermod -m -d /path/to/new/home/dir userNameHere`). If this is not configured correctly then the installer reports the issue with **[S0250]**.
- the user's home directory must be owned by the `dbadmin`'s primary group (use the `chown` and `chgrp` commands if necessary). If this is not configured correctly, then the installer reports the issue with identifier **[S0280]**.
- the user's home directory *should* have secure permissions. Specifically, it should not be writable by anyone or by the group. Ideally the permissions should be, when viewing with `ls`, `"---"` (nothing), or `"r-x"` (read and execute). If this is not configured as suggested then the installer reports this with HINT **[S0290]**.

TZ Environment Variable

This topic details how to set or change the TZ environment variable and update your tzdata package. If this variable is not set, then the installer reports this issue with the identifier: **S0305**.

Before installing Vertica, update the tzdata package for your system and set the default time zone for your database administrator account by specifying the TZ environmental variable. If your database administrator is being created by the `install_vertica` script, then set the TZ variable after you have installed Vertica.

Update tzdata Package

The tzdata package is a public-domain time zone database that is pre-installed on most Linux systems. The tzdata package is updated periodically for time-zone changes across the world. Micro Focus recommends that you update to the latest tzdata package before installing or updating Vertica.

Update your tzdata package with the following command:

- RedHat based systems: `yum update tzdata`
- Debian and Ubuntu systems: `apt-get install tzdata`

Setting the Default Time Zone

When a client receives the result set of a SQL query, all rows contain data adjusted, if necessary, to the same time zone. That time zone is the default time zone of the initiator node unless the client explicitly overrides it using the SQL [SET TIME ZONE](#) command described in the SQL Reference Manual. The default time zone of any node is controlled by the TZ environment variable. If TZ is undefined, the operating system time zone.

Important: The TZ variable must be set to the same value on all nodes in the cluster.

If your operating system timezone is not set to the desired timezone of the database then make sure that the Linux environment variable TZ is set to the desired value on all cluster hosts.

The installer returns a warning if the TZ variable is not set. If your operating system timezone is appropriate for your database, then the operating system timezone is used and the warning can be safely ignored.

Setting the Time Zone on a Host

Important: If you explicitly set the TZ environment variable at a command line before you start the Administration Tools, the current setting will not take effect. The Administration Tools uses SSH to start copies on the other nodes, so each time SSH is used, the TZ variable for the startup command is reset. TZ must be set in the `.profile` or `.bashrc` files on all nodes in the cluster to take affect properly.

You can set the time zone several different ways, depending on the Linux distribution or the system administrator's preferences.

- To set the system time zone on Red Hat and SUSE Linux systems, edit:

```
/etc/sysconfig/clock
```

- To set the TZ variable, edit, `/etc/profile`, or `/dbadmin/.bashrc` or `/home/dbadmin/.bash_profile` and add the following line (for example, for the US Eastern Time Zone):

```
export TZ="America/New_York"
```

For details on which timezone names are recognized by Vertica, see the appendix: [Using Time Zones With Vertica](#).

LANG Environment Variable Settings

This topic details how to set or change the LANG environment variable. The LANG environment variable controls the locale of the host. If this variable is not set, then the installer reports this issue with the identifier: **S0300**. If this variable is not set to a valid value, then the installer reports this issue with the identifier: **S0301**.

Set the Host Locale

Each host has a system setting for the Linux environment variable LANG. LANG determines the locale category for native language, local customs, and coded character set in the absence of the LC_ALL and other LC_ environment variables. LANG can be used by applications to determine which language to use for error messages and instructions, collating sequences, date formats, and so forth.

To change the `LANG` setting for the database administrator, edit `/etc/profile`, or `/dbadmin/.bashrc` or `/home/dbadmin/.bash_profile` on all cluster hosts and set the environment variable; for example:

```
export LANG=en_US.UTF8
```

The `LANG` setting controls the following in Vertica:

- OS-level errors and warnings, for example, "file not found" during [COPY](#) operations.
- Some formatting functions, such as [TO_CHAR](#) and [TO_NUMBER](#). See also [Template Patterns for Numeric Formatting](#).

The `LANG` setting does not control the following:

- Vertica specific error and warning messages. These are always in English at this time.
- Collation of results returned by SQL issued to Vertica. This must be done using a database parameter instead. See [Implement Locales for International Data Sets](#) section in the Administrator's Guide for details.

Note: If the `LC_ALL` environment variable is set, it supersedes the setting of `LANG`.

Package Dependencies

For successful Vertica installation, you must first install three packages on all nodes in your cluster before installing the database platform.

The required packages are:

- `openssh`—Required for Administration Tools connectivity between nodes.
- `which`—Required for Vertica operating system integration and for validating installations.
- `dialog`—Required for interactivity with Administration Tools.

Installing the Required Packages

The procedure you follow to install the required packages depends on the operating system on which your node or cluster is running. See your operating system's documentation for detailed information on installing packages.

- **For CentOS/Red Hat Systems**—Typically, you manage packages on Red Hat and CentOS systems using the yum utility.

Run the following yum commands to install each of the package dependencies. The yum utility guides you through the installation:

```
# yum install openssh  
# yum install which  
# yum install dialog
```

- **For Debian/Ubuntu Systems**—Typically, you use the apt-get utility to manage packages on Debian and Ubuntu systems.

Run the following apt-get commands to install each of the package dependencies. The apt-get utility guides you through the installation:

```
# apt-get install openssh  
# apt-get install which  
# apt-get install dialog
```

Installing Vertica

There are different paths you can take when installing Vertica. You can:

- Install Vertica on one or more hosts using the command line, and not use the Management Console.
- Install the Management Console, and from the Management Console install Vertica on one or more hosts by using the Management Console cluster creation wizard.
- Install Vertica on one or more hosts using the command line, then install the Management Console and import the cluster to be managed.

Installing Using the Command Line

Although Micro Focus supports installation on one node, two nodes, and multiple nodes, this section describes how to install the Vertica software on a cluster of nodes. It assumes that you have already performed the tasks in [Before You Install Vertica](#), and that you have a Vertica license key.

To install Vertica, complete the following tasks:

1. [Download and install the Vertica server package](#)
2. [Installing Vertica with the Installation Script](#)

Special notes

- Downgrade installations are not supported.
- Be sure that you download the RPM for the correct operating system and architecture.
- Vertica supports two-node clusters with zero fault tolerance (K=0 safety). This means that you can [add a node](#) to a single-node cluster, as long as the installation node (the node upon which you build) is not the loopback node (`localhost/127.0.0.1`).
- The Version 7.0 installer introduces new platform verification tests that prevent the install from continuing if the platform requirements are not met by your system. Manually verify that your system meets the requirements in [Before You Install Vertica](#) on your systems. These tests ensure that your platform meets the hardware and software

requirements for Vertica. Previous versions documented these requirements, but the installer did not verify all of the settings. If this is a fresh install, then you can simply run the installer and view a list of the failures and warnings to determine which configuration changes you must make.

Download and Install the Vertica Server Package

To download and install the Vertica server package:

1. Use a Web browser to log in to [myVertica portal](#).
2. Click the Download tab and download the Vertica server package to the Administration Host.

Be sure the package you download matches the operating system and the machine architecture on which you intend to install it. In the event of a node failure, you can use any other node to run the Administration Tools later.

3. If you installed a previous version of Vertica on any of the hosts in the cluster, use the Administration Tools to shut down any running database.

The database must stop normally; you cannot upgrade a database that requires recovery.

4. If you are using sudo, skip to the next step. If you are root, log in to the Administration Host as root (or log in as another user and switch to root).

```
$ su - root
password: root-password
#
```

Caution: When installing Vertica using an existing user as the dba, you must exit all UNIX terminal sessions for that user after setup completes and log in again to ensure that group privileges are applied correctly.

After Vertica is installed, you no longer need root privileges. To verify sudo, see [General Hardware and OS Requirements and Recommendations](#).

5. Use one of the following commands to run the RPM package installer:

- If you are root and installing an RPM:

```
# rpm -Uvh pathname
```

- If you are using sudo and installing an RPM:

```
$ sudo rpm -Uvh pathname
```

- If you are using Debian:

```
$ sudo dpkg -i pathname
```

where *pathname* is the Vertica package file you downloaded.

Note: If the package installer reports multiple dependency problems, or you receive the error "*ERROR: You're attempting to install the wrong RPM for this operating system*", then you are trying to install the wrong Vertica server package. Make sure that the machine architecture (32-bit or 64-bit) of the package you downloaded matches the operating system.

Installing Vertica with the Installation Script

You run the install script after you install the Vertica package. The install script is run on a single node, using a Bash shell, and it copies the Vertica package to all other hosts (identified by the `--hosts` argument) in your planned cluster.

The install script runs several tests on each of the target hosts to verify that the hosts meet the system and performance requirements for a Vertica node. The install script modifies some operating system configuration settings to meet these requirements. Other settings cannot be modified by the install script and must be manually reconfigured.

The installation script takes the following basic parameters:

- A list of hosts on which to install.
- Optionally, the Vertica RPM/DEB path and package file name if you have not pre-installed the server package on other potential hosts in the cluster.
- Optionally, a system user name. If you do not provide a user name, then the install script creates a new system user named `dbadmin`. If you do provide a username and the username does not exist on the system, then the install script creates that user.

For example:

```
# /opt/vertica/sbin/install_vertica --hosts node0001,node0002,node0003 \  
--rpm /tmp/vertica_8.1.x.x86_64.RHEL6.rpm \  
--dba-user mydba
```

Note: The install script sets up passwordless ssh for the administrator user across all the hosts. If passwordless ssh is already set up, the install script verifies that it is functioning correctly.

Basic Installation

1. As root (or sudo) run the install script. The script must be run by a BASH shell as root or as a user with sudo privileges. You can configure many options when running the install script. See [install_vertica Options](#) below for the complete list of options.

If the installer fails due to any requirements not being met, you can correct the issue and then run the installer again with the same command line options.

To perform a basic installation:

- As root:

```
# /opt/vertica/sbin/install_vertica --hosts host_list --rpm package_name --dba-user dba_  
username
```

- Using sudo:

```
$ sudo /opt/vertica/sbin/install_vertica --hosts host_list --rpm package_name --dba-user dba_  
username
```

Basic Installation Parameters

Option	Description
<code>--hosts <i>host_list</i></code>	A comma-separated list of IP addresses to include in the cluster; do not include space characters in the list. Examples: <pre>--hosts 127.0.0.1 --hosts 192.168.233.101,192.168.233.102,192.168.233.103</pre>

Option	Description
	<p>Note: Vertica stores only IP addresses in its configuration files. You can provide a hostname to the <code>--hosts</code> parameter, but it is immediately converted to an IP address when the script is run.</p>
<pre>--rpm package_name --deb package_name</pre>	<p>The path and name of the Vertica RPM package. Example:</p> <pre>--rpm /tmp/vertica_8.1.x.x86_64.RHEL6.rpm</pre> <p>For Debian and Ubuntu installs, provide the name of the Debian package, for example:</p> <pre>--deb /tmp/vertica_7.2.x86.deb</pre>
<pre>--dba-user dba_username</pre>	<p>The name of the Database Administrator system account to create. Only this account can run the Administration Tools. If you omit the <code>--dba-user</code> parameter, then the default database administrator account name is <code>dbadmin</code>.</p> <p>This parameter is optional for new installations done as root but must be specified when upgrading or when installing using <code>sudo</code>. If upgrading, use the <code>-u</code> parameter to specify the same DBA account name that you used previously. If installing using <code>sudo</code>, the user must already exist.</p> <p>Note: If you manually create the user, modify the user's <code>.bashrc</code> file to include the line: <code>PATH=/opt/vertica/bin:\$PATH</code> so that the Vertica tools such as <code>vsq</code> and <code>admintools</code> can be easily started by the <code>dbadmin</code> user.</p>

- When prompted for a password to log into the other nodes, provide the requested password. Doing so allows the installation of the package and system configuration on the other cluster nodes.
 - If you are root, this is the root password.
 - If you are using `sudo`, this is the sudo user password.

The password does not echo on the command line. For example:

```
Vertica Database 7.0 Installation Tool  
Please enter password for root@host01:password
```

3. If the dbadmin user, or the user specified in the argument `--dba-user`, does not exist, then the install script prompts for the password for the user. Provide the password. For example:

```
Enter password for new UNIX user dbadmin:password  
Retype new UNIX password for user dbadmin:password
```

4. Carefully examine any warnings or failures returned by `install_vertica` and correct the problems.

For example, insufficient RAM, insufficient network throughput, and too high readahead settings on the filesystem could cause performance problems later on. Additionally, LANG warnings, if not resolved, can cause database startup to fail and issues with VSQL. The system LANG attributes must be UTF-8 compatible. **Once you fix the problems, re-run the install script.**

5. When installation is successful, disconnect from the Administration Host, as instructed by the script. Then, complete the required post-installation steps.

At this point, root privileges are no longer needed and the database administrator can perform any remaining steps.

Install on a FIPS 140-2 Enabled Machine

Vertica supports the implementation of the Federal Information Processing Standard 140-2 (FIPS). FIPS mode can be enabled in the operating system, specifically Red Hat Enterprise Linux 6.6.

Note: FIPS enablement on the operating system occurs outside of Vertica.

During the installation process, the Vertica 8.0 installer detects whether the host is operating in FIPS mode, as follows:

- The installer searches for `/proc/sys/crypto/fips_enabled` and examines its content. If the file exists and contains a '1', the host is operating in FIPS mode and the following message appears:

```
/proc/sys/crypto/fips_enabled exists and contains '1', this is a FIPS system
```

- The installer then installs symbolic links to the system `libcrypto.so.10` and `libssl.so.10` in `/opt/vertica/lib`.
- If the file does not exist or does not contain a '1', the installer compares the version numbers of the host `libcrypto.so` and `libssl.so` to the library versions in the Vertica package. If the host library file names have a higher version number, they are linked to the system copies. Otherwise, the host uses the libraries from the Vertica package.

Important: The following message appears if the OpenSSL version is 1.0.1# (where # indicates versions f to t) or higher like 1.0.2h

```
No version information available
```

This message indicates that you are using a library different from the one that Vertica was built with. As long as you are using a library that is newer than 1.0.1e (but not yet 1.1), Vertica operates correctly.

Create Symbolic Links to OpenSSL

During Vertica installation the installer determines what library Vertica needs to execute and sets up the following symbolic links in `/opt/vertica/lib`:

- `libssl.so.10`
- `libcrypto.so.10`

These Vertica-created symbolic links are linked to the actual filenames located in the following locations:

- `/lib`
- `/lib64`
- `/usr/lib`
- `/usr/lib64`
- `/lib/x86_64-linux-gnu`
- `/lib/i386-linux-gnu`

- /usr/lib/x86_64-linux-gnu
- /usr/lib/i386-linux-gnu

During processing, the installer places the actual files in /opt/vertica/lib:

- libssl.so.1.0.1e
- libcrypto.so.1.0.1e

If you build an updated OpenSSL, the default names resulting from the OpenSSL build process are:

- libcrypto.so.1.0.0
- libssl.so.1.0.0

In this case, the installer looks at the installed files and determines that these are a newer version than 1.0.1.e. When you attempt to compile the libraries, compilation fails.

In order for it to be linked automatically, you can do one of the following:

- Rename the libraries to indicate the version from which it was built. The install script can find it.
- Create new symbolic links in opt/vertica/lib that point to the location of the newer OpenSSL libraries.

Important: Before creating new symbolic links contact your Customer Experience representative.

Create new symbolic links using the instructions provided by your operating system.

Important: If you create new symbolic links, do NOT run install_vertica again. Doing so overwrites the new symbolic links.

For more information see [Implementing FIPS 140-2](#).

Required Post-Installation Steps

1. Log in to the Database Administrator account on the administration host.
2. [Install the License Key](#)

3. Accept the EULA.
4. If you have not already done so, proceed to [Getting Started](#). Otherwise, proceed to [Configuring the Database](#) in the Administrator's Guide.

install_vertica Options

The table below details all options available to the `install_vertica` script. Most options have a long and short form. For example `--hosts` is interchangeable with `-s`. The only required options are `--hosts/-s` and `--rpm/--deb/-r`.

Option	Description
<code>--help</code>	Display help for this script.
<code>--hosts host_list,</code> <code>-s host_list</code>	<p>A comma-separated list of host names or IP addresses to include in the cluster. Do not include spaces in the list. The IP addresses or hostnames must be for unique hosts. You cannot list the same host using multiple IP addresses/hostnames.</p> <p>Examples:</p> <pre>--hosts host01,host02,host03 -s 192.168.233.101,192.168.233.102,192.168.233.103</pre> <p>Note: If you are upgrading an existing installation of Vertica, be sure to use the same host names that you used previously.</p>
<code>--rpm package_name,</code> <code>--deb package_name,</code> <code>-r package_name</code>	<p>The name of the RPM or Debian package. The install package must be provided if you are installing or upgrading multiple nodes and the nodes do not have the latest server package installed, or if you are adding a new node. The <code>install_vertica</code> and <code>update_vertica</code> scripts serially copy the server package to the other nodes and install the package. If you are installing or upgrading a large number of nodes, then consider manually installing the package on all nodes before running the upgrade script, as</p>

Option	Description
	<p>the script runs faster if it does not need to serially upload and install the package on each node.</p> <p>Example:</p> <pre data-bbox="764 436 1401 499">--rpm vertica_8.1.x.x86_64.RHEL6.rpm</pre>
<pre data-bbox="207 531 509 583">--data-dir data_directory, -d data_directory</pre>	<p>The default directory for database data and catalog files. The default is /home/dbadmin.</p> <div data-bbox="764 632 1401 856" style="background-color: #f0f0f0; padding: 5px;"> <p>Note: Do not use a shared directory over more than one host for this setting. Data and catalog directories must be distinct for each node. Multiple nodes must not be allowed to write to the same data or catalog directory.</p> </div>
<pre data-bbox="207 892 443 919">--temp-dir directory</pre>	<p>The temporary directory used for administrative purposes. If it is a directory within /opt/vertica, then it will be created by the installer. Otherwise, the directory should already exist on all nodes in the cluster. The location should allow dbadmin write privileges.</p> <p>The default is /tmp.</p> <div data-bbox="764 1220 1401 1320" style="background-color: #f0f0f0; padding: 5px;"> <p>Note: This is not a temporary data location for the database.</p> </div>
<pre data-bbox="207 1358 488 1411">--dba-user dba_username, -u dba_username</pre>	<p>The name of the Database Administrator system account to create. Only this account can run the Administration Tools. If you omit the --dba-user parameter, then the default database administrator account name is dbadmin.</p> <p>This parameter is optional for new installations done as root but must be specified when upgrading or when installing using sudo. If upgrading, use the -u parameter to specify the same DBA account name that you used previously. If installing using sudo, the user must already exist.</p>

Option	Description
	<p>Note: If you manually create the user, modify the user's <code>.bashrc</code> file to include the line: <code>PATH=/opt/vertica/bin:\$PATH</code> so that the Vertica tools such as <code>vsq</code> and <code>admintools</code> can be easily started by the <code>dbadmin</code> user.</p>
<code>--dba-group GROUP,</code> <code>-g GROUP</code>	<p>The UNIX group for DBA users. The default is <code>verticadba</code>.</p>
<code>--dba-user-home dba_home_directory,</code> <code>-l dba_home_directory</code>	<p>The home directory for the database administrator. The default is <code>/home/dbadmin</code>.</p>
<code>--dba-user-password</code> <code>dba_password,</code> <code>-p dba_password</code>	<p>The password for the database administrator account. If not supplied, the script prompts for a password and does not echo the input.</p>
<code>--dba-user-password-disabled</code>	<p>Disable the password for the <code>--dba-user</code>. This argument stops the installer from prompting for a password for the <code>--dba-user</code>. You can assign a password later using standard user management tools such as <code>passwd</code>.</p>
<code>--spread-logging,</code> <code>-w</code>	<p>Configures spread to output logging output to <code>/opt/vertica/log/spread_<hostname>.log</code>. Does not apply to upgrades.</p> <p>Note: Do not enable this logging unless directed to by Vertica Analytics Platform Technical Support.</p>
<code>--ssh-password password,</code> <code>-P password</code>	<p>The password to use by default for each cluster host. If not supplied, and the <code>-i</code> option is not used, then the script prompts for the password if and when necessary and does not echo the input. Do not use with the <code>-i</code> option.</p> <p>Special note about password:</p> <p>If you run the <code>install_vertica</code> script as root, specify the root password with the <code>-P</code> parameter:</p> <pre># /opt/vertica/sbin/install_vertica -P <root_passwd></pre>

Option	Description
	<p>If, however, you run the <code>install_vertica</code> script with the <code>sudo</code> command, the password for the <code>-P</code> parameter should be the password of the user who runs <code>install_vertica</code>, not the root password. For example if user <code>dbadmin</code> runs <code>install_vertica</code> with <code>sudo</code> and has a password with the value <code>dbapasswd</code>, then the value for <code>-P</code> should be <code>dbapasswd</code>:</p> <pre>\$ sudo /opt/vertica/sbin/install_vertica -P dbapasswd</pre>
<pre>--ssh-identity file, -i file</pre>	<p>The root private-key <i>file</i> to use if passwordless ssh has already been configured between the hosts. Verify that normal SSH works without a password before using this option. The file can be private key file (for example, <code>id_rsa</code>), or PEM file. Do not use with the <code>--ssh-password/-P</code> option.</p> <p>Vertica accepts the following:</p> <ul style="list-style-type: none"> • By providing an SSH private key which is not password protected. You cannot run the <code>install_vertica</code> script with the <code>sudo</code> command when using this method. • By providing a password-protected private key and using an SSH-Agent. Note that <code>sudo</code> typically resets environment variables when it is invoked. Specifically, the <code>SSH_AUTHSOCK</code> variable required by the SSH-Agent may be reset. Therefore, configure your system to maintain <code>SSH_AUTHSOCK</code> or invoke the <code>install_vertica</code> command using a method similar to the following: <code>sudo SSH_AUTHSOCK=\$SSH_AUTHSOCK /opt/vertica/sbin/install_vertica ...</code>
<pre>--config-file file, -z file</pre>	<p>Accepts an existing properties file created by <code>--record-config file_name</code>. This properties file contains key/value parameters that map to values in the <code>install_vertica</code> script, many</p>

Option	Description
<pre>--add-hosts host_list, -A host_list</pre>	<p>with Boolean arguments that default to false.</p> <p>A comma-separated list of hosts to add to an existing Vertica cluster.</p> <p>--add-hosts modifies an existing installation of Vertica by adding a host to the database cluster and then reconfiguring the spread. This is useful for increasing system performance or setting K-safety to one (1) or two (2).</p> <p>Notes:</p> <ul style="list-style-type: none"> If you have used the -T parameter to configure spread to use direct point-to-point communication within the existing cluster, you must use the -T parameter when you add a new host; otherwise, the new host automatically uses UDP broadcast traffic, resulting in cluster communication problems that prevent Vertica from running properly. <p>Examples:</p> <pre>--add-hosts host01 --add-hosts 192.168.233.101</pre> <ul style="list-style-type: none"> The <code>update_vertica</code> script described in Adding Nodes calls the <code>install_vertica</code> script to update the installation. You can use either the <code>install_vertica</code> or <code>update_vertica</code> script with the <code>--add-hosts</code> parameter.
<pre>--record-config file_name, -B file_name</pre>	<p>Accepts a file name, which when used in conjunction with command line options, creates a properties file that can be used with the <code>--config-file</code> parameter. This parameter creates the properties file and exits; it has no impact on installation.</p>
<pre>--clean</pre>	<p>Forcibly cleans previously stored configuration</p>

Option	Description
	<p>files. Use this parameter if you need to change the hosts that are included in your cluster. Only use this parameter when no database is defined. Cannot be used with <code>update_vertica</code>.</p>
<pre>--license { license_file CE }, -L { license_file CE }</pre>	<p>Silently and automatically deploys the license key to <code>/opt/vertica/config/share</code>. On multi-node installations, the <code>--license</code> option also applies the license to all nodes declared in the <code>--hosts host_list</code>. To activate your license, use the <code>--license</code> option with the <code>--accept-eula</code> option. If you do not use the <code>--accept-eula</code> option, you are asked to accept the EULA when you connect to your database. Once you accept the EULA, your license is activated.</p> <p>If specified with <code>CE</code>, automatically deploys the Community Edition license key, which is included in your download. You do not need to specify a license file.</p> <p>Examples:</p> <pre>--license CE --license /tmp/vlicense.dat</pre>
<pre>--remove-hosts host_list, -R host_list</pre>	<p>A comma-separated list of hosts to remove from an existing Vertica cluster.</p> <p><code>--remove-hosts</code> modifies an existing installation of Vertica by removing a host from the database cluster and then reconfiguring the spread. This is useful for removing an obsolete or over-provisioned system. For example:</p> <pre>---remove-hosts host01 -R 192.168.233.101</pre> <p>Notes:</p> <ul style="list-style-type: none"> If you used the <code>-T</code> parameter to configure spread to use direct point-to-point communication within the existing cluster, you

Option	Description
	<p>must use <code>-T</code> when you remove a host; otherwise, the hosts automatically use UDP broadcast traffic, resulting in cluster communication problems that prevents Vertica from running properly.</p> <ul style="list-style-type: none"> The <code>update_vertica</code> script described in Removing Nodes in the Administrator's Guide calls the <code>install_vertica</code> script to perform the update to the installation. You can use either the <code>install_vertica</code> or <code>update_vertica</code> script with the <code>-R</code> parameter.
<pre>--control-network { BCAST_ADDR default }, -S { BCAST_ADDR default }</pre>	<p>Takes either the value 'default' or a broadcast network IP address (<code>BCAST_ADDR</code>) to allow spread communications to be configured on a subnet that is different from other Vertica data communications. <code>--control-network</code> is also used to force a cluster-wide spread reconfiguration when changing spread related options.</p> <p>Note: The <code>--control-network</code> must match the subnet for at least some of the nodes in the database. If the provided address does not match the subnet of any node in the database then the installer displays an error and stops. If the provided address matches some, but not all of the node's subnets, then a warning is displayed, but the install continues. Ideally, the value for <code>--control-network</code> should match all node subnets.</p> <p>Examples:</p> <pre>--control-network default --control-network 10.20.100.255</pre>
<pre>--point-to-point, -T</pre>	<p>Configures spread to use direct point-to-point communication between all Vertica nodes. You</p>

Option	Description
	<p>should use this option if your nodes aren't located on the same subnet. You should also use this option for all virtual environment installations, regardless of whether the virtual servers are on the same subnet or not. The maximum number of spread daemons supported in point-to-point communication in Vertica is 80. It is possible to have more than 80 nodes by using large cluster mode, which does not install a spread daemon on each node.</p> <p>Cannot be used with <code>--broadcast</code>, as the setting must be either <code>--broadcast</code> or <code>--point-to-point</code>.</p> <p>Important: When changing the configuration from <code>--broadcast</code> (the default) to <code>--point-to-point</code> or from <code>--point-to-point</code> to <code>--broadcast</code>, the <code>--control-network</code> parameter must also be used.</p> <div style="background-color: #f0f0f0; padding: 5px; border: 1px solid #ccc;"> <p>Note: Spread always runs on UDP. <code>-T</code> does not denote TCP.</p> </div>
<p><code>--broadcast</code>, <code>-U</code></p>	<p>Specifies that Vertica use UDP broadcast traffic by spread between nodes on the subnet. This parameter is automatically used by default. No more than 80 spread daemons are supported by broadcast traffic. It is possible to have more than 80 nodes by using large cluster mode, which does not install a spread daemon on each node.</p> <p>Cannot be used with <code>--point-to-point</code>, as the setting must be either <code>--broadcast</code> or <code>--point-to-point</code>.</p> <p>Important: When changing the configuration from <code>--broadcast</code> (the default) to <code>--point-to-point</code> or from <code>--point-to-point</code> to <code>--broadcast</code>, the <code>--control-network</code> parameter must also be used.</p>

Option	Description
	<p>Note: Spread always runs on UDP. -U does not mean use UDP instead of TCP.</p>
<p>--accept-eula, -Y</p>	<p>Silently accepts the EULA agreement. On multi-node installations, the --accept-eula value is propagated throughout the cluster at the end of the installation, at the same time as the Administration Tools metadata.</p> <p>Use the --accept-eula option with the --license option to activate your license.</p>
<p>--no-system-configuration</p>	<p>By default, the installer makes system configuration changes to meet server requirements. If you do not want the installer to change any system properties, then use the --no-system-configuration. The installer presents warnings or failures for configuration settings that do not meet requirements that it normally would have automatically configured.</p> <p>Note: The system user account is still created/updated when using this parameter.</p>
<p>--failure-threshold</p>	<p>Stops the installation when the specified failure threshold is encountered.</p> <p>Options can be one of:</p> <ul style="list-style-type: none"> • HINT - Stop the install if a HINT or greater issue is encountered during the installation tests. HINT configurations are settings you should make, but the database runs with no significant negative consequences if you omit the setting. • WARN (default) - Stop the installation if a WARN or greater issue is encountered. WARN issues may affect the performance of the database. However, for basic testing purposes or Community Edition users, WARN issues can

Option	Description
	<p>be ignored if extreme performance is not required.</p> <ul style="list-style-type: none"> • FAIL - Stop the installation if a FAIL or greater issue is encountered. FAIL issues can have severely negative performance consequences and possible later processing issues if not addressed. However, Vertica can start even if FAIL issues are ignored. • HALT - Stop the installation if a HALT or greater issue is encountered. The database may not be able to be started if you choose his option. Not supported in production environments. • NONE - Do not stop the installation. The database may not start. Not supported in production environments.
<pre>--large-cluster, -2 [<integer> DEFAULT]</pre>	<p>Enables a large cluster layout, in which control message responsibilities are delegated to a subset of Vertica Analytics Platform nodes (called control nodes) to improve control message performance in large clusters. Consider using this parameter with more than 50 nodes.</p> <p>Options can be one of:</p> <ul style="list-style-type: none"> • <i><integer></i>—The number of control nodes you want in the cluster. Valid values are 1 to 120 for all new databases. • DEFAULT—Vertica Analytics Platform chooses the number of control nodes using calculations based on the total number of cluster nodes in the <code>--hosts</code> argument. <p>For more information, see Large Cluster in the Administrator's Guide.</p>

Installing Vertica Silently

This section describes how to create a properties file that lets you install and deploy Vertica-based applications quickly and without much manual intervention.

Note: The procedure assumes that you have already performed the tasks in [Before You Install Vertica](#).

Install the properties file:

1. Download and install the Vertica install package, as described in [Installing Vertica](#).
2. Create the properties file that enables non-interactive setup by supplying the parameters you want Vertica to use. For example:

The following command assumes a multi-node setup:

```
# /opt/vertica/sbin/install_vertica --record-config file_name --license /tmp/license.txt --  
accept-eula \  
# --dba-user-password password --ssh-password password --hosts host_list --rpm package_name
```

The following command assumes a single-node setup:

```
# /opt/vertica/sbin/install_vertica --record-config file_name --license /tmp/license.txt --  
accept-eula \  
# --dba-user-password password
```

Option	Description
<code>--record-file <i>file_name</i></code>	[Required] Accepts a file name, which when used in conjunction with command line options, creates a properties file that can be used with the <code>--config-file</code> option during setup. This flag creates the properties file and exits; it has no impact on installation.
<code>--license { <i>license_file</i> CE }</code>	Silently and automatically deploys the license key to <code>/opt/vertica/config/share</code> . On multi-node installations, the <code>--license</code> option also applies the license to all nodes declared in the <code>--hosts <i>host_list</i></code> . If specified with CE, automatically deploys the

Option	Description
	Community Edition license key, which is included in your download. You do not need to specify a license file.
<code>--accept-eula</code>	Silently accepts the EULA agreement during setup.
<code>--dba-user-password <i>password</i></code>	The password for the Database Administrator account; if not supplied, the script prompts for the password and does not echo the input.
<code>--ssh-password <i>password</i></code>	The root password to use by default for each cluster host; if not supplied, the script prompts for the password if and when necessary and does not echo the input.
<code>--hosts <i>host_list</i></code>	<p>A comma-separated list of hostnames or IP addresses to include in the cluster; do not include space characters in the list.</p> <p>Examples:</p> <pre>--hosts host01,host02,host03 --hosts 192.168.233.101,192.168.233.102,192.168.233.103</pre>
<code>--rpm <i>package_name</i></code> <code>--deb <i>package_name</i></code>	<p>The name of the RPM or Debian package that contained this script.</p> <p>Example:</p> <pre>--rpm vertica_8.1.x.x86_64.RHEL6.rpm</pre> <p>This parameter is required on multi-node installations if the RPM or DEB package is not already installed on the other hosts.</p>

See [Installing Vertica with the Installation Script](#) for the complete set of installation parameters.

Tip: Supply the parameters to the properties file once only. You can then install Vertica using just the `--config-file` parameter, as described below.

3. Use one of the following commands to run the installation script.

- If you are root:

```
/opt/vertica/sbin/install_vertica --config-file file_name
```

- If you are using sudo:

```
$ sudo /opt/vertica/sbin/install_vertica --config-file file_name
```

--config-file *file_name* accepts an existing properties file created by --record-config *file_name*. This properties file contains key/value parameters that map to values in the `install_vertica` script, many with boolean arguments that default to false

The command for a single-node install might look like this:

```
# /opt/vertica/sbin/install_vertica --config-file /tmp/vertica-inst.prp
```

4. If you did not supply a --ssh-password password parameter to the properties file, you are prompted to provide the requested password to allow installation of the RPM/DEB and system configuration of the other cluster nodes. If you are root, this is the root password. If you are using sudo, this is the sudo user password. The password does not echo on the command line.

Note: If you are root on a single-node installation, you are not prompted for a password.

5. If you did not supply a --dba-user-password password parameter to the properties file, you are prompted to provide the database administrator account password.

The installation script creates a new Linux user account (dbadmin by default) with the password that you provide.

6. Carefully examine any warnings produced by `install_vertica` and correct the problems if possible. For example, insufficient RAM, insufficient Network throughput and too high readahead settings on filesystem could cause performance problems later on.

Note: You can redirect any warning outputs to a separate file, instead of having them display on the system. Use your platforms standard redirected mechanisms. For

```
example: install_vertica [options] > /tmp/file 1>&2.
```

7. **Optionally** perform the following steps:

- [Install the ODBC and JDBC driver.](#)
- [Install the vsqll client application on non-cluster hosts.](#)

8. Disconnect from the Administration Host as instructed by the script. This is required to:

- Set certain system parameters correctly.
- Function as the Vertica database administrator.

At this point, Linux root privileges are no longer needed. The database administrator can perform the remaining steps.

Note: When creating a new database, the database administrator might want to use different data or catalog locations than those created by the installation script. In that case, a Linux administrator might need to create those directories and change their ownership to the database administrator.

- If you supplied the `--license` and `--accept-eula` parameters to the properties file, then proceed to the [Getting Started](#) and then see [Configuring the Database](#) in the Administrator's Guide. Otherwise:
 1. Log in to the Database Administrator account on the administration host.
 2. Accept the End User License Agreement and install the license key you downloaded previously as described in [Install the License Key](#).
 3. Proceed to [Getting Started](#) and then see [Configuring the Database](#) in the Administrator's Guide.

Notes

- Downgrade installations are not supported.
- The following is an example of the contents of the configuration properties file:

```
accept_eula = True  
license_file = /tmp/license.txt  
record_to = file_name  
root_password = password  
vertica_dba_group = verticadba  
vertica_dba_user = dbadmin  
vertica_dba_user_password = password
```

Installing Vertica on Amazon Web Services (AWS)

Beginning with Vertica 6.1.x, you can use Vertica on AWS by utilizing a pre-configured Amazon Machine Image (AMI). For details on installing and configuring a cluster on AWS, refer to [Installing and Running Vertica on AWS](#).

Installing and Configuring Management Console

This section describes how to install, configure, and upgrade Management Console (MC). If you need to back up your instance of MC, see [Backing Up MC](#) in the Administrator's Guide.

You can install MC before or after you install Vertica; however, consider installing Vertica and creating a database before you install MC.

Before You Install MC

Management Console (MC) 8.1.x is compatible with the latest hotfix version of Vertica server 7.2.3 and above. Read the following documents for more information:

- Supported Platforms document, at <http://my.vertica.com/docs>. The Supported Platforms document also lists supported browsers for MC.
- [Installation Overview and Checklist](#). Make sure you have everything ready for your Vertica configuration.
- [Before You Install Vertica](#). Read for required prerequisites for *all* Vertica configurations, including Management Console.

Driver Requirements for Linux SuSe Distributions

The MC (`vertica-console`) package contains the Oracle Implementation of Java 7 JRE and requires that you install the unixODBC driver manager on SuSe Linux platforms. unixODBC provides needed libraries `libodbc` and `libodbcinst`.

Port Requirements

When you use MC to create a Vertica cluster, the [Create Cluster Wizard](#) uses SSH on its default port (22).

Port 5444 is the default agent port and must be available for MC-to-node and node-to-node communications.

Port 5450 is the default MC port and must be available for node-to-MC communications.

See [Ensure Ports Are Available](#) for more information about port and firewall considerations.

Firewall Considerations

Make sure that a firewall or iptables are not blocking communications between the cluster's database, Management Console, and MC's agents on each cluster node.

IP Address Requirements

If you install MC on a server outside the Vertica cluster it will be monitoring, that server must be accessible to at least the public network interfaces on the cluster.

Hardware Requirements

Requirements	CPU	RAM	Disk Space
Minimum	4-core	4G	2G
Recommended	8-core	8G	2G

You can install MC on any node in the cluster, or its own dedicated node. When running the MC on a node in the cluster, note that MC shares RAM and time on CPU cores with other Vertica processes. See [Disk Space Requirements for Vertica](#).

Time Synchronization and MC's Self-Signed Certificate

When you [connect to MC](#) through a client browser, Vertica assigns each HTTPS request a self-signed certificate, which includes a timestamp. To increase security and protect against password replay attacks, the timestamp is valid for several seconds only, after which it expires.

To avoid being blocked out of MC, synchronize time on the hosts in your Vertica cluster, and on the MC host if it resides on a dedicated server. To recover from loss or lack of synchronization, resync system time and the Network Time Protocol. See [Set Up Time Synchronization](#) in [Installing Vertica](#).

SSL Requirements

The `openssl` package must be installed on your Linux environment so SSL can be set up during the MC configuration process. See [SSL Overview](#) in the Administrator's Guide.

File Permission Requirements

On your local workstation, you must have at least read/write privileges on any files you plan to upload to MC through the [Cluster Installation Wizard](#). These files include the Vertica server package, the license key (if needed), the private key file, and an optional CSV file of IP addresses.

Monitor Resolution

Management Console requires a minimum resolution of 1024 x 768, but Micro Focus recommends higher resolutions for optimal viewing.

Installing Management Console

You can install Management Console on any node you plan to include in the Vertica database cluster, as well as on its own, dedicated server outside the cluster.

Install Management Console on the MC Server

1. Download the MC package from the [myVertica](#) portal:

```
vertica-console-current-version.Linux-distro)
```

Save the package to a location on the target server, such as /tmp.

2. On the target server, log in as root or a user with sudo privileges.
3. Change to the directory where you saved the MC package.
4. Install MC using your local Linux distribution package management system—rpm, yum, zypper, apt, dpkg. For example:

Red Hat 6

```
# rpm -Uvh vertica-console-current-version.x86_64.RHEL6.rpm
```

Debian and Ubuntu

```
# dpkg -i vertica-console-current-version.deb
```

5. If you stopped the database before upgrading MC, restart the database.

As the root user, use the following command:

```
/etc/init.d/verticad start
```

For versions of Red Hat 7/CentOS 7 and above, run:

```
# systemctl start vertica-consoled
```

6. Open a browser and enter the URL of the MC installation, one of the following:

- IP address:

```
https://ip-address:mc-port/
```

- Server host name:

```
https://hostname:mc-port/
```

By default, *mc-port* is 5450.

7. If MC was not previously configured, the Configuration Wizard dialog box appears. Configuration steps are described in [Configuring MC](#).

If MC was previous configured, Vertica prompts you to accept the end-user license agreement (EULA) when you first log in to MC after the upgrade.

Configuring MC

After you [install MC](#), you need to configure it through a client browser connection. An MC configuration wizard walks you through creating the Linux MC super administrator account, storage locations, and other settings that MC needs to run. Information you provide during the configuration process is stored in the `/opt/vconsole/config/console.properties` file.

If you need to change settings after the configuration wizard ends, such as port assignments, you can do so later through Home > MC Settings page.

How to Configure MC

1. Open a browser session.
2. Enter the IP address or host name of the server on which you installed MC (or any cluster node's IP/host name if you already installed Vertica), and include the default MC port 5450. For example, you'll enter one of:

```
https://xx.xx.xx.xx:5450/ https://hostname:5450/
```

3. Follow the configuration wizard.

About Authentication for the MC Super Administrator

In the final step of the configuration process, you choose an authentication method for the MC super administrator. You can decide to have MC authenticate the MC super (in which case the process is complete), or you can choose LDAP.

If you choose LDAP, provide the following information for the newly-created MC super administrator:

- Corporate LDAP service host (IP address or host name)
- LDAP server running port (default 389)
- LDAP DN (distinguished name) for base search/lookup/authentication criteria

At a minimum, specify the dc (domain component) field. For example: `dc=vertica, dc=com` generates a unique identifier of the organization, like the corporate Web URL `vertica.com`

- Default search path for the organization unit (ou)

For example: `ou=sales, ou=engineering`

- Search attribute for the user name (uid), common name (cn), and so on

For example, `uid=jdoe, cn=Jane Doe`

- Binding DN and password for the MC super administrator.

In most cases, you provide the "Bind as administrator" fields, information used to establish the LDAP service connection for all LDAP operations, like search. Instead of using the administrator user name and password, the MC administrator could use his or her own LDAP credentials, as long as that user has search privileges.

If You Choose Bind Anonymously

Unless you specifically configure the LDAP server to deny anonymous binds, the underlying LDAP protocol will not cause MC's [Configure Authentication](#) process to fail if you choose "Bind anonymously" for the MC administrator. Before you use anonymous bindings for LDAP authentication on MC, be sure that your LDAP server is configured to explicitly disable/enable this option. For more information, see the article on [Infusion Technology Solutions](#) and the [OpenLDAP documentation](#) on access control.

What Happens Next

Shortly after you click Finish, you should see a status in the browser; however, for several seconds you might see only an empty page. During this brief period, MC runs as the local user 'root' long enough to bind to port number 5450. Then MC switches to the MC super administrator account that you just created, restarts MC, and displays the MC login page.

Where to Go Next

If you are a new MC user and this is your first MC installation, you might want to familiarize yourself with MC design. See [Management Console](#) in Vertica Concepts.

If you'd rather use MC now, the following following topics in the Administrator's Guide should help get you started:

If you want to ...	See ...
Use the MC interface to install Vertica on a cluster of hosts	Creating a Cluster Using MC
Create a new, empty Vertica database or import an existing Vertica database cluster into the MC interface	Managing Database Clusters
Create new MC users and map them to one or more Vertica databases that you manage through the MC interface	Managing Users and Privileges (About MC Users and About MC Privileges and Roles)
Monitor MC and one or more MC-managed Vertica databases	Monitoring Vertica Using Management Console
Change default port assignments or upload a new Vertica license or SSL certificate	Managing MC Settings
Compare MC functionality to functionality that the Administration Tools provides	Administration Tools and Management Console

Creating a Cluster Using MC

You can use Management Console to install a Vertica cluster on hosts where Vertica software has not been installed. The Cluster Installation wizard lets you specify the hosts you want to include in your Vertica cluster, loads the Vertica software onto the hosts, validates the hosts, and assembles the nodes into a cluster.

Management Console must be installed and configured before you can create a cluster on targeted hosts. See [Installing and Configuring the MC](#) for details.

Steps Required to Install a Vertica Cluster Using MC:

- [Install and configure MC](#)
- [Prepare the Hosts](#)
- [Create the private key file](#) and copy it to your local machine
- [Run the Cluster Installation Wizard](#)
- [Validate the hosts and create the cluster](#)
- [Create a new database on the cluster](#)

Prepare the Hosts

Before you can install a Vertica cluster using the MC, you must prepare each host that will become a node in the cluster. The cluster creation process runs validation tests against each host before it attempts to install the Vertica software. These tests ensure that the host is correctly configured to run Vertica.

Install Perl

The MC cluster installer uses Perl to perform the installation. Install Perl 5 on the target hosts before performing the cluster installation. Perl is available for download from www.perl.org.

Validate the Hosts

The validation tests provide:

- Warnings and error messages when they detect a configuration setting that conflicts with the Vertica requirements or any performance issue
- Suggestions for configuration changes when they detect an issue

Note: The validation tests do not automatically fix all problems they encounter.

All hosts must pass validation before the cluster can be created.

If you accepted the default configuration options when installing the OS on your host, then the validation tests will likely return errors, since some of the default options used on Linux systems conflict with Vertica requirements. See [Installing Vertica](#) for details on OS settings. To speed up the validation process you can perform the following steps on the prospective hosts before you attempt to validate the hosts. These steps are based on Red Hat Enterprise Linux and CentOS systems, but other supported platforms have similar settings.

On each host you want to include in the Vertica cluster, you must stage the host according to [Before You Install Vertica](#).

Create a Private Key File

Before you can install a cluster, Management Console must be able to access the hosts on which you plan to install Vertica. MC uses password-less SSH to connect to the hosts and install Vertica software using a private key file.

If you already have a private key file that allows access to all hosts in the potential cluster, you can use it in the cluster creation wizard.

Note: The private key file is required to complete the MC cluster installation wizard.

Create a Private Key File

1. Log into the server as root or as a user with sudo privileges.
2. Change to your home directory.

```
$ cd ~
```

3. Create an `.ssh` directory if one does not already exist.

```
$ mkdir .ssh
```

4. Generate a passwordless private key/public key pair.

```
$ ssh-keygen -q -t rsa -f ~/.ssh/vid_rsa -N ''
```

This command creates two files: `vid_rsa` and `vid_rsa.pub`. The `vid_rsa` file is the private key file that you upload to the MC so that it can access nodes on the cluster and install Vertica. The `vid_rsa.pub` file is copied to all other hosts so that they can be accessed by clients using the `vid_rsa` file.

5. Make your `.ssh` directory readable and writable only by yourself.

```
$ chmod 700 /root/.ssh
```

6. Change to the `.ssh` directory.

```
$ cd ~/.ssh
```

7. Edit `sshd.config` as follows to disable password authentication for root:

```
PermitRootLogin without-password
```

8. Concatenate the public key into to the file `vauthorized_keys2`.

```
$ cat vid_rsa.pub >> vauthorized_keys2
```

9. If the host from which you are creating the public key will also be in the cluster, copy the public key into the local-hosts authorized key file:

```
cat vid_rsa.pub >> authorized_keys
```

10. Make the files in your `.ssh` directory readable and writable only by yourself.

```
$ chmod 600 ~/.ssh/*
```

11. Create the `.ssh` directory on the other nodes.

```
$ ssh <host> "mkdir /root/.ssh"
```

12. Copy the vauthorized key file to the other nodes.

```
$ scp -r /root/.ssh/vauthorized_keys2 <host>:/root/.ssh/.
```

13. On each node, concatenate the `vauthorized_keys2` public key to the `authorized_keys` file and make the file readable and writable only by the owner.

```
$ ssh <host> "cd /root/.ssh;;cat vauthorized_keys2 >> authorized_keys; chmod 600 /root/.ssh/authorized_keys"
```

14. On each node, remove the `vauthorized_keys2` file.

```
$ ssh -i /root/.ssh/vid_rsa <host> "rm /root/.ssh/vauthorized_keys2"
```

15. Copy the `vid_rsa` file to the workstation from which you will access the MC cluster installation wizard. This file is required to install a cluster from the MC.

A complete example of the commands for creating the public key and allowing access to three hosts from the key is below. The commands are being initiated from the `docg01` host, and all hosts will be included in the cluster (`docg01` - `docg03`):

```
ssh docg01
cd ~/.ssh
ssh-keygen -q -t rsa -f ~/.ssh/vid_rsa -N ''
cat vid_rsa.pub > vauthorized_keys2
cat vid_rsa.pub >> authorized_keys
chmod 600 ~/.ssh/*
scp -r /root/.ssh/vauthorized_keys2 docg02:/root/.ssh/.
scp -r /root/.ssh/vauthorized_keys2 docg03:/root/.ssh/.
ssh docg02 "cd /root/.ssh;;cat vauthorized_keys2 >> authorized_keys; chmod 600 /root/.ssh/authorized_keys"
ssh docg03 "cd /root/.ssh;;cat vauthorized_keys2 >> authorized_keys; chmod 600 /root/.ssh/authorized_keys"
ssh -i /root/.ssh/vid_rsa docg02 "rm /root/.ssh/vauthorized_keys2"
ssh -i /root/.ssh/vid_rsa docg03 "rm /root/.ssh/vauthorized_keys2"
rm ~/.ssh/vauthorized_keys2
```

Use the MC Cluster Installation Wizard

The Cluster Installation Wizard guides you through the steps required to install a Vertica cluster on hosts that do not already have Vertica software installed.

Note: If you are using MC with the Vertica AMI on Amazon Web Services, note that the Create Cluster and Import Cluster options are not supported.

Prerequisites

Before you proceed, make sure you:

- [Installed and configured MC](#).
- [Prepared the hosts](#) that you will include in the Vertica database cluster.
- [Created the private key \(pem\) file](#) and copied it to your local machine.
- Obtained a copy of your Vertica license if you are installing the Premium Edition. If you are using the Community Edition, a license key is not required.
- Downloaded the Vertica server RPM (or DEB file).
- Have read/copy permissions on files stored on the local browser host that you will transfer to the host on which MC is installed.

Permissions on Files to Transfer to MC

On your local workstation, you must have at least read/write privileges on files you'll upload to MC through the Cluster Installation Wizard. These files include the Vertica server package, the license key (if needed), the private key file, and an optional CSV file of IP addresses.

Create a New Vertica Cluster Using MC

1. [Connect](#) to Management Console and log in as an MC administrator.
2. On MC's [Home page](#), click the **Provisioning** task. The Provisioning dialog appears.
3. Click **Create a new cluster**.
4. The Create Cluster wizard opens. Provide the following information:

- a. Cluster name—A label for the cluster
- b. Vertica Admin User—The user that is created on each of the nodes when they are installed, typically 'dbadmin'. This user has access to Vertica and is also an OS user on the host.
- c. Password for the Vertica Admin User—The password you enter (required) is set for each node when MC installs Vertica.

Note: MC does not support an empty password for the administrative user.

- d. Vertica Admin Path—Storage location for catalog files, which defaults to /home/dbadmin unless you specified a different path during MC configuration (or later on MC's Settings page).

Important: The Vertica Admin Path must be the same as the Linux database administrator's home directory. If you specify a path that is not the Linux dbadmin's home directory, MC returns an error.

5. Click **Next** and specify the private key file and host information:

- a. Click **Browse** and navigate to the private key file (vid_rsa) that you created earlier.

Note: You can change the private key file at the beginning of the validation stage by clicking the name of the private key file in the bottom-left corner of the page. However, you cannot change the private key file after validation has begun unless the first host fails validation due to an SSH login error.

- b. Include the host IP addresses. You have three options:

Specify later (but include number of nodes). This option allows you to specify the number of nodes, but not the specific IPs. You can specify the specific IPs before you validate hosts.

Import IP addresses from local file. You can specify the hosts in a CSV file using either IP addresses or host names.

Enter a range of IP addresses. You can specify a range of IPs to use for new nodes. For example 192.168.1.10 to 192.168.1.30. The range of IPs must be on the same or contiguous subnets.

6. Click **Next** and select the software and license:
 - a. Vertica Software. If one or more Vertica packages have been uploaded, you can select one from the list. Otherwise, select **Upload a new local vertica binary file** and browse to a Vertica server file on your local system.
 - b. Vertica License. Click **Browse** and navigate to a local copy of your Vertica license if you are installing the Premium Edition. Community Edition versions require no license key.
7. Click **Next**. The Create cluster page opens. If you did not specify the IP addresses, select each host icon and provide an IP address by entering the IP in the box and clicking **Apply** for each host you add.

You are now ready to [Validate Hosts and Create the Cluster](#).

Validate Hosts and Create the Cluster

Host validation is the process where the MC runs tests against each host in a [proposed cluster](#).

You can validate hosts only after you have completed the cluster installation wizard. You must validate hosts before the MC can install Vertica on each host.

At any time during the validation process, but before you create the cluster, you can add and remove hosts by clicking the appropriate button in the upper left corner of the page on MC. A Create Cluster button appears when all hosts that appear in the node list are validated.

How to Validate Hosts

To validate one or more hosts:

1. [Connect](#) to Management Console and log in as an MC administrator.
2. On the MC [Home page](#), click the **Databases and Clusters** task.
3. In the list of databases and clusters, select the cluster on which you have recently run the cluster installation wizard (**Creating...** appears under the cluster) and click **View**.
4. Validate one or several hosts:
 - To validate a single host, click the host icon, then click **Validate Host**.
 - To validate all hosts at the same time, click **All** in the Node List, then click **Validate Host**.

- To validate more than one host, but not all of them, Ctrl+click the host numbers in the node list, then click **Validate Host**.

5. Wait while validation proceeds.

The validation step takes several minutes to complete. The tests run in parallel for each host, so the number of hosts does not necessarily increase the amount of time it takes to validate all the hosts if you validate them at the same time. Hosts validation results in one of three possible states:

- Green check mark—The host is valid and can be included in the cluster.
- Orange triangle—The host can be added to the cluster, but warnings were generated. Click the tests in the host validation window to see details about the warnings.
- Red X—The host is not valid. Click the tests in the host validation window that have red X's to see details about the errors. You must correct the errors re-validate or remove the host before MC can create the cluster.

To remove an invalid host: Highlight the host icon or the IP address in the Node List and click **Remove Host**.

All hosts must be valid before you can create the cluster. Once all hosts are valid, a **Create Cluster** button appears near the top right corner of the page.

How to Create the Cluster

1. Click **Create Cluster** to install Vertica on each host and assemble the nodes into a cluster.

The process, done in parallel, takes a few minutes as the software is copied to each host and installed.

2. Wait for the process to complete. When the **Success** dialog opens, you can do one of the following:

- Optionally create a database on the new cluster at this time by clicking **Create Database**
- Click **Done** to create the database at a later time

See [Creating a Database on a Cluster](#) for details on creating a database on the new cluster.

Create a Database on a Cluster

After you use the [MC Cluster Installation Wizard](#) to create a Vertica cluster, you can create a database on that cluster through the MC interface. You can create the database on all cluster nodes or on a subset of nodes.

If a database had been created using the Administration Tools on any of the nodes, MC detects (autodiscovers) that database and displays it on the Manage (Cluster Administration) page so you can import it into the MC interface and begin monitoring it.

MC allows only one database running on a cluster at a time, so you might need to stop a running database before you can create a new one.

The following procedure describes how to create a database on a cluster that you created using the MC [Cluster Installation Wizard](#). To create a database on a cluster that you created by running the `install_vertica` script, see [Creating an Empty Database](#).

Create a Database on a Cluster

To create a new empty database on a new cluster:

1. If you are already on the **Databases and Clusters** page, skip to the next step. Otherwise:
 - a. [Connect](#) to MC and sign in as an MC administrator.
 - b. On the [Home page](#), click **Existing Infrastructure**.
2. If no databases exist on the cluster, continue to the next step. Otherwise:
 - a. If a database is running on the cluster on which you want to add a new database, select the database and click **Stop**.
 - b. Wait for the running database to have a status of *Stopped*.
3. Click the cluster on which you want to create the new database and click **Create Database**.
4. The Create Database wizard opens. Provide the following information:
 - Database name and password. See [Creating a Database Name and Password](#) for rules.
 - Optionally click **Advanced** to open the advanced settings and change the port, and catalog path, and data path. By default the MC application/web server port is 5450 and

paths are `/home/dbadmin`, or whatever you defined for the paths when you ran the cluster creation wizard. Do not use the default agent port 5444 as a new setting for the MC application/web server port. See **MC Settings > Configuration** for port values.

5. Click **Continue**.

6. Select nodes to include in the database.

The Database Configuration window opens with the options you provided and a graphical representation of the nodes appears on the page. By default, all nodes are selected to be part of this database (denoted by a green check mark). You can optionally click each node and clear **Include host in new database** to exclude that node from the database. Excluded nodes are gray. If you change your mind, click the node and select the **Include** check box.

7. Click **Create** in the Database Configuration window to create the database on the nodes.

The creation process takes a few moments and then the database is started and a **Success** message appears.

8. Click **OK** to close the success message.

The Database Manager page opens and displays the database nodes. Nodes not included in the database are gray.

After You Install Vertica

The tasks described in this section are optional and are provided for your convenience. When you have completed this section, proceed to one of the following:

- [Using This Guide](#) in Getting Started
- [Configuring the Database](#) in the Administrator's Guide

Install the License Key

If you did not supply the `-L` parameter during setup, or if you did not bypass the `-L` parameter for a [silent install](#), the first time you log in as the Database Administrator and run the Vertica Administration Tools or Management Console, Vertica requires you to install a license key.

Follow the instructions in [Managing Licenses](#) in the Administrator's Guide.

Optionally Install vsql Client Application on Non-Cluster Hosts

You can use the Vertica `vsql` executable image on a non-cluster Linux host to connect to a Vertica database.

- On Red Hat, CentOS, and SUSE systems, you can install the client driver RPM, which includes the `vsql` executable. See [Installing the Client RPM on Red Hat and SUSE](#) for details.
- If the non-cluster host is running the same version of Linux as the cluster, copy the image file to the remote system. For example:

```
$ scp host01:/opt/vertica/bin/vsql . $ ./vsql
```

- If the non-cluster host is running a different version of Linux than your cluster hosts, and that operating system is not Red Hat version 5 64-bit or SUSE 10/11 64-bit, you must install the Vertica server RPM in order to get `vsql`. Download the appropriate rpm package from the Download tab of the [myVertica portal](#) then log into the non-cluster host as root and install the rpm package using the command:

```
# rpm -Uvh filename
```

In the above command, *filename* is the package you downloaded. Note that you do not have to run the `install_Vertica` script on the non-cluster host in order to use `vsql`.

Notes

- Use the same [Command-Line Options](#) that you would on a cluster host.
- You cannot run `vsql` on a Cygwin bash shell (Windows). Use `ssh` to connect to a cluster host, then run `vsql`.

`vsql` is also available for additional platforms. See [Installing the vsql Client](#).

Installing Client Drivers

After you install Vertica, install drivers on the client systems from which you plan to access your databases. Micro Focus supplies drivers for ADO.NET, JDBC, ODBC, OLE DB, Perl, and Python. For instructions on installing these drivers, see [Client Drivers](#) in [Connecting to Vertica](#).

Creating a Database

To get started using Vertica immediately after installation, create a database. You can use either the Administration Tools or the Management Console.

Creating a Database Using the Administration Tools

Follow these step to create a database using the Administration Tools.

1. Log in as the database administrator, and type `admintools` to bring up the Administration Tools.
2. When the EULA (end-user license agreement) window opens, type `accept` to proceed. A window displays, requesting the location of the license key file you downloaded from the Micro Focus Web site. The default path is `/tmp/vlicense.dat`.

- If you are using the Vertica Community Edition, click **OK** without entering a license key.
 - If you are using the Vertica Premium Edition, type the absolute path to your license key (for example, `/tmp/vlicense.dat`) and click **OK**.
3. From the Administration Tools **Main Menu**, click **Configuration Menu**, and then click **OK**.
 4. Click **Create Database**, and click **OK** to start the database creation wizard.

To create a database using MC, refer [Creating a Database Using MC](#).

See Also

- [Using the Vertica Interfaces](#)

Upgrading Vertica

The process of upgrading your database with a new Vertica version includes:

- [Complete upgrade prerequisites](#)
- [Upgrade Vertica](#)
- [Perform post-upgrade tasks—required, recommended, and optional](#)

Click on the above links for detailed instructions.

Upgrade Paths

Upgrades are incremental. To upgrade successfully, use the following paths:

- Vertica 7.0 to 7.1
- Vertica 7.1 to 7.2
- Vertica 7.2 to 8.0
- Vertica 8.0 to 8.1

Note: You cannot upgrade Vertica from versions 7.x to a FIPS-enabled 8.0 system. For more information on FIPS see [Federal Information Processing Standard](#).

Be sure to read the Release Notes and New Features for each version in your path. Documentation for the current Vertica version is available in the RPM, and at <http://my.vertica.com/docs>, which also provides access to documentation for earlier versions.

To upgrade from an earlier version, please contact [Vertica Technical Support](#) for assistance.

Before You Upgrade

Before you upgrade the Vertica database, you must perform the following steps:

- [Perform a full database backup](#). This precautionary measure allows you to restore the current version, if the upgrade is unsuccessful.
- [Verify platform requirements](#) for the new version.
- [Check catalog storage space](#).
- [Uninstall the HDFS connector](#) (required only if you are upgrading from pre-7.2 versions).
- [Back up any Geospatial indexes](#) and save the results in a temporary table.

After you complete these tasks, shut down the database gracefully. This procedure is described in the Administrator's Guide: [Stopping the Database](#).

Verifying Platform Requirements

The Vertica installer checks the target platform as it runs, and stops whenever it determines the platform fails to meet an installation requirement. Before you update the server package on your systems, manually verify that your platform meets all hardware and software requirements (see [Platform Requirements and Recommendations](#)).

By default, the installer stops on all warnings. You can configure the level where the installer stops installation, through the installation parameter `--failure-threshold`. If you set the failure threshold to `FAIL`, the installer ignores warnings and stops only on failures.

Caution: Changing the failure threshold lets you immediately upgrade and bring up the Vertica database. However, Vertica cannot fully optimize performance until you correct all warnings.

Checking Catalog Storage Space

Compare how much space the catalog currently uses against space that is available in the same directory:

1. Use the `du` command to determine how much space the catalog directory now uses:

```
$ du -s -BG v_vmart_node0001_catalog
2G      v_vmart_node0001_catalog
```

2. Determine how much space is available in the same directory:

```
$ df -BG v_vmart_node0001_catalog
Filesystem      1G-blocks  Used Available Use% Mounted on
/dev/sda2              48G    19G    26G  43% /
```

Uninstalling HDFS Connector

Important: Perform this task only if you are upgrading from a pre-7.2 version.

As of version 7.2, the HDFS Connector is installed automatically. If you previously downloaded and installed this connector, uninstall it before you upgrade to this release of Vertica.

Back Up Geospatial Indexes

When you upgrade, the geospatial indexes are invalid. You must back up spatial indexes that contain polygon geometry data into a temporary table and rebuild them in the newer Place version using the temporary table as the set of input polygons.

The following steps backup your spatial indexes:

1. Build an index with [STV_Create_Index](#):

```
=> SELECT STV_Create_Index(123, ST_GeomFromText('POLYGON((1 2, 2 3, 3 1, 1 2))')
      USING PARAMETERS index='pol_idx') OVER();
 type  | polygons | SRID | min_x | min_y | max_x | max_y | info
-----+-----+-----+-----+-----+-----+-----+-----
 GEOMETRY | 1        | 0    | 1     | 1     | 3     | 3     |
(1 row)
```

2. Save the index polygons in a temporary table. Use [STV_Describe_Index](#) with the `list_polygons` option to get the polygons from the index. The `\d` command describes *temp-table*:

```
=> CREATE TABLE temp-table
      AS SELECT STV_Describe_Index(USING PARAMETERS index='pol_idx', list_polygons=true) OVER();

=> \d temp-table
                                List of Fields by Tables
 Schema | Table      | Column | Type      | Size | Default | Not Null | Primary Key | Foreign Key
-----+-----+-----+-----+-----+-----+-----+-----+-----
-----
```

```
public | temp-table | gid      | int      | 8      |      | f      | f      |      |
public | temp-table | state  | varchar(20) | 20     |      | f      | f      |      |
public | temp-table | geometry | geometry(141) | 141    |      | f      | f      |      |
(3 rows)
```

3. The temporary table contains a copy of all polygons and identifiers in the indexes. The following command shows the contents of the temporary table:

```
=> SELECT gid, state, ST_AsText(geometry) FROM temp-table;
gid | state  | ST_AsText
-----+-----+-----
123 | INDEXED | POLYGON ((1 2, 2 3, 3 1, 1 2))
(1 row)
```

After you upgrade, use the polygons table as input to rebuild the index. For details, see [Rebuild Geospatial Indexes](#).

Upgrade Vertica

Important: Before running the upgrade script, be sure to review the tasks described in [Before You Upgrade](#).

Repeat this procedure for each version in your [upgrade path](#):

1. Perform a full [full hard-link local backup](#) of your existing database. This precautionary measure lets you restore from the backup, if the upgrade is unsuccessful. If the upgrade fails, you can reinstall the previous version of Vertica and [restore your database](#) to that version.

If your upgrade path includes multiple versions, create a full backup with the first upgrade. For each subsequent upgrade, you can perform incremental backups. However, Micro Focus recommends full backups before each upgrade if disk space and time allow.

2. Use admintools to [stop the database](#).
3. On each host where an additional package is installed, such as the [R language pack](#), uninstall it. For example:

```
rpm -e vertica-R-lang
```

Important: If you omit this step and do not uninstall additional packages, the Vertica server package fails to install in the next step.

4. Make sure you are logged in as root or sudo and use one of the following commands to run the RPM package installer:

- If you are root and installing an RPM:

```
# rpm -Uvh pathname
```

- If you are using sudo and installing an RPM:

```
$ sudo rpm -Uvh pathname
```

- If you are using Debian:

```
$ sudo dpkg -i pathname
```

5. On the same node on which you just installed the RPM, run `update_vertica` as root or sudo. This installs the RPM on all the hosts in the cluster. For example:

Red Hat or CentOS

```
# /opt/vertica/sbin/update_vertica --rpm /home/dbadmin/vertica_8.1.x.x86_64.RHEL6.rpm --dba-user mydba
```

Debian

```
# /opt/vertica/sbin/update_vertica --deb /home/dbadmin/vertica-amd64.deb --dba-user mydba
```

The following requirements and restrictions apply:

- The DBADMIN user must be able to read the RPM or DEB file when upgrading. Some upgrade scripts are run as the DBADMIN user, and that user must be able to read the RPM or DEB file.
- Use the same options that you used when you last installed or upgraded the database. You can find these options in `/opt/vertica/config/admintools.conf`, on the `install_opts` line. For details on all options, see [Installing Vertica with the Installation Script](#).

Caution: If you omit any previous options, their default settings are restored. If you do so, or if you change any options, the upgrade script uses the new settings to reconfigure the cluster. This can cause issues with the upgraded database.

- Omit the `--hosts/-s host-list` parameter. The upgrade script automatically identifies cluster hosts.
 - If the root user is not in `/etc/sudoers`, an error appears. The installer reports this issue with **S0311**. See the [Sudoers Manual](#) for more information.
6. [Start the database](#). The start-up scripts analyze the database and perform necessary data and catalog updates for the new version.

If Vertica issues a warning stating that one or more packages cannot be installed, run the `admintools --force-reinstall` option to force reinstallation of the packages. For details, see [Reinstalling Packages](#).

7. Perform another database backup.

Post-Upgrade Tasks

After you complete the upgrade, review post-upgrade tasks in [After You Upgrade](#).

After You Upgrade

After you finish upgrading the Vertica server package on your cluster, a number of tasks remain.

Required Tasks

- [Upgrade client authentication](#) (required only if you are upgrading from pre-7.1 versions).
- Reinstall packages such as the [R language pack](#) that you uninstalled before upgrading. For each package, see its install/upgrade instructions. For R, see [Installing/Upgrading the R Language Pack for Vertica](#).

Note: Vertica Place is automatically reinstalled with the Vertica server package.

- If the upgrade was unable to install one or more packages, [reinstall them with admintools](#).
- [Upgrade Management Console](#).
- If your Vertica installation is integrated with Hadoop, [upgrade the HCatalog connector](#).

Recommended Tasks

Vertica strongly recommends that you [bundle data files](#) after completing the database upgrade.

Optional Tasks

- [Convert backups](#) so they are compatible with the new version. Database backups from pre-7.2 versions of Vertica are incompatible with the current version.
- Import directed queries that you exported from the previous version. For details, see [Batch Query Plan Export](#) and [Exporting Directed Queries from the Catalog](#).
- [Rebuild the geospatial indexes](#). For details about the pre-upgrade steps, see [Back Up Geospatial Indexes](#).

Upgrading Client Authentication

Important: Perform this task only if you are upgrading from a pre-7.1 version.

Vertica 7.1.0 changed the storage location for the client authentication records from the `vertica.conf` file to the database catalog. When you upgrade from an earlier version, client authentication records in the `vertica.conf` file are converted and inserted into the database catalog. Vertica updates the catalog information on all nodes in the cluster.

Authentication is not enabled after upgrading. As a result, all users can connect to the database. However, if they have a password, they must enter it.

After upgrading, perform the following steps to make sure that client authentication is configured correctly and enabled for use with a running database:

1. Review the client authentication methods that Vertica created during the upgrade by querying the following system tables:

System table	Contains information about...
CLIENT_AUTH	Client authentication methods that Vertica created for your database during the upgrade.
CLIENT_AUTH_PARAMS	Parameters that Vertica defined for GSS, Ident, and LDAP authentication methods.
USER_CLIENT_AUTH	An authentication method that you associate with a specific database user through the GRANT (Authentication) statement.

2. Review the `vertica.log` file to see which authentication records Vertica was not able to create during the upgrade.
3. Create required records as needed with [CREATE AUTHENTICATION](#).
4. After the upgrade, enable all defined authentication methods. For each method, enter an [ALTER AUTHENTICATION](#) statement:

```
=> ALTER AUTHENTICATION auth-method-name ENABLE;
```

5. If you use LDAP over SSL/TLS, you must define the new parameters:

- `tls_reqcert`
- `tls_cacert`

To do so, use [ALTER AUTHENTICATION](#) as follows:

```
=> ALTER AUTHENTICATION Ldap1 SET host='ldaps://abc.dc.com', binddn_prefix='CN=',  
binddn_suffix=',OU=Unit2,DC=dc,DC=com', basedn='dc=DC,dc=com',  
tls_cacert='/home/dc.com.ca.cer', tls_reqcert='never';
```

6. Create an authentication method (`LOCAL TRUST` or `LOCAL PASSWORD`) with a very high priority such as 10,000. Grant this method to the `DBADMIN` user, and set the priority using [ALTER AUTHENTICATION](#). For example:

```
=> CREATE AUTHENTICATION dbadmin_default TRUST LOCAL;  
=> ALTER AUTHENTICATION dbadmin_default PRIORITY 10000;
```

With its high priority, this new authentication method supersedes any authentication methods you create for PUBLIC. Even if you make changes to PUBLIC authentication methods, the DBADMIN user can connect to the database at any time.

Reinstalling Packages

In most cases, Vertica automatically reinstalls all default packages when you restart your database for the first time after running the upgrade script. Occasionally, however, one or more packages might fail to reinstall correctly.

To verify that Vertica succeeded in reinstalling all packages:

1. Restart the database after upgrading.
2. Enter an incorrect password.

If any packages failed to reinstall, Vertica issues a message that specifies the uninstalled packages. In this case, run the `admintools` command `install_package` with the option `--force-reinstall`:

```
$ admintools -t install_package -d db-name -p password -P pkg-spec --force-reinstall
```

Options

Option	Function
<code>-d <i>db-name</i></code> <code>--dbname=<i>db-name</i></code>	Database name
<code>-p <i>password</i></code> <code>--password=<i>password</i></code>	Database administrator password
<code>-P <i>pkg</i></code> <code>--package=<i>pkg-spec</i></code>	Specifies which packages to install, where <i>pkg</i> is one of the following: <ul style="list-style-type: none">• The name of a package—for example, <code>flextable</code>• <code>all</code>: All available packages• <code>default</code> : All default packages that are currently installed
<code>--force-reinstall</code>	Force installation of a package even if it is already installed.

Option	Function

Examples

Force reinstallation of default packages:

```
$ admintools -t install_package -d VMart -p 'password' -P default --force-reinstall
```

Force reinstallation of one package, flextable:

```
$ admintools -t install_package -d VMart -p 'password' -P flextable --force-reinstall
```

Upgrading the Advanced Analytics Package 7.2.x to Machine Learning 8.0.x

If you installed the Advanced Analytics package on a 7.2.x Vertica cluster, then you will need to run the following upgrade script to ensure backward comparability with the 8.1.x machine learning functions.

The following command should be run as the dbadmin user:

```
$ vsql -f /opt/vertica/packages/MachineLearning/ddl/install_backward_compatibility.sql
```

Upgrading Management Console

Before You Upgrade

1. Log in as root or a user with sudo privileges on the server where MC is already installed.
2. Open a terminal window and shut down the MC process:

```
# /etc/init.d/vertica-console stop
```

For versions of Red Hat 7/CentOS 7 and above, use:

```
# systemctl stop vertica-console
```

3. Back up MC to preserve configuration metadata.

Important: A full backup is required in order to restore MC to its previous state. Restoring MC is essential if the upgrade fails, or you decide to revert to the previous version of Vertica. For details, see [Backing Up MC](#).

4. Stop the database if the following conditions are true:
 - You are upgrading MC on a Vertica host where Vertica version 7.1.2-5 or below is installed.
 - MC was installed on an Ubuntu or Debian platform.

Tip: If you upgrade from Vertica 7.2.0 or later, the configuration file `/opt/vconsole/config/console.properties` retains its previous settings. These include the setting for `messageCenter.maxEntries`, which controls the number of displayed messages. To improve performance, consider setting `messageCenter.maxEntries` to a value less than 1000.

Extended Monitoring Upgrade Recommendations

If you use [Extended Monitoring](#) to monitor a database with MC, Micro Focus recommends the following upgrade procedure to avoid data loss.

1. Log in to MC as an administrator.
2. To stop the monitored database, navigate to the Existing Infrastructure > Databases and Clusters page, select the monitored database and click **Stop**.
3. On MC Settings > MC Storage DB Setup, click **Disable Streaming** to stop the storage database's collection of monitoring data.
4. To stop the storage database, navigate to the Existing Infrastructure > Databases and Clusters page, select the monitored database and click **Stop**.
5. Upgrade MC and Vertica according to Upgrade MC and [Upgrading Vertica](#) instructions.
6. To start the storage database, navigate to the Existing Infrastructure > Databases and Clusters page, select the monitored database and click **Start**.
7. Start the monitored database.

8. On MC Settings > MC Storage DB Setup, click **Enable Streaming** to enable collection of monitoring data.

To avoid data loss, enable streaming soon after starting your monitored database. While your storage database is down and streaming is disabled, the Kafka server can retain data from your running monitored database for a limited amount of time. Data loss occurs when the data exceeds the Kafka retention policy's log size or retention time limits.

Upgrade MC

1. Download the MC package from the [myVertica](#) portal:
`vertica-console-current-version.Linux-distro)`
Save the package to a location on the target server, such as `/tmp`.
2. On the target server, log in as root or a user with sudo privileges.
3. Change to the directory where you saved the MC package.
4. Install MC using your local Linux distribution package management system—rpm, yum, zypper, apt, dpkg. For example:

Red Hat 6

```
# rpm -Uvh vertica-console-current-version.x86_64.RHEL6.rpm
```

Debian and Ubuntu

```
# dpkg -i vertica-console-current-version.deb
```

5. If you stopped the database before upgrading MC, restart the database.

As the root user, use the following command:

```
/etc/init.d/verticad start
```

For versions of Red Hat 7/CentOS 7 and above, run:

```
# systemctl start vertica-consoled
```

6. Open a browser and enter the URL of the MC installation, one of the following:

- IP address:

```
https://ip-address:mc-port/
```

- Server host name:

```
https://hostname:mc-port/
```

By default, *mc-port* is 5450.

7. If MC was not previously configured, the Configuration Wizard dialog box appears. Configuration steps are described in [Configuring MC](#).

If MC was previous configured, Vertica prompts you to accept the end-user license agreement (EULA) when you first log in to MC after the upgrade.

Recommended Post-Upgrade Tasks

After you complete your upgrade, it is strongly recommended that you use the meta-function [COMPACT_STORAGE](#) to upgrade existing storage bundles to the `.gt` format. Bundling reduces the number of files in your file system by at least 50 percent and improves the performance of file-intensive operations. Improved operations include backups, restores, mergeouts, and moveouts.

Rebuild Geospatial Indexes

Before you upgrade server versions, you must [back up your geospatial indexes](#) in a temporary table. After you upgrade, use [STV_Create_Index](#) with the temporary table as input to rebuild the index, and set the `overwrite` parameter to true to prevent a failure if there is an existing index with the same name:

```
=> SELECT STV_Create_Index(gid, geometry USING PARAMETERS index='pol_idx_new', overwrite=true) OVER()  
FROM temp-table;  
  type | polygons | SRID | min_x | min_y | max_x | max_y | info  
-----+-----+-----+-----+-----+-----+-----+-----  
GEOMETRY | 1       | 0   | 1     | 1     | 3     | 3     |  
(1 row)
```

Now, you can use the index `pol_idx_new` in the Place version.

Upgrading the Streaming Data Scheduler Utility

If you have integrated Vertica with a streaming data application, such as Apache Kafka, you must update the streaming data scheduler utility after you update Vertica.

Note: Schedulers upgraded from version 7.2.x to version 8.0.x are not backwards compatible.

From a command prompt, enter the following command:

```
/opt/vertica/packages/kafka/bin/vkconfig scheduler --upgrade --upgrade-to-schema schema_name
```

Running the upgrade task more than once has no effect.

For more information on the Scheduler utility, refer to [Scheduler Utility Options](#).

Upgrading Pre-7.2 Backups

In version 7.2 and later, Vertica no longer relies on hard links to perform backups. As a result, pre-7.2 backups are not compatible with later Vertica versions. To resolve this issue, vbr includes the vbr task `7.2_upgrade`. This task copies an existing pre-7.2 backup and creates a 7.2.x-compatible version of it.

Note: Micro Focus recommends that you run this task before performing the first backup of the upgraded database.

To upgrade a backup:

1. Specify the vbr task `7.2_upgrade` in the following form:

```
vbr -t 7.2_upgrade --old-config-file outdated-configfile.ini -c new-configfile.ini
```

2. Verify that the `snapshotName` parameter is the same in the old and new configuration files.

The new configuration file assigns new backup locations for the upgraded backup. This approach preserves the existing backup so you can continue to perform incremental backups on the upgraded backup. After the upgrade is complete, Vertica no longer requires the old configuration file.

If you do not upgrade the backup, the next backup that Vertica executes on the new database is a full backup that subsequently supports incremental backups.

Uninstalling Vertica

For each host in the cluster:

1. Choose a host machine and log in as root (or log in as another user and switch to root).

```
$ su - root  
password: root-password
```

2. Find the name of the package that is installed:

RPM

```
# rpm -qa | grep vertica
```

DEB

```
# dpkg -l | grep vertica
```

3. Remove the package:

RPM

```
# rpm -e package
```

DEB

```
# dpkg -r package
```

Note: If you want to delete the configuration file used with your installation, you can choose to delete the `/opt/vertica/` directory and all subdirectories using this command: `# rm -rf /opt/vertica/`

For each client system:

1. Delete the JDBC driver jar file.
2. Delete ODBC driver data source names.
3. Delete the ODBC driver software:
 - a. In Windows, go to **Start > Control Panel > Add or Remove Programs**.
 - b. Locate Vertica.
 - c. Click **Remove**.

Uninstalling Management Console

The `uninstall` command shuts down Management Console and removes most of the files that MC installation script installed.

To uninstall MC:

1. Log in to the target server as root.
2. Stop Management Console:

```
# /etc/init.d/vertica-console stop
```

For versions of Red Hat 7/CentOS 7 and above, use:

```
# systemctl stop vertica-console
```

3. Look for previously-installed versions of MC and note the version:

RPM

```
# rpm -qa | grep vertica
```

DEB

```
# dpkg -l | grep vertica
```

4. Remove the package:

RPM

```
# rpm -e vertica-console
```

DEB

```
# dpkg -r vertica-console
```

5. Optionally, delete the MC directory and all subdirectories:

```
# rm -rf /opt/vconsole
```

To Reinstall MC

See [Installing and Configuring Management Console](#)

Troubleshooting the Vertica Install

The topics described in this section are performed automatically by the `install_vertica` script and are described in [Installing Vertica](#). If you did not encounter any installation problems, proceed to the [Administrator's Guide](#) for instructions on how to configure and operate a database.

Validation Scripts

Vertica provides several validation utilities that can be used prior to deploying Vertica to help determine if your hosts and network can properly handle the processing and network traffic required by Vertica. These utilities can also be used if you are encountering performance issues and need to troubleshoot the issue.

After you install the Vertica RPM, you have access to the following scripts in `/opt/vertica/bin`:

- [Vcpuperf](#) - a CPU performance test used to verify your CPU performance.
- [Vioperf](#) - an Input/Output test used to verify the speed and consistency of your hard drives.
- [Vnetperf](#) - a Network test used to test the latency and throughput of your network between hosts.

These utilities can be run at any time, but are well suited to use before running the `install_vertica` script.

Vcpuperf

The `vcpuperf` utility measures your server's CPU processing speed and compares it against benchmarks for common server CPUs. The utility performs a CPU test and measures the time it takes to complete the test. The lower the number scored on the test, the better the performance of the CPU.

The `vcpuperf` utility also checks the high and low load times to determine if CPU throttling is enabled. If a server's low-load computation time is significantly longer than the high-load computation time, CPU throttling may be enabled. CPU throttling is a power-saving feature. However, CPU throttling can reduce the performance of your server. Vertica recommends disabling CPU throttling to enhance server performance.

Syntax

```
vcpuperf [-q]
```

Option

Option	Description
-q	Run in quiet mode. Quiet mode displays only the CPU Time, Real Time, and high and low load times.

Returns

- CPU Time: the amount of time it took the CPU to run the test.
- Real Time: the total time for the test to execute.
- High load time: The amount of time to run the load test while simulating a high CPU load.
- Low load time: The amount of time to run the load test while simulating a low CPU load.

Example

The following example shows a CPU that is running slightly slower than the expected time on a Xeon 5670 CPU that has CPU throttling enabled.

```
[root@node1 bin]# /opt/vertica/bin/vcpuperf
Compiled with: 4.1.2 20080704 (Red Hat 4.1.2-52) Expected time on Core 2, 2.53GHz: ~9.5s
Expected time on Nehalem, 2.67GHz: ~9.0s
Expected time on Xeon 5670, 2.93GHz: ~8.0s

This machine's time:
CPU Time: 8.540000s
Real Time:8.710000s

Some machines automatically throttle the CPU to save power.
This test can be done in <100 microseconds (60-70 on Xeon 5670, 2.93GHz).
Low load times much larger than 100-200us or much larger than the corresponding high load time
indicate low-load throttling, which can adversely affect small query / concurrent performance.

This machine's high load time: 67 microseconds.
This machine's low load time: 208 microseconds.
```

Vioperf

The `vioperf` utility quickly tests the performance of your host's input and output subsystem. The utility performs the following tests:

- sequential write
- sequential rewrite
- sequential read
- skip read (read non-contiguous data blocks)

The utility verifies that the host reads the same bytes that it wrote and prints its output to `STDOUT`. The utility also logs the output to a JSON formatted file.

For data in HDFS, the utility tests reads but not writes.

Syntax

```
vioperf [--help] [--duration=<INTERVAL>] [--log-interval=<INTERVAL>]
  [--log-file=<FILE>] [--condense-log] [--thread-count=<N>] [--max-buffer-size=<SIZE>]
  [--preserve-files] [--disable-crc] [--disable-direct-io] [--debug]
  [<DIR>*]
```

Minimum and Recommended I/O Performance

- The minimum required I/O is 20 MB/s read/write per physical processor core on each node, in full duplex (reading and writing) simultaneously, concurrently on all nodes of the cluster.
- The recommended I/O is 40 MB/s per physical core on each node.
- The minimum required I/O rate for a node with 2 hyper-threaded six-core CPUs (12 physical cores) is 240 MB/s. Vertica recommends 480 MB/s.

For example, the I/O rate for a node with 2 hyper-threaded six-core CPUs (12 physical cores) is 240 MB/s required minimum, 480 MB/s recommended.

Options

Option	Description
<code>--help</code>	Prints a help message and exits.
<code>--duration</code>	The length of time <code>vioprobe</code> runs performance tests. The default is 5 minutes. Specify the interval in seconds, minutes, or hours with any of these suffixes: <ul style="list-style-type: none">• Seconds: <code>s</code>, <code>sec</code>, <code>secs</code>, <code>second</code>, <code>seconds</code>. Example: <code>--duration=60sec</code>• Minutes: <code>m</code>, <code>min</code>, <code>mins</code>, <code>minute</code>, <code>minutes</code>. Example: <code>--duration=10min</code>• Hours: <code>h</code>, <code>hr</code>, <code>hrs</code>, <code>hour</code>, <code>hours</code>. Example: <code>--duration=1hrs</code>
<code>--log-interval</code>	The interval at which the log file reports summary information. The default interval is 10 seconds. This option uses the same interval notation as <code>--duration</code> .
<code>--log-file</code>	The path and name where log file contents are written, in JSON. If not specified, then <code>vioperf</code> creates a file named <code>resultsdate-time</code> . JSON in the current directory.
<code>--condense-log</code>	Directs <code>vioperf</code> to write the log file contents in condensed format, one JSON entry per line, rather than as indented JSON syntax.
<code>--thread-count=<N></code>	The number of execution threads to use. By default, <code>vioperf</code> uses all threads available on the host machine.
<code>--max-buffer-size=<SIZE></code>	The maximum size of the in-memory buffer to use for reads or writes. Specify the units with any of these suffixes: <ul style="list-style-type: none">• Bytes: <code>b</code>, <code>byte</code>, <code>bytes</code>.• Kilobytes: <code>k</code>, <code>kb</code>, <code>kilobyte</code>, <code>kilobytes</code>.• Megabytes: <code>m</code>, <code>mb</code>, <code>megabyte</code>, <code>megabytes</code>.• Gigabytes: <code>g</code>, <code>gb</code>, <code>gigabyte</code>, <code>gigabytes</code>.

Option	Description
<code>--preserve-files</code>	Directs <code>vioperf</code> to keep the files it writes. This parameter is ignored for HDFS tests, which are read-only. Inspecting the files can help diagnose write-related failures.
<code>--disable-crc</code>	Directs <code>vioperf</code> to ignore CRC checksums when validating writes. Verifying checksums can add overhead, particularly when running <code>vioperf</code> on slower processors. This parameter is ignored for HDFS tests.
<code>--disable-direct-io</code>	<p>When reading from or writing to a local file system, <code>vioperf</code> goes directly to disk by default, bypassing the operating system's page cache. Using direct I/O allows <code>vioperf</code> to measure performance quickly without having to fill the cache.</p> <p>Disabling this behavior can produce more realistic performance results but slows down the operation of <code>vioperf</code>.</p>
<code>--debug</code>	Directs <code>vioperf</code> to report verbose error messages.
<DIR>	<p>Zero or more directories to test. If you do not specify a directory, <code>vioperf</code> tests the current directory. To test the performance of each disk, specify different directories mounted on different disks.</p> <p>To test reads from a directory on HDFS:</p> <ul style="list-style-type: none">• Use a URL in the <code>hdfs</code> scheme that points to a single directory (not a path) containing files at least 10MB in size. For best results, use 10GB files and verify that there is at least one file per <code>vioperf</code> thread.• If you do not specify a host and port, set the <code>HADOOP_CONF_DIR</code> environment variable to a path including the Hadoop configuration files. This value is the same value that you use for the <code>HadoopConfDir</code> configuration parameter in Vertica. For more information see Configuring the hdfs Scheme.• If the HDFS cluster uses Kerberos, set the <code>HADOOP_USER_NAME</code> environment variable to a Kerberos principal.

Returns

The utility returns the following information:

Heading	Description
test	The test being run (Write, ReWrite, Read, or Skip Read)
directory	The directory in which the test is being run.
counter name	The counter type of the test being run. Can be either MB/s or Seeks per second.
counter value	The value of the counter in MB/s or Seeks per second across all threads. This measurement represents the bandwidth at the exact time of measurement. Contrast with counter value (avg).
counter value (10 sec avg)	The average amount of data in MB/s, or the average number of Seeks per second, for the test being run in the duration specified with --log-interval. The default interval is 10 seconds. The counter value (avg) is the average bandwidth since the last log message, across all threads.
counter value/core	The counter value divided by the number of cores.
counter value/core (10 sec avg)	The counter value (10 sec avg) divided by the number of cores.
thread count	The number of threads used to run the test.
%CPU	The available CPU percentage used during this test.
%IO Wait	The CPU percentage in I/O Wait state during this test. I/O wait state is the time working processes are blocked while waiting for I/O operations to complete.
elapsed time	The amount of time taken for a particular test. If you run the test multiple times, elapsed time increases the next time the test is run.
remaining time	The time remaining until the next test. Based on the --duration option, each of the tests is run at least once. If the test set is run multiple times, then remaining time is how much longer the test will run. The remaining time value is cumulative. Its total is added to elapsed time each time the same test is run again.

Example

Invoking `vioperf` from a terminal outputs the following message and sample results:

```
[dbadmin@v_vmart_node0001 ~]$ /opt/vertica/bin/vioperf --duration=60s
The minimum required I/O is 20 MB/s read and write per physical processor core on each node, in full duplex
i.e. reading and writing at this rate simultaneously, concurrently on all nodes of the cluster.
The recommended I/O is 40 MB/s per physical core on each node.
For example, the I/O rate for a server node with 2 hyper-threaded six-core CPUs is 240 MB/s required minimum, 480 MB/s recommended.

Using direct io (buffer size=1048576, alignment=512) for directory "/home/dbadmin"

test      | directory      | counter name          | counter value | counter value (10 sec avg) |
counter value/core | counter value/core (10 sec avg) | thread count | %CPU | %IO Wait | elapsed
time (s)| remaining time (s)
-----
-----
----

96       |              | 95                   | 2             | 71           | 27           | 15
| 0
SkipRead  | /home/dbadmin | seeks/s              | 659           | 659           |
329.5    |              | 329.5               | 2             | 2            | 85           | 10
| 5
SkipRead  | /home/dbadmin | seeks/s              | 677           | 714           |
338.5    |              | 357                  | 2             | 2            | 59           | 15
| 0
```

Note: When evaluating performance for minimum and recommended I/O, include the Write and Read values in your evaluation. ReWrite and SkipRead values are not relevant to determining minimum and recommended I/O.

Vnetperf

The vnetperf utility allows you to measure the network performance of your hosts. It can measure network latency and the throughput for both the TCP and UDP protocols.

Important: This utility introduces a high network load and must not be used on a running Vertica cluster or database performance is degraded.

Using this utility you can detect:

- if throughput is low for all hosts or a particular host,
- if latency is high for all hosts or a particular host,
- bottlenecks between one or more hosts or subnets,
- too low a limit in the number of TCP connections that can be established simultaneously,
- and if there is a high rate of packet loss on the network.

The latency test measures the latency from the host running the script to the other hosts. Any host that has a particularly high latency should be investigated further.

The throughput tests measure both UDP and TCP throughput. You can specify a rate limit in MB/s to use for these tests, or allow the utility to use a range of throughputs to be used.

Syntax

```
vnetperf [options] [tests]
```

Recommended Network Performance

- The maximum recommended RTT (round-trip time) latency is 1000 microseconds. The ideal RTT latency is 200 microseconds or less. Vertica recommends that clock skew be kept to under 1 second.
- The minimum recommended throughput is 100 MB/s. Ideal throughput is 800 MB/s or more.

Note: UDP numbers may be lower, multiple network switches may reduce performance results.

Options

Option	Description
<code>--condense</code>	Condense the log into one JSON entry per line, instead of indented JSON syntax.
<code>--collect-logs</code>	Collect the test log files from each host.
<code>--datarate <i>rate</i></code>	Limit the throughput to this rate in MB/s. A rate of 0 loops the tests through several different rates. The default is 0.
<code>--duration <i>seconds</i></code>	The time limit for each test to run in seconds. The default is 1.
<code>--hosts <i>host1,host2,...</i></code>	A comma-separated list of hosts on which to run the tests. Do not use spaces between the comma's and the host names.
<code>--hosts <i>file</i></code>	A hosts file that specifies the hosts on which to run the tests. If the <code>--hosts</code> argument is not used, then the utility attempts to access admintools and determine the hosts in the cluster.
<code>--identity-file <i>file</i></code>	If using passwordless SSH/SCP access between the hosts, then specify the key file used to gain access to the hosts.
<code>--ignore-bad-hosts</code>	If set, run the tests on the reachable hosts even if some hosts are not reachable. If not set, and a host is unreachable, then no tests are run on any hosts.
<code>--log-dir <i>directory</i></code>	If <code>--collect-logs</code> is set, the directory in which to place the collected logs. The default directory is named <code>logs.netperf.<timestamp></code>
<code>--log-level <i>LEVEL</i></code>	The log level to use. Possible values are: INFO, ERROR, DEBUG, and WARN. The default is WARN.
<code>--list-tests</code>	Lists the tests that can be run by this utility.
<code>--output-file <i>file</i></code>	The file that JSON results are written to. The default is <code>results.<timestamp>.json</code> .

Option	Description
<code>--ports port1,port2,port3</code>	The port numbers to use. If only one is specified then the next two numbers in sequence are also used. The default ports are 14159,14160, 14161.
<code>--scp-options 'options'</code>	Using this argument, you can specify one or more standard SCP command line arguments enclosed in single quotes. SCP is used to copy test binaries over to the target hosts.
<code>--ssh-options 'options'</code>	Using this argument, you can specify one or more standard SSH command line arguments enclose in single quotes. SSH is used to issue test commands on the target hosts.
<code>--vertica-install directory</code>	If specified, then the utility assumes Vertica is installed on each of the hosts and to use the test binaries on the target system rather than copying them over using SCP.

Tests

Note: If the tests argument is omitted then all tests are run.

Test	Description
latency	Test the latency to each of the hosts.
tcp-throughput	Test the TCP throughput amongst the hosts.
udp-throughput	Test the UDP throughput amongst the hosts.

Returns

For each host it returns the following:

Latency test returns:

- The Round Trip Time (rtt) latency for each host in milliseconds.
- Clock Skew = the difference in time shown by the clock on the target host relative to the host running the utility.

UDP and TCP throughput tests return:

- The date/time and test name.
- The rate limit in MB/s.
- The node being tested.
- Sent and Received data in MB/s and bytes.
- The duration of the test in seconds.

Example

```
/opt/vertica/bin/vnetperf --condense -hosts 10.20.100.66,10.20.100.67 --identity-file  
'/root/.ssh/vid_rsa'
```

Enable Secure Shell (SSH) Logins

The administrative account must be able to use Secure Shell (SSH) to log in (ssh) to all hosts without specifying a password. The shell script `install_vertica` does this automatically. This section describes how to do it manually if necessary.

1. If you do not already have SSH installed on all hosts, log in as root on each host and install it now. You can download a free version of the SSH connectivity tools from [OpenSSH](#).
2. Log in to the Vertica administrator account (dbadmin in this example).
3. Make your home directory (~) writable only by yourself. Choose one of:

```
$ chmod 700 ~
```

or

```
$ chmod 755 ~
```

where:

700 includes	755 includes
400 read by owner	400 read by owner

200 write by owner	200 write by owner
100 execute by owner	100 execute by owner
	040 read by group
	010 execute by group
	004 read by anybody (other)
	001 execute by anybody

4. Change to your home directory:

```
$ cd ~
```

5. Generate a private key/ public key pair:

```
$ ssh-keygen -t rsaGenerating public/private rsa key pair.  
Enter file in which to save the key (/home/dbadmin/.ssh/id_rsa):  
Created directory '/home/dbadmin/.ssh'.  
Enter passphrase (empty for no passphrase):  
Enter same passphrase again:  
Your identification has been saved in /home/dbadmin/.ssh/id_rsa.  
Your public key has been saved in /home/dbadmin/.ssh/id_rsa.pub.
```

6. Make your .ssh directory readable and writable only by yourself:

```
$ chmod 700 ~/.ssh
```

7. Change to the .ssh directory:

```
$ cd ~/.ssh
```

8. Copy the file id_rsa.pub onto the file authorized_keys2.

```
$ cp id_rsa.pub authorized_keys2
```

9. Make the files in your .ssh directory readable and writable only by yourself:

```
$ chmod 600 ~/.ssh/*
```

10. For each cluster host:

```
$ scp -r ~/.ssh <host>:.
```

11. Connect to each cluster host. The first time you ssh to a new remote machine, you could get a message similar to the following:

```
$ ssh dev0 Warning: Permanently added 'dev0,192.168.1.92' (RSA) to the list of known hosts.
```

This message appears only the first time you ssh to a particular remote host.

Upgrading Your Operating System on Nodes in Your Vertica Cluster

If you need to upgrade the operating system on the nodes in your Vertica cluster, check with the documentation for your Linux distribution to make sure they support the particular upgrade you are planning.

For example, the following articles provide information about upgrading Red Hat:

- [How do I upgrade from Red Hat Enterprise Linux 6 to Red Hat Enterprise Linux 7?](#)
- [Does Red Hat support upgrades between major versions of Red Hat Enterprise Linux?](#)

After you confirm that you can perform the upgrade, follow the steps at [Best Practices for Upgrading the Operating System on Nodes in a Vertica Cluster](#).

Upgrading the Operating System on the Nodes in Your Vertica Cluster

For information about upgrading the operating system on the nodes in your Vertica cluster, see [Best Practices for Upgrading the Operating System on Nodes in a Vertica Cluster](#).

Using Time Zones With Vertica

Vertica uses the TZ environment variable on each node, if it has been set, for the default current time zone. Otherwise, Vertica uses the operating system time zone.

The TZ variable can be set by the operating system during login (see `/etc/profile`, `/etc/profile.d`, or `/etc/bashrc`) or by the user in `.profile`, `.bashrc` or `.bash-profile`.

TZ must be set to the same value on each node when you start Vertica.

The following command returns the current time zone for your database:

```
=> SHOW TIMEZONE;
  name |      setting
-----+-----
timezone | America/New_York
(1 row)
```

You can also use the `SET TIMEZONE TO { value | 'value' }` command to set the time zone for a single session.

There is no database default time zone; instead, `TIMESTAMP WITH TIMEZONE (TIMESTAMPTZ)` data is stored in GMT (UTC) by converting data from the current local time zone to GMT.

When `TIMESTAMPTZ` data is used, data is converted back to use the current local time zone, which might be different from the local time zone where the data was stored. This conversion takes into account Daylight Saving Time (Summer Time), if applicable, depending on the year and date, to know when the Daylight Saving Time change occurred.

`TIMESTAMP WITHOUT TIMEZONE` data stores the timestamp, as given, and retrieves it exactly as given. The current time zone is ignored. The same is true for `TIME WITHOUT TIMEZONE`. For `TIME WITH TIMEZONE (TIMETZ)`, however, the current time zone setting is stored along with the given time, and that time zone is used on retrieval.

Note: Micro Focus recommends that you use `TIMESTAMPTZ`, not `TIMETZ`.

`TIMESTAMPTZ` uses the current time zone on both input and output, such as in the following example:

```
=> CREATE TEMP TABLE s (tstz TIMESTAMPTZ);=> SET TIMEZONE TO 'America/New_York';
=> INSERT INTO s VALUES ('2009-02-01 00:00:00');
=> INSERT INTO s VALUES ('2009-05-12 12:00:00');
=> SELECT tstz AS 'Local timezone', tstz AT TIMEZONE 'America/New_York' AS 'America/New_York',
      tstz AT TIMEZONE 'GMT' AS 'GMT' FROM s;
```

Local timezone	America/New_York	GMT
2009-02-01 00:00:00-05	2009-02-01 00:00:00	2009-02-01 05:00:00
2009-05-12 12:00:00-04	2009-05-12 12:00:00	2009-05-12 16:00:00

(2 rows)

The `-05` in the Local time zone column above shows that the data is displayed in EST, while `-04` indicates EDT. The other two columns show the `TIMESTAMP WITHOUT TIMEZONE` at the specified time zone.

The next example illustrates what occurs if the current time zone is changed to, for example, Greenwich Mean Time:

```
=> SET TIMEZONE TO 'GMT';=> SELECT tstz AS 'Local timezone', tstz AT TIMEZONE 'America/New_York' AS
      'America/New_York', tstz AT TIMEZONE 'GMT' as 'GMT' FROM s;
```

Local timezone	America/New_York	GMT
2009-02-01 05:00:00+00	2009-02-01 00:00:00	2009-02-01 05:00:00
2009-05-12 16:00:00+00	2009-05-12 12:00:00	2009-05-12 16:00:00

(2 rows)

The `+00` in the Local time zone column above indicates that `TIMESTAMPTZ` is displayed in 'GMT'.

The approach of using TIMESTAMPTZ fields to record events captures the GMT of the event, as expressed in terms of the local time zone. Later, it allows for easy conversion to any other time zone, either by setting the local time zone or by specifying an explicit AT TIMEZONE clause.

The following example shows how TIMESTAMP WITHOUT TIMEZONE fields work in Vertica.

```
=> CREATE TEMP TABLE tnoz (ts TIMESTAMP);=> INSERT INTO tnoz VALUES('2009-02-01 00:00:00');
=> INSERT INTO tnoz VALUES('2009-05-12 12:00:00');
=> SET TIMEZONE TO 'GMT';
=> SELECT ts AS 'No timezone', ts AT TIMEZONE 'America/New_York' AS
       'America/New_York', ts AT TIMEZONE 'GMT' AS 'GMT' FROM tnoz;
       No timezone      | America/New_York      | GMT
-----+-----+-----
2009-02-01 00:00:00 | 2009-02-01 05:00:00+00 | 2009-02-01 00:00:00+00
2009-05-12 12:00:00 | 2009-05-12 16:00:00+00 | 2009-05-12 12:00:00+00
(2 rows)
```

The +00 at the end of a timestamp indicates that the setting is TIMESTAMP WITH TIMEZONE in GMT (the current time zone). The 'America/New_York' column shows what the 'GMT' setting was when you recorded the time, assuming you read a normal clock in the time zone 'America/New_York'. What this shows is that if it is midnight in the 'America/New_York' time zone, then it is 5 am GMT.

Note: 00:00:00 Sunday February 1, 2009 in America/New_York converts to 05:00:00 Sunday February 1, 2009 in GMT.

The 'GMT' column displays the GMT time, assuming the input data was captured in GMT.

If you don't set the time zone to GMT, and you use another time zone, for example 'America/New_York', then the results display in 'America/New_York' with a -05 and -04, showing the difference between that time zone and GMT.

```
=> SET TIMEZONE TO 'America/New_York';
=> SHOW TIMEZONE;
       name | setting
-----+-----
timezone | America/New_York
(1 row)
=> SELECT ts AS 'No timezone', ts AT TIMEZONE 'America/New_York' AS
       'America/New_York', ts AT TIMEZONE 'GMT' AS 'GMT' FROM tnoz;
       No timezone      | America/New_York      | GMT
-----+-----+-----
2009-02-01 00:00:00 | 2009-02-01 00:00:00-05 | 2009-01-31 19:00:00-05
2009-05-12 12:00:00 | 2009-05-12 12:00:00-04 | 2009-05-12 08:00:00-04
(2 rows)
```

In this case, the last column is interesting in that it returns the time in New York, given that the data was captured in 'GMT'.

Getting Started

Welcome to Getting Started. This guide serves as a tutorial, walking you through the process of configuring an Vertica Analytics Platform database and running example queries.

Prerequisites

Before you start, Micro Focus recommends that you read [Vertica Concepts](#) to gain a quick understanding of unfamiliar concepts.

Using This Guide

Getting Started shows how to set up a Vertica database and run simple queries that perform common database tasks.

Who Should Use This Guide?

Getting Started targets anyone who wants to learn how to create and run a Vertica database. This guide requires no special knowledge at this point, although a rudimentary knowledge of basic SQL commands is useful when you begin to run queries.

What You Need

The examples in this guide require one of the following:

- Vertica installed on one host or a cluster of hosts. Vertica recommends a minimum of three hosts in the cluster.
- Vertica installed on a virtual machine (VM).

For further instructions about installation, see [Installing Vertica](#).

Accessing Your Database

You access your database with an SSH client or the terminal utility in your Linux console, such as `vsql`. Throughout this guide, you use the following user interfaces:

- Linux command line (shell) interface
- [Vertica Administration Tools](#)
- [vsql client interface](#)
- [Vertica Management Console](#)

Downloading and Starting the Vertica Community Edition VM

For a hands-on introduction to Vertica, you can use the Vertica Community Edition Virtual Machine (Vertica CE VM), which is available for download on my.vertica.com.

The Vertica CE VM is a pre-configured Linux environment that includes the Vertica Analytic Database and client tools. After you download and startup the VM, you no longer need internet access. Everything you need is available locally within the VM environment. The VM includes a user guide that steps you through a set of typical tasks involved in administering your Vertica database and querying data.

Requirements

The Vertica CE VM is packaged as an Open Virtualization Architecture (OVA) file that can be imported into a virtualization application that supports the OVA format. If you do not already have a virtualization product, you can download and install one of the free VM players, such as:

- VMWare Workstation Player
- Oracle VirtualBox

The Vertica CE VM requires between 20 and 50 GB of available disk space on the host computer. The OVA file alone is about 8 GB on download. When you import the OVA file into the VM player, it is uncompressed to about 16 GB. The VM can use up to a maximum of 50 GB, depending on the operations you perform.

Download the Vertica CE VM

1. Sign in or create an account on my.vertica.com. You must be logged in to download the VM.
2. On the Downloads page, locate the Vertica CE VM OVA file, the *Vertica CE VM User Guide* and the short introductory video.

- a. Watch the video for a quick overview.
- b. Download the user guide if you would like to save it outside the VM. Otherwise, you can use the copy of the user guide that is included in the VM itself.
- c. Download the OVA file.

Note: Because of its size, the OVA file takes some time to download.

Start Up the Vertica CE VM

1. Start your VM player.
2. In the VM player, select **Open** (VMware) or **Import** (VirtualBox) and select the Vertica CE VM OVA file. This initial load process may take some time.
3. Start the Vertica CE VM.
4. Log in to the Vertica CE VM:
User name: **Vertica DBA**

Password: **password**

What's In the VM?

In the Vertica CE VM, you will find these components up and running and ready for use:

- Vertica Analytic Database Community Edition
- Vertica VMart example database
- Vertica Management Console
- Vertica Administration Tools
- vsql
- The complete Vertica documentation set
- The *Vertica CE VM User Guide*

Note: VMart is fully loaded, except for the `online_sales` fact table and its two unique dimensions. Instructions for loading the missing data are provided as an exercise in the *Vertica CE VM User Guide*.

The Vertica CE VM Environment

The Vertica CE VM is a CentOS 7.3 Virtual Machine. The VM is configured with the following settings:

- 2 CPUs
- 4 GB of RAM
- 50 GB HDD

The Vertica Community Edition database that is running in the VM has a single node.

Note: The Vertica VM is not supported for production use.

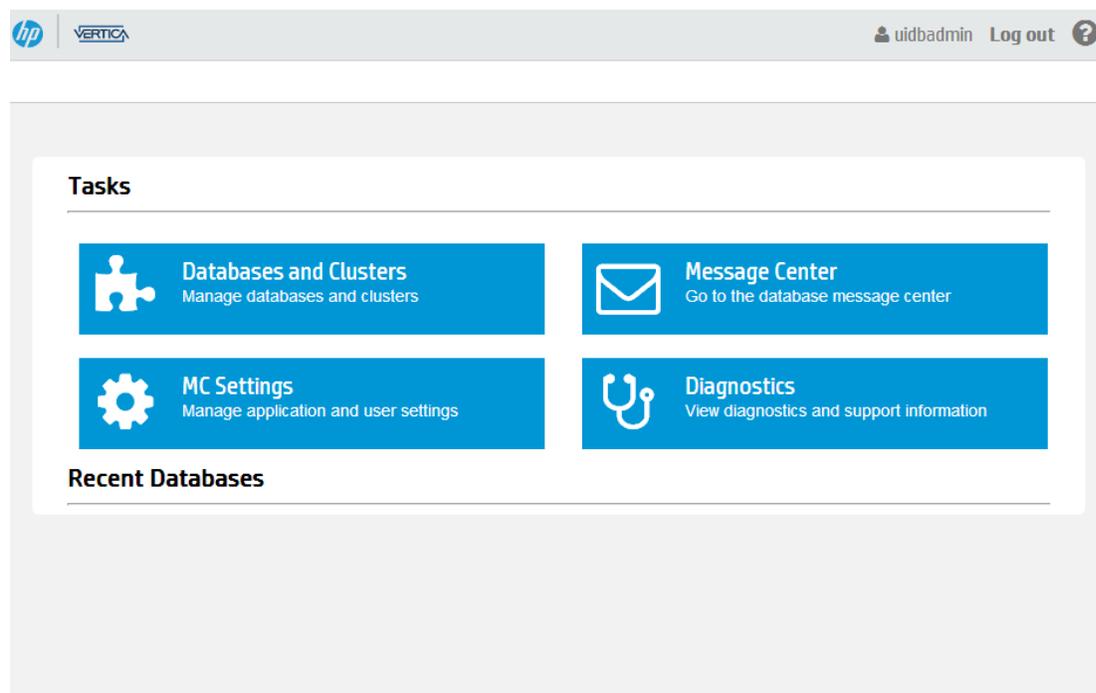

Using the Vertica Interfaces

Vertica provides a set of tools that allows you to perform administrative tasks quickly and easily. The administration tasks in Vertica can be done using the Management Console (MC) or the Administration Tools. The MC provides a unified view of your Vertica cluster through a browser connection, while the Administration Tools are implemented using Dialog, a graphical user interface that works in terminal (character-cell) windows.

Using Management Console

The Management Console provides some, but not all, of the functionality that the Administration Tools provides. In addition, the MC provides extended functionality not available in the Administration Tools, such as a graphical view of your Vertica database and detailed monitoring charts and graphs.

Most of the information you need to use MC is available on the MC interface, as seen in the following two screenshots. For installation instructions, see [Installing and Configuring Management Console](#) in the Installation Guide. For an introduction to MC functionality, architecture, and security, see [Management Console](#) in [Vertica Concepts](#).

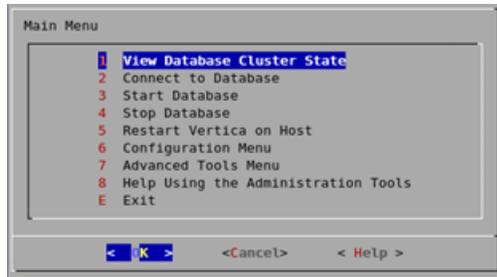

Configuration	Unix user (for application server)	uidbadadmin
SSL certificates	Unix user group (for application server)	uidbadadmin
Authentication	HP Vertica user home path	/home/uidbadadmin
User management		
Resource access	HP Vertica license path	<input type="text" value="/home/uidbadadmin"/>
HP Vertica Installation	HP Vertica database catalog path	<input type="text" value="/home/uidbadadmin"/>
Theme	HP Vertica database data path	<input type="text" value="/home/uidbadadmin"/>
	HP Vertica database temp path	<input type="text" value="/home/uidbadadmin"/>
	Application server running port	<input type="text" value="5450"/>
	Default HP Vertica agent port	<input type="text" value="5444"/>

Running the Administration Tools

A man page is available for convenient access to Administration Tools details. If you are running as the dbadmin user, type `man admintools`. If you are running as a different user, type `man -M /opt/vertica/man admintools`. If possible, always run the Administration Tools using the database administrator account (dbadmin) on the administration host.

The Administration Tools interface responds to mouse clicks in some terminal windows, particularly local Linux windows, but you might find that it responds only to keystrokes. For a quick reference to keystrokes, see [Using Keystrokes in the Administration Tools Interface](#) in this guide.

When you run Administration Tools, the **Main Menu** dialog box appears with a dark blue background and a title on top. The screen captures used in this documentation set are cropped down to the dialog box itself, as shown in the following screenshot.

First Time Only

The first time you log in as the database administrator and run the Administration Tools, complete the following steps.

1. In the EULA (end-user license agreement) window, type `accept` to proceed. A window displays, requesting the location of the license key file you downloaded from the Micro Focus Web site. The default path is `/tmp/vlicense.dat`.
2. Type the absolute path to your license key (for example, `/tmp/vlicense.dat`) and click **OK**.
3. To return to the command line, select **Exit** and click **OK**.

Using Keystrokes in the Administration Tools Interface

The following table is a quick reference to keystroke usage in the Administration Tools interface. See [Using the Administration Tools](#) in the Administrator's Guide for full details.

Return	Run selected command.
Tab	Cycle between OK , Cancel , Help , and menu.
Up/Down Arrow	Move cursor up and down in menu, window, or help file.
Space	Select item in list.
Character	Select corresponding command from menu.

Introducing the VMart Example Database

Vertica ships with a sample multi-schema database called the VMart Example Database, which represents a database that might be used by a large supermarket (VMart) to access information about its products, customers, employees, and online and physical stores. Using this example, you can create, run, optimize, and test a multi-schema database.

The VMart database contains the following schema:

- `public` (automatically created in any newly created Vertica database)
- `store`
- `online_Sales`

VMart Database Location and Scripts

If you installed Vertica from the RPM package, the VMart schema is installed in the `/opt/vertica/examples/VMart_Schema` directory. This folder contains the following script files that you can use to get started quickly. Use the scripts as templates for your own applications.

Script/file name	Description
<code>vmart_count_data.sql</code>	SQL script that counts rows of all example database tables, which you can use to verify load.
<code>vmart_define_schema.sql</code>	SQL script that defines the logical schema for each table and referential integrity constraints.
<code>vmart_gen.cpp</code>	Data generator source code (C++).
<code>vmart_gen</code>	Data generator executable

	file.
<code>vmart_load_data.sql</code>	SQL script that loads the generated sample data to the corresponding tables using COPY DIRECT.
<code>vmart_queries.sql</code>	SQL script that contains concatenated sample queries for use as a training set for the Database Designer.
<code>vmart_query_##.sql</code>	SQL scripts that contain individual queries; for example, <code>vmart_query_01</code> through <code>vmart_query_09.sql</code>
<code>vmart_schema_drop.sql</code>	SQL script that drops all example database tables.

For more information about the schema, tables, and queries included with the VMart example database, see the [Appendix](#).

Installing and Connecting to the VMart Example Database

Follow the steps in this section to create the fully functioning, multi-schema VMart example database that you'll use to run sample queries. The number of example databases you create within a single Vertica installation is limited only by the disk space available on your system; however, Micro Focus strongly recommends that you start only one example database at a time to avoid unpredictable results.

Vertica provides two options to install the example database:

- A quick installation that lets you create the example database and start using it immediately. See [Quick Installation Using a Script](#) in this guide for details. Use this method to bypass the schema and table creation processes and start querying immediately.
- An advanced-but-simple example database installation using the Administration Tools interface. See [Advanced Installation](#) in this guide for details. Use this method to better understand the database creation process and practice creating schema and tables, and loading data.

Note: Both installation methods create a database named VMart. If you try both installation methods, you will either need to drop the VMart database you created (see [Restoring the Status of Your Host](#) in this guide) or create the subsequent database with a new name. However, Micro Focus strongly recommends that you start only one example database at a time to avoid unpredictable results

This tutorial uses Vertica-provided queries, but you can follow the same set of procedures later, when you create your own design and use your own queries file.

After you install the VMart database, the database has started. Connect to it using the steps in [Step 3: Connecting to the Database](#).

Quick Installation Using a Script

The script you need to perform a quick installation is located in `/opt/vertica/sbin` and is called `install_example`. This script creates a database on the default port (5433), generates data, creates the schema and a default superprojection, and loads the data. The folder also contains a `delete_example` script, which stops and drops the database.

1. In a terminal window, log in as the database administrator.

```
$ su dbadmin  
Password: (your password)
```

2. Change to the /examples directory.

```
$ cd /opt/vertica/examples
```

3. Run the install script:

```
$ /opt/vertica/sbin/install_example VMart
```

After installation, you should see the following:

```
[dbadmin@localhost examples]$ /opt/vertica/sbin/install_example VMart  
Installing VMart example example database  
Mon Jul 22 06:57:40 PDT 2013  
Creating Database  
Completed  
Generating Data. This may take a few minutes.  
Completed  
Creating schema  
Completed  
Loading 5 million rows of data. Please stand by.  
Completed  
Removing generated data files  
Example data
```

The example database log files, `ExampleInstall.txt` and `ExampleDelete.txt`, are written to `/opt/vertica/examples/log`.

To start using your database, continue to [Connecting to the Database](#) in this guide. To drop the example database, see [Restoring the Status of Your Host](#) in this guide.

Advanced Installation

To perform an advanced-but-simple installation, set up the VMart example database environment and then create the database using the Administration Tools or Management Console.

Note: If you installed the VMart database using the quick installation method, you cannot complete the following steps because the database has already been created.

To try the advanced installation, drop the example database (see [Restoring the Status of Your Host](#) on this guide) and perform the advanced Installation, or create a new example

database with a different name. However, Micro Focus strongly recommends that you install only one example database at a time to avoid unpredictable results.

The advanced installation requires the following steps:

- [Step 1: Setting Up the Example Environment](#)
- [Step 2: Creating the Example Database](#)
- [Step 3: Connecting to the Database](#)
- [Step 4: Defining the Database Schema](#)
- [Step 5: Loading Data](#)

Step 1: Setting Up the Example Environment

1. Stop all databases running on the same host on which you plan to install your example database.

If you are unsure if other databases are running, run the Administration Tools and select **View Cluster State**. The State column should show DOWN values on pre-existing databases.

If databases are running, click **Stop Database** in the **Main Menu** of the Administration Tools interface and click **OK**.

2. In a terminal window, log in as the database administrator:

```
$ su dbadmin  
Password:
```

3. Change to the `/VMart_Schema` directory.

```
$ cd /opt/vertica/examples/VMart_Schema
```

Do not change directories while following this tutorial. Some steps depend on being in a specific directory.

4. Run the sample data generator.

```
$ ./vmart_gen
```

5. Let the program run with the default parameters, which you can review in the README file.

```
Using default parameters
datadirectory = ./
numfiles = 1
seed = 2
null = ' '
timefile = Time.txt
numfactsalesrows = 5000000
numfactorderrows = 300000
numprodkeys = 60000
numstorekeys = 250
numpromokeys = 1000
numvendkeys = 50
numcustkeys = 50000
numempkeys = 10000
numwarehousekeys = 100
numshippingkeys = 100
numonlinepagekeys = 1000
numcallcenterkeys = 200
numfactonlinesalesrows = 5000000
numinventoryfactrows = 300000
gen_load_script = false
Data Generated successfully !

Using default parameters
datadirectory = ./
numfiles = 1
seed = 2
null = ' '
timefile = Time.txt
numfactsalesrows = 5000000
numfactorderrows = 300000
numprodkeys = 60000
numstorekeys = 250
numpromokeys = 1000
numvendkeys = 50
numcustkeys = 50000
numempkeys = 10000
numwarehousekeys = 100
numshippingkeys = 100
numonlinepagekeys = 1000
numcallcenterkeys = 200
numfactonlinesalesrows = 5000000
numinventoryfactrows = 300000
gen_load_script = false
Data Generated successfully !
```

6. If the `vmart_gen` executable does not work correctly, recompile it as follows, and run the sample data generator script again.

```
$ g++ vmart_gen.cpp -o vmart_gen  
$ chmod +x vmart_gen  
$ ./vmart_gen
```

Step 2: Creating the Example Database

To create the example database: use the Administration Tools or Management Console, as described in this section.

Creating the Example Database Using the Administration Tools

In this procedure, you create the example database using the Administration Tools. To use the Management Console, go to the next section.

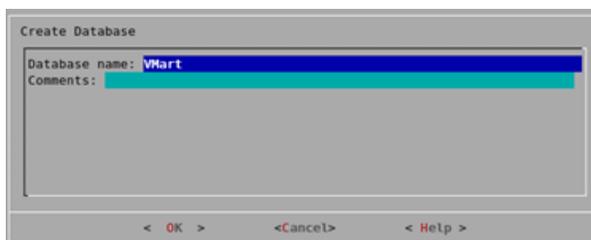

Note: If you have not used Administration Tools before, see [Running the Administration Tools](#) in this guide.

1. Run the Administration Tools.

```
$ /opt/vertica/bin/admintools
```

or simply type `admintools`

2. From the Administration Tools **Main Menu**, click **Configuration Menu** and click **OK**.
3. Click **Create Database** and click **OK**.
4. Name the database **VMart** and click **OK**.

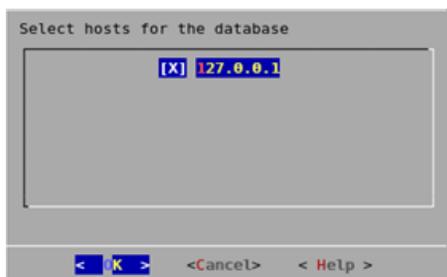

5. Click **OK** to bypass the password and click **Yes** to confirm.

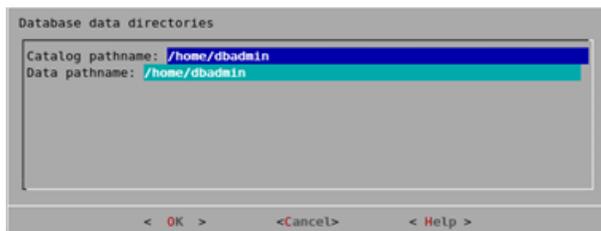

There is no need for a database administrator password in this tutorial. When you create a production database, however, always specify an administrator password. Otherwise, the database is permanently set to trust authentication (no passwords).

6. Select the hosts you want to include from your Vertica cluster and click **OK**.

This example creates the database on a one-host cluster. Micro Focus recommends a minimum of three hosts in the cluster. If you are using the Vertica Community Edition, you are limited to three nodes.

7. Click **OK** to select the default paths for the data and catalog directories.

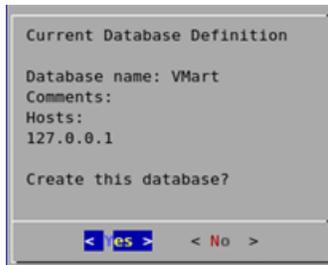

- Catalog and data paths must contain only alphanumeric characters and cannot have leading space characters. Failure to comply with these restrictions could result in database creation failure.
- When you create a production database, you'll likely specify other locations than the default. See [Prepare Disk Storage Locations](#) in the Administrator's Guide for more information.

8. Since this tutorial uses a one-host cluster, a K-safety warning appears. Click **OK**.

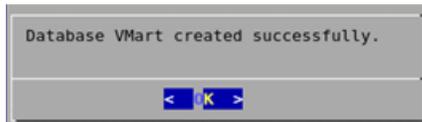

9. Click **Yes** to create the database.

During database creation, Vertica automatically creates a set of node definitions based on the database name and the names of the hosts you selected and returns a success message.

10. Click **OK** to close the **Database VMart created successfully** message.

Creating the Example Database Using Management Console

In this procedure, you create the example database using Management Console. To use the Administration Tools, follow the steps in the preceding section.

Note: To use Management Console, the console should already be installed and you should be familiar with its concepts and layout. See [Using Management Console](#) in this guide for a brief overview, or for detailed information, see [Management Console](#) in [Vertica Concepts](#) and [Installing and Configuring Management Console](#) in [Installing Vertica](#).

1. Connect to Management Console and log in.
2. On the Home page, under **Manage Information**, click **Existing Infrastructure** to go to the Databases and Clusters page.

Prepare data and databases

Provision Databases
Create, import and connect

Database(s): VMart
CPU Type: Intel(R) Xeon(R) CPU E5-2695 v2 @ 2.40GHz
Vertica Version: 7.2.0

Buttons: API Key, View, Remove, Create Database

4. Follow the on-screen wizard, which prompts you to provide the following information:
 - Database name, which must be between 3–25 characters, starting with a letter, and followed by any combination of letters, numbers, or underscores.
 - (Optional) database administrator password for the database you want to create and connect to.
 - IP address of a node in your database cluster, typically the IP address of the administration host.
5. Click **Next**.

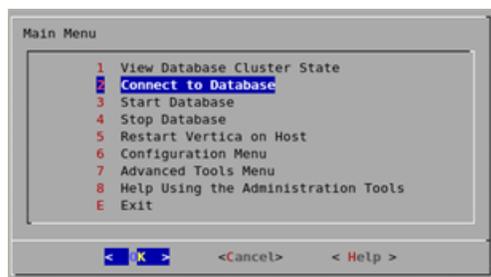

Step 3: Connecting to the Database

Regardless of the installation method you used, follow these steps to connect to the database.

1. As `dbadmin`, run the Administration Tools.

```
$ /opt/vertica/bin/admintools
```

or simply type `admintools`.
2. If you are already in the Administration Tools, navigate to the Main Menu page.
3. Select **Connect to Database**, click **OK**.

To configure and load data into the VMart database, complete the following steps:

- [Step 4: Defining the Database Schema](#)
- [Step 5: Loading Data](#)

If you installed the VMart database using the Quick Installation method, the schema, tables, and data are already defined. You can choose to drop the example database (see

[Restoring the Status of Your Host](#) in this guide) and perform the Advanced Installation, or continue straight to [Querying Your Data](#) in this guide.

Step 4: Defining the Database Schema

The VMart database installs with sample scripts with SQL commands that are intended to represent queries that might be used in a real business. The `vmart_define_schema.sql` script runs a script that defines the VMart schema and creates tables. You must run this script before you load data into the VMart database.

This script performs the following tasks:

- Defines two schemas in the VMart database schema: *online_sales* and *store*.
- Defines tables in both schemas.
- Defines constraints on those tables.

```
Vmart=> \i vmart_define_schema.sql
CREATE SCHEMA
CREATE SCHEMA
CREATE TABLE
ALTER TABLE
CREATE TABLE
CREATE TABLE
ALTER TABLE
CREATE TABLE
ALTER TABLE
CREATE TABLE
CREATE TABLE
CREATE TABLE
ALTER TABLE
```

Step 5: Loading Data

Now that you have created the schemas and tables, you can load data into a table by running the `vmart_load_data.sql` script. This script loads data from the 15 `.tbl` text files in `opt/vertica/examples/VMart_Schema` into the tables that `vmart_design_schema.sql` created.

It might take several minutes to load the data on a typical hardware cluster. Check the load status by monitoring the `vertica.log` file, as described in [Monitoring Log Files](#) in the Administrator's Guide.

```
VMart=> \i vmart_load_data.sql
Rows Loaded
-----
1826
(1 row)
Rows Loaded
-----
60000
(1 row)
Rows Loaded

```
5000000  
(1 row)  
  
Rows Loaded  
-----  
300000  
(1 row)  
VMart=>
```

Querying Data

The VMart database installs with sample scripts that contain SQL commands that represent queries that might be used in a real business. Use basic SQL commands to query the database, or try out the following command. Once you're comfortable running the example queries, you might want to write your own.

Note: The data that your queries return might differ from the example output shown in this guide because the sample data generator is random.

Type the following SQL command to return the values for five products with the lowest fat content in the Dairy department. The command selects the fat content from Dairy department products in the `product_dimension` table in the `public` schema, orders them from low to high and limits the output to the first five (the five lowest fat contents).

```
VMart => SELECT fat_content
        FROM ( SELECT DISTINCT fat_content
              FROM product_dimension
              WHERE department_description
                IN ('Dairy') ) AS food
        ORDER BY fat_content
        LIMIT 5;
```

Your results will be similar to the following:

```
fat_content
-----
80
81
82
83
84
(5 rows)
```

The preceding example is from the `vmart_query_01.sql` file. You can execute more sample queries using the scripts that installed with the VMart database or write your own. For a list of the sample queries supplied with Vertica, see the [Appendix](#).

Backing Up and Restoring the Database

Vertica supplies a comprehensive utility, the `vbr` Python script, that lets you back up and restore a full database, as well as create backups of specific schema or tables. The `vbr` utility creates backup directories during its initial execution; subsequently running the utility creates subdirectories.

The following information is intended to introduce the backup and restore functions. For more detailed information, see [Backing Up and Restoring the Database](#) in the *Administrator's Guide*.

Backing Up the Database

Use `vbr` to save your data to a variety of locations:

- A local directory on the nodes in a cluster
- One or more hosts outside of the cluster
- A different Vertica cluster (effectively cloning your database)

Note: Creating a database backup on a different cluster does not provide disaster recovery. The cloned database you create with `vbr` is entirely separate from the original, and is not kept synchronized with the database from which it is cloned.

When to Back up the Database

In addition to any guidelines established by your organization, Micro Focus recommends that you back up your database:

- Before you upgrade Vertica to another release.
- Before you drop a partition.
- After you load a large volume of data.
- If the epoch in the latest backup is earlier than the current ancient history mark (AHM).

- Before and after you add, remove, or replace nodes in your database cluster.
- After recovering a cluster from a crash.

Note: When you restore a database backup, you must restore to a cluster that is identical to the one where you created the backup. For this reason, always create a new backup after adding, removing, or replacing nodes.

Ideally, create regular backups of your full database. You can run the Vertica `vbr` utility from a cron job or other task scheduler.

Creating the Backup Configuration File

The `vbr` utility uses a configuration file for the information required to back up and restore a full- or object-level backup. The configuration file defines where the database backup is saved, the temporary directories it uses, and which nodes, schema, and/or tables in the database are to be backed up. You cannot run `vbr` without a configuration file, and no default file exists.

To invoke the script to set up a configuration file, enter this command:

```
$ vbr --setupconfig
```

The script prompts you to answer the following questions regarding the configuration file. Type **Enter** to accept the default value in parentheses. See [VBR Configuration File Reference](#) in the Administrator's Guide for information about specific questions.

```
[dbadmin@localhost ~]$ /opt/vertica/bin/vbr --setupconfig
Snapshot name (backup_snapshot): fullbak1
Number of restore points (1): 3
Specify objects (no default):
Object restore mode (coexist, createOrReplace or create)
(createOrReplace):
Vertica user name (dbadmin):
Save password to avoid runtime prompt? (n) [y/n]: y
Password to save in vbr config file (no default):
Node v_vmart_node0001
Backup host name (no default): 194.66.82.11
Backup directory (no default): /home/dbadmin/backups
Config file name (fullbak1.ini):
Password file name (no default value) (no default):pwdfile
Change advanced settings? (n) [y/n]: n
```

```
Saved vbr configuration to fullbak1.ini.  
Saved vbr database password to pwdfile.ini.
```

After you answer the required questions, vbr generates a configuration file with the information you supplied. Use the `Config file` name you specified when you run the `--task backup` or other commands. The `vbr` utility uses the configuration file contents for both backup and restore tasks.

Creating Full and Incremental Backups

Before you create a database backup, ensure the following:

- Your database is running.
- All of the backup hosts are up and available.
- The backup location host has sufficient disk space to store the backups.
- The user who starts the utility has write access to the target directories on the host backup location.

Run the `vbr` script from a terminal using the database administrator account from an initiator node in your database cluster. You cannot run the utility as root.

Use the `--task backup` and `--config-file filename` directives as shown in this example.

```
[release@qco55srv01:/scratch_b/qa/vertica/QA/VT_Scenario 0]$ vbr -t backup --config $FULLBAK_CONFIG  
Starting backup of database VTDB.  
Participating nodes: v_vmart_node0001, v_vmart_node0002, v_vmart_node0003, v_vmart_node0004.  
Snapshotting database.  
Snapshot complete.  
Approximate bytes to copy: 2315056043 of 2356089422 total.  
[=====] 100%  
Copying backup metadata.  
Finalizing backup.  
Backup complete!
```

By default, there is no screen output other than the progress bar.

If you do not specify a configuration file, the `vbr` utility searches for one at this location:

```
/opt/vertica/config/vbr.ini
```

If the utility does not locate the configuration you specify, it searches for one at `opt/vertica/config/vbr.ini`. If no file exists there, it fails with an error.

The first time you run the `vbr` utility, it performs a full backup; subsequent runs with the same configuration file create an incremental backup. When creating incremental backups, the utility copies new storage containers, which can include data that existed the last time you backed up the database, along with new and changed data since then. By default, `vbr` saves one archive backup, unless you set the `restorePointLimit` parameter value in the configuration file to a value greater than 1.

Restoring the Database

To restore a full database backup, ensure that:

- The database is down.
- All of the backup hosts are up and available.
- The backup directory exists and contains the backups from which to restore.

To begin a full database backup restore, log in using the database administrator's account. You cannot run the utility as root. For detailed instructions on restoring a database, refer to [Recovering the Database](#).

Using Database Designer to Create a Comprehensive Design

The Vertica Database Designer:

- Analyzes your logical schema, sample data, and, optionally, your sample queries.
- Creates a physical schema design (a set of projections) that can be deployed automatically or manually.
- Can be used by anyone without specialized database knowledge.
- Can be run and rerun any time for additional optimization without stopping the database.
- Uses strategies to provide optimal query performance and data compression.

Use Database Designer to create a comprehensive design, which allows you to create new projections for all tables in your database.

You can also use Database Designer to create an incremental design, which creates projections for all tables referenced in the queries you supply. For more information, see [Incremental Design](#) in the Administrator's Guide.

You can create a comprehensive design with Database Designer using Management Console or through Administration Tools. You can also choose to run Database Designer programmatically (See [About Running Database Designer Programmatically](#)).

This section shows you how to:

- [Running Database Designer with Management Console](#)
- [Run Database Designer with Administration Tools](#)

Running Database Designer with Management Console

In this tutorial, you'll create a comprehensive design with Database Designer through the Management Console interface. If, in the future, you have a query that you want to optimize, you can create an enhanced (incremental) design with additional projections. You can tune

these projections specifically for the query you provide. See [Comprehensive Design](#) in the Administrator's Guide for more information.

Note: To run Database Designer outside Administration Tools, you must be a dbadmin user. If you are not a dbadmin user, you must have the DBDUSER role assigned to you and own the tables for which you are designing projections.

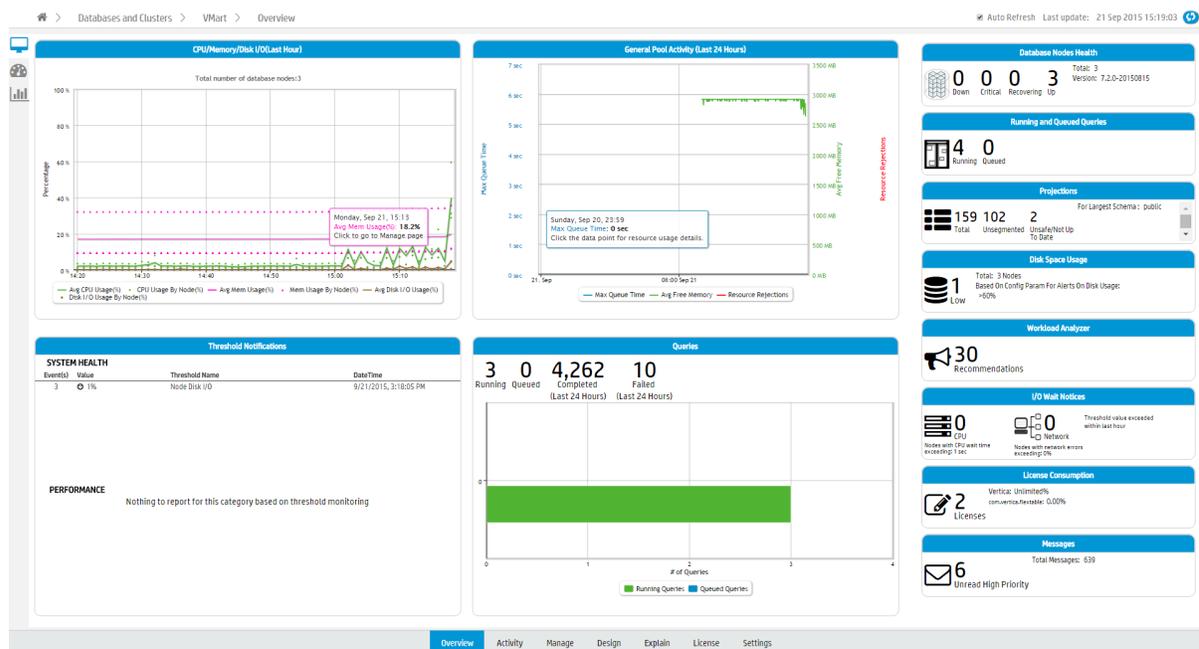

You can choose to create the design manually or use the wizard. To create a design manually, see [Creating a Design Manually](#) in the Administrator's Guide.

Set your browser so that it does not cache pages. If a browser caches pages, you may not be able to see the new design added.

Follow these steps to use the wizard to create the comprehensive design in Management Console:

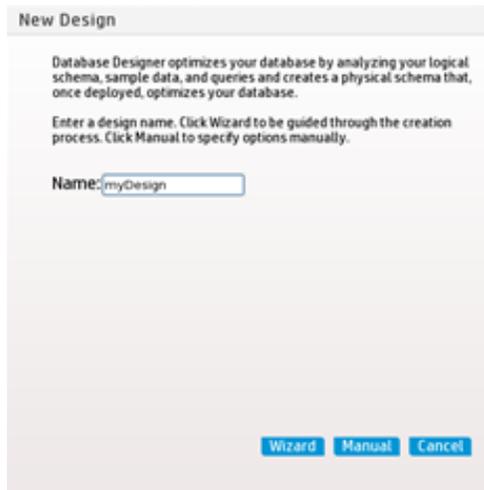

1. Log in to Management Console.
2. Verify that your database is up and running.
3. Choose the database for which you want to create the design. You can find the database under the **Recent Databases** section or by clicking **Existing Infrastructure** to reach the Databases and Clusters page.

The database overview page opens:

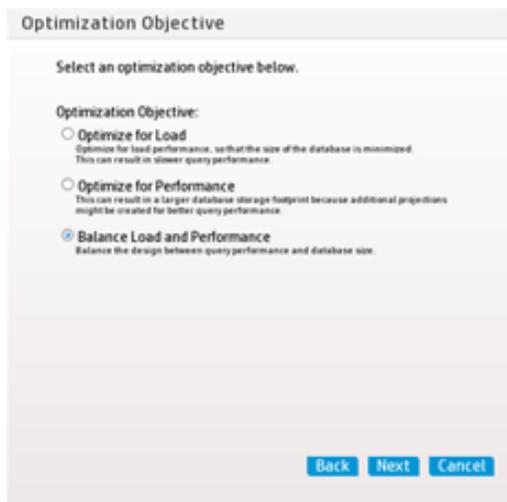

4. At the bottom of the screen, click the **Design** button.

5. In the **New Design** dialog box, enter the design name.

6. Click **Wizard** to continue.
7. Create an initial design. For **Design Type**, select **Comprehensive** and click **Next**.
8. In the **Optimization Objective** window, select **Balance Load and Performance** to create a design that is balanced between database size and query performance. Click **Next**.

9. Select the schemas. Because the VMart design is a multi-schema database, select all three schemas (public, store, and online_sales) for your design in the **Select Sample Data** window. Click **Next**.

If you include a schema that contains tables without data, the design could be suboptimal. You can choose to continue, but Vertica recommends that you deselect the schemas that contain empty tables before you proceed.

10. Choose the K-safety value for your design. The K-Safety value determines the number of buddy projections you want database designer to create.
11. Choose Analyze Correlations Mode. Analyze Correlations Mode determines if Database Designer analyzes and considers column correlations when creating the design.
 - **Ignore:** When creating a design, ignore any column correlations in the specified tables.
 - **Consider existing:** Consider the existing correlations in the tables when creating the design. If you set the mode to 1, and there are no existing correlations, Database Designer does not consider correlations.
 - **Analyze missing:** Analyze column correlations on tables where the correlation analysis was not previously performed. When creating the design, consider all column correlations (new and existing).
 - **Analyze all:** Analyze all column correlations in the tables and consider them when creating the design. Even if correlations exist for a table, reanalyze the table for correlations.

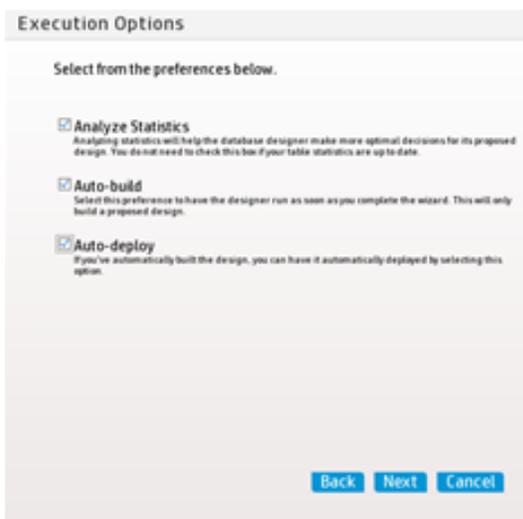

Click **Next**.

12. Submit query files to Database Designer in one of two ways:

- Supply your own query files by selecting the **Browse** button.
- Click **Use Query Repository**, which submits recently executed queries from the QUERY_REQUESTS system table.

Click **Next**.

13. In the **Execution Options** window, select all the options you want. You can select all three options or fewer.

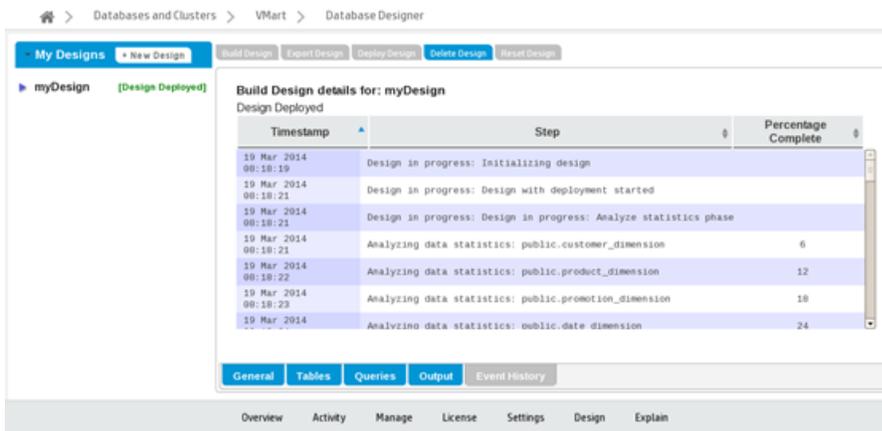

The three options are:

- **Analyze statistics:** Select this option to run statistics automatically after design deploy to help Database Designer make more optimal decisions for its proposed design.
- **Auto-build:** Select this option to run Database Designer as soon as you complete the wizard. This option only builds the proposed design.
- **Auto-deploy:** Select this option for auto-build designs that you want to deploy automatically.

14. Click **Submit Design**.

The **Database Designer** page opens:

- If you chose to automatically deploy your design, Database Designer executes in the background.
- If you did not select the **Auto-build** or **Auto-deploy** options, you can click **Build Design** or **Deploy Design** on the **Database Designer** page.

15. In the **My Designs** pane, view the status of your design:
 - When the deployment completes, the **My Design** pane shows **Design Deployed**.
 - The event history window shows the details of the design build and deployment.

To run Database Designer with Administration Tools, see [Run Database Designer with Administration Tools](#) in this guide.

Run Database Designer with Administration Tools

In this procedure, you create a comprehensive design with Database Designer using the Administration Tools interface. If, in the future, you have a query that you want to optimize, you can create an enhanced (incremental) design with additional projections. You can tune these projections specifically for the query you provide. See [Incremental Design](#) in the Administrator's Guide for more information.

Follow these steps to create the comprehensive design using Database Designer in Administration Tools:

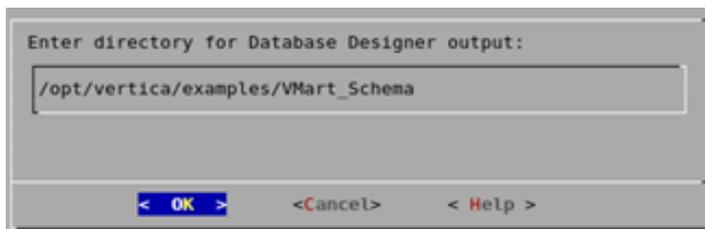

1. If you are not in Administration Tools, exit the vsql session and access Administration Tools:
 - Type `\q` to exit vsql.
 - Type `admintools` to access the Administration Tools Main Menu.

2. Start the database for which you want to create a design.
3. From the **Main Menu**, click **Configuration Menu** and then click **OK**.
4. From the **Configuration Menu**, click **Run Database Designer** and then click **OK**.
5. When the **Select a database for design** dialog box opens, select **VMart** and then click **OK**.

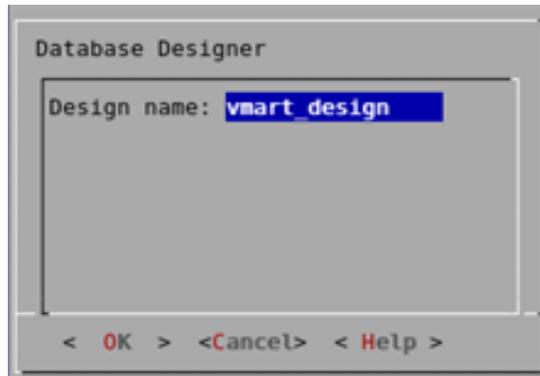

If you are prompted to enter the password for the database, click **OK** to bypass the message. Because no password was assigned when you installed the VMart database, you do not need to enter one now.

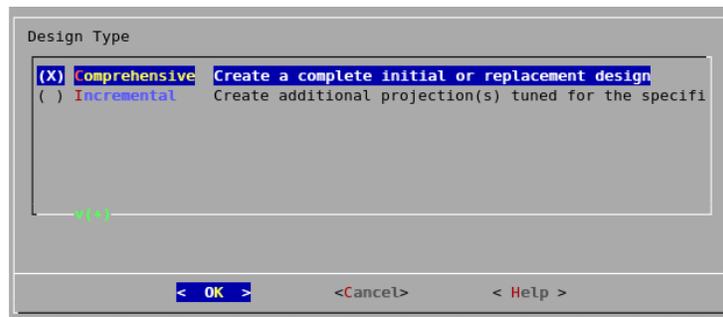

6. Click **OK** to accept the default directory for storing Database Designer output and log files.

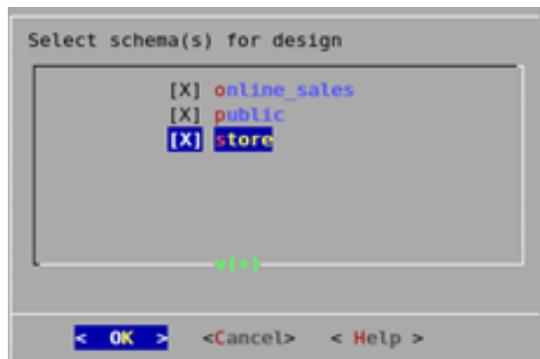

7. In the **Database Designer** window, enter a name for the design, for example, `vmart_design`, and click **OK**. Design names can contain only alphanumeric characters or underscores. No other special characters are allowed.

8. Create a complete initial design. In the **Design Type** window, click **Comprehensive** and click **OK**.

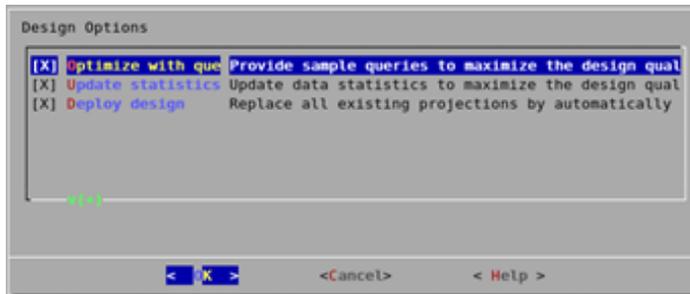

9. Select the schemas. Because the VMart design is a multi-schema database, you can select all three schemas (online_sales, public, and store) for your design. Click **OK**.

If you include a schema that contains tables without data, the Administration Tools notifies you that designing for tables without data could be suboptimal. You can choose to continue, but Micro Focus recommends that you deselect the schemas that contain empty tables before you proceed.

10. In the **Design Options** window, accept all three options and click **OK**.

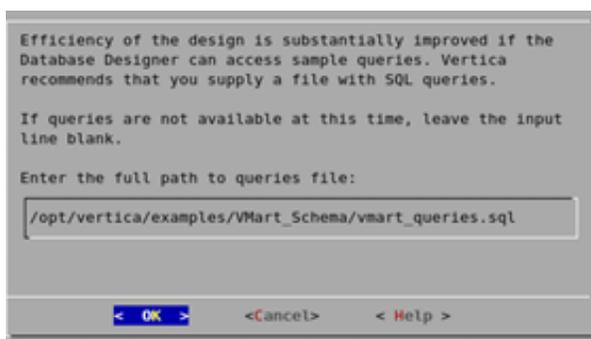

The three options are:

- **Optimize with queries:** Supplying the Database Designer with queries is especially important if you want to optimize the database design for query performance. Micro Focus recommends that you limit the design input to 100 queries.
- **Update statistics:** Accurate statistics help the Database Designer choose the best strategy for data compression. If you select this option, the database statistics are updated to maximize design quality.
- **Deploy design:** The new design deploys automatically. During deployment, new projections are added, some existing projections retained, and any necessary existing projections removed. Any new projections are refreshed to populate them with data.

11. Because you selected the **Optimize with queries** option, you must enter the full path to the file containing the queries that will be run on your database. In this example, it is:

```
/opt/vertica/examples/VMart_Schema/vmart_queries.sql
```

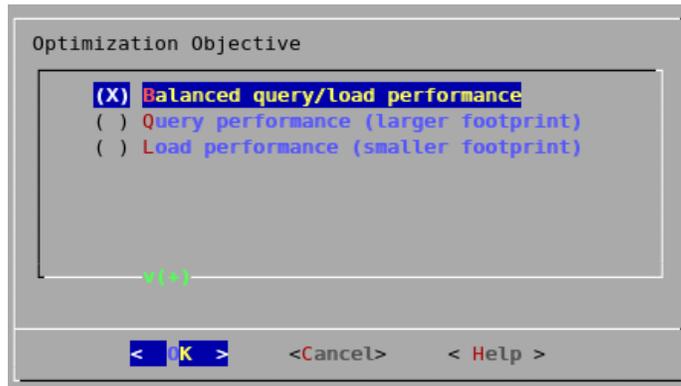

The queries in the query file must be delimited with a semicolon (;).

12. Choose the K-safety value you want and click **OK**. The design K-Safety determines the number of buddy projections you want database designer to create.

If you create a comprehensive design on a single node, you are not prompted to enter a K-safety value.

13. In the **Optimization Objective** window, select **Balanced query/load performance** to create a design that is balanced between database size and query performance. Click **OK**.

14. When the informational message displays, click **Proceed**.

Database Designer automatically performs these actions:

- Sets up the design session.
- Examines table data.
- Loads queries from the query file you provided (in this example, `/opt/vertica/examples/VMart_Schema/vmart_queries.sql`).
- Creates the design.

Deploys the design or saves a SQL file containing the commands to create the design, based on your selections in the Design Options window.

Depending on system resources, the design process could take several minutes. You should allow this process to complete uninterrupted. If you must cancel the session, use Ctrl+C.

```
Database Designer started.  
  
For large databases a design session could take a long time; allow it to complete uninterrupted.  
Use Ctrl+C if you must cancel the session.  
  
Setting up design session...  
  
Examining table data...  
  
Loading queries from '/opt/vertica/examples/VMart_Schema/vmart_queries.sql'.  
Processed 9 SQL statement(s), all accepted and considered in the design.  
No existing projections found.  
  
Creating design and deploying projections...
```

15. When Database Designer finishes, press **Enter** to return to the Administration Tools menu. Examine the steps taken to create the design. The files are in the directory you specified to store the output and log files. In this example, that directory is `/opt/vertica/examples/VMart_Schema`. For more information about the script files, see [About Database Designer](#), in the Administrator's Guide.

For additional information about managing your designs, see [Creating a Database Design](#) in the Administrator's Guide.

Restoring the Status of Your Host

When you finish the tutorial, you can restore your host machines to their original state. Use the following instructions to clean up your host and start over from scratch.

Stopping and Dropping the Database

Follow these steps to stop and/or drop your database. A database must be stopped before it can be dropped.

1. If connected to the database, disconnect by typing `\q`.
2. In the Administration Tools **Main Menu** dialog box, click **Stop Database** and click **OK**.
3. In the **Select database to stop** window, select the database you want to stop and click **OK**.
4. After stopping the database, click **Configuration Menu** and click **OK**.
5. Click **Drop Database** and click **OK**.
6. In the **Select database to drop** window, select the database you want to drop and click **OK**.
7. Click **Yes** to confirm.
8. In the next window type `yes` (lowercase) to confirm and click **OK**.

Alternatively, use the `delete_example` script, which stops and drops the database:

1. If connected to the database, disconnect by typing `\q`.
2. In the Administration Tools **Main Menu** dialog box, select **Exit**.
3. Log in as the database administrator.
4. Change to the `/examples` directory.

```
$ cd /opt/vertica/examples
```

5. Run the `delete_example` script.

```
$ /opt/vertica/sbin/delete_example Vmart
```

Uninstalling Vertica

See [Uninstalling Vertica](#).

Optional Steps

You can also choose to:

- Remove the `dbadmin` account on all cluster hosts.
- Remove any example database directories you created.

Changing the GUI Appearance

The appearance of the Graphical User Interface (GUI) depends on the color and font settings used by your terminal window. The screen captures in this document were made using the default color and font settings in a PuTTY terminal application running on a Windows platform.

Note: If you are using a remote terminal application, such as PuTTY or a Cygwin bash shell, make sure your window is at least 81 characters wide and 23 characters high.

If you are using PuTTY, take these steps to make the Administration Tools look like the screen captures in this document.

1. In a PuTTY window, right-click the title area and select **Change Settings**.
2. Create or load a saved session.
3. In the **Category** dialog, click **Window > Appearance**.
4. In the **Font** settings, click the **Change...** button.
5. Select **Font:** Courier New, **Regular Size:** 10.
6. Click **Apply**.

Repeat these steps for each existing session that you use to run the Administration Tools.

You can also change the translation to support UTF-8.

1. In a PuTTY window, right-click the title area and select **Change Settings**.
2. Create or load a saved session.
3. In the **Category** dialog, click **Window > Translation**.
4. In the **Received data assumed to be in which character set** drop-down menu, select **UTF-8**.
5. Click **Apply**.

Appendix: VMart Example Database Schema, Tables, and Scripts

The Appendix provides detailed information about the VMart example database's schema, tables, and scripts.

The VMart example database contains three different schemas:

- `public`
- `store`
- `online_sales`

The term “schema” has several related meanings in Vertica:

- In SQL statements, a schema refers to named namespace for a logical schema.
- Logical schema refers to a set of tables and constraints.
- Physical schema refers to a set of projections.

Each schema contains tables that are created and loaded during database installation. See the schema maps for a list of tables and their contents:

- [public Schema Map](#)
- [store Schema Map](#)
- [online_sales Schema Map](#)

The VMart database installs with sample scripts that contain SQL commands that represent queries that might be used in a real business. The sample scripts are available in the [Sample Scripts](#) section of this Appendix. Once you're comfortable running the example queries, you might want to write your own.

Tables

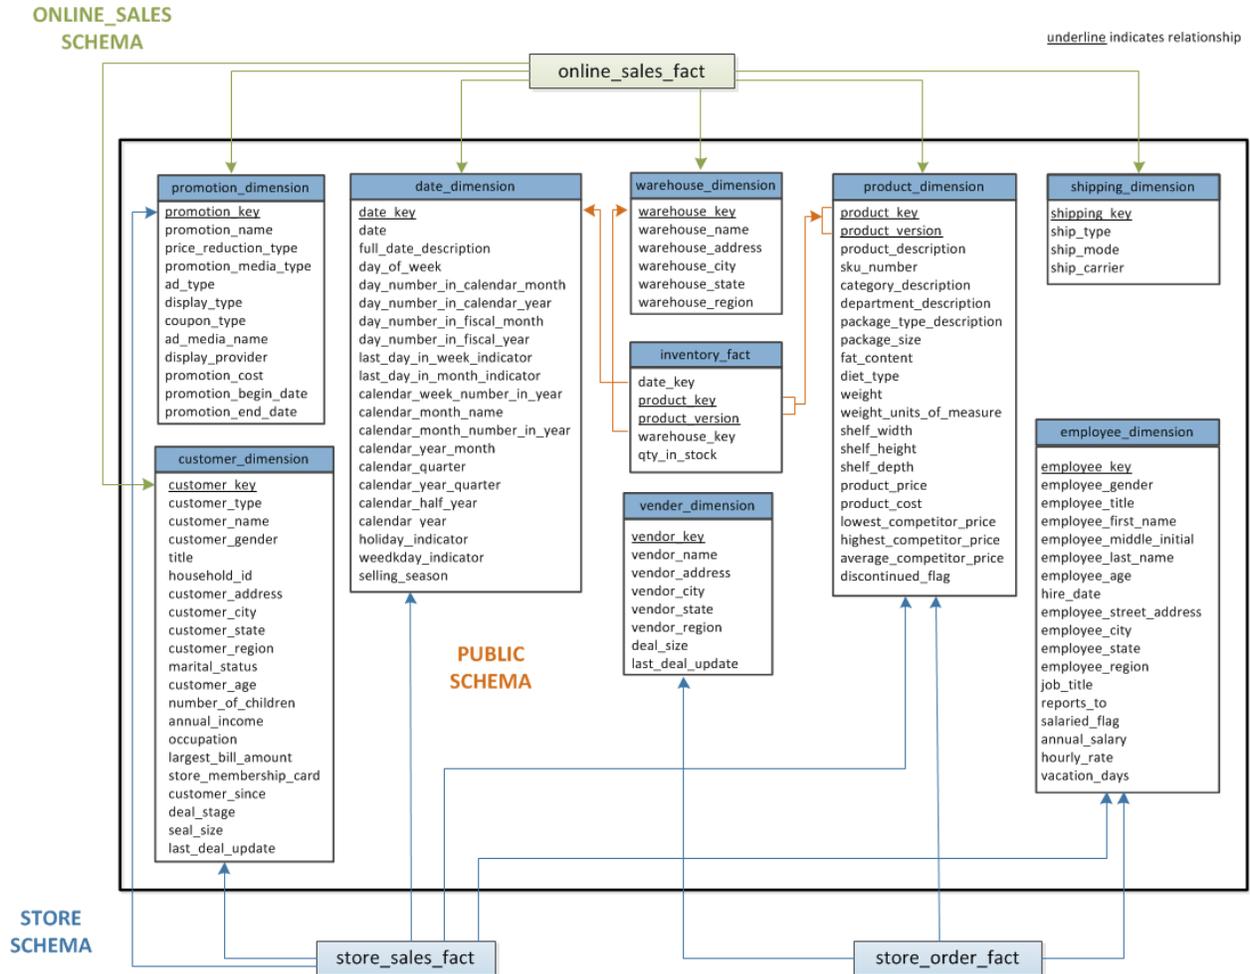

The three schemas in the VMart database include the following tables:

<code>public</code> Schema	<code>store</code> Schema	<code>online_sales</code>
----------------------------	---------------------------	---------------------------

		Schema
inventory_fact	store_orders_fact	online_sales_fact
customer_dimension	store_sales_fact	call_center_dimension
date_dimension	store_dimension	online_page_dimension
employee_dimension		
product_dimension		
promotion_dimension		
shipping_dimension		
vendor_dimension		
warehouse_dimension		

public Schema Map

The `public` schema is a snowflake schema. The following graphic illustrates the `public` schema and its relationships with tables in the `online_sales` and `store` schemas.

inventory_fact

This table contains information about each product in inventory.

Column Name	Data Type	NULLS
date_key	INTEGER	No
product_key	INTEGER	No
product_version	INTEGER	No
warehouse_key	INTEGER	No
qty_in_stock	INTEGER	No

customer_dimension

This table contains information about all the retail chain's customers.

Column Name	Data Type	NULLs
customer_key	INTEGER	No
customer_type	VARCHAR(16)	Yes
customer_name	VARCHAR(256)	Yes
customer_gender	VARCHAR(8)	Yes
title	VARCHAR(8)	Yes
household_id	INTEGER	Yes
customer_address	VARCHAR(256)	Yes
customer_city	VARCHAR(64)	Yes
customer_state	CHAR(2)	Yes
customer_region	VARCHAR(64)	Yes
marital_status	VARCHAR(32)	Yes
customer_age	INTEGER	Yes
number_of_children	INTEGER	Yes
annual_income	INTEGER	Yes
occupation	VARCHAR(64)	Yes
largest_bill_amount	INTEGER	Yes
store_membership_card	INTEGER	Yes
customer_since	DATE	Yes
deal_stage	VARCHAR(32)	Yes
deal_size	INTEGER	Yes

last_deal_update	DATE	Yes
------------------	------	-----

date_dimension

This table contains information about dates. It is generated from a file containing correct date/time data.

Column Name	Data Type	NULLs
date_key	INTEGER	No
date	DATE	Yes
full_date_description	VARCHAR(18)	Yes
day_of_week	VARCHAR(9)	Yes
day_number_in_calendar_month	INTEGER	Yes
day_number_in_calendar_year	INTEGER	Yes
day_number_in_fiscal_month	INTEGER	Yes
day_number_in_fiscal_year	INTEGER	Yes
last_day_in_week_indicator	INTEGER	Yes
last_day_in_month_indicator	INTEGER	Yes
calendar_week_number_in_year	INTEGER	Yes
calendar_month_name	VARCHAR(9)	Yes
calendar_month_number_in_year	INTEGER	Yes
calendar_year_month	CHAR(7)	Yes
calendar_quarter	INTEGER	Yes
calendar_year_quarter	CHAR(7)	Yes
calendar_half_year	INTEGER	Yes
calendar_year	INTEGER	Yes

holiday_indicator	VARCHAR(10)	Yes
weekday_indicator	CHAR(7)	Yes
selling_season	VARCHAR(32)	Yes

employee_dimension

This table contains information about all the people who work for the retail chain.

Column Name	Data Type	NULLs
employee_key	INTEGER	No
employee_gender	VARCHAR(8)	Yes
courtesy_title	VARCHAR(8)	Yes
employee_first_name	VARCHAR(64)	Yes
employee_middle_initial	VARCHAR(8)	Yes
employee_last_name	VARCHAR(64)	Yes
employee_age	INTEGER	Yes
hire_date	DATE	Yes
employee_street_address	VARCHAR(256)	Yes
employee_city	VARCHAR(64)	Yes
employee_state	CHAR(2)	Yes
employee_region	CHAR(32)	Yes
job_title	VARCHAR(64)	Yes
reports_to	INTEGER	Yes
salaried_flag	INTEGER	Yes
annual_salary	INTEGER	Yes
hourly_rate	FLOAT	Yes

vacation_days	INTEGER	Yes
---------------	---------	-----

product_dimension

This table describes all products sold by the department store chain.

Column Name	Data Type	NULLs
product_key	INTEGER	No
product_version	INTEGER	No
product_description	VARCHAR(128)	Yes
sku_number	CHAR(32)	Yes
category_description	CHAR(32)	Yes
department_description	CHAR(32)	Yes
package_type_description	CHAR(32)	Yes
package_size	CHAR(32)	Yes
fat_content	INTEGER	Yes
diet_type	CHAR(32)	Yes
weight	INTEGER	Yes
weight_units_of_measure	CHAR(32)	Yes
shelf_width	INTEGER	Yes
shelf_height	INTEGER	Yes
shelf_depth	INTEGER	Yes
product_price	INTEGER	Yes
product_cost	INTEGER	Yes
lowest_competitor_price	INTEGER	Yes
highest_competitor_price	INTEGER	Yes

average_competitor_price	INTEGER	Yes
discontinued_flag	INTEGER	Yes

promotion_dimension

This table describes every promotion ever done by the retail chain.

Column Name	Data Type	NULLs
promotion_key	INTEGER	No
promotion_name	VARCHAR(128)	Yes
price_reduction_type	VARCHAR(32)	Yes
promotion_media_type	VARCHAR(32)	Yes
ad_type	VARCHAR(32)	Yes
display_type	VARCHAR(32)	Yes
coupon_type	VARCHAR(32)	Yes
ad_media_name	VARCHAR(32)	Yes
display_provider	VARCHAR(128)	Yes
promotion_cost	INTEGER	Yes
promotion_begin_date	DATE	Yes
promotion_end_date	DATE	Yes

shipping_dimension

This table contains information about shipping companies that the retail chain uses.

Column Name	Data Type	NULLs
shipping_key	INTEGER	No

ship_type	CHAR(30)	Yes
ship_mode	CHAR(10)	Yes
ship_carrier	CHAR(20)	Yes

vendor_dimension

This table contains information about each vendor that provides products sold through the retail chain.

Column Name	Data Type	NULLs
vendor_key	INTEGER	No
vendor_name	VARCHAR(64)	Yes
vendor_address	VARCHAR(64)	Yes
vendor_city	VARCHAR(64)	Yes
vendor_state	CHAR(2)	Yes
vendor_region	VARCHAR(32)	Yes
deal_size	INTEGER	Yes
last_deal_update	DATE	Yes

warehouse_dimension

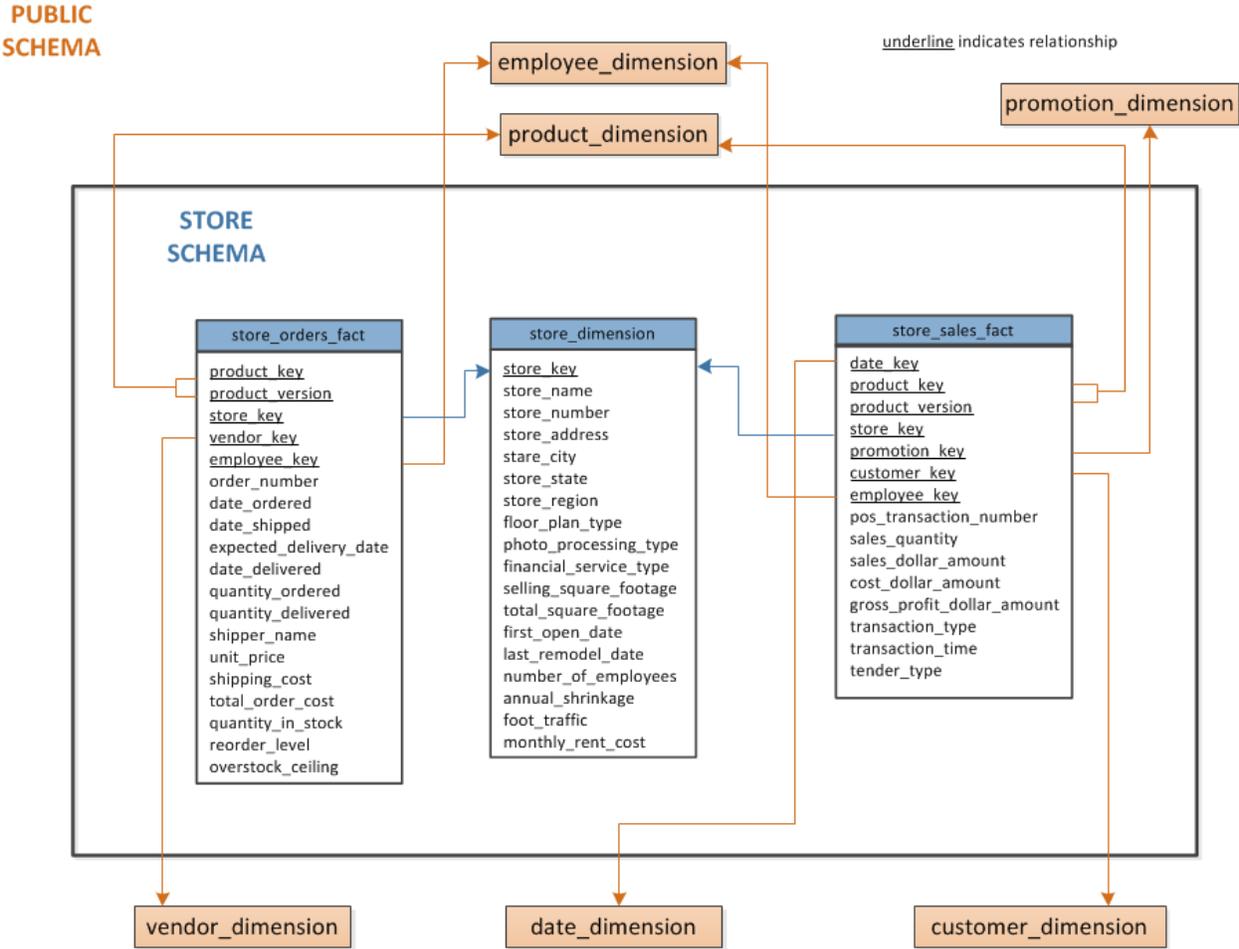

This table provides information about each of the chain's warehouses.

Column Name	Data Type	NULLs
warehouse_key	INTEGER	No
warehouse_name	VARCHAR(20)	Yes
warehouse_address	VARCHAR(256)	Yes
warehouse_city	VARCHAR(60)	Yes

warehouse_state	CHAR(2)	Yes
warehouse_region	VARCHAR(32)	Yes

store Schema Map

The store schema is a snowflake schema that contains information about the retail chain’s bricks-and-mortar stores. The following graphic illustrates the store schema and its relationship with tables in the public schema.

store_orders_fact

This table contains information about all orders made at the company's brick-and-mortar stores.

Column Name	Data Type	NULLs
product_key	INTEGER	No
product_version	INTEGER	No
store_key	INTEGER	No
vendor_key	INTEGER	No
employee_key	INTEGER	No
order_number	INTEGER	No
date_ordered	DATE	Yes
date_shipped	DATE	Yes
expected_delivery_date	DATE	Yes
date_delivered	DATE	Yes
quantity_ordered	INTEGER	Yes
quantity_delivered	INTEGER	Yes
shipper_name	VARCHAR(32)	Yes
unit_price	INTEGER	Yes
shipping_cost	INTEGER	Yes
total_order_cost	INTEGER	Yes
quantity_in_stock	INTEGER	Yes
reorder_level	INTEGER	Yes
overstock_ceiling	INTEGER	Yes

store_sales_fact

This table contains information about all sales made at the company's brick-and-mortar stores.

Column Name	Data Type	NULLs
date_key	INTEGER	No
product_key	INTEGER	No
product_version	INTEGER	No
store_key	INTEGER	No
promotion_key	INTEGER	No
customer_key	INTEGER	No
employee_key	INTEGER	No
pos_transaction_number	INTEGER	No
sales_quantity	INTEGER	Yes
sales_dollar_amount	INTEGER	Yes
cost_dollar_amount	INTEGER	Yes
gross_profit_dollar_amount	INTEGER	Yes
transaction_type	VARCHAR(16)	Yes
transaction_time	TIME	Yes
tender_type	VARCHAR(8)	Yes

store_dimension

This table contains information about each brick-and-mortar store within the retail chain.

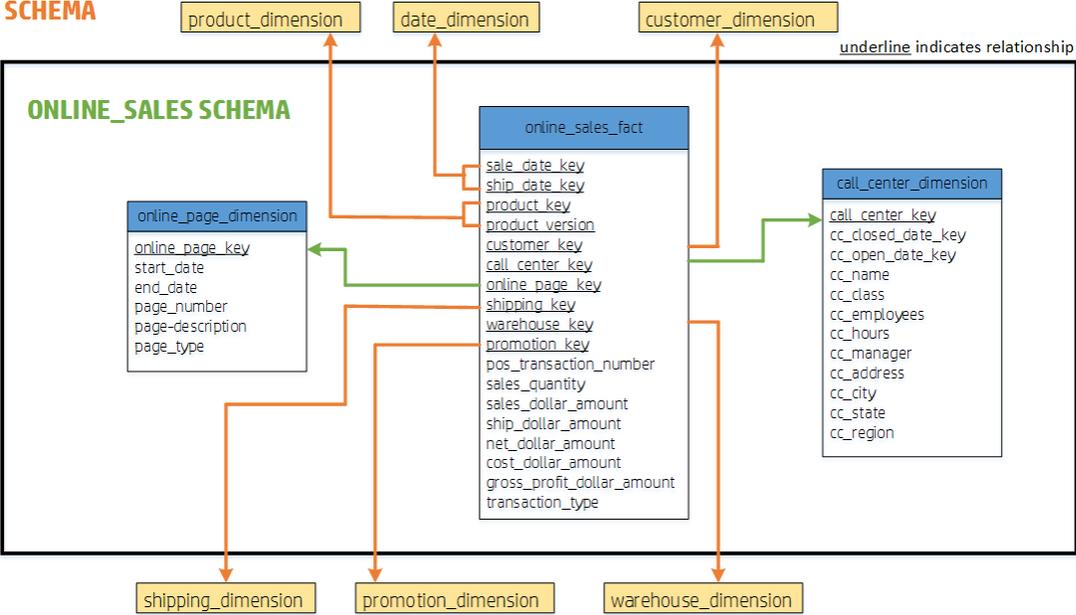

Column Name	Data Type	NULLs
store_key	INTEGER	No

store_name	VARCHAR(64)	Yes
store_number	INTEGER	Yes
store_address	VARCHAR(256)	Yes
store_city	VARCHAR(64)	Yes
store_state	CHAR(2)	Yes
store_region	VARCHAR(64)	Yes
floor_plan_type	VARCHAR(32)	Yes
photo_processing_type	VARCHAR(32)	Yes
financial_service_type	VARCHAR(32)	Yes
selling_square_footage	INTEGER	Yes
total_square_footage	INTEGER	Yes
first_open_date	DATE	Yes
last_remodel_date	DATE	Yes
number_of_employees	INTEGER	Yes
annual_shrinkage	INTEGER	Yes
foot_traffic	INTEGER	Yes
monthly_rent_cost	INTEGER	Yes

online_sales Schema Map

The `online_sales` schema is a snowflake schema that contains information about the retail chains. The following graphic illustrates the `online_sales` schema and its relationship with tables in the `public` schema.

PUBLIC SCHEMA

online_sales_fact

This table describes all the items purchased through the online store front.

Column Name	Data Type	NULLs
sale_date_key	INTEGER	No
ship_date_key	INTEGER	No
product_key	INTEGER	No
product_version	INTEGER	No
customer_key	INTEGER	No
call_center_key	INTEGER	No
online_page_key	INTEGER	No
shipping_key	INTEGER	No
warehouse_key	INTEGER	No
promotion_key	INTEGER	No

pos_transaction_number	INTEGER	No
sales_quantity	INTEGER	Yes
sales_dollar_amount	FLOAT	Yes
ship_dollar_amount	FLOAT	Yes
net_dollar_amount	FLOAT	Yes
cost_dollar_amount	FLOAT	Yes
gross_profit_dollar_amount	FLOAT	Yes
transaction_type	VARCHAR(16)	Yes

call_center_dimension

This table describes all the chain's call centers.

Column Name	Data Type	NULLs
call_center_key	INTEGER	No
cc_closed_date	DATE	Yes
cc_open_date	DATE	Yes
cc_date	VARCHAR(50)	Yes
cc_class	VARCHAR(50)	Yes
cc_employees	INTEGER	Yes
cc_hours	CHAR(20)	Yes
cc_manager	VARCHAR(40)	Yes
cc_address	VARCHAR(256)	Yes
cc_city	VARCHAR(64)	Yes
cc_state	CHAR(2)	Yes
cc_region	VARCHAR(64)	Yes

online_page_dimension

This table describes all the pages in the online store front.

Column Name	Data Type	NULLs
online_page_key	INTEGER	No
start_date	DATE	Yes
end_date	DATE	Yes
page_number	INTEGER	Yes
page_description	VARCHAR(100)	Yes
page_type	VARCHAR(100)	Yes

Sample Scripts

You can create your own queries, but the VMart example directory includes sample query script files to help you get started quickly.

You can find the following sample scripts at this path `/opt/vertica/examples/VMart_Schema`.

To run any of the scripts, enter

```
=> \i <script_name>
```

Alternatively, type the commands from the script file manually.

Note: The data that your queries return might differ from the example output shown in this guide because the sample data generator is random.

vmart_query_01.sql

```
-- vmart_query_01.sql  
-- FROM clause subquery
```

```
-- Return the values for five products with the
-- lowest-fat content in the Dairy department

SELECT fat_content
FROM (
  SELECT DISTINCT fat_content
  FROM product_dimension
  WHERE department_description
  IN ('Dairy') ) AS food
ORDER BY fat_content
LIMIT 5;
```

Output

```
fat_content
-----
      80
      81
      82
      83
      84
(5 rows)
```

vmart_query_02.sql

```
-- vmart_query_02.sql
-- WHERE clause subquery
-- Asks for all orders placed by stores located in Massachusetts
-- and by vendors located elsewhere before March 1, 2003:

SELECT order_number, date_ordered
FROM store.store_orders_fact orders
WHERE orders.store_key IN (
  SELECT store_key
  FROM store.store_dimension
  WHERE store_state = 'MA')
  AND orders.vendor_key NOT IN (
  SELECT vendor_key
  FROM public.vendor_dimension
  WHERE vendor_state = 'MA')
  AND date_ordered < '2012-03-01';
```

Output

```
order_number | date_ordered
-----+-----
      53019 | 2012-02-10
      222168 | 2012-02-05
      160801 | 2012-01-08

Administrator's Guide

Welcome to the Vertica Administrator's Guide. This document describes how to set up and maintain an Vertica Analytics Platform database.

Prerequisites

This document assumes that you have already:

- Become familiar with the concepts discussed in the [Vertica Concepts](#).
- Performed the procedures described in the [Installing Vertica](#):
 - Constructed a hardware platform.
 - Installed Linux.
 - Installed Vertica (configured a cluster of hosts).
- Followed the [Tutorial](#) in Getting Started to experiment with setting up an example database.

Administration Overview

This document describes the functions performed by an Vertica database administrator (DBA). Perform these tasks using only the dedicated database administrator account that was created when you installed Vertica. The examples in this documentation set assume that the administrative account name is dbadmin.

- To perform certain cluster configuration and administration tasks, the DBA (users of the administrative account) must be able to supply the root password for those hosts. If this requirement conflicts with your organization's security policies, these functions must be performed by your IT staff.
- If you perform administrative functions using a different account from the account provided during installation, Vertica encounters file ownership problems.
- If you share the administrative account password, make sure that only one user runs the Administration Tools at any time. Otherwise, automatic configuration propagation does not work correctly.
- The Administration Tools require that the calling user's shell be `/bin/bash`. Other shells give unexpected results and are not supported.

Managing Licenses

You must license Vertica in order to use it. Micro Focus supplies your license in the form of one or more license files, which encode the terms of your license. The licenses that are available include:

- `vlicense.dat`, for columnar tables.
- `vlicense_565_bytes.dat`, for data stored in a Hadoop environment with Vertica for SQL on Apache Hadoop.

To prevent introducing special characters that invalidate the license, do not open the license files in an editor or email client. Opening the file in this way can introduce special characters, such as line endings and file terminators, that may not be visible within the editor. Whether visible or not, these characters invalidate the license.

Applying License Files

For ease of Vertica Premium Edition and SQL on Hadoop installation, Micro Focus recommends that you copy the license file to `/tmp/vlicense.dat` on the Administration host.

Be careful not to change the license key file in any way when copying the file between Windows and Linux, or to any other location. To help prevent applications from trying to alter the file, enclose the license file in an archive file (such as a `.zip` or `.tar` file).

After copying the license file from one location to another, check that the copied file size is identical to that of the one you received from Vertica.

Obtaining a License Key File

To obtain a license key (for example, for Premium Edition or SQL on Hadoop), contact Vertica at: <http://www.vertica.com/about/contact-us/>

Your Vertica Community Edition download package includes the Community Edition license, which allows three nodes and 1TB of data. The Vertica Community Edition license does not expire.

Understanding Vertica Licenses

Vertica has flexible licensing terms. It can be licensed on the following bases:

- Term-based (valid until a specific date)
- Size-based (valid to store up to a specified amount of raw data)
- Both term- and size-based
- Unlimited duration and data storage
- Node-based with an unlimited number of CPUs and users (one node is a server acting as a single computer system, whether physical or virtual)

Vertica Community Edition licenses include 1 terabyte data and a limit of 3 nodes.

Vertica for SQL on Apache Hadoop is a separate product with its own license. This documentation covers both products. Consult your license agreement for details about available features and limitations.

Your license key has your licensing bases encoded into it. If you are unsure of your current license, you can [view your license information from within Vertica](#).

Vertica Analytics Platform License Types

Vertica Analytics Platform is a full-featured offering with all analytical functions described in this documentation. It is best used for advanced analytics and enterprise data warehousing. There are two editions, Community Edition and Premium Edition.

Vertica Community Edition: You can download and start using Community Edition for free. The Community Edition license allows customers the following:

- 3 node limit
- 1 terabyte data limit

Community Edition licenses cannot be installed co-located in a Hadoop infrastructure and used to query data stored in Hadoop formats.

Vertica Premium Edition: You can purchase the Premium Edition license. The Premium Edition license entitles customers to:

- No node limit
- Data amount as specified by the license
- Store data in HDFS and read limited data from HDFS, as specified in your license

Premium Edition licenses cannot be installed co-located in a Hadoop infrastructure.

Note: Vertica does not support license downgrades.

Vertica for SQL on Apache Hadoop License

Vertica for SQL on Apache Hadoop is a license for running Vertica on a Hadoop environment. This allows users to run Vertica on data that is in a shared storage environment. It is best used for exploring data in a Hadoop data lake. It can be used only in co-located Hadoop environments to query data stored in Hadoop (Hortonworks, MapR, or Cloudera).

Customers can purchase this term-based SQL on Apache Hadoop license per the number of nodes they plan to use in their Hadoop environment. The license then audits the number of nodes being used for compliance.

Installing or Upgrading a License Key

The steps you follow to apply your Vertica license key vary, depending on the type of license you are applying and whether you are upgrading your license. This section describes the following:

- [New Vertica License Installations](#)
- [Vertica License Renewals or Upgrades](#)

New Vertica License Installations

1. Copy the license key file to your Administration Host.
2. Ensure the license key's file permissions are set to 400 (read permissions).

3. Install Vertica as described in the Installing Vertica if you have not already done so. The interface prompts you for the license key file.
4. To install Community Edition, leave the default path blank and click **OK**. To apply your evaluation or Premium Edition license, enter the absolute path of the license key file you downloaded to your Administration Host and press **OK**. The first time you log in as the Database Administrator and run the Administration Tools, the interface prompts you to accept the End-User License Agreement (EULA).

Note: If you installed Management Console, the MC administrator can point to the location of the license key during Management Console configuration.

5. Choose **View EULA**.
6. Exit the EULA and choose **Accept EULA** to officially accept the EULA and continue installing the license, or choose **Reject EULA** to reject the EULA and return to the Advanced Menu.

Vertica License Renewals or Upgrades

If your license is expiring or you want your database to grow beyond your licensed data size, you must renew or upgrade your license. Once you have obtained your renewal or upgraded license key file, you can install it using Administration Tools or Management Console.

Uploading or Upgrading a License Key Using Administration Tools

1. Copy the license key file to your Administration Host.
2. Ensure the license key's file permissions are set to 400 (read permissions).
3. Start your database, if it is not already running.
4. In the Administration Tools, select **Advanced > Upgrade License Key** and click **OK**.
5. Enter the absolute path to your new license key file and click **OK**. The interface prompts you to accept the End-User License Agreement (EULA).
6. Choose **View EULA**.

7. Exit the EULA and choose Accept EULA to officially accept the EULA and continue installing the license, or choose Reject EULA to reject the EULA and return to the Advanced Tools menu.

Uploading or Upgrading a License Key Using Management Console

1. From your database's Overview page in Management Console, click the License tab. The License page displays. You can view your installed licenses on this page.
2. Click Install New License at the top of the License page.
3. Browse to the location of the license key from your local computer and upload the file.
4. Click Apply at the top of the page. Management Console prompts you to accept the End-User License Agreement (EULA).
5. Select the check box to officially accept the EULA and continue installing the license, or click Cancel to exit.

Note: As soon as you renew or upgrade your license key from either your Administration Host or Management Console, Vertica applies the license update. No further warnings appear.

Viewing Your License Status

You can use several functions to display your license terms and current status.

Examining Your License Key

Use the [DISPLAY_LICENSE](#) SQL function described in the SQL Reference Manual to display the license information. This function displays the dates for which your license is valid (or Perpetual if your license does not expire) and any raw data allowance. For example:

```
=> SELECT DISPLAY_LICENSE();
          DISPLAY_LICENSE
-----
Vertica Systems, Inc.
```

```
1/1/2011  
12/31/2011  
30  
50TB  
(1 row)
```

You can also query the [LICENSES](#) system table to view information about your installed licenses. This table displays your license types, the dates for which your licenses are valid, and the size and node limits your licenses impose.

Alternatively, use the [LICENSES](#) table in Management Console. On your database Overview page, click the License tab to view information about your installed licenses.

Viewing Your License Compliance

If your license includes a raw data size allowance, Vertica periodically audits your database's size to ensure it remains compliant with the license agreement. If your license has a term limit, Vertica also periodically checks to see if the license has expired. You can see the result of the latest audits using the [GET_COMPLIANCE_STATUS](#) function.

```
=> select GET_COMPLIANCE_STATUS();  
          GET_COMPLIANCE_STATUS  
  
-----  
Raw Data Size: 2.00GB +/- 0.003GB  
License Size : 4.000GB  
Utilization  : 50%  
Audit Time   : 2011-03-09 09:54:09.538704+00  
Compliance Status : The database is in compliance with respect to raw data size.  
License End Date: 04/06/2011  
Days Remaining: 28.59  
(1 row)
```

To see how your ORC/Parquet data is affecting your license compliance, see [Viewing License Compliance for Hadoop File Formats](#).

Viewing Your License Status Through MC

Information about license usage is on the Settings page. See [Monitoring Database Size for License Compliance](#).

Viewing License Compliance for Hadoop File Formats

You can use the [EXTERNAL_TABLE_DETAILS](#) system table to gather information about your use of Hadoop file formats. This information can help you assess your compliance with your Vertica license.

Vertica computes the values in this table at query time, so to avoid performance problems, restrict your queries to filter by `table_schema`, `table_name`, or `source_format`. These three columns are the only columns you can use in a predicate, but you may use all of the usual predicate operators.

```
=> SELECT * FROM EXTERNAL_TABLE_DETAILS
      WHERE source_format = 'PARQUET' OR source_format = 'ORC';
-[ RECORD 1 ]-----+-----
-----
schema_oid      | 45035996273704978
table_schema    | public
table_oid       | 45035996273760390
table_name      | ORC_demo
source_format   | ORC
total_file_count | 5
total_file_size_bytes | 789
source_statement | COPY FROM 'ORC_demo/*' ORC
file_access_error |
-[ RECORD 2 ]-----+-----
-----
schema_oid      | 45035196277204374
table_schema    | public
table_oid       | 45035996274460352
table_name      | Parquet_demo
source_format   | PARQUET
total_file_count | 3
total_file_size_bytes | 498
source_statement | COPY FROM 'Parquet_demo/*' PARQUET
file_access_error |
```

When computing the size of an external table, Vertica counts all data found in the location specified by the `COPY FROM` clause. If you have a directory that contains ORC and delimited files, for example, and you define your external table with `"COPY FROM *"` instead of `"COPY FROM *.orc"`, this table includes the size of the delimited files. (You would probably also

encounter errors when querying that external table.) When you query this table Vertica does not validate your table definition; it just uses the path to find files to report.

Calculating the Database Size

You can use your Vertica software until your columnar data reaches the maximum raw data size that the license agreement provides. This section describes when data is monitored, what data is included in the estimate, and the general methodology used to produce an estimate. For more information about monitoring for data size, see [Monitoring Database Size for License Compliance](#).

How Vertica Estimates Raw Data Size

Vertica uses statistical sampling to calculate an accurate estimate of the raw data size of the database. In this context, *raw data* means the uncompressed data stored in a single Vertica database. For the purpose of license size audit and enforcement, Vertica evaluates the raw data size as if the data had been exported from the database in text format, rather than as compressed data.

Vertica conducts your database size audit using statistical sampling. This method allows Vertica to estimate the size of the database without significantly affecting database performance. The trade-off between accuracy and impact on performance is a small margin of error, inherent in statistical sampling. Reports on your database size include the margin of error, so you can assess the accuracy of the estimate. To learn more about simple random sampling, see [Simple Random Sampling](#).

Excluding Data From Raw Data Size Estimate

Not all data in the Vertica database is evaluated as part of the raw data size. Specifically, Vertica excludes the following data:

- Multiple projections (underlying physical copies) of data from a logical database entity (table). Data appearing in multiple projections of the same table is counted only once.
- Data stored in temporary tables.
- Data accessible through external table definitions.

- Data that has been deleted, but that remains in the database. To understand more about deleting and purging data, see [Purging Deleted Data](#).
- Data stored in the WOS.
- Data stored in system and work tables such as monitoring tables, Data Collector tables, and Database Designer tables.
- Delimiter characters.
- Data stored in SET USING denormalized columns. For information on denormalized (flattened) tables, see [Flattened Tables](#).

Evaluating Data Type Footprint Size

Vertica treats the data sampled for the estimate as if it had been exported from the database in text format (such as printed from vsql). This means that Vertica evaluates the data type footprint sizes as follows:

- Strings and binary types (CHAR, VARCHAR, BINARY, VARBINARY) are counted as their actual size in bytes using UTF-8 encoding.
- Numeric data types are counted as if they had been printed. Each digit counts as a byte, as does any decimal point, sign, or scientific notation. For example, -123.456 counts as eight bytes (six digits plus the decimal point and minus sign).
- Date/time data types are counted as if they had been converted to text, including any hyphens or other separators. For example, a timestamp column containing the value for noon on July 4th, 2011 would be 19 bytes. As text, vsql would print the value as 2011-07-04 12:00:00, which is 19 characters, including the space between the date and the time.

Using AUDIT to Estimate Database Size

To supply a more accurate database size estimate than statistical sampling can provide, use the [AUDIT](#) function to perform a full audit. This function has parameters to set both the `error_tolerance` and `confidence_level`. Using one or both of these parameters increases or decreases the function's performance impact.

For instance, lowering the `error_tolerance` to zero (0) and raising the `confidence_level` to 100, provides the most accurate size estimate, and increases the performance impact of calling the AUDIT function. During a detailed, low error-tolerant audit, all of the data in the

database is dumped to a raw format to calculate its size. Since performing a stringent audit can significantly affect database performance, never perform a full audit of a production database. See [AUDIT](#) for details.

Note: Unlike estimating raw data size using statistical sampling, a full audit performs SQL queries on the full database contents, *including* the contents of the WOS.

Monitoring Database Size for License Compliance

Your Vertica license can include a data storage allowance. The allowance can consist of data in columnar tables, flex tables, or both types of data. The `AUDIT()` function estimates the columnar table data size and any flex table materialized columns. The `AUDIT_FLEX()` function estimates the amount of `__raw__` column data in flex or columnar tables. In regards to license data limits, data in `__raw__` columns is calculated at 1/10th the size of structured data. Monitoring data sizes for columnar and flex tables lets you plan either to schedule deleting old data to keep your database in compliance with your license, or to consider a license upgrade for additional data storage.

Note: An audit of columnar data includes flex table real and materialized columns, but not `__raw__` column data.

Viewing Your License Compliance Status

Vertica periodically runs an audit of the columnar data size to verify that your database is compliant with your license terms. You can view the results of the most recent audit by calling the `GET_COMPLIANCE_STATUS` function.

```
=> select GET_COMPLIANCE_STATUS();
          GET_COMPLIANCE_STATUS
-----
Raw Data Size: 2.00GB +/- 0.003GB
License Size : 4.000GB
Utilization  : 50%
Audit Time   : 2011-03-09 09:54:09.538704+00
Compliance Status : The database is in compliance with respect to raw data size.
License End Date: 04/06/2011
Days Remaining: 28.59
(1 row)
```

Periodically running `GET_COMPLIANCE_STATUS` to monitor your database's license status is usually enough to ensure that your database remains compliant with your license. If your database begins to near its columnar data allowance, you can use the other auditing functions described below to determine where your database is growing and how recent deletes affect the database size.

Manually Auditing Columnar Data Usage

You can manually check license compliance for all columnar data in your database using the `AUDIT_LICENSE_SIZE` function. This function performs the same audit that Vertica periodically performs automatically. The `AUDIT_LICENSE_SIZE` check runs in the background, so the function returns immediately. You can then query the results using `GET_COMPLIANCE_STATUS`.

Note: When you audit columnar data, the results include any flex table real and materialized columns, but not data in the `__raw__` column. Materialized columns are virtual columns that you have promoted to real columns. Columns that you define when creating a flex table, or which you add with `ALTER TABLE . . . ADD COLUMN` statements are real columns. All `__raw__` columns are real columns. However, since they consist of unstructured or semi-structured data, they are audited separately.

An alternative to `AUDIT_LICENSE_SIZE` is to use the `AUDIT` function to audit the size of the columnar tables in your entire database by passing an empty string to the function. This function operates synchronously, returning when it has estimated the size of the database.

```
=> SELECT AUDIT('');
      AUDIT
-----
      76376696
(1 row)
```

The size of the database is reported in bytes. The `AUDIT` function also allows you to control the accuracy of the estimated database size using additional parameters. See the entry for the `AUDIT` function in the SQL Reference Manual for full details. Vertica does not count the `AUDIT` function results as an official audit. It takes no license compliance actions based on the results.

Note: The results of the `AUDIT` function do not include flex table data in `__raw__` columns. Use the `AUDIT_FLEX` function to monitor data usage flex tables.

Manually Auditing __raw__ Column Data

You can use the [AUDIT_FLEX](#) function to manually audit data usage for flex or columnar tables with a __raw__ column. The function calculates the encoded, compressed data stored in ROS containers for any __raw__ columns. Materialized columns in flex tables are calculated by the [AUDIT](#) function. The [AUDIT_FLEX](#) results do not include data in the __raw__ columns of temporary flex tables.

Targeted Auditing

If audits determine that the columnar table estimates are unexpectedly large, consider schemas, tables, or partitions that are using the most storage. You can use the [AUDIT](#) function to perform targeted audits of schemas, tables, or partitions by supplying the name of the entity whose size you want to find. For example, to find the size of the `online_sales` schema in the [VMart](#) example database, run the following command:

```
=> SELECT AUDIT('online_sales');
      AUDIT
-----
35716504
(1 row)
```

You can also change the granularity of an audit to report the size of each object in a larger entity (for example, each table in a schema) by using the granularity argument of the [AUDIT](#) function. See the [AUDIT](#) function in the SQL Reference Manual.

Using Management Console to Monitor License Compliance

You can also get information about data storage of columnar data (for columnar tables and for materialized columns in flex tables) through the Management Console. This information is available in the database Overview page, which displays a grid view of the database's overall health.

- The needle in the license meter adjusts to reflect the amount used in megabytes.
- The grace period represents the term portion of the license.

- The Audit button returns the same information as the AUDIT() function in a graphical representation.
- The Details link within the License grid (next to the Audit button) provides historical information about license usage. This page also shows a progress meter of percent used toward your license limit.

Managing License Warnings and Limits

Term License Warnings and Expiration

The term portion of an Vertica license is easy to manage—you are licensed to use Vertica until a specific date. If the term of your license expires, Vertica alerts you with messages appearing in the Administration Tools and vsql. For example:

```
=> CREATE TABLE T (A INT);  
NOTICE: Vertica license is in its grace period  
HINT: Renew at http://www.vertica.com/  
CREATE TABLE
```

Contact Vertica at <http://www.vertica.com/about/contact-us/> as soon as possible to renew your license, and then [install the new license](#). After the grace period expires, Vertica stops processing queries.

Data Size License Warnings and Remedies

If your Vertica columnar license includes a raw data size allowance, Vertica periodically audits the size of your database to ensure it remains compliant with the license agreement. For details of this audit, see [Calculating the Database Size](#). You should also monitor your database size to know when it will approach licensed usage. Monitoring the database size helps you plan to either upgrade your license to allow for continued database growth or delete data from the database so you remain compliant with your license. See [Monitoring Database Size for License Compliance](#) for details.

If your database's size approaches your licensed usage allowance (above 75% of license limits), you will see warnings in the Administration Tools , vsql, and Management Console. You have two options to eliminate these warnings:

- Upgrade your license to a larger data size allowance.
- Delete data from your database to remain under your licensed raw data size allowance. The warnings disappear after Vertica's next audit of the database size shows that it is no longer close to or over the licensed amount. You can also manually run a database audit (see [Monitoring Database Size for License Compliance](#) for details).

If your database continues to grow after you receive warnings that its size is approaching your licensed size allowance, Vertica displays additional warnings in more parts of the system after a grace period passes.

If Your Vertica Premium Edition Database Size Exceeds Your Licensed Limits

If your Premium Edition database size exceeds your licensed data allowance, all successful queries from ODBC and JDBC clients return with a status of `SUCCESS_WITH_INFO` instead of the usual `SUCCESS`. The message sent with the results contains a warning about the database size. Your ODBC and JDBC clients should be prepared to handle these messages instead of assuming that successful requests always return `SUCCESS`.

Note: These warnings for Premium Edition are in addition to any warnings you see in Administration Tools, vsql, and Management Console.

If Your VerticaCommunity Edition Database Size Exceeds 1 Terabyte

If your Community Edition database size exceeds the limit of 1 terabyte, you will no longer be able to load or modify data in your database. In addition, you will not be able to delete data from your database.

To bring your database under compliance, you can choose to:

- Drop database tables. You can also consider truncating a table or dropping a partition. See [TRUNCATE TABLE](#) or [DROP_PARTITION](#).
- Upgrade to Vertica Premium Edition (or an evaluation license).

Exporting License Audit Results to CSV

You can use `admintools` to audit a database for license compliance and export the results in CSV format, as follows:

```
admintools -t license_audit [--password=password] --database=database] [--file=csv-file] [--quiet]
```

where:

- *database* must be a running database. If the database is password protected, you must also supply the password.
- `--file csv-file` directs output to the specified file. If *csv-file* already exists, the tool returns an error message. If this option is unspecified, output is directed to `stdout`.
- `--quiet` specifies that the tool should run in quiet mode; if unspecified, status messages are sent to `stdout`.

Running the `license_audit` tool is equivalent to invoking the following SQL statements:

```
select audit('');
select audit_flex('');
select * from dc_features_used;
select * from v_catalog.license_audits;
select * from v_catalog.user_audits;
```

Audit results include the following information:

- Log of used Vertica features
- Estimated database size
- Raw data size allowed by your Vertica license
- Percentage of licensed allowance that the database currently uses
- Audit timestamps

The following truncated example shows the raw CSV output that `license_audit` generates:

```
FEATURES_USED
features_used,feature,date,sum
features_used,metafunction::get_compliance_status,2014-08-04,1
features_used,metafunction::bootstrap_license,2014-08-04,1
...
```

Configuring the Database

This section provides information about:

- The [Configuration Procedure](#)
- [Configuration Parameters](#)
- Designing a [logical schema](#)
- Creating the [physical schema](#)

You'll also want to set up a security scheme. See [Implementing Security](#).

See also implementing [locales](#) for international data sets.

Note: Before you begin this section, Micro Focus strongly recommends that you follow the [Tutorial](#) in Getting Started to quickly familiarize yourself with creating and configuring a fully-functioning example database.

Configuration Procedure

This section describes the tasks required to set up an Vertica database. It assumes that you have obtained a valid license key file, installed the Vertica rpm package, and run the installation script as described in [Installing Vertica](#).

You'll complete the configuration procedure using:

- Administration Tools

If you are unfamiliar with Dialog-based user interfaces, read [Using the Administration Tools Interface](#) before you begin. See also the [Administration Tools Reference](#) for details.

- vsql interactive interface
- Database Designer, described in [Creating a Database Design](#)

Note: You can also perform certain tasks using [Management Console](#). Those tasks point to the appropriate topic.

- Follow the configuration procedure in the order presented in this book.
- Micro Focus strongly recommends that you first use the [Tutorial](#) in Getting Started to experiment with creating and configuring a database.
- Although you may create more than one database (for example, one for production and one for testing), you may create only one active database for each installation of Vertica Analytics Platform
- The generic configuration procedure described here can be used several times during the development process and modified each time to fit changing goals. You can omit steps such as preparing actual data files and sample queries, and run the Database Designer without optimizing for queries. For example, you can create, load, and query a database several times for development and testing purposes, then one final time to create and load the production database.

Prepare Disk Storage Locations

You must create and specify directories in which to store your catalog and data files (physical schema). You can specify these locations when you install or configure the database, or later during database operations. Both the catalog and data directories must be owned by the database administrator.

The directory you specify for database catalog files (the catalog path) is used across all nodes in the cluster. For example, if you specify `/home/catalog` as the catalog directory, Vertica uses that catalog path on all nodes. The catalog directory should always be separate from any data file directories.

Note: Do not use a shared directory for more than one node. Data and catalog directories must be distinct for each node. Multiple nodes must not be allowed to write to the same data or catalog directory.

The data path you designate is also used across all nodes in the cluster. Specifying that data should be stored in `/home/data`, Vertica uses this path on all database nodes.

Do not use a single directory to contain both catalog and data files. You can store the catalog and data directories on different drives, which can be either on drives local to the host (recommended for the catalog directory) or on a shared storage location, such as an external disk enclosure or a SAN.

Before you specify a catalog or data path, be sure the parent directory exists on all nodes of your database. Creating a database in `admintools` also creates the catalog and data directories, but the parent directory must exist on each node.

You do not need to specify a disk storage location during installation. However, you can do so by using the `--data-dir` parameter to the `install_vertica` script. See [Specifying Disk Storage Location During Installation](#)

See Also

- [Specifying Disk Storage Location on MC](#)
- [Specifying Disk Storage Location During Database Creation](#)
- [Configuring Disk Usage to Optimize Performance](#)
- [Using Shared Storage With Vertica](#)

Specifying Disk Storage Location During Installation

You can specify the disk storage location when you:

- Install Vertica (see below).
- [Create a database using the Administration Tools](#).
- [Install and configure Management Console](#).

Specifying Disk Storage Location When You Install

When you install Vertica, the `--data-dir` parameter in the `install_vertica` [script](#) lets you specify a directory to contain database data and catalog files. The script defaults to the database administrator's default home directory `/home/dbadmin`.

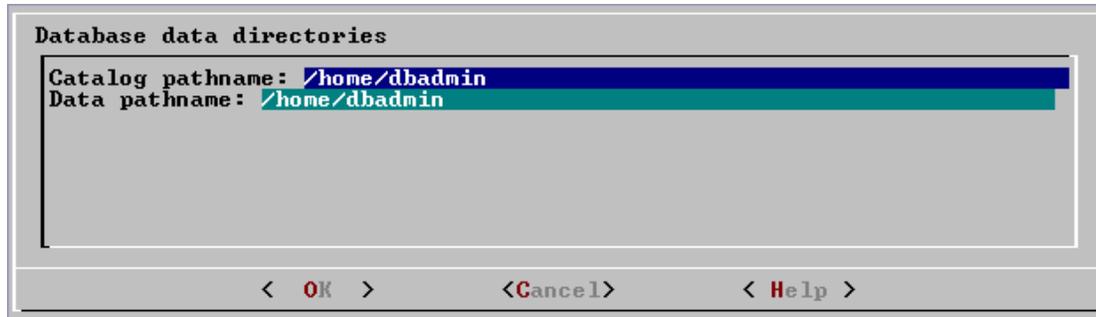

Important: Replace this default with a directory that has adequate space to hold your data and catalog files.

Requirements

- The data and catalog directory must exist on each node in the cluster.
- The directory on each node must be owned by the database administrator
- Catalog and data path names must contain only alphanumeric characters and cannot have leading space characters. Failure to comply with these restrictions will result in database creation failure.
- Vertica refuses to overwrite a directory if it appears to be in use by another database. Therefore, if you created a database for evaluation purposes, dropped the database, and want to reuse the database name, make sure that the disk storage location previously used has been completely cleaned up. See [Managing Storage Locations](#) for details.

Specifying Disk Storage Location During Database Creation

When you invoke the [Create Database](#) command in the Administration Tools, a dialog box allows you to specify the catalog and data locations. These locations must exist on each host in the cluster and must be owned by the database administrator.

When you click **OK**, Vertica automatically creates the following subdirectories:

```
catalog-pathname/database-name/node-name_catalog/data-pathname/database-name/node-name_data/
```

For example, if you use the default value (the database administrator's home directory) of `/home/dbadmin` for the Stock Exchange example database, the catalog and data directories are created on each node in the cluster as follows:

```
/home/dbadmin/Stock_Schema/stock_schema_node1_host01_catalog/home/dbadmin/Stock_Schema/stock_schema_node1_host01_data
```

Notes

- Catalog and data path names must contain only alphanumeric characters and cannot have leading space characters. Failure to comply with these restrictions will result in database creation failure.
- Vertica refuses to overwrite a directory if it appears to be in use by another database. Therefore, if you created a database for evaluation purposes, dropped the database, and want to reuse the database name, make sure that the disk storage location previously used has been completely cleaned up. See [Managing Storage Locations](#) for details.

Specifying Disk Storage Location on MC

You can use the MC interface to specify where you want to store database metadata on the cluster in the following ways:

- When you configure MC the first time
- When you create new databases using on MC

See [Configuring Management Console](#).

Configuring Disk Usage to Optimize Performance

Once you have created your initial storage location, you can add additional storage locations to the database later. Not only does this provide additional space, it lets you control disk usage and increase I/O performance by isolating files that have different I/O or access patterns. For example, consider:

- Isolating execution engine temporary files from data files by creating a separate storage location for temp space.
- Creating labeled storage locations and storage policies, in which selected database objects are stored on different storage locations based on measured performance statistics or predicted access patterns.

See [Managing Storage Locations](#) for details.

Using Shared Storage With Vertica

If using shared SAN storage, ensure there is no contention among the nodes for disk space or bandwidth.

- Each host must have its own catalog and data locations. Hosts cannot share catalog or data locations.
- Configure the storage so that there is enough I/O bandwidth for each node to access the storage independently.

Viewing Database Storage Information

You can view node-specific information on your Vertica cluster through the Management Console. See [Monitoring Using MC](#) for details.

Disk Space Requirements for Vertica

In addition to actual data stored in the database, Vertica requires disk space for several data reorganization operations, such as mergeout and [managing nodes](#) in the cluster. For best results, Micro Focus recommends that disk utilization per node be no more than sixty percent (60%) for a K-Safe=1 database to allow such operations to proceed.

In addition, disk space is temporarily required by certain query execution operators, such as hash joins and sorts, in the case when they cannot be completed in memory (RAM). Such operators might be encountered during queries, recovery, refreshing projections, and so on. The amount of disk space needed (known as temp space) depends on the nature of the queries, amount of data on the node and number of concurrent users on the system. By default, any unused disk space on the data disk can be used as temp space. However, Micro Focus recommends provisioning temp space separate from data disk space. See [Configuring Disk Usage to Optimize Performance](#).

Disk Space Requirements for Management Console

You can install Management Console on any node in the cluster, so it has no special disk requirements, other than disk space you allocate for your database cluster. See [Disk Space Requirements for Vertica](#).

Prepare the Logical Schema Script

Designing a logical schema for an Vertica database is no different from designing one for any other SQL database. Details are described more fully in [Designing a Logical Schema](#).

To create your logical schema, prepare a SQL script (plain text file, typically with an extension of .sql) that:

1. Creates additional schemas (as necessary). See [Using Multiple Schemas](#).
2. Creates the tables and column constraints in your database using the [CREATE TABLE](#) command.
3. Defines the necessary table constraints using the [ALTER TABLE](#) command.
4. Defines any views on the table using the [CREATE VIEW](#) command.

You can generate a script file using:

- A schema designer application.
- A schema extracted from an existing database.
- A text editor.
- One of the example database `example-name_define_schema.sql` scripts as a template. (See the example database directories in `/opt/vertica/examples`.)

In your script file, make sure that:

- Each statement ends with a semicolon.
- You use [data types](#) supported by Vertica, as described in the SQL Reference Manual.

Once you have created a database, you can test your schema script by executing it as described in [Create the Logical Schema](#). If you encounter errors, drop all tables, correct the errors, and run the script again.

Prepare Data Files

Prepare two sets of data files:

- Test data files. Use test files to test the database after the partial data load. If possible, use part of the actual data files to prepare the test data files.
- Actual data files. Once the database has been tested and optimized, use your data files for your initial [Bulk-Loading Data](#).

How to Name Data Files

Name each data file to match the corresponding table in the logical schema. Case does not matter.

Use the extension `.tbl` or whatever you prefer. For example, if a table is named `Stock_Dimension`, name the corresponding data file `stock_dimension.tbl`. When using multiple data files, append `_nnn` (where `nnn` is a positive integer in the range 001 to 999) to the file name. For example, `stock_dimension.tbl_001`, `stock_dimension.tbl_002`, and so on.

Prepare Load Scripts

Note: You can postpone this step if your goal is to test a logical schema design for validity.

Prepare SQL scripts to load data directly into physical storage using the [COPY...DIRECT](#) statement using `vsq`, or through ODBC as described in [Connecting to Vertica](#).

You need scripts that load the:

- Large tables
- Small tables

Micro Focus recommends that you load large tables using multiple files. To test the load process, use files of 10GB to 50GB in size. This size provides several advantages:

- You can use one of the data files as a sample data file for the Database Designer.
- You can load just enough data to [Perform a Partial Data Load](#) before you load the remainder.
- If a single load fails and rolls back, you do not lose an excessive amount of time.
- Once the load process is tested, for multi-terabyte tables, break up the full load in file sizes of 250–500GB.

See [Bulk-Loading Data](#) and the following additional topics for details:

- [Bulk-Loading Data](#)
- [Using Load Scripts](#)
- [Using Parallel Load Streams](#)
- [Enforcing Constraints](#)
- [About Load Errors](#)

Tip: You can use the load scripts included in the example databases in Getting Started as templates.

Create an Optional Sample Query Script

The purpose of a sample query script is to test your schema and load scripts for errors.

Include a sample of queries your users are likely to run against the database. If you don't have any real queries, just write simple SQL that collects counts on each of your tables. Alternatively, you can skip this step.

Create an Empty Database

Two options are available for creating an empty database:

- Using the Management Console
- Using Administration Tools

Although you can create more than one database (for example, one for production and one for testing), there can be only one active database for each installation of Vertica Analytics Platform.

Creating a Database Name and Password

Database Names

Database names must conform to the following rules:

- Be between 1-30 characters
- Begin with a letter
- Follow with any combination of letters (upper and lowercase), numbers, and/or underscores.

Database names are case sensitive; however, Micro Focus strongly recommends that you do not create databases with names that differ only in case. For example, do not create a database called `mydatabase` and another called `MyDataBase`.

Database Passwords

Database passwords can contain letters, digits, and special characters listed in the next table. Passwords cannot include non-ASCII Unicode characters.

The allowed password length is between 0-100 characters. The database superuser can change a Vertica user's maximum password length using [ALTER PROFILE](#).

You use [Profiles](#) to specify and control password definitions. For instance, a profile can define the maximum length, reuse time, and the minimum number or required digits for a password, as well as other details.

The following table lists special (ASCII) characters that Vertica permits in database passwords. Special characters can appear anywhere in a password string. For example, `mypas$word` or `$mypasswordare` all valid.

Caution: Using special characters outside of the ones listed below could cause database instability.

Character	Description
#	pound sign
!	exclamation point
+	plus sign
*	asterisk
?	question mark
,	comma
.	period
/	forward slash
=	equals sign
~	tilde
-	minus sign
\$	dollar sign
_	underscore
:	colon
	space
"	double quote
'	single quote
%	percent sign
&	ampersand

(parenthesis
)	parenthesis
;	semicolon
<	less than sign
>	greater than sign
@	at sign
`	back quote
[square bracket
]	square bracket
\	backslash
^	caret
	vertical bar
{	curly bracket
}	curly bracket

- [Password Guidelines](#)
- [ALTER PROFILE](#)
- [CREATE PROFILE](#)
- [DROP PROFILE](#)

Create an Empty Database Using MC

You can create a new database on an existing Vertica cluster through the Management Console interface.

Database creation can be a long-running process, lasting from minutes to hours, depending on the size of the target database. You can close the web browser during the process and sign

back in to MC later; the creation process continues unless an unexpected error occurs. See the **Notes** section below the procedure on this page.

You currently need to use command line scripts to define the database schema and load data. Refer to the topics in [Configuration Procedure](#). You should also run the Database Designer, which you access through the Administration Tools, to create either a comprehensive or incremental design. Consider using the [Tutorial](#) in Getting Started to create a sample database you can start monitoring immediately.

How to Create an Empty Database on an MC-managed Cluster

1. If you are already on the **Databases and Clusters** page, skip to the next step; otherwise:
 - a. [Connect](#) to MC and sign in as an MC administrator.
 - b. On the [Home page](#), click **Existing Infrastructure** to view the Databases and Clusters page.
2. If no databases exist on the cluster, continue to the next step; otherwise:
 - a. If a database is running on the cluster on which you want to add a new database, select the database and click **Stop**.
 - b. Wait for the running database to have a status of *Stopped*.
3. Click the cluster on which you want to create the new database and click **Create Database**.
4. The Create Database wizard opens. Provide the following information:
 - Database name and password. See [Creating a Database Name and Password](#) for rules.
 - Optionally click **Advanced** to open the advanced settings and change the port, catalog path, and data path. By default the MC application/web server port is 5450 and paths are `/home/dbadmin`, or whatever you defined for the paths when you ran the Cluster Creation Wizard or the `install_vertica` script. Do not use the default agent port 5444 as a new setting for the MC port. See **MC Settings > Configuration** for port values.
5. Click **Continue**.
6. Select nodes to include in the database.

The Database Configuration window opens with the options you provided and a graphical representation of the nodes appears on the page. By default, all nodes are selected to be part of this database (denoted by a green check mark). You can optionally click each node

and clear **Include host in new database** to exclude that node from the database. Excluded nodes are gray. If you change your mind, click the node and select the **Include** check box.

7. Click **Create** in the **Database Configuration** window to create the database on the nodes.

The creation process takes a few moments, after which the database starts and a **Success** message appears on the interface.

8. Click **OK** to close the success message.

The Manage page opens and displays the database nodes. Nodes not included in the database are colored gray, which means they are standby nodes you can include later. To add nodes to or remove nodes from your Vertica cluster, which are not shown in standby mode, you must run the `install_vertica` script.

Notes

- If warnings occur during database creation, nodes will be marked on the UI with an Alert icon and a message.
 - Warnings do not prevent the database from being created, but you should address warnings after the database creation process completes by viewing the database **Message Center** from the MC Home page.
 - Failure messages display on the database **Manage** page with a link to more detailed information and a hint with an actionable task that you must complete before you can continue. Problem nodes are colored red for quick identification.
 - To view more detailed information about a node in the cluster, double-click the node from the Manage page, which opens the **Node Details** page.
- To create MC users and grant them access to an MC-managed database, see [About MC Users](#) and [Creating an MC User](#).

See Also

- [Creating a Cluster Using MC](#)
- [Troubleshooting with MC Diagnostics](#)
- [Restarting MC](#)

Create a Database Using Administration Tools

1. Run the Administration Tools from your Administration Host as follows:

```
$ /opt/vertica/bin/admintools
```

If you are using a remote terminal application, such as PuTTY or a Cygwin bash shell, see [Notes for Remote Terminal Users](#).

2. Accept the license agreement and specify the location of your license file. For more information see [Managing Licenses](#) for more information.

This step is necessary only if it is the first time you have run the Administration Tools

3. On the Main Menu, click **Configuration Menu**, and click **OK**.
4. On the Configuration Menu, click **Create Database**, and click **OK**.
5. Enter the name of the database and an optional comment, and click **OK**. See [Creating a Database Name and Password](#) for naming guidelines and restrictions.
6. Establish the superuser password for your database.
 - To provide a password enter the password and click **OK**. Confirm the password by entering it again, and then click **OK**.
 - If you don't want to provide the password, leave it blank and click **OK**. If you don't set a password, Vertica prompts you to verify that you truly do not want to establish a superuser password for this database. Click **Yes** to create the database without a password or **No** to establish the password.

Caution: If you do not enter a password at this point, the superuser password is set to empty. Unless the database is for evaluation or academic purposes, Micro Focus strongly recommends that you enter a superuser password. See [Creating a Database Name and Password](#) for guidelines.

7. Select the hosts to include in the database from the list of hosts specified when Vertica was installed (`install_vertica -s`), and click **OK**.
8. Specify the directories in which to store the data and catalog files, and click **OK**.

Note: Do not use a shared directory for more than one node. Data and catalog directories must be distinct for each node. Multiple nodes must not be allowed to write to the same data or catalog directory.

9. Catalog and data path names must contain only alphanumeric characters and cannot have leading spaces. Failure to comply with these restrictions results in database creation failure.

For example:

Catalog pathname: /home/dbadmin

Data Pathname: /home/dbadmin

10. Review the **Current Database Definition** screen to verify that it represents the database you want to create, and then click **Yes** to proceed or **No** to modify the database definition.
11. If you click **Yes**, Vertica creates the database you defined and then displays a message to indicate that the database was successfully created.

Note: : For databases created with 3 or more nodes, Vertica automatically sets K-safety to 1 to ensure that the database is fault tolerant in case a node fails. For more information, see [Failure Recovery](#) in the Administrator's Guide and [MARK_DESIGN_KSAFE](#)

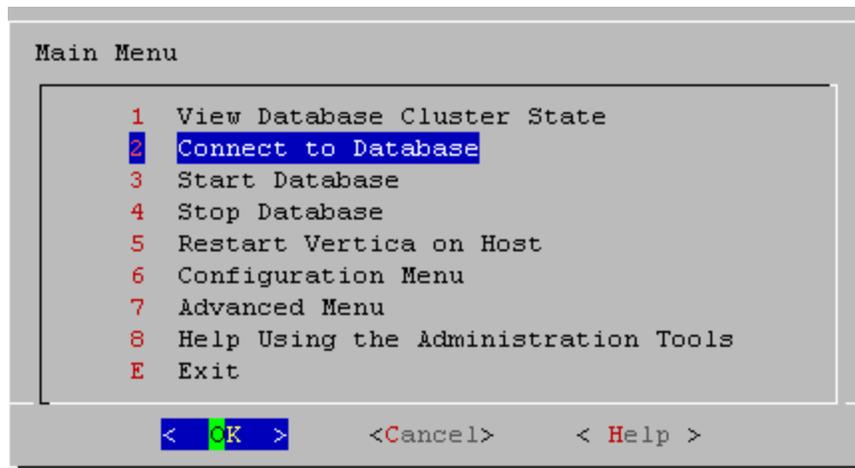

12. Click **OK** to acknowledge the message.

Create the Logical Schema

1. **Connect to the database.**

In the Administration Tools Main Menu, click **Connect to Database** and click **OK**.

See [Connecting to the Database](#) for details.

The vsql welcome script appears:

```
Welcome to vsql, the Vertica Analytic Database interactive terminal.
Type: \h or \? for help with vsql commands
      \g or terminate with semicolon to execute query
      \q to quit

=>
```

2. Run the logical schema script

Using the [\i meta-command](#) in vsql to run the SQL [logical schema script](#) that you prepared earlier.

3. Disconnect from the database

Use the [\q meta-command](#) in vsql to return to the Administration Tools.

Perform a Partial Data Load

Micro Focus recommends that for large tables, you perform a partial data load and then test your database before completing a full data load. This load should load a representative amount of data.

1. Load the small tables.

Load the small table data files using the SQL [load scripts](#) and [data files](#) you prepared earlier.

2. Partially load the large tables.

Load 10GB to 50GB of table data for each table using the SQL [load scripts](#) and [data files](#) that you prepared earlier.

For more information about projections, see [Physical Schema](#) in Vertica Concepts.

Test the Database

Test the database to verify that it is running as expected.

Check queries for syntax errors and execution times.

1. Use the vsql [\timing meta-command](#) to enable the display of query execution time in milliseconds.
2. Execute the SQL sample query script that you prepared earlier.
3. Execute several ad hoc queries.

Optimize Query Performance

Optimizing the database consists of optimizing for compression and tuning for queries. (See [Creating a Database Design](#).)

To optimize the database, use the Database Designer to create and deploy a design for optimizing the database. See the [Tutorial](#) in Getting Started for an example of using the Database Designer to create a Comprehensive Design.

After you have run the Database Designer, use the techniques described in [Query Optimization](#) in Analyzing Data to improve the performance of certain types of queries.

Note: The database response time depends on factors such as type and size of the application query, database design, data size and data types stored, available computational power, and network bandwidth. Adding nodes to a database cluster does not necessarily improve the system response time for every query, especially if the response time is already short, e.g., less than 10 seconds, or the response time is not hardware bound.

Complete the Data Load

To complete the load:

1. Monitor system resource usage.

Continue to run the `top`, `free`, and `df` utilities and watch them while your load scripts are running (as described in [Monitoring Linux Resource Usage](#)). You can do this on any or all nodes in the cluster. Make sure that the system is not swapping excessively (watch `kswapd` in `top`) or running out of swap space (watch for a large amount of used swap space in `free`).

Note: Vertica requires a dedicated server. If your loader or other processes take up significant amounts of RAM, it can result in swapping.

2. Complete the large table loads.

Run the remainder of the large table load scripts.

Test the Optimized Database

Check query execution times to test your optimized design:

1. Use the `vsql \timing` meta-command to enable the display of query execution time in milliseconds.

Execute a SQL sample query script to test your schema and load scripts for errors.

Note: Include a sample of queries your users are likely to run against the database. If you don't have any real queries, just write simple SQL that collects counts on each of your tables. Alternatively, you can skip this step.

2. Execute several ad hoc queries

- a. Run Administration Tools and select [Connect to Database](#).
- b. Use the `\i` meta-command to execute the query script; for example:

```
vmartdb=> \i vmart_query_03.sql customer_name | annual_income
-----+-----
James M. McNulty |          999979
Emily G. Vogel   |          999998
(2 rows)
Time: First fetch (2 rows): 58.411 ms. All rows formatted: 58.448 ms
vmartdb=> \i vmart_query_06.sql
store_key | order_number | date_ordered
-----+-----
```

```
45 | 202416 | 2004-01-04
113 | 66017 | 2004-01-04
121 | 251417 | 2004-01-04
24 | 250295 | 2004-01-04
9 | 188567 | 2004-01-04
166 | 36008 | 2004-01-04
27 | 150241 | 2004-01-04
148 | 182207 | 2004-01-04
198 | 75716 | 2004-01-04
(9 rows)
Time: First fetch (9 rows): 25.342 ms. All rows formatted: 25.383 ms
```

Once the database is optimized, it should run queries efficiently. If you discover queries that you want to optimize, you can modify and update the design. See [Incremental Design](#) in the Administrator's Guide.

Set Up Incremental (Trickle) Loads

Once you have a working database, you can use trickle loading to load new data while concurrent queries are running.

Trickle load is accomplished by using the COPY command (without the DIRECT keyword) to load 10,000 to 100,000 rows per transaction into the WOS. This allows Vertica to batch multiple loads when it writes data to disk. While the COPY command defaults to loading into the WOS, it will write ROS if the WOS is full.

See [Trickle Loading Data](#) for details.

- [COPY](#)
- [Loading Data Through ODBC](#)

Implement Locales for International Data Sets

Locale specifies the user's language, country, and any special variant preferences, such as collation. Vertica uses locale to determine the behavior of certain string functions. Locale also determines the collation for various SQL commands that require ordering and comparison, such as aggregate `GROUP BY` and `ORDER BY` clauses, joins, and the analytic `ORDER BY` clause.

The default locale for a Vertica database is `en_US@collation=binary` (English US). You can define a new default locale that is used for all sessions on the database. You can also override the locale for individual sessions. However, projections are always collated using the default `en_US@collation=binary` collation, regardless of the session collation. Any locale-specific collation is applied at query time.

If you set the locale to null, Vertica sets the locale to `en_US_POSIX`. You can set the locale back to the default locale and collation by issuing the `vsql` meta-command `\locale`. For example:

```
=> set locale to '';
INFO 2567: Canonical locale: 'en_US_POSIX'
Standard collation: 'LEN'
English (United States, Computer)
SET
=> \locale en_US@collation=binary;
INFO 2567: Canonical locale: 'en_US'
Standard collation: 'LEN_KBINARY'
English (United States)
=> \locale
en_US@collation=binary;
```

You can set locale through [ODBC](#), [JDBC](#), and [ADO.net](#).

ICU Locale Support

Vertica uses the ICU library for locale support; you must specify locale using the ICU locale syntax. The locale used by the database session is not derived from the operating system (through the `LANG` variable), so Micro Focus recommends that you set the `LANG` for each node running `vsql`, as described in the next section.

While ICU library services can specify collation, currency, and calendar preferences, Vertica supports only the collation component. Any keywords not relating to collation are rejected. Projections are always collated using the `en_US@collation=binary` collation regardless of the session collation. Any locale-specific collation is applied at query time.

The `SET DATESTYLE TO . . .` command provides some aspects of the calendar, but Vertica supports only dollars as currency.

Changing DB Locale for a Session

This examples sets the session locale to Thai.

1. At the operating-system level for each node running `vsq`, set the `LANG` variable to the locale language as follows:

```
export LANG=th_TH.UTF-8
```

Note: If setting the `LANG=` as shown does not work, the operating system support for locales may not be installed.

2. For each Vertica session (from ODBC/JDBC or `vsq`) set the language locale.

From `vsq`:

```
\locale th_TH
```

3. From ODBC/JDBC:

```
"SET LOCALE TO th_TH;"
```

4. In PUTTY (or ssh terminal), change the settings as follows:

```
settings > window > translation > UTF-8
```

5. Click **Apply** and then click **Save**.

All data loaded must be in UTF-8 format, not an ISO format, as described in [Loading UTF-8 Format Data](#). Character sets like ISO 8859-1 (Latin1), which are incompatible with UTF-8, are not supported, so functions like `SUBSTRING` do not work correctly for multibyte characters. Thus, settings for locale should *not* work correctly. If the translation setting `ISO-8859-11:2001` (Latin/Thai) works, the data is loaded incorrectly. To convert data correctly, use a utility program such as Linux [iconv](#).

Note: The maximum length parameter for `VARCHAR` and `CHAR` data type refers to the number of octets (bytes) that can be stored in that field, not the number of characters. When using multi-byte UTF-8 characters, make sure to size fields to accommodate from 1

to 4 bytes per character, depending on the data.

- [Supported Locales](#)
- [About Locale](#)
- [SET LOCALE](#)
- [ICU User Guide](#)

Specify the Default Locale for the Database

After you start the database, the default locale configuration parameter, `DefaultSessionLocale`, sets the initial locale. You can override this value for individual sessions.

To set the locale for the database, use the configuration parameter as follows:

```
=> ALTER DATABASE mydb SET DefaultSessionLocale = 'ICU-Locale-identifier';
```

For example:

```
=> ALTER DATABASE mydb SET DefaultSessionLocale = 'en_GB';
```

Override the Default Locale for a Session

To override the default locale for a specific session, use one of the following commands:

- The `vsq` command

```
\locale <ICU-Locale-identifier>;
```

For example:

```
=> \locale en_GBINFO:  
INFO 2567: Canonical locale: 'en_GB'  
Standard collation: 'LEN'  
English (United Kingdom)
```

- The statement `SET LOCALE TO <ICU-locale-identifier>`.

```
=> SET LOCALE TO en_GB;  
INFO 2567: Canonical locale: 'en_GB'  
Standard collation: 'LEN'  
English (United Kingdom)
```

You can also use the [Specifying Locale: Short Form](#) of a locale in either of these commands:

```
=> SET LOCALE TO LEN;  
INFO 2567: Canonical locale: 'en'  
Standard collation: 'LEN'  
English
```

```
=> \locale LEN  
INFO 2567: Canonical locale: 'en'  
Standard collation: 'LEN'  
English
```

You can use these commands to override the locale as many times as needed during a database session. The session locale setting applies to any subsequent commands issued in the session.

- [SET LOCALE](#)

Server versus Client Locale Settings

Vertica differentiates database server locale settings from client application locale settings:

- Server locale settings only impact collation behavior for server-side query processing.
- Client applications verify that locale is set appropriately in order to display characters correctly.

The following sections describe best practices to ensure predictable results.

Server Locale

The server session locale should be set as described in [Specify the Default Locale for the Database](#). If locales vary across different sessions, set the server locale at the start of each session from your client.

vsqI Client

- If the database does not have a default session locale, [set the server locale for the session to the desired locale](#).
- The locale setting in the terminal emulator where the vsqI client runs should be set to be equivalent to session locale setting on the server side (ICU locale). By doing so, the data is collated correctly on the server and displayed correctly on the client.
- All input data for vsqI should be in UTF-8, and all output data is encoded in UTF-8
- Vertica does not support non UTF-8 encodings and associated locale values; .
- For instructions on setting locale and encoding, refer to your terminal emulator documentation.

ODBC Clients

- ODBC applications can be either in ANSI or Unicode mode. If the user application is Unicode, the encoding used by ODBC is UCS-2. If the user application is ANSI, the data must be in single-byte ASCII, which is compatible with UTF-8 used on the database server. The ODBC driver converts UCS-2 to UTF-8 when passing to the Vertica server and converts data sent by the Vertica server from UTF-8 to UCS-2.
- If the user application is not already in UCS-2, the application must convert the input data to UCS-2, or unexpected results could occur. For example:
 - For non-UCS-2 data passed to ODBC APIs, when it is interpreted as UCS-2, it could result in an invalid UCS-2 symbol being passed to the APIs, resulting in errors.
 - The symbol provided in the alternate encoding could be a valid UCS-2 symbol. If this occurs, incorrect data is inserted into the database.
- If the database does not have a default session locale, ODBC applications should set the desired server session locale using `SQLSetConnectAttr` (if different from database wide setting). By doing so, you get the expected collation and string functions behavior on the server.

JDBC and ADO.NET Clients

- JDBC and ADO.NET applications use a UTF-16 character set encoding and are responsible for converting any non-UTF-16 encoded data to UTF-16. The same cautions apply as for ODBC if this encoding is violated.
- The JDBC and ADO.NET drivers convert UTF-16 data to UTF-8 when passing to the Vertica server and convert data sent by Vertica server from UTF-8 to UTF-16.
- If there is no default session locale at the database level, JDBC and ADO.NET applications should set the correct server session locale by executing the [SET LOCALE TO](#) command in order to get the expected collation and string functions behavior on the server. For more information, see [SET LOCALE](#).

Change Transaction Isolation Levels

By default, Vertica uses the `READ COMMITTED` isolation level for all sessions. You can change the default isolation level for the database or for a given session.

A transaction retains its isolation level until it completes, even if the session's isolation level changes during the transaction. Vertica internal processes (such as the Tuple Mover and refresh operations) and DDL operations always run at the `SERIALIZABLE` isolation level to ensure consistency.

Database Isolation Level

The configuration parameter [TransactionIsolationLevel](#) specifies the database isolation level, and is used as the default for all sessions. Use [ALTER DATABASE](#) to change the default isolation level. For example:

```
=> ALTER DATABASE mydb SET TransactionIsolationLevel = 'SERIALIZABLE';  
ALTER DATABASE  
=> ALTER DATABASE mydb SET TransactionIsolationLevel = 'READ COMMITTED';  
ALTER DATABASE
```

Changes to the database isolation level only apply to future sessions. Existing sessions and their transactions continue to use their original isolation level.

Use [SHOW CURRENT](#) to view the database isolation level:

```
=> SHOW CURRENT TransactionIsolationLevel;  
level | name | setting
```

```
-----+-----+-----  
DATABASE | TransactionIsolationLevel | READ COMMITTED  
(1 row)
```

Session Isolation Level

[SET SESSION CHARACTERISTICS AS TRANSACTION](#) changes the isolation level for a specific session. For example:

```
=> SET SESSION CHARACTERISTICS AS TRANSACTION ISOLATION LEVEL SERIALIZABLE;  
SET
```

Use [SHOW](#) to view the current session's isolation level:

```
=> SHOW TRANSACTION_ISOLATION;
```

See Also

[Transactions](#)

Configuration Parameters

Configuration parameters are settings that affect database behavior. You can use configuration parameters to enable, disable, or tune features related to different database aspects like Tuple Mover, security, Database Designer, or projections. Configuration parameters have default values, stored in the Vertica database.

You can modify certain parameters to configure your Vertica database in two ways:

- Management Console [browser-based interface](#)
- [VSQL statements](#)

Before you modify a database parameter, review all documentation about the parameter to determine the context under which you can change it. Some parameter changes require a database restart to take effect. The `CHANGE_REQUIRES_RESTART` column in the system table [CONFIGURATION_PARAMETERS](#) indicates whether a parameter requires a restart.

Managing Configuration Parameters: Management Console

To change database settings for any MC-managed database, click the **Settings** tab at the bottom of the Overview, Activity, or Manage pages. The database must be running.

The Settings page defaults to parameters in the General category. To change other parameters, click an option from the tab panel on the left.

		Current value	Default value
Tuple mover	Analyze row count interval	60 seconds	60
Epoch mgmt	Compress network data	false	false
Monitoring	Maximum client sessions	50	50
Password	Transaction isolation level	READ COMMITTED	READ COMMITTED
Profiling	Transaction mode	READ WRITE	READ WRITE
Snapshot			
I18N			
License			

Some settings require you to restart the database, and MC prompts you to do so. You can ignore the prompt, but those changes take effect only after the database restarts.

Some settings are specific to Management Console, such as changing MC or agent port assignments. For more information, see [Managing MC Settings](#) in Using Management Console.

Managing Configuration Parameters: VSQL

You can configure all parameters at database scope. Some parameters can also be set and cleared at node and session scopes.

Caution: Vertica is designed to operate with minimal configuration changes. Be careful to set and change configuration parameters according to documented guidelines.

For detailed information about managing configuration parameters, see:

- [Viewing Configuration Parameter Values](#)
- [Setting Configuration Parameter Values](#)
- [Clearing Configuration Parameters](#)

Viewing Configuration Parameter Values

You can view active configuration parameter values in two ways:

- [SHOW statements](#)
- [Query related system tables](#)

SHOW Statements

Use the following SHOW statements to view active configuration parameters:

- **SHOW CURRENT**: Returns settings of active configuration parameter values. Vertica checks settings at all levels, in the following ascending order of precedence:
 - session
 - node
 - database

If no values are set at any scope, SHOW CURRENT returns the parameter's default value.

- **SHOW DATABASE**: Displays configuration parameter values set for the database.
- **SHOW SESSION**: Displays configuration parameter values set for the current session.
- **SHOW NODE**: Displays configuration parameter values set for a node.

If a configuration parameter requires a restart to take effect, the values in a SHOW CURRENT statement might differ from values in other SHOW statements. To see which parameters require restart, query the [CONFIGURATION_PARAMETERS](#) system table.

System Tables

You can query two system tables for configuration parameters:

- [SESSION_PARAMETERS](#) returns session-scope parameters.
- [CONFIGURATION_PARAMETERS](#) returns parameters for all scopes: database, node, and session.

Setting Configuration Parameter Values

You can set configuration parameters at three scopes:

- Database
- Node
- Session

Database Scope

You can set one or more parameter values at the database scope with [ALTER DATABASE . .SET](#):

```
ALTER DATABASE dbname SET parameter-name = value[,...];
```

For example:

```
ALTER DATABASE mydb SET AnalyzeRowCountInterval = 3600, FailoverToStandbyAfter = '5 minutes';
```

Node Scope

You can set one or more parameter values at the node scope with [ALTER NODE . .SET](#):

```
ALTER NODE node-name SET parameter-name = value[,...];
```

For example, to prevent clients from connecting to `v_vmart_node0001`, set the `MaxClientSessions` configuration parameter to `0`:

```
=> ALTER NODE v_vmart_node0001 SET MaxClientSessions = 0;
```

Session Scope

You can set one or more parameter values at the session scope with [ALTER SESSION . .SET](#):

```
ALTER SESSION SET parameter-name = value[,...];
```

For example:

```
=> ALTER SESSION SET ForceUDxFencedMode = 1;
```

Clearing Configuration Parameters

You can clear configuration parameter settings at three scopes:

- Database
- Node
- Session

Database Scope

ALTER DATABASE . . CLEAR clears one or more parameter values at the database scope, and resets them to their default values as follows:

```
ALTER DATABASE dbname CLEAR parameter-name[, ...];
```

For example:

```
ALTER DATABASE mydb CLEAR AnalyzeRowCountInterval, FailoverToStandbyAfter;
```

Node Scope

ALTER NODE . . CLEAR clears one or more parameter values at the node scope, and resets them to their database settings, if any. If the parameters are not set at the database scope, Vertica resets them to their default value.

```
ALTER NODE node-name CLEAR parameter-name[, ...];
```

The following example clears MaxClientSessions on node v_vmart_node0001:

```
ALTER NODE v_vmart_node0001 CLEAR MaxClientSessions;
```

Session Scope

ALTER SESSION . . CLEAR clears one or more parameter values at the session scope, and resets them to their node or database settings, if any. If the parameters are not set at either scope, Vertica resets them to their default value.

```
ALTER SESSION CLEAR parameter-name[, ...];
```

For example:

```
=> ALTER SESSION CLEAR ForceUDxFencedMode;
```

Configuration Parameter Categories

Vertica configuration parameters are grouped into the following categories:

[General Parameters](#)

[Tuple Mover Parameters](#)

[Projection Parameters](#)

[Epoch Management Parameters](#)

[Monitoring Parameters](#)

[Profiling Parameters](#)

[Security Parameters](#)

[Database Designer Parameters](#)

[Internationalization Parameters](#)

[Data Collector Parameters](#)

[Text Search Parameters](#)

[Kerberos Authentication Parameters](#)

[Hadoop Parameters](#)

[User-Defined Session Parameters](#)

[Constraint Enforcement Parameters](#)

General Parameters

You use these general parameters to configure Vertica.

Parameter	Description
AnalyzeRowCountInterval	Specifies how often Vertica checks the number of projection rows and whether the threshold set by ARCCommitPercentage has been crossed. For more information, see Collecting Statistics .

Parameter	Description
	<p>Default Value: 60 seconds</p>
<p>ApplyEventsDuringSALCheck</p>	<p>When enabled, Vertica uses catalog events to filter out dropped corrupt partitions during node startup. Dropping corrupt partitions can speed node recovery.</p> <p>When disabled, Vertica reports corrupt partitions, but takes no action. Leaving corrupt partitions in place can reset the current projection checkpoint epoch to the epoch before the corruption occurred.</p> <p>This parameter has no effect on unpartitioned tables.</p> <p>Default Value: 0</p>
<p>ApportionedFileMinimumPortionsSizeKB</p>	<p>Specifies the minimum portion size (in kilobytes) for use with apportioned file loads. Vertica apports a file load across multiple nodes only if:</p> <ul style="list-style-type: none"> • The load can be divided into portions at least equaling this value. • EnableApportionedFileLoad and EnableApportionLoad are set to 1 (enabled). <p>See also EnableApportionLoad and EnableApportionedFileLoad.</p> <p>Default Value: 1024</p>
<p>ARCCommitPercentage</p>	<p>Sets the threshold percentage of WOS to ROS rows, which determines when to aggregate projection row counts and commit the result to the catalog. Vertica performs this action when the WOS to ROS percentage exceeds this setting.</p> <p>Default Value: 3 (percent)</p>

Parameter	Description
BlockedSocketGracePeriod	<p>Sets how long a session socket remains blocked while awaiting client input or output for a given query.</p> <p>Default Value: None (Socket blocking can continue indefinitely.)</p> <p>See Handling Session Socket Blocking.</p>
CatalogCheckpointPercent	<p>Specifies the threshold at which a checkpoint is created for the database catalog.</p> <p>By default, this parameter is set to 50 (percent), so when transaction logs reach 50% of the size of the last checkpoint, Vertica adds a checkpoint. Each checkpoint demarcates all changes to the catalog since the last checkpoint.</p> <p>Default Value: 50 (percent)</p>
ClusterSequenceCacheMode	<p>Indicates whether the initiator node requests cache for other nodes in a cluster, and then sends cache to other nodes along with the execution plan. Enabled by default. When disabled, all nodes request their own cache.</p> <p>Default Value: 1 (enabled)</p> <p>Valid Values:</p> <ul style="list-style-type: none">• 1: Initiator node requests cache.• 0: All nodes request their own cache. <p>See Distributing Named Sequences.</p>
CompressCatalogOnDisk	<p>Compresses the size of the catalog on disk when enabled (value set to 1 or 2).</p> <p>Default Value: 1</p> <p>Valid Values:</p>

Parameter	Description
	<ul style="list-style-type: none"> • 0: No compression. • 1: Compress checkpoints and system transaction logs. • 2: Compress checkpoints and all transaction logs. <p>Consider enabling this parameter if the catalog disk partition is small (<50 GB) and the metadata is large (hundreds of tables, partitions, or nodes).</p>
CompressNetworkData	<p>Compresses all data sent over the internal network when enabled (value set to 1). This compression speeds up network traffic at the expense of added CPU load. If the network is throttling database performance, enable compression to correct the issue.</p> <p>Default Value: 0</p>
CopyFromVerticaWithIdentity	<p>Allows COPY FROM VERTICA and EXPORT TO VERTICA to load values into Identity (or Auto-increment) columns. The destination Identity column is not incremented automatically. To disable the default behavior, set this parameter to 0 (zero).</p> <p>Default Value: 1</p>
DatabaseHeartBeatInterval	<p>Determines the interval (in seconds) at which each node performs a health check and communicates a heartbeat. If a node does not receive a message within five times of the specified interval, the node is evicted from the cluster. Setting the interval to 0 disables the feature.</p> <p>Default Value: 120</p>

Parameter	Description
	See Automatic Eviction of Unhealthy Nodes .
DivideZeroByZeroThrowsError	<p>If set to 1, returns an error if a division by zero operation is requested. Otherwise, returns 0 as the result of a division by zero operation.</p> <p>Default Value: 1</p>
EnableApportionedChunkingInDefaultLoadParser	<p>Enables the built-in parser for delimited files to take advantage of both apportioned load and cooperative parse for potentially better performance.</p> <p>Default Value: 1</p>
EnableApportionedFileLoad	<p>Enables automatic apportioning across nodes of file loads using COPY FROM. Vertica attempts to apportion the load if:</p> <ul style="list-style-type: none"> • This parameter and EnableApportionLoad are both enabled. • The parser supports apportioning. • The load is divisible into portion sizes of at least the value of ApportionedFileMinimumPortionSizeKB. <p>Setting this parameter does not guarantee that loads will be apportioned, but disabling it guarantees that they will not be.</p> <p>Default Value: 1</p> <p>See Using Parallel Load Streams.</p>
EnableApportionLoad	Enables automatic apportioning across

Parameter	Description
	<p>nodes of data loads using COPY WITH SOURCE. Vertica attempts to apportion the load if:</p> <ul style="list-style-type: none"> • This parameter is enabled. • The source and parser both support apportioning. <p>Setting this parameter does not guarantee that loads will be apportioned, but disabling it guarantees that they will not be.</p> <p>Default Value: 1</p> <p>See Using Parallel Load Streams.</p>
<p>EnableBetterFlexTypeGuessing</p>	<p>Enables more accurate type guessing when assigning data types to non-string keys in a flex table <code>__raw__</code> column with <code>COMPUTE_FLEXTABLE_KEYS</code> or <code>COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW</code>. This option is on by default. Turning this option off uses a limited set of Vertica data type assignments.</p> <p>Default Value: 1</p> <p>See Setting Flex Table Configuration Parameters.</p>
<p>EnableCooperativeParse</p>	<p>Implements multi-threaded parsing capabilities on a node. You can use this parameter for both delimited and fixed-width loads. Enabled by default.</p> <p>Default Value: 1</p>
<p>EnableDataTargetParallelism</p>	<p>Enables multiple threads for sorting and writing data to ROS, improving data loading performance. Enabled by default.</p> <p>Default Value: 1</p>

Parameter	Description
EnableForceOuter	<p>Determines whether Vertica uses a table's <code>force_outer</code> value to implement a join. For more information, see Controlling Join Inputs.</p> <p>Default Value: 0 (forced join inputs disabled)</p>
EnableMetadataMemoryTracking	<p>Enables Vertica to track memory used by database metadata in the METADATA resource pool.</p> <div data-bbox="857 714 1404 1365" style="background-color: #f0f0f0; padding: 10px;"> <p>Note: You may notice a performance degradation when loading data in 8.0 SP1 and later for some COPY statements, typically for loads with a large number of columns and large catalogs, in comparison with Vertica 8.0. This degradation occurs because the number of threads used to load the data is computed based on the available memory in the General Pool. Tracking the catalog size separately in the new METADATA resource pool can reduce amount of memory available in the General Pool and can affect this thread calculation.</p> </div> <p>Default Value: 1</p>
EnableResourcePoolCPUAffinity	<p>Aligns queries to the resource pool of the processing CPU. When disabled (value is set to 0), queries run on any CPU, regardless of the <code>CPU_AFFINITY_SET</code> of the resource pool. Enabled by default.</p> <p>Default Value: 1</p>
EnableStorageBundling	<p>Enables storing multiple ROS containers as a single file. Each ROS must be less than the size specified in</p>

Parameter	Description
	<p>MaxBundleableROSSizeKB. In environments with many small storage files, bundling improves the performance of any file-intensive operations, including backups, restores, mergeouts and moveouts.</p> <p>Default Value: 1</p>
<p>EnableUniquenessOptimization</p>	<p>Enables query optimization that is based on guaranteed uniqueness of column values. Columns that can be guaranteed to include unique values include:</p> <ul style="list-style-type: none"> • Columns that are defined with AUTO_INCREMENT or IDENTITY constraints • Primary key columns where key constraints are enforced • Columns that are constrained to unique values, either individually or as a set <p>Default Value: 1 (enabled)</p>
<p>EnableWithClauseMaterialization</p>	<p>Enables materialization of WITH clause results. When materialization is enabled, Vertica evaluates each WITH clause once and stores results in a temporary table. This parameter can only be set at session level.</p> <p>Default Value: 0 (disabled)</p> <p>See WITH Clauses in SELECT in Analyzing Data.</p>
<p>ExternalTablesExceptionsLimit</p>	<p>Determines the maximum number of COPY exceptions and rejections allowed when a SELECT statement references an external table. Set to -1 to remove any exceptions limit. See Validating External</p>

Parameter	Description
	<p>Tables.</p> <p>Default Value: 100</p>
FailoverToStandbyAfter	<p>Specifies the length of time that an active standby node waits before taking the place of a failed node.</p> <p>This parameter is set to an interval literal.</p> <p>Default Value: None</p>
FencedUDxMemoryLimitMB	<p>Sets the maximum amount of memory, in megabytes (MB), that a fenced-mode UDF can use. If a UDF attempts to allocate more memory than this limit, that attempt triggers an exception. For more information, see Fenced Mode in Extending Vertica.</p> <p>Default Value: -1 (no limit)</p>
FlexTableDataTypeGuessMultiplier	<p>Specifies a multiplier that the COMPUTE_FLEXTABLE_KEYS and COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW functions use when assigning a data type and column width for the flex keys table. Both functions assign each key a data type, and multiply the longest key value by this factor to estimate column width.</p> <p>Default Value: 2.0: The column width multiplier. Must be a value in the following range:</p> <p>Any value that results in a column width neither less than 20 bytes nor greater than FlexTableRawSize. This range is a cap to round sizes up or down, accordingly.</p> <p>See Setting Flex Table Configuration Parameters.</p>

Parameter	Description
FlexTableRowSize	<p>Specifies the default column width for the <code>__raw__</code> column of new flex tables.</p> <p>Default Value: 130000</p> <p>Value range: 1 – 32000000</p>
JavaBinaryForUDx	<p>Sets the full path to the Java executable that Vertica uses to run Java UDxs. See Installing Java on Vertica Hosts in <i>Extending Vertica</i>.</p>
JavaClassPathForUDx	<p>Sets the Java classpath for the JVM that executes Java UDxs. This parameter must list all directories containing JAR files that Java UDxs import.</p> <p>Default Value:</p> <p><code>\${vertica_home}/packages/hcat/lib/*</code></p> <p>See Handling Java UDx Dependencies in <i>Extending Vertica</i>.</p>
MaxAutoSegColumns	<p>Specifies the number of columns (0–1024) to segment automatically when creating auto-projections from COPY and INSERT INTO statements. Setting this parameter to zero (0) uses all columns in the hash segmentation expression.</p> <p>Default Value: 32</p>
MaxBundleableROSSizeKB	<p>Specifies the minimum size, in kilobytes, of an independent ROS file. When <code>EnableStorageBundling</code> is true, Vertica bundles storage container ROS files below this size into a single file. Bundling improves the performance of any file-intensive operations, including backups, restores, mergeouts and moveouts.</p> <p>If you enable storage bundling and specify this parameter with a value of 0, Vertica bundles <code>.fdb</code> and <code>.pidx</code> files without</p>

Parameter	Description
	<p>bundling other storage container files.</p> <p>Default Value: 1024</p>
MaxClientSessions	<p>Determines the maximum number of client sessions that can run on a single node of the database. The default value allows for five additional administrative logins. These logins prevent DBAs from being locked out of the system if non-dbadmin users reach the login limit.</p> <div data-bbox="857 716 1403 1031" style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p>Tip: Setting this parameter to 0 prevents new client sessions from being opened while you are shutting down the database. Restore the parameter to its original setting after you restart the database. For details, see Managing Sessions.</p> </div> <p>Default Value: 50 user logins and 5 additional administrative logins</p>
MaxTieredPoolScale	<p>Specifies the threshold for allocating chunks of memory from the system or dedicated pools for Vertica system components—for example, for WOS containers. Above this threshold, Vertica allocates memory from the system (malloc), and returns it when no longer needed. Below this threshold, Vertica allocates memory from dedicated pools (talloc), which manage smaller memory allocations more efficiently.</p> <p>Tiered memory management facilitates more efficient use of resources, and minimizes the risk of any one process (such as the database catalog) from preemptively allocating and retaining excessive amounts of memory.</p>

Parameter	Description
	<p>Set this parameter to the desired power of 2, any value ≥ 20. For example, for 128 MB, set the parameter to 27 (2^{27}).</p> <p>This parameter cannot be set below 20 (1MB). Any allocation that is less than 20 always uses talloc, regardless of this parameter setting. This parameter must be set at the database level, and takes effect only on database restart.</p> <p>Default Value: 27 (128 MB)</p>
PatternMatchAllocator	<p>Overrides the heap memory allocator for the pattern-match library when set to 1. The Perl Compatible Regular Expressions (PCRE) pattern-match library evaluates regular expressions. Restart the database for this parameter to take effect.</p> <p>Default Value: 0</p> <p>See Regular Expression Functions.</p>
PatternMatchingUseJit	<p>Enables just-in-time compilation (to machine code) of regular expression pattern matching functions used in queries. Using this parameter can usually improve pattern matching performance on large tables. The Perl Compatible Regular Expressions (PCRE) pattern-match library evaluates regular expressions. Restart the database for this parameter to take effect.</p> <p>Default Value: 1</p> <p>See Regular Expression Functions.</p>
PcreJitStackSizeScaleFactor	<p>Determines the maximum size of the Perl Compatible Regular Expressions (PCRE) just-in-time stack. The maximum stack size will be $\text{PcreJitStackSizeScaleFactor} * 1024 * 1024$ bytes.</p>

Parameter	Description
	<p>Default Value: 32</p>
<p>PatternMatchStackAllocator</p>	<p>Overrides the stack memory allocator for the pattern-match library when set to 1. The Perl Compatible Regular Expressions (PCRE) pattern-match library evaluates regular expressions. Restart the database for this parameter to take effect.</p> <p>Default Value: 1</p> <p>See Regular Expression Functions.</p>
<p>SegmentAutoProjection</p>	<p>Determines whether auto-projections are segmented by default. Set to 0 to disable.</p> <p>Default Value: 1</p>
<p>TerraceRoutingFactor</p>	<p>Specifies a value large enough that it cannot be enabled by default, even for the largest clusters. Use the Terrace Routing equation to find the appropriate value for your cluster.</p> <p>Default Value: 1000.0</p> <p>See Terrace Routing.</p>
<p>TransactionIsolationLevel</p>	<p>Changes the isolation level for the database. After modification, Vertica uses the new transaction level for every new session. Existing sessions and their transactions continue to use the original isolation level.</p> <p>Default Value: READ COMMITTED</p> <p>See Change Transaction Isolation Levels.</p>
<p>TransactionMode</p>	<p>Specifies whether transactions are in read/write or read-only modes. Read/write is the default. Existing sessions and their transactions continue to use the original isolation level.</p>

Parameter	Description
	Default Value: READ WRITES
UDxFencedBlockTimeout	<p>Specifies the number of seconds to wait for output before aborting a UDx running in Fenced Mode. If the server aborts a UDx for this reason, it produces an error message similar to "ERROR 3399: Failure in UDx RPC call: timed out in receiving a UDx message". If you see this error frequently, you can increase this limit. UDxs running in fenced mode do not run in the server process, so increasing this value does not impede server performance.</p> <p>Default Value: 60</p>

Tuple Mover Parameters

These parameters control how the Tuple Mover operates.

Parameters	Description
ActivePartitionCount	<p>Sets the number of active partitions. The active partitions are those most recently created. For example:</p> <pre>=> ALTER DATABASE mydb SET ActivePartitionCount = 2;</pre> <p>For information about how the Tuple Mover treats active (and inactive) partitions during a mergeout operation, see Mergeout.</p> <p>Default Value: 1</p>
CancelTMTimeout	<p>When partition, copy table, and rebalance operations encounter a conflict with an internal Tuple Mover job, those operations attempt to cancel the conflicting Tuple Mover job. This parameter specifies the amount of time, in seconds, that the blocked operation waits for the Tuple Mover cancellation to take effect. If the operation is unable to cancel the Tuple Mover job within limit specified</p>

Parameters	Description
	<p>by this parameter, the operation displays an error and rolls back.</p> <p>Default Value: 300</p>
EnableTMONRecoveringNode	<p>When enabled, allows Tuple Mover to perform moveout and mergeout activities on nodes with a node state of RECOVERING. Enabling Tuple Mover reduces the number of ROS containers generated during recovery. Having fewer than 1024 ROS containers per projection allows Vertica to maintain optimal recovery performance.</p> <p>Default Value: 1</p>
MaxMrgOutROSSizeMB	<p>Specifies in MB the maximum size of ROS containers that are candidates for mergeout operations. The Tuple Mover avoids merging ROS containers that are larger than this setting.</p> <p>Default Value: -1 (no maximum limit)</p>
MergeOutInterval	<p>Specifies in seconds how long the Tuple Mover waits between checks for new ROS files to merge out. If ROS containers are added frequently, consider a value less than the default.</p> <p>Default Value: 600</p>
MoveOutInterval	<p>Specifies in seconds how long Tuple Mover waits between checks for new data in the WOS to move to ROS.</p> <p>Default Value: 300</p>
MoveOutMaxAgeTime	<p>Specifies in seconds how long the Tuple Mover waits before it is forced to write the WOS to disk.</p> <p>Default Value: 1800</p>
MoveOutSizePct	<p>The percentage of the WOS that can be filled with data before the Tuple Mover performs a moveout operation.</p> <p>Default Value: 0</p>
PurgeMergeoutPercent	<p>Specifies as a percentage the threshold of deleted records in a ROS container that invokes an automatic mergeout</p>

Parameters	Description
	<p>operation, to purge those records. Vertica only counts the number of 'aged-out' delete vectors—that is, delete vectors that are as 'old' or older than the ancient history mark (AHM) epoch.</p> <p>This threshold applies to all ROS containers for non-partitioned tables. It also applies to ROS containers of all inactive partitions. In both cases, aged-out delete vectors are permanently purged from the ROS container.</p> <div style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p>Note: This configuration parameter only applies to automatic mergeout operations. It does not apply to manual mergeout operations that are invoked by calling meta-functions <code>DO_TM_TASK('mergeout')</code> and <code>PURGE</code>.</p> </div> <p>Default Value: 20 (percent)</p>

Projection Parameters

The following configuration parameters help you manage projections.

Parameters	Description
AnalyzeRowCountInterval	<p>Specifies how often Vertica checks the number of projection rows and whether the threshold set by <code>ARCCommitPercentage</code> has been crossed.</p> <p>For more information, see Collecting Statistics.</p> <p>Default Value: 60 seconds</p>
ARCCommitPercentage	<p>Sets the threshold percentage of WOS to ROS rows, which determines when to aggregate projection row counts and commit the result to the catalog. Vertica performs this action when the WOS to ROS percentage exceeds this setting.</p> <p>Default Value: 3 (percent)</p>
ContainersPerProjectionLimit	<p>Specifies how many ROS containers Vertica creates</p>

Parameters	Description
	<p>per projection before ROS pushback occurs.</p> <p>Default Value: 1024</p> <div style="background-color: #f0f0f0; padding: 5px; border: 1px solid #ccc;"> <p>Caution: Increasing this parameter's value can cause serious degradation of database performance. Vertica strongly recommends that you not modify this parameter without first consulting with Customer Support professionals.</p> </div>
<p>EnableGroupByProjections</p>	<p>When set to 1, you can create live aggregate projections. For more information, see Live Aggregate Projections.</p> <p>Default Value: 1</p>
<p>EnableExprsInProjections</p>	<p>When set to 1, you can create projections that use expressions to calculate column values. For more information, see Aggregating Data Through Expressions.</p> <p>Default Value: 1</p>
<p>EnableTopKProjections</p>	<p>When set to 1, you can create Top-K projections that let you retrieve Top-K data quickly. For more information, see Top-K Projections.</p> <p>Default Value: 1</p>
<p>MaxAutoSegColumns</p>	<p>Specifies the number of columns (0 –1024) to segment automatically when creating auto-projections from COPY and INSERT INTO statements.</p> <p>Set to 0 to use all columns in the hash segmentation expression.</p> <p>Default Value: 32</p>
<p>RebalanceQueryStorageContainers</p>	<p>By default, prior to performing a rebalance, Vertica performs a system table query to compute the size of all projections involved in the rebalance task. This query enables Vertica to optimize the rebalance to most efficiently utilize available disk space. This</p>

Parameters	Description
	<p>query can, however, significantly increase the time required to perform the rebalance.</p> <p>By disabling the system table query, you can reduce the time required to perform the rebalance. If your nodes are low on disk space, disabling the query increases the chance that a node runs out of disk space. In that situation, the rebalance fails.</p> <p>Default Value: 1</p>
SegmentAutoProjection	<p>Determines whether auto-projections are segmented by default. Set to 0 to disable.</p>

Epoch Management Parameters

The following table describes the epoch management parameters for configuring Vertica.

Parameters	Description
AdvanceAHMInterval	<p>Determines how frequently (in seconds) Vertica checks the history retention status.</p> <p>Note: AdvanceAHMInterval cannot be set to a value that is less than the EpochMapInterval.</p> <p>Default Value: 180 (3 minutes)</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET AdvanceAHMInterval = '3600';</pre>
AHMBackupManagement	<p>Blocks the advancement of the Ancient History Mark (AHM). When this parameter is enabled, the AHM epoch cannot be later than the epoch of your latest full backup. If you advance the AHM to purge and delete data, do not enable this parameter.</p> <p>Note: Do not enable this parameter before taking full backups, as it would prevent the AHM from advancing.</p> <p>Default Value: 0</p> <p>Example:</p>

Parameters	Description
	<pre>ALTER DATABASE mydb SET AHMBackupManagement = '1';</pre>
<p>EpochMapInterval</p>	<p>Determines the granularity of mapping between epochs and time available to historical queries. When a historical queries <code>AT TIME T</code> request is issued, Vertica maps it to an epoch within a granularity of EpochMapInterval seconds. It similarly affects the time reported for Last Good Epoch during Failure Recovery. Note that it does not affect internal precision of epochs themselves.</p> <p>Tip: Decreasing this interval increases the number of epochs saved on disk. Therefore, consider reducing the HistoryRetentionTime parameter to limit the number of history epochs that Vertica retains.</p> <p>Default Value: 180 (3 minutes)</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET EpochMapInterval = '300';</pre>
<p>HistoryRetentionTime</p>	<p>Determines how long deleted data is saved (in seconds) as an historical reference. When the specified time since the deletion has passed, you can purge the data. Use the -1 setting if you prefer to use HistoryRetentionEpochs to determine which deleted data can be purged.</p> <p>Note: The default setting of 0 effectively prevents the use of the Administration Tools 'Roll Back Database to Last Good Epoch' option because the AHM remains close to the current epoch and a rollback is not permitted to an epoch prior to the AHM.</p> <p>Tip: If you rely on the Roll Back option to remove recently loaded data, consider setting a day-wide window to remove loaded data. For example:</p> <pre>ALTER DATABASE mydb SET HistoryRetentionTime = 86400;</pre> <p>Default Value: 0 (Data saved when nodes are down.)</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET HistoryRetentionTime = '240';</pre>
<p>HistoryRetentionEpochs</p>	<p>Specifies the number of historical epochs to save, and therefore, the amount of deleted data.</p>

Parameters	Description
	<p>Unless you have a reason to limit the number of epochs, Micro Focus recommends that you specify the time over which deleted data is saved.</p> <p>If you specify both <code>History</code> parameters, <code>HistoryRetentionTime</code> takes precedence. Setting both parameters to <code>-1</code>, preserves all historical data.</p> <p>See Setting a Purge Policy.</p> <p>Default Value: <code>-1</code> (Disabled)</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET HistoryRetentionEpochs = '40';</pre>

Monitoring Parameters

The following table describes the monitoring parameters for configuring Vertica.

Parameters	Description
<code>SnmpTrapDestinationsList</code>	<p>Defines where Vertica sends traps for SNMP. See Configuring Reporting for SNMP.</p> <p>Default Value: none</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET SnmpTrapDestinationsList = 'localhost 162 public';</pre>
<code>SnmpTrapsEnabled</code>	<p>Enables event trapping for SNMP. See Configuring Reporting for SNMP.</p> <p>Default Value: 0</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET SnmpTrapsEnabled = 1;</pre>
<code>SnmpTrapEvents</code>	<p>Define which events Vertica traps through SNMP. See Configuring Reporting for SNMP.</p> <p>Default Value: Low Disk Space, Read Only File System, Loss of K Safety, Current Fault Tolerance at Critical Level, Too Many ROS Containers, WOS Over Flow, Node State Change, Recovery</p>

Parameters	Description
	<p>Failure, Stale Checkpoint, and CRC Mismatch.</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET SnmpTrapEvents = 'Low Disk Space, Recovery Failure';</pre>
SyslogEnabled	<p>Enables event trapping for syslog. See Configuring Reporting for Syslog.</p> <p>Default Value: 0</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET SyslogEnabled = 1);</pre>
SyslogEvents	<p>Defines events that generate a syslog entry. See Configuring Reporting for Syslog.</p> <p>Default Value: none</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET SyslogEvents = 'Low Disk Space, Recovery Failure';</pre>
SyslogFacility	<p>Defines which SyslogFacility Vertica uses. See Configuring Reporting for Syslog.</p> <p>Default Value: user</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET SyslogFacility = 'ftp';</pre>

Profiling Parameters

The following table describes the profiling parameters for configuring Vertica. See [Profiling Database Performance](#) for more information on profiling queries.

Parameters	Description
GlobalIEEProfiling	<p>Enables profiling for query execution runs in all sessions on all nodes.</p> <p>Default Value: 0</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET GlobalIEEProfiling = 1;</pre>

GlobalQueryProfiling	<p>Enables query profiling for all sessions on all nodes.</p> <p>Default Value: 0</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET GlobalQueryProfiling = 1;</pre>
GlobalSessionProfiling	<p>Enables session profiling for all sessions on all nodes.</p> <p>Default Value: 0</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET GlobalSessionProfiling = 1;</pre>

Security Parameters

Use these client authentication configuration parameters and general security parameters to configure security.

Parameters	Description
DefaultIdleSessionTimeout	<p>Indicates a default session timeout value when the parameter idlesessiontimeout is not set for the user.</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET defaultidlesessiontimeout = '300 secs';</pre>
EnableAllRolesOnLogin	<p>Automatically enables all roles granted to a user once that user logs in. Enabling this eliminates the need for the user to run SET ROLE <rolenames>. Valid values are:</p> <p>0 - does not automatically enable roles</p> <p>1 - automatically enables roles</p> <p>Default Value: 0</p>
EnabledCipherSuites	<p>Indicates which SSL cipher-suites to use for secure client-server communication.</p> <p>Default Value: ALL : !ADH : !LOW : !EXP : !MD5 : !RC4 : @STRENGTH</p> <p>This setting excludes weaker cipher suites.</p> <p>Find a complete mapping of cipher suite names from JSSE to OpenSSL at openssl.org.</p>

Parameters	Description
EnableSSL	<p>Enables SSL for the server. See Implementing SSL.</p> <p>Default Value: 0</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET EnableSSL = '1';</pre>
GlobalHeirUserName	<p>The user name which inherits objects previously owned by dropped users (using CASCADE). This prevents the loss of data owned by dropped users. If the user name indicated here does not exist, the system automatically creates the user.</p> <p>Valid Values:</p> <p><auto> (default) - re-parents objects to the dbadmin user by default.</p> <p>Note: When setting to the default, include the angle brackets < >.</p> <p><username> - re-parents objects to the username you enter.</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET PARAMETER GlobalHeirUsername='userheir1';</pre> <p>If you do not set this parameter, the objects of dropped users do not get re-parented.</p>
RequireFIPS	<p>This parameter indicates whether the FIPS mode is enabled or disabled. Upon startup Vertica automatically sets this parameter, and you cannot modify it.</p> <p>0 - Disabled FIPS</p> <p>1 - Enabled FIPS</p> <p>The value of this parameter matches the contents of the file, crypto.fips_enabled. See Implement FIPS on the Server.</p>
RestrictSystemTables	<p>Prohibits non-database administrator users from viewing sensitive information in system tables. Valid values are:</p> <p>0 - Allows all users to access system tables</p> <p>1 — Limits access to system tables to database administrator users</p>

Parameters	Description
	<p>Default Value: 0</p> <p>See System Table Restriction.</p>
SecurityAlgorithm	<p>Sets the algorithm for the function that hash authentication uses MD5 or SHA-512.</p> <p>Default Value: 'NONE '</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET SecurityAlgorithm = 'SHA512';</pre>
SSLCA	<p>Sets the SSL certificate authority.</p> <p>Default Value: No default value</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET SSLCA = '<contents of certificate authority root.crt file>';</pre> <p>Include the contents of the certificate authority, root . crt, file, but do not include the file name.</p>
SSLCertificate	<p>Sets the SSL certificate. If your SSL certificate is a certificate chain, cut and paste only the top-most certificate of the certificate chain to set this value.</p> <p>Default Value: No default value</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET SSLCertificate = '<contents of server.crt file>';</pre> <p>Include the contents of the server . crt file, but do not include the file name.</p> <p>Note: This parameter gets set automatically during upgrade to 7.1 if you set EnableSSL=1 prior to the upgrade.</p>
SSLPrivateKey	<p>Specifies the server's private key. The value of this parameter is visible only to dbadmin users.</p> <p>Default Value: No default value</p>

Parameters	Description
	<p>Example:</p> <pre>ALTER DATABASE mydb SET SSLPrivateKey = '<contents of server.key file>';</pre> <p>Include the contents of the server .key file, but do not include the file name.</p> <p>Note: This parameter gets set automatically during upgrade to 7.1 if you set EnableSSL=1 prior to the upgrade.</p>

View parameter values with the statement, `SHOW DATABASE`. You must be a database superuser to view the value:

```
SHOW DATABASE mydb SSLCertificate;
```

[Configuring SSL](#)

Database Designer Parameters

The following table describes the parameters for configuring the Vertica Database Designer.

Parameter	Description
<code>DBDCorrelationSampleRowCount</code>	<p>Minimum number of table rows at which Database Designer discovers and records correlated columns.</p> <p>Default Value: 4000</p>
<code>DBDLogInternalDesignProcess</code>	<p>Enables or disables Database Designer logging.</p> <p>Default value: 0 (False)</p>
<code>DBDUseOnlyDesignerResourcePool</code>	<p>Enables use of the DBD pool by the Vertica Database Designer.</p> <p>When set to false, design processing is mostly</p>

Parameter	Description
	<p>contained by the user's resource pool, but might spill over into some system resource pools for less-intensive tasks</p> <p>Default value: 0 (False)</p>

Internationalization Parameters

The following table describes the internationalization parameters for configuring Vertica.

Parameters	Description
DefaultIntervalStyle	<p>Sets the default interval style to use. If set to 0 (default), the interval is in PLAIN style (the SQL standard), no interval units on output. If set to 1, the interval is in UNITS on output. This parameter does not take effect until the database is restarted.</p> <p>Default Value: 0</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET DefaultIntervalStyle = 1;</pre>
DefaultSessionLocale	<p>Sets the default session startup locale for the database. This parameter does not take effect until the database is restarted.</p> <p>Default Value: en_US@collation=binary</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET DefaultSessionLocale = 'en_GB';</pre>
EscapeStringWarning	<p>Issues a warning when back slashes are used in a string literal. This is provided to help locate back slashes that are being treated as escape characters so they can be fixed to follow the Standard conforming string syntax instead.</p> <p>Default Value: 1</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET EscapeStringWarning = '1';</pre>
StandardConformingStrings	<p>Determines whether ordinary string literals ('...') treat</p>

Parameters	Description
	<p>backslashes (\) as string literals or escape characters. When set to '1', backslashes are treated as string literals, when set to '0', back slashes are treated as escape characters.</p> <p>Tip: To treat backslashes as escape characters, use the Extended string syntax:</p> <pre>(E ' . . . ');</pre> <p>See String Literals (Character) in the SQL Reference Manual.</p> <p>Default Value: 1</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET StandardConformingStrings = '0';</pre>

Data Collector Parameters

The following table lists the Data Collector parameter for configuring Vertica.

Parameter	Description
EnableDataCollector	<p>Enables and disables the Data Collector, which is the Workload Analyzer's internal diagnostics utility. Affects all sessions on all nodes. Use 0 to turn off data collection.</p> <p>Default value: 1 (Enabled)</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET EnableDataCollector = 0;</pre>

For more information, see the following topics in the SQL Reference Manual:

- [Data Collector Functions](#)
- [ANALYZE_WORKLOAD](#)
- [V_MONITOR.DATA_COLLECTOR](#)
- [V_MONITOR.TUNING_RECOMMENDATIONS](#)

See also the following topics in the Administrator's Guide

- [Retaining Monitoring Information](#)
- [Analyzing Workloads](#)
- [Tuning Recommendations](#)
- [Analyzing Workloads Through Management Console](#) and [Through an API](#)

Text Search Parameters

You can configure Vertica for text search using these parameters.

Parameters	Description
TextIndexMaxTokenLength	<p>Controls the maximum size of a token in a text index. If the parameter is set to a value greater than 65000 characters, then the tokenizer truncates the token at 65000 characters.</p> <p>You should avoid setting this parameter near 65000 (the maximum value). Doing so can result in a significant decrease in performance. For optimal performance, the parameter should be set to the maximum token value of your tokenizer.</p> <p>Default Value: 128 characters</p> <p>Example:</p> <pre>ALTER DATABASE database_name SET PARAMETER TextIndexMaxTokenLength=760;</pre>

Kerberos Authentication Parameters

The following parameters let you configure the Vertica principal for Kerberos authentication and specify the location of the Kerberos keytab file.

Parameter	Description
KerberosServiceName	<p>Provides the service name portion of the Vertica Kerberos principal. By default, this parameter is 'vertica'. For example: vertica/host@EXAMPLE.COM.</p>
KerberosHostname	<p>[Optional] Provides the instance or host name portion of the Vertica Kerberos principal. For example: vertica/host@EXAMPLE.COM</p>

Parameter	Description
	<p>If you omit the optional KerberosHostname parameter, Vertica uses the return value from the <code>gethostname()</code> function. Assuming each cluster node has a different host name, those nodes will each have a different principal, which you must manage in that node's keytab file.</p>
KerberosRealm	<p>Provides the realm portion of the Vertica Kerberos principal. A realm is the authentication administrative domain and is usually formed in uppercase letters; for example: <code>vertica/host@EXAMPLE.COM</code>.</p>
KerberosKeytabFile	<p>Provides the location of the keytab file that contains credentials for the Vertica Kerberos principal. By default, this file is located in <code>/etc</code>. For example: <code>KerberosKeytabFile=/etc/krb5.keytab</code>.</p> <p>Notes:</p> <ul style="list-style-type: none"> The principal must take the form <code>KerberosServiceName/KerberosHostName@KerberosRealm</code> The keytab file must be readable by the file owner who is running the process (typically the Linux <code>dbadmin</code> user assigned file permissions <code>0600</code>).

Hadoop Parameters

The following table describes the general parameters for configuring integration with Apache Hadoop. See [Integrating with Apache Hadoop](#) for more information.

Parameter	Description
HadoopConfDir	<p>A directory path containing the XML configuration files copied from Hadoop. The same path must be valid on every Vertica node. You can use the <code>VERIFY_HADOOP_CONF_DIR</code> meta-function to test that the value is set correctly. Setting this parameter is required to read data from HDFS.</p> <p>When you set this parameter, any previously-cached configuration information is flushed.</p>

	<p>Default Value: obtained from environment if possible</p> <p>Requires Restart: No</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET HadoopConfDir = '/hadoop/hcat/conf';</pre>
--	--

The following table describes the parameters for configuring the HCatalog Connector. See [Using the HCatalog Connector](#) in Integrating with Apache Hadoop for more information.

Parameter	Description
HCatalogConnectorUseHiveServer2	<p>When enabled, Vertica internally uses HiveServer2 instead of WebHCat to get metadata from Hive.</p> <p>Default Value: 1 (enabled)</p> <p>Requires Restart: No</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET HCatalogConnectorUseHiveServer2 = 0;</pre>
HCatalogConnectorUseLibHDFSPP	<p>Whether the HCatalog Connector should use the hdfs scheme instead of webhdfs to read native formats. Using the hdfs scheme requires additional configuration but can have better performance.</p> <p>Default Value: 1 (enabled)</p> <p>Requires Restart: No</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET HCatalogConnectorUseLibHDFSPP = 1;</pre>
HCatConnectionTimeout	<p>The number of seconds the HCatalog Connector waits for a successful connection to the HiveServer2 (or WebHCat) server before returning a timeout error.</p> <p>Default Value: 0 (Wait indefinitely)</p> <p>Requires Restart: No</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET HCatConnectionTimeout = 30;</pre>
HCatSlowTransferLimit	<p>The lowest transfer speed (in bytes per second) that the HCatalog Connector allows when retrieving data from the HiveServer2 (or WebHCat) server. In some cases, the data transfer rate from the server to</p>

	<p>Vertica is below this threshold. In such cases, after the number of seconds specified in the HCatSlowTransferTime parameter pass, the HCatalog Connector cancels the query and closes the connection.</p> <p>Default Value: 65536</p> <p>Requires Restart: No</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET HCatSlowTransferLimit = 32000;</pre>
HCatSlowTransferTime	<p>The number of seconds the HCatalog Connector waits before testing whether the data transfer from the server is too slow. See the HCatSlowTransferLimit parameter.</p> <p>Default Value: 60</p> <p>Requires Restart: No</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET HCatSlowTransferTime = 90;</pre>

Note: You can override the HCatalog configuration parameters when creating an HCatalog schema. See [CREATE HCATALOG SCHEMA](#) in the SQL Reference Manual for an explanation.

User-Defined Session Parameters

Use the following Vertica use-defined session parameters to configure Kafka SSL when not using a scheduler.

The kafka_ parameters configure SSL authentication for Kafka. Refer to [Using SSL with Kafka](#) for more information.

Parameter	Description
kafka_SSL_CA	<p>The contents of the certificate authority certificate.</p> <p>Default Value: none</p> <p>Example:</p> <pre>=> ALTER SESSION SET UDPARAMETER kafka_SSL_CA='MIIBOQIBAAJBAIOL';</pre>

Parameter	Description
kafka_SSL_Certificate	<p>The contents of the SSL certificate.</p> <p>Default Value: none</p> <p>Example:</p> <pre>=> ALTER SESSION SET UDPARAMETER kafka_SSL_Certificate='XrM0704dV/nJ5g';</pre>
kafka_SSL_PrivateKey_secret	<p>The private key used to encrypt the session. Vertica does not log this information.</p> <p>Default Value: none</p> <p>Example:</p> <pre>=> ALTER SESSION SET UDPARAMETER kafka_SSL_PrivateKey_secret='A60iThKtezaCk7F';</pre>
kafka_SSL_PrivateKeyPassword_secret	<p>The password used to create the private key. Vertica does not log this information.</p> <p>Default Value: none</p> <p>Example:</p> <pre>ALTER SESSION SET UDPARAMETER kafka_SSL_PrivateKeyPassword_secret='secret';</pre>
kafka_Enable_SSL	<p>Enables SSL authentication for Vertica-Kafka integration.</p> <p>Default Value: 0</p> <p>Example:</p> <pre>=> ALTER SESSION SET kafka_Enable_SSL=1;</pre>
MaxSessionUDParameterSize	<p>Sets the maximum length of a value in a user-defined session parameter.</p> <p>Default Value: 1000</p> <p>Example:</p> <pre>=> ALTER SESSION SET MaxSessionUDParameterSize = 2000</pre>

Constraint Enforcement Parameters

The following configuration parameters enforce constraints.

Use the [ALTER DATABASE](#) statement to set these parameters. You do not need to restart your database after setting them.

- The parameter settings apply for any check constraint, and any primary or unique key constraint that you have not explicitly enabled or disabled within a [CREATE TABLE](#) or [ALTER TABLE](#) statement.
- Any new check constraint, and any primary or unique key constraint that you create or alter is set according to the value of the corresponding parameter unless you specifically enabled or disabled the constraint.

Important: Setting a constraint as enabled or disabled when you create or alter it using [CREATE TABLE](#) or [ALTER TABLE](#) overrides the parameter setting.

Parameters	Description
EnableNewCheckConstraintsByDefault	<p>Set to 1 (the default) to automatically enable newly created check constraints that you specified through CREATE TABLE or ALTER TABLE statements. However, if you have explicitly disabled a constraint when you created or altered it, it is not enforced.</p> <p>Default Value: 1 (Enabled)</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET EnableNewCheckConstraintsByDefault = 0;</pre>
EnableNewPrimaryKeysByDefault	<p>Set to 1 to automatically enable newly created primary key constraints that you specified through CREATE TABLE or ALTER TABLE statements. However, if you have explicitly disabled a constraint when you created or altered it, it is not enforced.</p>

Parameters	Description
	<p>Default Value: 0 (Disabled)</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET EnableNewPrimaryKeysByDefault = 1;</pre>
EnableNewUniqueKeysByDefault	<p>Set to 1 to automatically enable newly created unique constraints that you specified through CREATE TABLE or ALTER TABLE statements. However, if you have explicitly disabled a constraint when you created or altered it, it is not enforced.</p> <p>Default Value: 0 (Disabled)</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET EnableNewUniqueKeysByDefault = 1;</pre>

Note: Vertica recommends enabling primary key enforcement if you have enabled unique key enforcement.

Numeric Precision Parameters

The following configuration parameters let you configure numeric precision for numeric data types. For more about using these parameters, see [Numeric Data Type Overflow with SUM, SUM_FLOAT, and AVG](#).

Parameters	Description
AllowNumericOverflow	<p>When set to 1 (True), allows silent numeric overflow. When true, Vertica does not implicitly extend precision of numeric data types.</p> <p>Default Value: 1 (True)</p> <p>When set to 0 (False), Vertica produces an overflow error, if a result exceeds the precision set by NumericSumExtraPrecisionDigits.</p> <p>Vertica ignores the value of NumericSumExtraPrecisionDigits when</p>

Parameters	Description
	<p>AllowNumericOverflow is true.</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET PARAMETER AllowNumericOverflow=0;</pre>
NumericSumExtraPrecisionDigits	<p>Vertica produces an overflow error, if a result exceeds the specified precision, By default this specified precision is six places beyond the DDL-specified precision.</p> <p>Default Value: 6</p> <p>This parameter setting only applies if AllowNumericOverflow is set to 0 (False).</p> <p>Possible Values: 0 to 20.</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET PARAMETER NumericSumExtraPrecisionDigits=8</pre>

Vertica Library for Amazon Web Services Parameters

Use these parameters to configure the Verticalibrary for Amazon Web Services (AWS). All parameters listed are case sensitive.

Parameter	Description
aws_id	<p>Your AWS access key ID.</p> <p>Example:</p> <pre>=> ALTER SESSION SET UDPARAMETER FOR awslib aws_id='<YOUR AWS ID>';</pre>
aws_secret	<p>Your AWS secret access key.</p> <p>Example:</p> <pre>=> ALTER SESSION SET UDPARAMETER FOR awslib aws_secret='<YOUR AWS KEY>';</pre>
aws_region	<p>The region your S3 bucket is located. aws_region can only be configured with</p>

Parameter	Description
	<p>one region at a time. If you need to access buckets in multiple regions, you must re-set the parameter each time you change regions.</p> <p>Default value: us-east-1</p> <p>You can find more information about AWS regions in the Amazon Documentation.</p> <p>Example:</p> <pre>=> ALTER SESSION SET UDPARAMETER FOR awslib aws_region='<REGION IDENTIFIER>';</pre>
aws_ca_path	<p>The path which Vertica will use when looking for SSL server certificates.</p> <p>Default value: system dependent</p> <p>Example:</p> <pre>=> ALTER SESSION SET UDPARAMETER FOR awslib aws_ca_path= /home/user/ssl_folder;</pre>
aws_ca_bundle	<p>The path which Vertica will use when looking for a SSL server certificate bundle.</p> <p>Default value: system dependent</p> <p>Example:</p> <pre>=> ALTER SESSION SET UDPARAMETER FOR awslib aws_ca_bundle= /home/user/ssl_folder/ca_bundle;</pre>
aws_proxy	<p>A string value which allows you to set an HTTP/HTTPS proxy for the AWS library.</p> <p>Example:</p> <pre>=> ALTER SESSION SET UDPARAMETER FOR awslib aws_proxy='192.168.1.1:8080;</pre>
aws_verbose	<p>When enabled, logs libcurl debug messages to dbLog.</p> <p>Default value: false</p> <p>Example:</p> <pre>=> ALTER SESSION SET UDPARAMETER FOR awslib aws_verbose= 1;</pre>
aws_max_send_	<p>Sets the maximum transfer speed when sending data to AWS S3 in bytes per second.</p>

Parameter	Description
speed	<p>Example:</p> <p>The following example sets a maximum send speed of 1KB/S:</p> <pre>=> ALTER SESSION SET UDPARAMETER FOR awslib aws_max_send_speed= 1024;</pre>
aws_max_recv_speed	<p>Sets the maximum transfer speed when receiving data to AWS S3 in bytes per second.</p> <p>Example:</p> <p>The following example sets a maximum receive speed of 100KB/S:</p> <pre>=> ALTER SESSION SET UDPARAMETER FOR awslib aws_max_recv_speed= 102400;</pre>

- [Import AWS Library](#)

Designing a Logical Schema

Designing a logical schema for a Vertica database is the same as designing for any other SQL database. A logical schema consists of objects such as schemas, tables, views and referential Integrity constraints that are visible to SQL users. Vertica supports any relational schema design that you choose.

Using Multiple Schemas

Using a single schema is effective if there is only one database user or if a few users cooperate in sharing the database. In many cases, however, it makes sense to use additional schemas to allow users and their applications to create and access tables in separate namespaces. For example, using additional schemas allows:

- Many users to access the database without interfering with one another.

Individual schemas can be configured to grant specific users access to the schema and its tables while restricting others.

- Third-party applications to create tables that have the same name in different schemas, preventing table collisions.

Unlike other RDBMS, a schema in an Vertica database is not a collection of objects bound to one user.

Multiple Schema Examples

This section provides examples of when and how you might want to use multiple schemas to separate database users. These examples fall into two categories: using multiple private schemas and using a combination of private schemas (i.e. schemas limited to a single user) and shared schemas (i.e. schemas shared across multiple users).

Using Multiple Private Schemas

Using multiple private schemas is an effective way of separating database users from one another when sensitive information is involved. Typically a user is granted access to only one schema and its contents, thus providing database security at the schema level. Database users can be running different applications, multiple copies of the same application, or even multiple instances of the same application. This enables you to consolidate applications on one database to reduce management overhead and use resources more effectively. The following examples highlight using multiple private schemas.

Using multiple schemas to separate users and their unique applications

In this example, both database users work for the same company. One user (HRUser) uses a Human Resource (HR) application with access to sensitive personal data, such as salaries, while another user (MedUser) accesses information regarding company healthcare costs through a

healthcare management application. HRUser should not be able to access company healthcare cost information and MedUser should not be able to view personal employee data.

To grant these users access to data they need while restricting them from data they should not see, two schemas are created with appropriate user access, as follows:

- HRSchema—A schema owned by HRUser that is accessed by the HR application.
- HealthSchema—A schema owned by MedUser that is accessed by the healthcare management application.

Using multiple schemas to support multitenancy

This example is similar to the last example in that access to sensitive data is limited by separating users into different schemas. In this case, however, each user is using a virtual instance of the same application.

An example of this is a retail marketing analytics company that provides data and software as a service (SaaS) to large retailers to help them determine which promotional methods they use are most effective at driving customer sales.

In this example, each database user equates to a retailer, and each user only has access to its own schema. The retail marketing analytics company provides a virtual instance of the same application to each retail customer, and each instance points to the user's specific schema in which to create and update tables. The tables in these schemas use the same names because they are created by instances of the same application, but they do not conflict because they are in separate schemas.

Example of schemas in this database could be:

- MartSchema—A schema owned by MartUser, a large department store chain.
- PharmSchema—A schema owned by PharmUser, a large drug store chain.

Using multiple schemas to migrate to a newer version of an application

Using multiple schemas is an effective way of migrating to a new version of a software application. In this case, a new schema is created to support the new version of the software, and the old schema is kept as long as necessary to support the original version of the software. This is called a “rolling application upgrade.”

For example, a company might use a HR application to store employee data. The following schemas could be used for the original and updated versions of the software:

- HRSchema—A schema owned by HRUser, the schema user for the original HR application.
- V2HRSchema—A schema owned by V2HRUser, the schema user for the new version of the HR application.

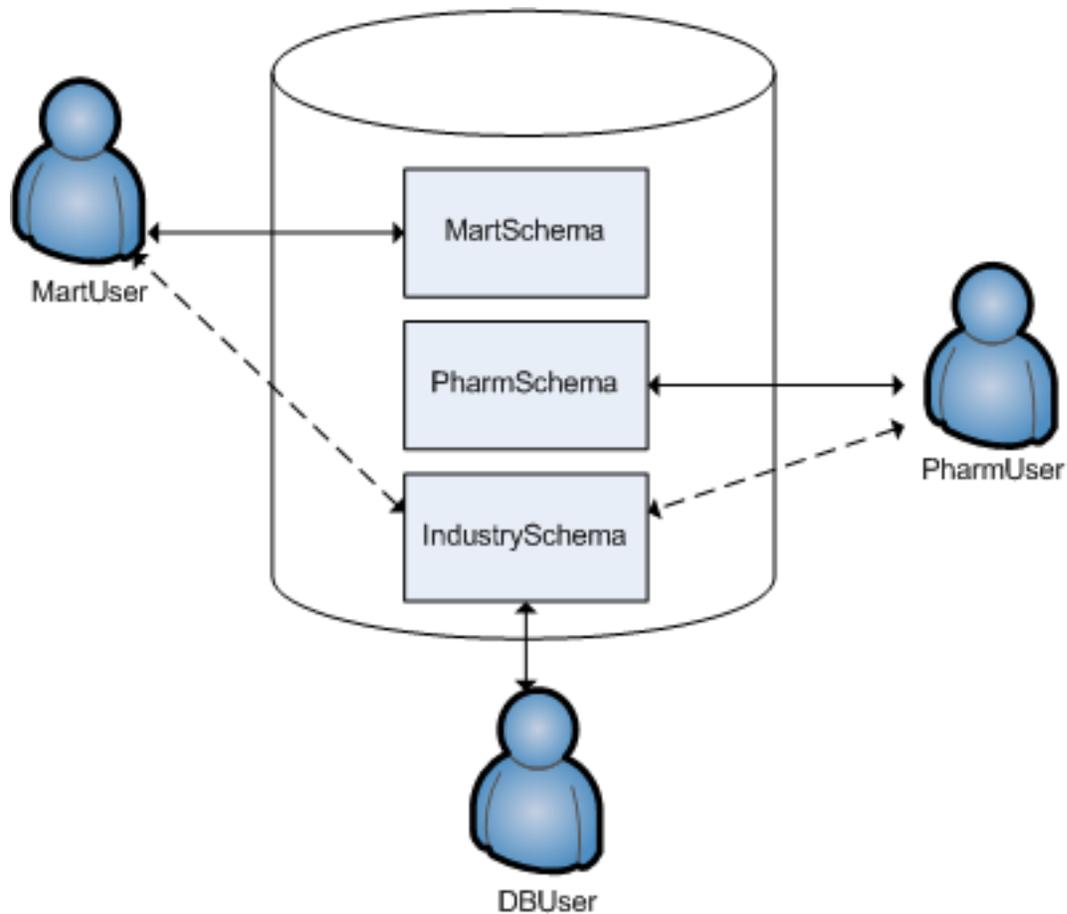

Combining Private and Shared Schemas

The previous examples illustrate cases in which all schemas in the database are private and no information is shared between users. However, users might want to share common data. In the retail case, for example, MartUser and PharmUser might want to compare their per store sales of a particular product against the industry per store sales average. Since this information is an industry average and is not specific to any retail chain, it can be placed in a schema on which both users are granted USAGE privileges. (For more information about schema privileges, see [Schema Privileges](#).)

Example of schemas in this database might be:

- MartSchema—A schema owned by MartUser, a large department store chain.
- PharmSchema—A schema owned by PharmUser, a large drug store chain.
- IndustrySchema—A schema owned by DBUser (from the retail marketing analytics company) on which both MartUser and PharmUser have USAGE privileges. It is unlikely that retailers would be given any privileges beyond USAGE on the schema and SELECT on one or

more of its tables.

Creating Schemas

You can create as many schemas as necessary for your database. For example, you could create a schema for each database user. However, schemas and users are not synonymous as they are in Oracle.

By default, only a superuser can create a schema or give a user the right to create a schema. (See [GRANT \(Database\)](#) in the SQL Reference Manual.)

To create a schema use the [CREATE SCHEMA](#) statement, as described in the SQL Reference Manual.

Specifying Objects in Multiple Schemas

Once you create two or more schemas, each SQL statement or function must identify the schema associated with the object you are referencing. You can specify an object within multiple schemas by:

- Qualifying the object name by using the schema name and object name separated by a dot. For example, to specify `MyTable`, located in `Schema1`, qualify the name as `Schema1.MyTable`.
- Using a search path that includes the desired schemas when a referenced object is unqualified. By [Setting Search Paths](#), Vertica will automatically search the specified schemas to find the object.

Setting Search Paths

Each user session has a search path of schemas. Vertica uses this search path to find tables and user-defined functions (UDFs) that are unqualified by their schema name. A session search path is initially set from the user's profile. You can change the session's search path at any time by calling `SET SEARCH_PATH`. This search path remains in effect until the next `SET SEARCH_PATH` statement, or the session ends.

Viewing the Current Search Path

`SHOW SEARCH_PATH` returns the session's current search path. For example:

```
=> SHOW SEARCH_PATH;
  name      |                setting
-----+-----
search_path | "$user", public, v_catalog, v_monitor, v_internal
```

Schemas are listed in descending order of precedence. The first schema has the highest precedence in the search order. If this schema exists, it is also defined as the current schema, which is used for tables that are created with unqualified names. You can identify the current schema by calling the function `CURRENT_SCHEMA`:

```
=> SELECT CURRENT_SCHEMA;
 current_schema
-----
public
(1 row)
```

Setting the User Search Path

A session search path is initially set from the user's profile. If the search path in a user profile is not set by [CREATE USER](#) or [ALTER USER](#), it is set to the database default:

```
=> CREATE USER agent007;
CREATE USER
=> \c - agent007
You are now connected as user "agent007".
=> SHOW SEARCH_PATH;
  name      |                               setting
-----+-----
search_path | "$user", public, v_catalog, v_monitor, v_internal
```

`$user` resolves to the session user name—in this case, `agent007`—and has the highest precedence. If a schema `agent007`, exists, Vertica begins searches for unqualified tables in that schema. Also, calls to [CURRENT_SCHEMA](#) return this schema. Otherwise, Vertica uses `public` as the current schema and begins searches in it.

Use [ALTER USER](#) to modify an existing user's search path. These changes overwrite all non-system schemas in the search path, including `$USER`. System schemas are untouched. Changes to a user's search path take effect only when the user starts a new session; current sessions are unaffected.

Important: After modifying the user's search path, [verify that the user has access privileges to all schemas that are on the updated search path.](#)

For example, the following statements modify `agent007`'s search path, and grant access privileges to schemas and tables that are on the new search path:

```
=> ALTER USER agent007 SEARCH_PATH store, public;
ALTER USER
=> GRANT ALL ON SCHEMA store, public TO agent007;
GRANT PRIVILEGE
=> GRANT SELECT ON ALL TABLES IN SCHEMA store, public TO agent007;
GRANT PRIVILEGE
=> \c - agent007
You are now connected as user "agent007".
=> SHOW SEARCH_PATH;
  name      |                               setting
-----+-----
search_path | store, public, v_catalog, v_monitor, v_internal
(1 row)
```

To verify a user's search path, query the system table [USERS](#):

```
=> SELECT search_path FROM USERS WHERE user_name='agent007';
      search_path
-----
```

```
store, public, v_catalog, v_monitor, v_internal  
(1 row)
```

To revert a user's search path to the database default settings, call `ALTER USER` and set the search path to `DEFAULT`. For example:

```
=> ALTER USER agent007 SEARCH_PATH DEFAULT;  
ALTER USER  
=> SELECT search_path FROM USERS WHERE user_name='agent007';  
          search_path  
-----  
"$user", public, v_catalog, v_monitor, v_internal  
(1 row)
```

Ignored Search Path Schemas

Vertica only searches among existing schemas to which the current user has access privileges. If a schema in the search path does not exist or the user lacks access privileges to it, Vertica silently excludes it from the search. For example, if `agent007` lacks `SELECT` privileges to schema `public`, Vertica silently skips this schema. Vertica returns with an error only if it cannot find the table anywhere on the search path.

Setting Session Search Path

Vertica initially sets a session's search path from the user's profile. You can change the current session's search path with [SET SEARCH_PATH](#). You can use `SET SEARCH_PATH` in two ways:

- Explicitly set the session search path to one or more schemas. For example:

```
=> \c - agent007  
You are now connected as user "agent007".  
dbadmin=> SHOW SEARCH_PATH;  
  name | setting  
-----+-----  
search_path | "$user", public, v_catalog, v_monitor, v_internal  
(1 row)  
  
=> SET SEARCH_PATH TO store, public;  
SET  
=> SHOW SEARCH_PATH;  
  name | setting  
-----+-----  
search_path | store, public, v_catalog, v_monitor, v_internal  
(1 row)
```

- Set the session search path to the database default:

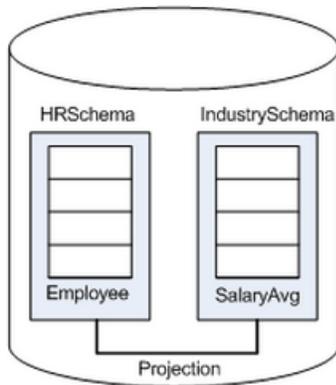

```
=> SET SEARCH_PATH TO DEFAULT;
SET
=> SHOW SEARCH_PATH;
  name | setting
-----+-----
search_path | "$user", public, v_catalog, v_monitor, v_internal
(1 row)
```

SET SEARCH_PATH overwrites all non-system schemas in the search path, including \$USER. System schemas are untouched.

Creating Objects That Span Multiple Schemas

Vertica supports views that reference tables across multiple schemas. For example, a user might need to compare employee salaries to industry averages. In this case, the application queries two schemas:

- Shared schema IndustrySchema for salary averages
- Private schema HRSchema for company-specific salary information

Best Practice: When creating objects that span schemas, use qualified table names. This naming convention avoids confusion if the query path or table structure within the schemas changes at a later date.

Tables in Schemas

In Vertica you can create persistent and temporary tables, through [CREATE TABLE](#) and [CREATE TEMPORARY TABLE](#), respectively.

For detailed information on both types, see [Creating Tables](#) and [Creating Temporary Tables](#).

Persistent Tables

CREATE TABLE creates a table in the Vertica logical schema. For example:

```
CREATE TABLE vendor_dimension (  
  vendor_key      INTEGER      NOT NULL PRIMARY KEY,  
  vendor_name     VARCHAR(64),  
  vendor_address  VARCHAR(64),  
  vendor_city     VARCHAR(64),  
  vendor_state    CHAR(2),  
  vendor_region   VARCHAR(32),  
  deal_size       INTEGER,  
  last_deal_update DATE  
);
```

For detailed information, see [Creating Tables](#).

Temporary Tables

CREATE TEMPORARY TABLE creates a table whose data persists only during the current session. Temporary table data is never visible to other sessions.

Temporary tables can be used to divide complex query processing into multiple steps. Typically, a reporting tool holds intermediate results while reports are generated—for example, the tool first gets a result set, then queries the result set, and so on.

CREATE TEMPORARY TABLE can create tables at two scopes, global and local, through the keywords **GLOBAL** and **LOCAL**, respectively:

- **GLOBAL** (default): The table definition is visible to all sessions. However, table data is session-scoped.
- **LOCAL**: The table definition is visible only to the session in which it is created. When the session ends, Vertica automatically drops the table.

For detailed information, see [Creating Temporary Tables](#).

Creating a Database Design

A *design* is a physical storage plan that optimizes query performance. Data in Vertica is physically stored in projections. When you initially load data into a table using `INSERT`, `COPY` (or `COPY LOCAL`), Vertica creates a default superprojection for the table. This superprojection ensures that all of the data is available for queries. However, these superprojections might not optimize database performance, resulting in slow query performance and low data compression.

To improve performance, create a design for your Vertica database that optimizes query performance and data compression. You can create a design in several ways:

- [Use Database Designer](#), a tool that recommends a design for optimal performance.
- [Manually create a design](#)
- Use Database Designer to create an initial design and then manually modify it.

Database Designer can help you minimize how much time you spend on manual database tuning. You can also use Database Designer to redesign the database incrementally as requirements such as workloads change over time.

Database Designer runs as a background process. This is useful if you have a large design that you want to run overnight. An active SSH session is not required, so design and deploy operations continue to run uninterrupted if the session ends.

Tip: Micro Focus recommends that you first globally optimize your database using the Comprehensive setting in Database Designer. If the performance of the comprehensive design is not adequate, you can design custom projections using an incremental design and manually, as described in [Creating Custom Designs](#).

About Database Designer

Vertica Database Designer uses sophisticated strategies to create a design that provides excellent performance for ad-hoc queries and specific queries while using disk space efficiently.

During the design process, Database Designer analyzes the logical schema definition, sample data, and sample queries, and creates a physical schema (projections) in the form of a SQL script that you deploy automatically or manually. This script creates a minimal set of superprojections to ensure K-safety.

In most cases, the projections that Database Designer creates provide excellent query performance within physical constraints while using disk space efficiently.

General Design Options

When you run Database Designer, several general options are available:

- Create a comprehensive or incremental design.
- Optimize for query execution, load, or a balance of both.
- Require K-safety.
- Recommend unsegmented projections when feasible.
- Analyze statistics before creating the design.

Design Input

Database Designer bases its design on the following information that you provide:

- **Design queries** that you typically run during normal database operations.
- **Design tables** that contain sample data.

Output

Database Designer yields the following output:

- A design script that creates the projections for the design in a way that meets the optimization objectives and distributes data uniformly across the cluster.
- A deployment script that creates and refreshes the projections for your design. For comprehensive designs, the deployment script contains commands that remove non-optimized projections. The deployment script includes the full design script.
- A backup script that contains SQL statements to deploy the design that existed on the system before deployment. This file is useful in case you need to revert to the pre-deployment design.

Design Restrictions

Database Designer-generated designs:

- Exclude live aggregate or Top-K projections. You must create these manually. See [CREATE PROJECTION \(Live Aggregate Projections\)](#).
- Do not sort, segment, or partition projections on LONG VARBINARY and LONG VARCHAR columns.

Post-Design Options

While running Database Designer, you can choose to deploy your design automatically after the deployment script is created, or to deploy it manually, after you have reviewed and tested the design. Vertica recommends that you test the design on a non-production server before deploying the design to your production server.

How Database Designer Creates a Design

Design Recommendations

Database Designer-generated designs can include the following recommendations:

- Sort buddy projections in the same order, which can significantly improve load, recovery, and site node performance. All buddy projections have the same base name so that they can be identified as a group.

Note: If you manually create projections, Database Designer recommends a buddy with the same sort order, if one does not already exist. By default, Database Designer recommends both super and non-super segmented projections with a buddy of the same sort order and segmentation.

- Accepts unlimited queries for a comprehensive design.
- Allows you to analyze column correlations. Correlation analysis typically only needs to be performed once and only if the table has more than DBDCorrelationSampleRowCount

(default: 4000) rows.

By default, Database Designer does not analyze column correlations. To set the correlation analysis mode, use [DESIGNER_SET_ANALYZE_CORRELATIONS_MODE](#)

- Identifies similar design queries and assigns them a signature.

For queries with the same signature, Database Designer weights the queries, depending on how many queries have that signature. It then considers the weighted query when creating a design.

- Recommends and creates projections in a way that minimizes data skew by distributing data uniformly across the cluster.
- Produces higher quality designs by considering UPDATE, DELETE, and SELECT statements.

Who Can Run Database Designer

To use Administration Tools to run Database Designer and create an optimal database design, you must be a DBADMIN user.

To run Database Designer programmatically or using Management Console, you must be one of two types of users:

- DBADMIN user
- Have been assigned the DBDUSER role and be the owner of database tables for which you are creating a design

Granting and Enabling the DBDUSER Role

For a non-DBADMIN user to be able to run Database Designer using Management Console, follow the steps described in [Allowing the DBDUSER to Run Database Designer Using Management Console](#).

For a non-DBADMIN user to be able to run Database Designer programmatically, following the steps described in [Allowing the DBDUSER to Run Database Designer Programmatically](#).

Important: When you grant the DBDUSER role, make sure to associate a resource pool with that user to manage resources during Database Designer runs. (For instructions about how to associate a resource pool with a user, see [User Profiles](#).)

Multiple users can run Database Designer concurrently without interfering with each other or using up all the cluster resources. When a user runs Database Designer, either using the Management Console or programmatically, its execution is mostly contained by the user's resource pool, but may spill over into system resource pools for less-intensive tasks.

Allowing the DBDUSER to Run Database Designer Using Management Console

To allow a user with the DBDUSER role to run Database Designer using Management Console, you first need to create the user on the Vertica server.

As DBADMIN, take these steps on the server:

1. Add a temporary folder to all cluster nodes.

```
=> CREATE LOCATION '/tmp/dbd' ALL NODES;
```

2. Create the user who needs access to Database Designer.

```
=> CREATE USER new_user;
```

3. Grant the user the privilege to create schemas on the database for which they want to create a design.

```
=> GRANT CREATE ON DATABASE new_database TO new_user;
```

4. Grant the DBDUSER role to the new user.

```
=> GRANT DBDUSER TO new_user;
```

5. On all nodes in the cluster, grant the user access to the temporary folder.

```
=> GRANT ALL ON LOCATION '/tmp/dbd' TO new_user;
```

6. Grant the new user access to the database schema and its tables.

```
=> GRANT ALL ON SCHEMA user_schema TO new_user;  
=> GRANT ALL ON ALL TABLES IN SCHEMA user_schema TO new_user;
```

After you have completed this task, you need to do the following to map the MC user to the new_user you created in the previous steps:

1. Log in to Management Console as an MC Super user.
2. Click **MC Settings**.
3. Click **User Management**.
4. To create a new MC user, click **Add**. To use an existing MC user, select the user and click **Edit**.
5. Next to the **DB access level** window, click **Add**.
6. In the **Add Permissions** window, do the following:
 - a. From the **Choose a database** drop-down list, select the database for which you want the user to be able to create a design.
 - b. In the **Database username** field, enter the user name you created on the Vertica server, `new_user` in this example.
 - c. In the Database password field, enter the password for the database you selected in step a.
 - d. In the **Restrict access** drop-down list, select the level of MC user you want for this user.
7. Click **OK** to save your changes.
8. Log out of the MC Super user account.

The MC user is now mapped to the user that you created on the Vertica server. Log in as the MC user and use Database Designer to create an optimized design for your database.

For more information about mapping MC users, see [Mapping an MC User to a Database user's Privileges](#).

Allowing the DBDUSER to Run Database Designer Programmatically

To allow a user with the DBDUSER role to run Database Designer programmatically, take these steps:

1. The DBADMIN user must grant the DBDUSER role:

```
=> GRANT DBDUSER TO <username>;
```

This role persists until the DBADMIN user revokes it.

- For a non-DBADMIN user to run the Database Designer programmatically or using Management Console, one of the following two steps must happen first:
 - If the user's default role is already DBDUSER, skip this step. Otherwise, The user must enable the DBDUSER role:

```
=> SET ROLE DBDUSER;
```

- The DBADMIN must add DBDUSER as the default role for that user:

```
=> ALTER USER <username> DEFAULT ROLE DBDUSER;
```

DBDUSER Capabilities and Limitations

The DBDUSER role has the following capabilities and limitations:

- A DBDUSER cannot create a design with a K-safety less than the system K-safety. If the designs violate the current K-safety by not having enough buddy projections for the tables, the design does not complete.
- A DBDUSER cannot explicitly change the ancient history mark (AHM), even during deployment of their design.

When you create a design, you automatically have privileges to manipulate the design. Other tasks may require that the DBDUSER have additional privileges:

To...	DBDUSER must have...
Add design tables	<ul style="list-style-type: none">USAGE privilege on the design table schemaOWNER privilege on the design table
Add a single design query	<ul style="list-style-type: none">Privilege to execute the design query
Add a file of design queries	<ul style="list-style-type: none">Read privilege on the storage location that contains the query filePrivilege to execute all the queries in the file
Add design queries from the result of a user query	<ul style="list-style-type: none">Privilege to execute the user queryPrivilege to execute each design query retrieved from the results of the user query

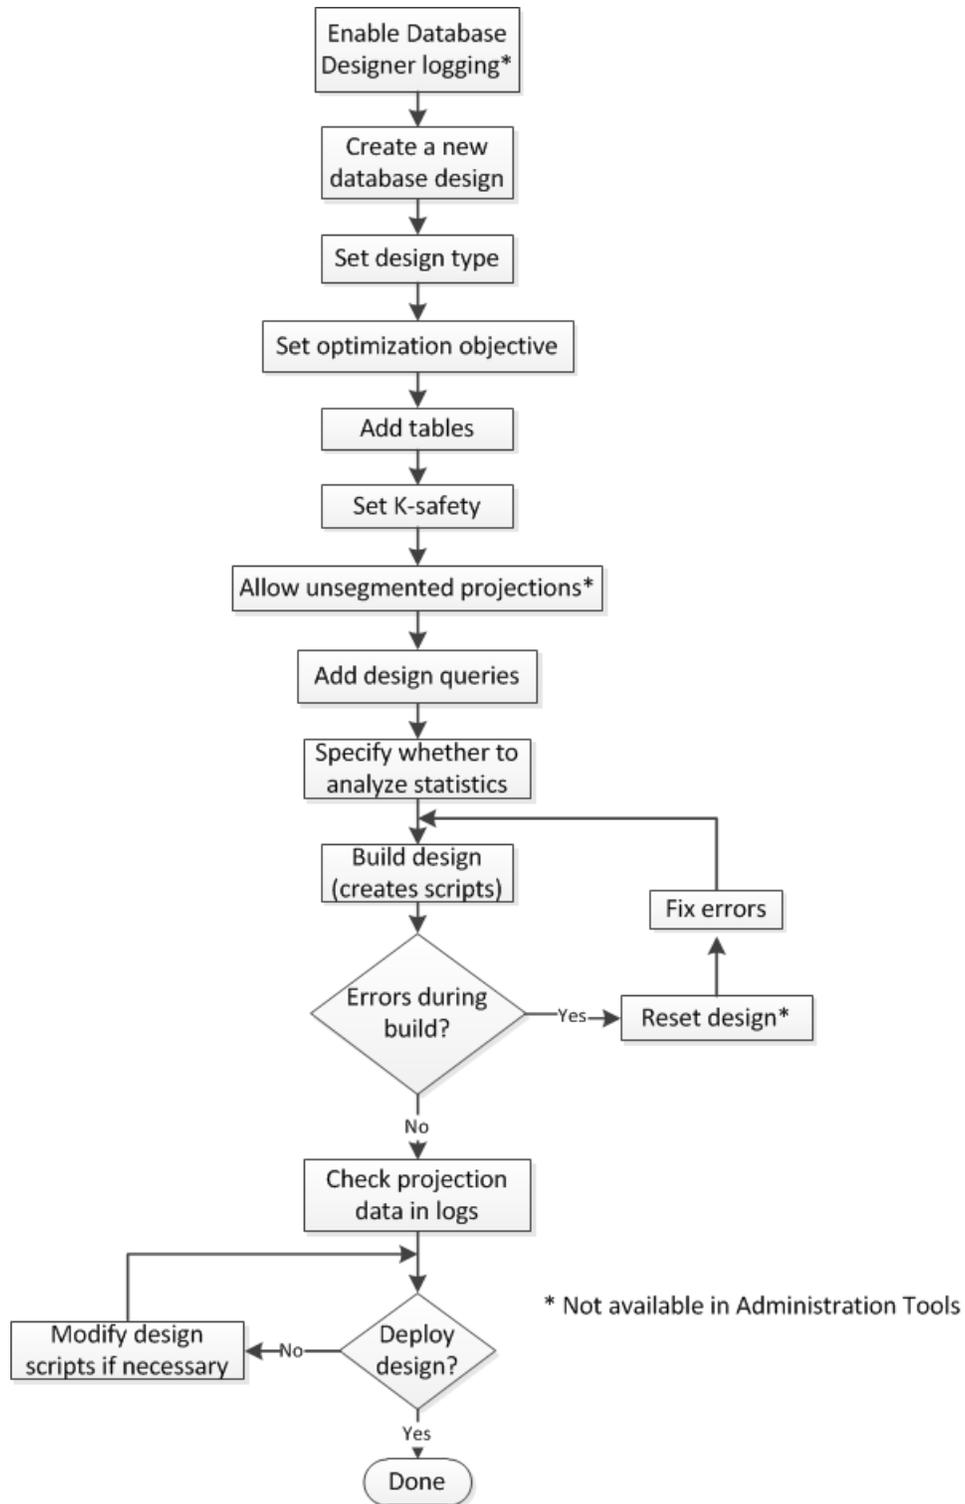

To...	DBDUSER must have...
Create the design and deployment scripts	<ul style="list-style-type: none">• WRITE privilege on the storage location of the design script• WRITE privilege on the storage location of the deployment script

Workflow for Running Database Designer

Vertica provides three ways to run Database Designer:

- [Creating a Database Design in Management Console](#)
- [Using Administration Tools to Create a Design](#)
- [Running Database Designer Programmatically](#)

The following workflow is common to all these ways to run Database Designer:

Logging Projection Data for Database Designer

When you run Database Designer, the Optimizer proposes a set of ideal projections based on the options that you specify. When you deploy the design, Database Designer creates the design based on these projections. However, space or budget constraints may prevent Database Designer from creating all the proposed projections. In addition, Database Designer may not be able to implement the projections using ideal criteria.

To get information about the projections, first enable the Database Designer logging capability. When enabled, Database Designer stores information about the proposed projections in two Data Collector tables. After Database Designer deploys the design, these logs contain information about which proposed projections were actually created. After deployment, the logs contain information about:

- Projections that the Optimizer proposed
- Projections that Database Designer actually created when the design was deployed
- Projections that Database Designer created, but not with the ideal criteria that the Optimizer identified.
- The DDL used to create all the projections
- Column optimizations

If you do not deploy the design immediately, review the log to determine if you want to make any changes. If the design has been deployed, you can still manually create some of the projections that Database Designer did not create.

To enable the Database Designer logging capability, see [Enabling Logging for Database Designer](#)

To view the logged information, see [Viewing Database Designer Logs](#).

Enabling Logging for Database Designer

By default, Database Designer does not log information about the projections that the Optimizer proposed and the Database Designer deploys.

To enable Database Designer logging, enter the following command:

```
=> ALTER DATABASE mydb SET DBDLogInternalDesignProcess = 1;
```

To disable Database Designer logging, enter the following command:

```
=> ALTER DATABASE mydb SET DBDLogInternalDesignProcess = 0;
```

For more information about logging, see:

- [Logging Projection Data for Database Designer](#)
- [Viewing Database Designer Logs](#)

Viewing Database Designer Logs

You can find data about the projections that Database Designer considered and deployed in two Data Collector tables:

- DC_DESIGN_PROJECTION_CANDIDATES
- DC_DESIGN_QUERY_PROJECTION_CANDIDATES

DC_DESIGN_PROJECTION_CANDIDATES

The DC_DESIGN_PROJECTION_CANDIDATES table contains information about all the projections that the Optimizer proposed. This table also includes the DDL that creates them. The `is_a_winner` field indicates if that projection was part of the actual deployed design. To view the DC_DESIGN_PROJECTION_CANDIDATES table, enter:

```
=> SELECT * FROM DC_DESIGN_PROJECTION_CANDIDATES;
```

DC_DESIGN_QUERY_PROJECTION_CANDIDATES

The DC_DESIGN_QUERY_PROJECTION_CANDIDATES table lists plan features for all design queries.

Possible features are:

- FULLY DISTRIBUTED JOIN
- MERGE JOIN
- GROUPBY PIPE
- FULLY DISTRIBUTED GROUPBY
- RLE PREDICATE

- VALUE INDEX PREDICATE
- LATE MATERIALIZATION

For all design queries, the DC_DESIGN_QUERY_PROJECTION_CANDIDATES table includes the following plan feature information:

- Optimizer path cost.
- Database Designer benefits.
- Ideal plan feature and its description, which identifies how the referenced projection should be optimized.
- If the design was deployed, the actual plan feature and its description is included in the table. This information identifies how the referenced projection was actually optimized.

Because most projections have multiple optimizations, each projection usually has multiple rows. To view the DC_DESIGN_QUERY_PROJECTION_CANDIDATES table, enter:

```
=> SELECT * FROM DC_DESIGN_QUERY_PROJECTION_CANDIDATES;
```

To see example data from these tables, see [Database Designer Logs: Example Data](#).

Database Designer Logs: Example Data

In the following example, Database Designer created the logs after creating a comprehensive design for the VMart sample database. The output shows two records from the DC_DESIGN_QUERY_PROJECTION_CANDIDATES table.

The first record contains information about the customer_dimension_dbd_1_sort_\$customer_gender__\$annual_income\$ projection. The record includes the CREATE PROJECTION statement that Database Designer used to create the projection. The is_a_winner column is t, indicating that Database Designer created this projection when it deployed the design.

The second record contains information about the product_dimension_dbd_2_sort_\$product_version__\$product_key\$ projection. For this projection, the is_a_winner column is f. The Optimizer recommended that Database Designer create this projection as part of the design. However, Database Designer did not create the projection when it deployed the design. The log includes the DDL for the CREATE PROJECTION statement. If you want to add the projection manually, you can use that DDL. For more information, see [Creating a Design Manually](#).

The next example shows the contents of two records in the DC_DESIGN_QUERY_PROJECTION_CANDIDATES. Both of these rows apply to projection id 45035996273726626.

In the first record, the Optimizer recommends that Database Designer optimize the customer_gender column for the GROUPBY PIPE algorithm.

In the second record, the Optimizer recommends that Database Designer optimize the public.customer_dimension table for late materialization. Late materialization can improve the performance of joins that might spill to disk.

Specifying Parameters for Database Designer

Before you run Database Designer to create a design, provide information that allows Database Designer to create the optimal physical schema:

- [Design Name](#)
- [Design Types](#)
- [Optimization Objectives](#)
- [Design Tables with Sample Data](#)
- [Design Queries](#)
- [K-safety](#)

- [Replicated and Segmented Projections](#)
- [Statistics Analysis](#)

Design Name

All designs that Database Designer creates must have a name that you specify. The design name must be alphanumeric or underscore (_) characters, and can be no more than 32 characters long. (Administrative Tools and Management Console limit the design name to 16 characters.)

The design name becomes part of the files that Database Designer generates, including the deployment script, allowing the files to be easily associated with a particular Database Designer run.

Design Types

The Database Designer can create two distinct design types. The design you choose depends on what you are trying to accomplish:

- [Comprehensive Design](#)
- [Incremental Design](#)

Comprehensive Design

A comprehensive design creates an initial or replacement design for all the tables in the specified schemas. Create a comprehensive design when you are creating a new database.

To help Database Designer create an efficient design, load representative data into the tables before you begin the design process. When you load data into a table, Vertica creates an unoptimized superprojection so that Database Designer has projections to optimize. If a table has no data, Database Designer cannot optimize it.

Optionally, supply Database Designer with representative queries that you plan to use so Database Designer can optimize the design for them. If you do not supply any queries, Database Designer creates a generic optimization of the superprojections that minimizes storage, with no query-specific projections.

During a comprehensive design, Database Designer creates deployment scripts that:

- Create new projections to optimize query performance, only when they do not already exist.
- Create replacement buddy projections when Database Designer changes the encoding of pre-existing projections that it has decided to keep.

Incremental Design

After you create and deploy a comprehensive database design, it's likely that your database will change over time in various ways. You should periodically consider using Database Designer to create incremental designs that address these changes. Changes that warrant an incremental design can include:

- Significant data additions or updates
- New or modified queries that you run regularly
- Performance issues with one or more queries
- Schema changes

Optimization Objectives

When creating a design, Database Designer can optimize the design for one of three objectives:

- **Load:** Database Designer creates a design that is optimized for loads, minimizing database size, potentially at the expense of query performance.
- **Performance:** Database Designer creates a design that is optimized for fast query performance. Because it recommends a design for optimized query performance, this design might recommend more than the Load or Balanced objectives, potentially resulting in a larger database storage size.
- **Balanced:** Database Designer creates a design whose objectives are balanced between database size and query performance.

A fully optimized query has an optimization ratio of 0.99. Optimization ratio is the ratio of a query's benefits achieved in the design produced by the Database Designer to that achieved in the ideal plan. Check the optimization ratio with the OptRatio parameter in designer.log.

Design Tables with Sample Data

You *must* specify one or more design tables for Database Designer to deploy a design. If your schema is empty, it does not appear as a design table option.

When you specify design tables, consider the following:

- To create the most efficient projections for your database, load a moderate amount of representative data into tables before running Database Designer. Database Designer considers the data in this table when creating the design.
- If your design tables have a large amount of data, the Database Designer run takes a long time; if your tables have too little data, the design is not optimized. Vertica recommends that 10 GB of sample data is sufficient for creating an optimal design.
- If you submit a design table with no data, Database Designer ignores it.
- If one of your design tables has been dropped, you will not be able to build or deploy your design.

Design Queries

If you supply representative queries that you run on your database to Database Designer, it optimizes the performance of those queries.

Database Designer checks the validity of all queries when you add them to your design and again when it builds the design. If a query is invalid, Database Designer ignores it.

The query file can contain up to 100 queries. Each query can be assigned a weight that indicates its relative importance so that Database Designer can prioritize it when creating the design. Database Designer groups queries that affect the design that Database Designer creates in the same way and considers one weighted query when creating a design.

The following options apply, depending on whether you create an incremental or comprehensive design:

- Design queries are required for incremental designs.
- Design queries are optional for comprehensive designs. If you do not provide design queries, Database Designer recommends a generic design that does not consider specific queries.

Query Repository

Using Management Console, you can submit design queries from the [QUERY_REQUESTS](#) system table. This is called *the query repository*.

The QUERY_REQUESTS table contains queries that users have run recently. For a comprehensive design, you can submit up to 200 queries from the QUERY_REQUESTS table to Database Designer to be considered when creating the design. For an incremental design, you can submit up to 100 queries from the QUERY_REQUESTS table.

Replicated and Segmented Projections

When creating a comprehensive design, Database Designer creates projections based on data statistics and queries. It also reviews the submitted design tables to decide whether projections should be segmented (distributed across the cluster nodes) or replicated (duplicated on all cluster nodes).

For detailed information, see the following sections:

- [Replicated Projections](#)
- [Segmented Projections](#)

Replicated Projections

Replication occurs when Vertica stores identical copies of data across all nodes in a cluster.

If you are running on a single-node database, *all* projections are replicated because segmentation is not possible in a single-node database.

Assuming that *largest-row-count* equals the number of rows in the design table with the largest number of rows, Database Designer recommends that a projection be replicated if any of the following conditions is true:

- *largest-row-count* < 1,000,000 and number of rows in the table <= 10% of *largest-row-count*
- *largest-row-count* >= 10,000,000 and number of rows in the table <= 1% of *largest-row-count*
- The number of rows in the table <= 100,000

For more information about replication, see [High Availability With Projections](#) in Vertica Concepts.

Segmented Projections

Segmentation occurs when Vertica distributes data evenly across multiple database nodes so that all nodes participate in query execution. Projection segmentation provides high availability and recovery, and optimizes query execution.

When running Database Designer programmatically or using Management Console, you can specify to allow Database Designer to recommend unsegmented projections in the design. If you do not specify this, Database Designer recommends only segmented projections.

Database Designer recommends segmented superprojections for large tables when deploying to multiple node clusters, and recommends replicated superprojections for smaller tables.

Database Designer does not segment projections on:

- Single-node clusters
- LONG VARCHAR and LONG VARBINARY columns

For more information about segmentation, see [High Availability With Projections](#) in Vertica Concepts.

Statistics Analysis

By default, Database Designer analyzes statistics for the design tables when adding them to the design. This option is optional, but Vertica recommends that you analyze statistics because accurate statistics help Database Designer optimize compression and query performance.

Analyzing statistics takes time and resources. If the current statistics for the design tables are up to date, do not bother analyzing the statistics. When in doubt, analyze the statistics to make sure they are current.

For more information, see [Collecting Statistics](#).

Building a Design

After you have created design tables and loaded data into them, and then specified the parameters you want Database Designer to use when creating the physical schema, direct Database Designer to create the scripts necessary to build the design.

Note: You cannot stop a running database if Database Designer is building a database design.

When you build a database design, Vertica generates two scripts:

- **Deployment script:** *design-name_deploy.sql*—Contains the SQL statements that create projections for the design you are deploying, deploy the design, and drop unused projections. When the deployment script runs, it creates the optimized design. For details about how to run this script and deploy the design, see [Deploying a Design](#).
- **Design script:** *design-name_design.sql*—Contains the CREATE PROJECTION statements that Database Designer uses to create the design. Review this script to make sure you are happy with the design.

The design script is a subset of the deployment script. It serves as a backup of the DDL for the projections that the deployment script creates.

When you create a design using Management Console:

- If you submit a large number of queries to your design and build it right immediately, a timing issue could cause the queries not to load before deployment starts. If this occurs, you might see one of the following errors:
 - No queries to optimize for
 - No tables to design projections for

To accommodate this timing issue, you may need to reset the design, check the **Queries** tab to make sure the queries have been loaded, and then rebuild the design. Detailed instructions are in:

- [Using the Wizard to Create a Design](#)
- [Creating a Design Manually](#)
- The scripts are deleted when deployment completes. To save a copy of the deployment script after the design is built but before the deployment completes, go to the **Output** window and copy and paste the SQL statements to a file.

Resetting a Design

You must reset a design when:

- You build a design and the output scripts described in [Building a Design](#) are not created.
- You build a design but Database Designer cannot complete the design because the queries it expects are not loaded.

Resetting a design discards all the run-specific information of the previous Database Designer build, but retains its configuration (design type, optimization objectives, K-safety, etc.) and tables and queries.

After you reset a design, review the design to see what changes you need to make. For example, you can fix errors, change parameters, or check for and add additional tables or queries. Then you can rebuild the design.

You can only reset a design in Management Console or by using the [DESIGNER_RESET_DESIGN](#) function.

Deploying a Design

After running Database Designer to generate a deployment script, Vertica recommends that you test your design on a non-production server before you deploy it to your production server.

Both the design and deployment processes run in the background. This is useful if you have a large design that you want to run overnight. Because an active SSH session is not required, the design/deploy operations continue to run uninterrupted, even if the session is terminated.

Note: You cannot stop a running database if Database Designer is building or deploying a database design.

Database Designer runs as a background process. Multiple users can run Database Designer concurrently without interfering with each other or using up all the cluster resources. However, if multiple users are deploying a design on the same tables at the same time, Database Designer may not be able to complete the deployment. To avoid problems, consider the following:

- Schedule potentially conflicting Database Designer processes to run sequentially overnight so that there are no concurrency problems.
- Avoid scheduling Database Designer runs on the same set of tables at the same time.

There are two ways to deploy your design:

- [Deploying Designs Using Database Designer](#)
- [Deploying Designs Manually](#)

Deploying Designs Using Database Designer

Micro Focus recommends that you run Database Designer and deploy optimized projections right after loading your tables with sample data because Database Designer provides projections optimized for the current state of your database.

If you choose to allow Database Designer to automatically deploy your script during a comprehensive design and are running Administrative Tools, Database Designer creates a backup script of your database's current design. This script helps you re-create the design of projections that may have been dropped by the new design. The backup script is located in the output directory you specified during the design process.

If you choose not to have Database Designer automatically run the deployment script (for example, if you want to maintain projections from a pre-existing deployment), you can manually run the deployment script later. See [Deploying Designs Manually](#).

To deploy a design while running Database Designer, do one of the following:

- In Management Console, select the design and click **Deploy Design**.
- In the Administration Tools, select **Deploy design** in the **Design Options** window.

If you are running Database Designer programmatically, use `DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY` and set the `deploy` parameter to 'true'.

Once you have deployed your design, query the `DEPLOY_STATUS` system table to see the steps that the deployment took:

```
vmartdb=> SELECT * FROM V_MONITOR.DEPLOY_STATUS;
```

Deploying Designs Manually

If you choose not to have Database Designer deploy your design at design time, you can deploy the design later using the deployment script:

1. Make sure that you have a database that contains the same tables and projections as the database on which you ran Database Designer. The database should also contain sample data.
2. To deploy the projections to a test or production environment, use the following `vsq` command to execute the deployment script, where *design-name* is the name of the database design:

```
=> \i design-name_deploy.sql
```

How to Create a Design

There are three ways to create a design using Database Designer:

- From Management Console, open a database and select the **Design** page at the bottom of the window.

For details about using Management Console to create a design, see [Creating a Database Design in Management Console](#)

- Programmatically, using the techniques described in [About Running Database Designer Programmatically](#) in Analyzing Data. To run Database Designer programmatically, you must be a **DBADMIN** or have been granted the **DBDUSER** role and enabled that role.
- From the Administration Tools menu, by selecting **Configuration Menu > Run Database Designer**. You must be a DBADMIN user to run Database Designer from the Administration Tools.

For details about using Administration Tools to create a design, see [Using Administration Tools to Create a Design](#).

The following table shows what Database Designer capabilities are available in each tool:

Database Designer Capability	Management Console	Running Database Designer Programmatically	Administrative Tools
Create design	Yes	Yes	Yes
Design name length (# of characters)	16	32	16
Build design (create design and deployment scripts)	Yes	Yes	Yes
Create backup script			Yes
Set design type (comprehensive or incremental)	Yes	Yes	Yes
Set optimization objective	Yes	Yes	Yes
Add design tables	Yes	Yes	Yes
Add design queries file	Yes	Yes	Yes
Add single design query		Yes	

Database Designer Capability	Management Console	Running Database Designer Programmatically	Administrative Tools
Use query repository	Yes	Yes	
Set K-safety	Yes	Yes	Yes
Analyze statistics	Yes	Yes	Yes
Require all unsegmented projections	Yes	Yes	
View event history	Yes	Yes	
Set correlation analysis mode (Default = 0)		Yes	

Using Administration Tools to Create a Design

To use the Administration Tools interface to create an optimized design for your database, you must be a DBADMIN user. Follow these steps:

1. Log in as the dbadmin user and start Administration Tools.
2. From the main menu, start the database for which you want to create a design. The database must be running before you can create a design for it.
3. On the main menu, select **Configuration Menu** and click **OK**.
4. On the Configuration Menu, select **Run Database Designer** and click **OK**.
5. On the **Select a database to design** window, enter the name of the database for which you are creating a design and click **OK**.
6. On the **Enter the directory for Database Designer output** window, enter the full path to the directory to contain the design script, deployment script, backup script, and log files, and click **OK**.

For information about the scripts, see [Building a Design](#).

7. On the **Database Designer** window, enter a name for the design and click **OK**.

For more information about design names, see [Design Name](#).

8. On the **Design Type** window, choose which type of design to create and click **OK**.

For a description of the design types, see [Design Types](#)

9. The **Select schema(s) to add to query search path** window lists all the schemas in the database that you selected. Select the schemas that contain representative data that you want Database Designer to consider when creating the design and click **OK**.

For more information about choosing schema and tables to submit to Database Designer, see [Design Tables with Sample Data](#).

10. On the **Optimization Objectives** window, select the objective you want for the database optimization:

- **Optimize with Queries**

For more information, see [Design Queries](#).

- **Update statistics**

For more information see [Statistics Analysis](#).

- **Deploy design**

For more information, see [Deploying a Design](#).

For details about these objectives, see [Optimization Objectives](#).

11. The final window summarizes the choices you have made and offers you two choices:

- **Proceed** with building the design, and deploying it if you specified to deploy it immediately. If you did not specify to deploy, you can review the design and deployment scripts and deploy them manually, as described in [Deploying Designs Manually](#).

- **Cancel** the design and go back to change some of the parameters as needed.

12. Creating a design can take a long time. To cancel a running design from the Administration Tools window, enter **Ctrl+C**.

To create a design for the VMart example database, see [Using Database Designer to Create a Comprehensive Design](#) in Getting Started.

Running Database Designer Programmatically

Vertica provides a set of meta-functions that enable programmatic access to Database Designer functionality. Run Database Designer programmatically to perform the following tasks:

- Optimize performance on tables that you own.
- Create or update a design without requiring superuser or DBADMIN intervention.
- Add individual queries and tables, or add data to your design, and then rerun Database Designer to update the design based on this new information.
- Customize the design.
- Use recently executed queries to set up your database to run Database Designer automatically on a regular basis.
- Assign each design query a *query weight* that indicates the importance of that query in creating the design. Assign a higher weight to queries that you run frequently so that Database Designer prioritizes those queries in creating the design.

For more details about Database Designer functions, see [Database Designer Function Categories](#).

Database Designer Function Categories

Database Designer functions perform the following operations, generally performed in the following order:

1. [Create a design](#).
2. [Set design properties](#).
3. [Populate a design](#).
4. [Create design and deployment scripts](#).
5. [Get design data](#).
6. [Clean up](#).

For detailed information, see [Workflow for Running Database Designer Programmatically](#).

Create a design

[DESIGNER_CREATE_DESIGN](#) directs Database Designer to create a design.

Set design properties

The following functions let you specify properties of a particular design:

DESIGNER_SET_DESIGN_TYPE	Specifies whether the design is comprehensive or incremental.
DESIGNER_DESIGN_PROJECTION_ENCODINGS	Analyzes encoding in the specified projections and creates a script that implements encoding recommendations.
DESIGNER_SET_DESIGN_KSAFETY	Sets the K-safety value for a comprehensive design.
DESIGNER_SET_OPTIMIZATION_OBJECTIVE	Specifies whether the design optimizes for query or load performance.
DESIGNER_SET_PROPOSE_UNSEGMENTED_PROJECTIONS	Enables inclusion of unsegmented projections in the design.
DESIGNER_SET_ANALYZE_CORRELATIONS_MODE	Determines how the design handles column correlations.

Populate a design

The following functions let you add tables and queries to your Database Designer design:

DESIGNER_ADD_DESIGN_TABLES	Adds the specified tables to a design.
DESIGNER_ADD_DESIGN_QUERY	Adds queries to the design and weights them.
DESIGNER_ADD_DESIGN_QUERIES	
DESIGNER_ADD_DESIGN_QUERIES_FROM_RESULTS	

Create design and deployment scripts

The following functions populate the Database Designer workspace and create design and deployment scripts. You can also analyze statistics, deploy the design automatically, and drop the workspace after the deployment:

DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY	Populates the design and creates design and deployment scripts.
DESIGNER_WAIT_FOR_DESIGN	Waits for a currently running design to complete.

Reset a design

[DESIGNER_RESET_DESIGN](#) discards all the run-specific information of the previous Database Designer build or deployment of the specified design but retains its configuration.

Get design data

The following functions display information about projections and scripts that the Database Designer created:

DESIGNER_OUTPUT_ALL_DESIGN_PROJECTIONS	Sends to standard output DDL statements that define design projections.
DESIGNER_OUTPUT_DEPLOYMENT_SCRIPT	Sends to standard output a design's deployment script.

Clean up

The following functions cancel any running Database Designer operation or drop a Database Designer design and all its contents:

DESIGNER_CANCEL_POPULATE_DESIGN	Cancels population or deployment operation for the specified design if it is currently running.
DESIGNER_DROP_DESIGN	Removes the schema associated with the specified design and all its contents.
DESIGNER_DROP_ALL_DESIGNS	Removes all Database Designer-related schemas associated with the current user.

Workflow for Running Database Designer Programmatically

The following example shows the steps you take to create a design by running Database Designer programmatically.

Note: Be sure to back up the existing design using the [EXPORT_CATALOG](#) function before running the Database Designer functions on an existing schema. You must explicitly back up the current design when using Database Designer to create a new comprehensive design.

Before you run this example, you should have the DBDUSER role, and you should have enabled that role using the SET ROLE DBDUSER command:

1. Create a table in the public schema:

```
=> CREATE TABLE T(  
  x INT,  
  y INT,  
  z INT,  
  u INT,  
  v INT,  
  w INT PRIMARY KEY  
);
```

2. Add data to the table:

```
\! perl -e 'for ($i=0; $i<100000; ++$i) {printf("%d, %d, %d, %d, %d, %d\n", $i/10000, $i/100,  
$i/10, $i/2, $i, $i);}'  
| vsql -c "COPY T FROM STDIN DELIMITER ',' DIRECT;"
```

3. Create a second table in the public schema:

```
=> CREATE TABLE T2(  
  x INT,  
  y INT,  
  z INT,  
  u INT,  
  v INT,  
  w INT PRIMARY KEY  
);
```

4. Copy the data from table T1 to table T2 and commit the changes:

```
=> INSERT /*+DIRECT*/ INTO T2 SELECT * FROM T;  
=> COMMIT;
```

5. Create a new design:

```
=> SELECT DESIGNER_CREATE_DESIGN('my_design');
```

This command adds information to the [DESIGNS](#) system table in the V_MONITOR schema.

6. Add tables from the public schema to the design :

```
=> SELECT DESIGNER_ADD_DESIGN_TABLES('my_design', 'public.t');  
=> SELECT DESIGNER_ADD_DESIGN_TABLES('my_design', 'public.t2');
```

These commands add information to the [DESIGN_TABLES](#) system table.

7. Create a file named `queries.txt` in `/tmp/examples`, or another directory where you have READ and WRITE privileges. Add the following two queries in that file and save it. Database Designer uses these queries to create the design:

```
SELECT DISTINCT T2.u FROM T JOIN T2 ON T.z=T2.z-1 WHERE T2.u > 0;  
SELECT DISTINCT w FROM T;
```

8. Add the queries file to the design and display the results—the numbers of accepted queries, non-design queries, and unoptimizable queries:

```
=> SELECT DESIGNER_ADD_DESIGN_QUERIES  
      ('my_design',  
       '/tmp/examples/queries.txt',  
       'true'  
      );
```

The results show that both queries were accepted:

```
Number of accepted queries           =2  
Number of queries referencing non-design tables =0  
Number of unsupported queries       =0  
Number of illegal queries           =0
```

The `DESIGNER_ADD_DESIGN_QUERIES` function populates the [DESIGN_QUERIES](#) system table.

9. Set the design type to **comprehensive**. (This is the default.) A comprehensive design creates an initial or replacement design for all the design tables:

```
=> SELECT DESIGNER_SET_DESIGN_TYPE('my_design', 'comprehensive');
```

10. Set the optimization objective to **query**. This setting creates a design that focuses on faster query performance, which might recommend additional projections. These projections could result in a larger database storage footprint:

```
=> SELECT DESIGNER_SET_OPTIMIZATION_OBJECTIVE('my_design', 'query');
```

11. Create the design and save the design and deployment scripts in `/tmp/examples`, or another directory where you have READ and WRITE privileges. The following command:

- Analyzes statistics
- Doesn't deploy the design.
- Doesn't drop the design after deployment.
- Stops if it encounters an error.

```
=> SELECT DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY  
  ('my_design',  
   '/tmp/examples/my_design_projections.sql',  
   '/tmp/examples/my_design_deploy.sql',  
   'True',  
   'False',  
   'False',  
   'False'  
  );
```

This command adds information to the following system tables:

- [DEPLOYMENT_PROJECTION_STATEMENTS](#)
- [DEPLOYMENT_PROJECTIONS](#)
- [OUTPUT_DEPLOYMENT_STATUS](#)

12. Examine the status of the Database Designer run to see what projections Database Designer recommends. In the `deployment_projection_name` column:

- `rep` indicates a replicated projection
- `super` indicates a superprojection

The `deployment_status` column is pending because the design has not yet been deployed.

For this example, Database Designer recommends four projections:

```
=> \x
Expanded display is on.
=> SELECT * FROM OUTPUT_DEPLOYMENT_STATUS;
-[ RECORD 1 ]-----+-----
deployment_id      | 45035996273795970
deployment_projection_id | 1
deployment_projection_name | T_DBD_1_rep_my_design
deployment_status   | pending
error_message      | N/A
-[ RECORD 2 ]-----+-----
deployment_id      | 45035996273795970
deployment_projection_id | 2
deployment_projection_name | T2_DBD_2_rep_my_design
deployment_status   | pending
error_message      | N/A
-[ RECORD 3 ]-----+-----
deployment_id      | 45035996273795970
deployment_projection_id | 3
deployment_projection_name | T_super
deployment_status   | pending
error_message      | N/A
-[ RECORD 4 ]-----+-----
deployment_id      | 45035996273795970
deployment_projection_id | 4
deployment_projection_name | T2_super
deployment_status   | pending
error_message      | N/A
```

13. View the script `/tmp/examples/my_design_deploy.sql` to see how these projections are created when you run the deployment script. In this example, the script also assigns the encoding schemes `RLE` and `COMMONDELTA_COMP` to columns where appropriate.
14. Deploy the design from the directory where you saved it:

```
=> \i /tmp/examples/my_design_deploy.sql
```

15. Now that the design is deployed, delete the design:

```
=> SELECT DESIGNER_DROP_DESIGN('my_design');
```

Privileges for Running Database Designer Functions

Non-DBADMIN users with the [DBDUSER role](#) can run Database Designer [functions](#). Two steps are required to enable users to run these functions:

1. A DBADMIN or superuser grants the user the DBDUSER role:

```
=> GRANT DBDUSER TO username;
```

This role persists until the DBADMIN revokes it.

2. Before the DBDUSER can run Database Designer functions, one of the following must occur:

- The user enables the DBDUSER role:

```
=> SET ROLE DBDUSER;
```

- The superuser sets the user's default role to DBDUSER:

```
=> ALTER USER username DEFAULT ROLE DBDUSER;
```

General DBDUSER Limitations

As a DBDUSER, the following restrictions apply:

- You can set a design's [K-safety](#) to a value less than or equal to system K-safety. You cannot change system K-safety.
- You cannot explicitly change the ancient history mark (AHM), even during design deployment.

Design Dependencies and Privileges

Individual design tasks are likely to have dependencies that require specific privileges:

Task	Required privileges
Add tables to a design	<ul style="list-style-type: none">• USAGE privilege on the design table schema• OWNER privilege on the design table
Add a single design query to the design	<ul style="list-style-type: none">• Privilege to execute the design query
Add a query file to the design	<ul style="list-style-type: none">• Read privilege on the storage location that contains the query file

Task	Required privileges
	<ul style="list-style-type: none">• Privilege to execute all the queries in the file
Add queries from the result of a user query to the design	<ul style="list-style-type: none">• Privilege to execute the user query• Privilege to execute each design query retrieved from the results of the user query
Create design and deployment scripts	<ul style="list-style-type: none">• WRITE privilege on the storage location of the design script• WRITE privilege on the storage location of the deployment script

Resource Pool for Database Designer Users

When you grant a user the DBDUSER role, be sure to associate a resource pool with that user to manage resources during Database Designer runs. This allows multiple users to run Database Designer concurrently without interfering with each other or using up all cluster resources.

Note: When a user runs Database Designer, execution is mostly contained in the user's resource pool. However, Vertica might also use other system resource pools to perform less-intensive tasks.

Creating Custom Designs

Micro Focus strongly recommends that you use the physical schema design produced by Database Designer, which provides K-safety, excellent query performance, and efficient use of storage space. If any queries run less as efficiently than you expect, consider using the Database Designer incremental design process to optimize the database design for the query.

If the projections created by Database Designer still do not meet your needs, you can write custom projections, from scratch or based on projection designs created by Database Designer.

If you are unfamiliar with writing custom projections, start by modifying an existing design generated by Database Designer.

Custom Design Process

To create a custom design or customize an existing one:

1. Plan the new design or modifications to an existing one. See [Planning Your Design](#).
2. Create or modify projections. See [Design Fundamentals](#) and [CREATE PROJECTION](#) for more detail.
3. Deploy projections to a test environment. See [Writing and Deploying Custom Projections](#).
4. Test and modify projections as needed.
5. After you finalize the design, deploy projections to the production environment.

Planning Your Design

The syntax for creating a design is easy for anyone who is familiar with SQL. As with any successful project, however, a successful design requires some initial planning. Before you create your first design:

- Become familiar with standard design requirements and plan your design to include them. See [Design Requirements](#).
- Determine how many projections you need to include in the design. See [Determining the Number of Projections to Use](#).
- Determine the type of compression and encoding to use for columns. See [Data Encoding and Compression](#).
- Determine whether or not you want the database to be K-safe. Vertica recommends that all production databases have a minimum K-safety of one (K=1). Valid K-safety values are 0, 1, and 2. See [Using Database Designer](#).

Design Requirements

A physical schema design is a script that contains CREATE PROJECTION statements. These statements determine which columns are included in projections and how they are optimized.

If you use Database Designer as a starting point, it automatically creates designs that meet all fundamental design requirements. If you intend to create or modify designs manually, be aware that all designs must meet the following requirements:

- Every design must create at least one superprojection for every table in the database that is used by the client application. These projections provide complete coverage that enables users to perform ad-hoc queries as needed. They can contain joins and they are usually configured to maximize performance through sort order, compression, and encoding.
- Query-specific projections are optional. If you are satisfied with the performance provided through superprojections, you do not need to create additional projections. However, you can maximize performance by tuning for specific query work loads.
- Micro Focus recommends that all production databases have a minimum K-safety of one (K=1) to support high availability and recovery. (K-safety can be set to 0, 1, or 2.) See [High Availability With Projections](#) in Vertica Concepts and [Using Database Designer](#).

- Vertica recommends that if you have more than 20 nodes, but small tables, do not create replicated projections. If you create replicated projections, the catalog becomes very large and performance may degrade. Instead, consider segmenting those projections.

Determining the Number of Projections to Use

In many cases, a design that consists of a set of superprojections (and their buddies) provides satisfactory performance through compression and encoding. This is especially true if the sort orders for the projections have been used to maximize performance for one or more query predicates (WHERE clauses).

However, you might want to add additional query-specific projections to increase the performance of queries that run slowly, are used frequently, or are run as part of business-critical reporting. The number of additional projections (and their buddies) that you create should be determined by:

- Your organization's needs
- The amount of disk space you have available on each node in the cluster
- The amount of time available for loading data into the database

As the number of projections that are tuned for specific queries increases, the performance of these queries improves. However, the amount of disk space used and the amount of time required to load data increases as well. Therefore, you should create and test designs to determine the optimum number of projections for your database configuration. On average, organizations that choose to implement query-specific projections achieve optimal performance through the addition of a few query-specific projections.

Designing for K-Safety

Micro Focus recommends that all production databases have a minimum K-safety of one ($K=1$). Valid K-safety values for production databases are 1 and 2. Non-production databases do not have to be K-safe and can be set to 0.

A K-safe database must have at least three nodes, as shown in the following table:

K-safety level	Number of required nodes
1	3+
2	5+

Note: Vertica only supports K-safety levels 1 and 2.

You can set K-safety to 1 or 2 only when the physical schema design meets certain redundancy requirements. See [Requirements for a K-Safe Physical Schema Design](#).

Using Database Designer

To create designs that are K-safe, Micro Focus recommends that you use the Database Designer. When creating projections with Database Designer, projection definitions that meet K-safe design requirements are recommended and marked with a K-safety level. Database Designer creates a script that uses the [MARK_DESIGN_KSAFE](#) function to set the K-safety of the physical schema to 1. For example:

```
=> \i VMart_Schema_design_opt_1.sql  
CREATE PROJECTION  
CREATE PROJECTION  
mark_design_ksafe  
-----  
Marked design 1-safe  
(1 row)
```

By default, Vertica creates K-safe superprojections when database K-safety is greater than 0.

Monitoring K-Safety

Monitoring tables can be accessed programmatically to enable external actions, such as alerts. You monitor the K-safety level by querying the [SYSTEM](#) table for settings in columns `DESIGNED_FAULT_TOLERANCE` and `CURRENT_FAULT_TOLERANCE`.

Loss of K-Safety

When K nodes in your cluster fail, your database continues to run, although performance is affected. Further node failures could potentially cause the database to shut down if the failed node's data is not available from another functioning node in the cluster.

See Also

[K-Safety](#) in Vertica Concepts

Requirements for a K-Safe Physical Schema Design

Database Designer automatically generates designs with a K-safety of 1 for clusters that contain at least three nodes. (If your cluster has one or two nodes, it generates designs with a K-safety of 0. You can modify a design created for a three-node (or greater) cluster, and the K-safe requirements are already set.

If you create custom projections, your physical schema design must meet the following requirements to be able to successfully recover the database in the event of a failure:

- Segmented projections must be segmented across all nodes. Refer to [Designing for Segmentation](#) and [Designing Segmented Projections for K-Safety](#).
- Replicated projections must be replicated on all nodes. See [Designing Unsegmented Projections for K-Safety](#).
- Segmented projections must have K+1 buddy projections—projections with identical columns and segmentation criteria, where corresponding segments are placed on different nodes.

You can use the [MARK_DESIGN_KSAFE](#) function to find out whether your schema design meets requirements for K-safety.

Requirements for a Physical Schema Design with No K-Safety

If you use Database Designer to generate an comprehensive design that you can modify and you do not want the design to be K-safe, set K-safety level to 0 (zero).

If you want to start from scratch, do the following to establish minimal projection requirements for a functioning database with no K-safety (K=0):

1. Define at least one superprojection for each table in the logical schema.
2. Replicate (define an exact copy of) each dimension table superprojection on each node.

Designing Segmented Projections for K-Safety

Projections must comply with database K-safety requirements. In general, you must create buddy projections for each segmented projection, where the number of buddy projections is $K+1$. Thus, if system K-safety is set to 1, each projection segment must be duplicated by one buddy; if K-safety is set to 2, each segment must be duplicated by two buddies.

Automatic Creation of Buddy Projections

You can use `CREATE PROJECTION` so it automatically creates the number of buddy projections required to satisfy K-safety, by including `SEGMENTED BY ... ALL NODES`. If `CREATE PROJECTION` specifies K-safety (`KSAFE=n`), Vertica uses that setting; if the statement omits `KSAFE`, Vertica uses system K-safety.

In the following example, `CREATE PROJECTION` creates segmented projection `ttt_p1` for table `ttt`. Because system K-safety is set to 1, Vertica requires a buddy projection for each segmented projection. The `CREATE PROJECTION` statement omits `KSAFE`, so Vertica uses system K-safety and creates two buddy projections: `ttt_p1_b0` and `ttt_p1_b1`:

```
=> SELECT mark_design_ksafe(1);

  mark_design_ksafe
-----
Marked design 1-safe
(1 row)

=> CREATE TABLE ttt (a int, b int);
WARNING 6978: Table "ttt" will include privileges from schema "public"
CREATE TABLE

=> CREATE PROJECTION ttt_p1 as SELECT * FROM ttt SEGMENTED BY HASH(a) ALL NODES;
CREATE PROJECTION

=> SELECT projection_name from projections WHERE anchor_table_name='ttt';
  projection_name
-----
  ttt_p1_b0
  ttt_p1_b1
(2 rows)
```

Vertica automatically names buddy projections by appending the suffix `_bn` to the projection base name—for example `ttt_p1_b0`.

Manual Creation of Buddy Projections

If you create a projection on a single node, and system K-safety is greater than 0, you must manually create the number of buddies required for K-safety. For example, you can create projection `xxx_p1` for table `xxx` on a single node, as follows:

```
=> CREATE TABLE xxx (a int, b int);  
WARNING 6978: Table "xxx" will include privileges from schema "public"  
CREATE TABLE  
  
=> CREATE PROJECTION xxx_p1 AS SELECT * FROM xxx SEGMENTED BY HASH(a) NODES v_vmart_node0001;  
CREATE PROJECTION
```

Because K-safety is set to 1, a single instance of this projection is not K-safe. Attempts to insert data into its anchor table `xxx` return with an error like this:

```
=> INSERT INTO xxx VALUES (1, 2);  
ERROR 3586: Insufficient projections to answer query  
DETAIL: No projections that satisfy K-safety found for table xxx  
HINT: Define buddy projections for table xxx
```

In order to comply with K-safety, you must create a buddy projection for projection `xxx_p1`. For example:

```
=> CREATE PROJECTION xxx_p1_buddy AS SELECT * FROM xxx SEGMENTED BY HASH(a) NODES v_vmart_node0002;  
CREATE PROJECTION
```

Table `xxx` now complies with K-safety and accepts DML statements such as `INSERT`:

```
VMart=> INSERT INTO xxx VALUES (1, 2);  
OUTPUT  
-----  
      1  
(1 row)
```

See Also

For general information about segmented projections and buddies, see [Projection Segmentation](#) in Vertica Concepts. For information about designing for K-safety, see [Using Database Designer](#) and [Designing for Segmentation](#).

Designing Unsegmented Projections for K-Safety

In many cases, dimension tables are relatively small, so you do not need to segment them. Accordingly, you should design a K-safe database so projections for its dimension tables are replicated without segmentation on all cluster nodes. You create these projections with a `CREATE PROJECTION` statement that includes the keywords `UNSEGMENTED ALL NODES`. These keywords specify to create identical instances of the projection on all cluster nodes.

The following example shows how to create an unsegmented projection for the table `store.store_dimension`:

```
=> CREATE PROJECTION store.store_dimension_proj (storekey, name, city, state)
      AS SELECT store_key, store_name, store_city, store_state
      FROM store.store_dimension
      UNSEGMENTED ALL NODES;
CREATE PROJECTION
```

Vertica uses the same name to identify all instances of the unsegmented projection—in this example, `store.store_dimension_proj`. The keyword `ALL NODES` specifies to replicate the projection on all nodes:

```
=> \dj store.store_dimension_proj
      List of projections
Schema | Name | Owner | Node | Comment
-----+-----+-----+-----+-----
store | store_dimension_proj | dbadmin | v_vmart_node0001 |
store | store_dimension_proj | dbadmin | v_vmart_node0002 |
store | store_dimension_proj | dbadmin | v_vmart_node0003 |
(3 rows)
```

For more information about projection name conventions, see [Projection Naming](#).

Designing for Segmentation

You segment projections using hash segmentation. Hash segmentation allows you to segment a projection based on a built-in hash function that provides even distribution of data across multiple nodes, resulting in optimal query execution. In a projection, the data to be hashed consists of one or more column values, each having a large number of unique values and an acceptable amount of skew in the value distribution. Primary key columns that meet the criteria could be an excellent choice for hash segmentation.

Note: For detailed information about using hash segmentation in a projection, see [CREATE PROJECTION](#) in the SQL Reference Manual.

When segmenting projections, determine which columns to use to segment the projection. Choose one or more columns that have a large number of unique data values and acceptable skew in their data distribution. Primary key columns are an excellent choice for hash segmentation. The columns must be unique across all the tables being used in a query.

Design Fundamentals

Although you can write custom projections from scratch, Vertica recommends that you use Database Designer to create a design to use as a starting point. This ensures that you have projections that meet basic requirements.

Writing and Deploying Custom Projections

Before you write custom projections, be sure to review the topics in [Planning Your Design](#) carefully. Failure to follow these considerations can result in non-functional projections.

To manually modify or create a projection:

1. Write a script to create the projection, using the [CREATE PROJECTION](#) statement.
2. Use the `\i` meta-command in vsql to run the script.

Note: You must have a database loaded with a logical schema.

3. For a K-safe database, use the function `SELECT get_projections('table_name')` to verify that the projections were properly created. Good projections are noted as being "safe." This means that the projection has enough buddies to be K-safe.
4. If you added the new projection to a database that already has projections that contain data, you need to update the newly created projection to work with the existing projections. By default, the new projection is out-of-date (not available for query processing) until you refresh it.
5. Use the [MAKE_AHM_NOW](#) function to set the Ancient History Mark (AHM) to the greatest allowable epoch (now).
6. Use [DROP PROJECTION](#) to drop any previous projections that are no longer needed.

These projections can waste disk space and reduce load speed if they remain in the database.

7. Run the [ANALYZE_STATISTICS](#) function on all projections in the database. This function collects and aggregates data samples and storage information from all nodes on which a projection is stored, and then writes statistics into the catalog. For example:

```
=>SELECT ANALYZE_STATISTICS ('');
```

Designing Superprojections

Superprojections have the following requirements:

- They must contain every column within the table.
- For a K-safe design, superprojections must either be replicated on all nodes within the database cluster (for dimension tables) or paired with buddies and segmented across all nodes (for very large tables and medium large tables). See [Physical Schema](#) and [High Availability With Projections](#) in Vertica Concepts for an overview of projections and how they are stored. See [Using Database Designer](#) for design specifics.

To provide maximum usability, superprojections need to minimize storage requirements while maximizing query performance. To achieve this, the sort order for columns in superprojections is based on storage requirements and commonly used queries.

Sort Order Benefits

Column sort order is an important factor in minimizing storage requirements, and maximizing query performance.

Minimize Storage Requirements

Minimizing storage saves on physical resources and increases performance by reducing disk I/O. You can minimize projection storage by prioritizing low-cardinality columns in its sort order. This reduces the number of rows Vertica stores and accesses to retrieve query results.

After identifying projection sort columns, analyze their data and choose the most effective encoding method. The Vertica optimizer gives preference to columns with run-length encoding (RLE), so be sure to use it whenever appropriate. Run-length encoding replaces sequences (runs) of identical values with a single pair that contains the value and number of occurrences. Therefore, it is especially appropriate to use it for low-cardinality columns whose run length is large.

Maximize Query Performance

You can facilitate query performance through column sort order as follows:

- Where possible, sort order should prioritize columns with the lowest cardinality.
- Do not sort projections on columns of type LONG VARBINARY and LONG VARCHAR.

For more information

See [Combine RLE and Sort Order](#) for examples that address storage and query requirements.

Choosing Sort Order: Best Practices

When choosing sort orders for your projections, Vertica has several recommendations that can help you achieve maximum query performance, as illustrated in the following examples.

Combine RLE and Sort Order

When dealing with predicates on low-cardinality columns, use a combination of RLE and sorting to minimize storage requirements and maximize query performance.

Suppose you have a `students` table contain the following values and encoding types:

Column	# of Distinct Values	Encoded With
<code>gender</code>	2 (M or F)	RLE
<code>pass_fail</code>	2 (P or F)	RLE
<code>class</code>	4 (freshman, sophomore, junior, or senior)	RLE
<code>name</code>	10000 (too many to list)	Auto

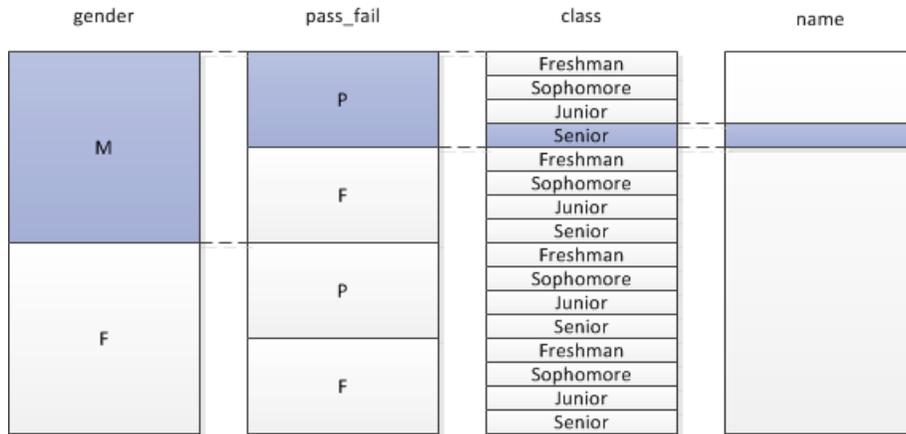

You might have queries similar to this one:

```
SELECT name FROM students WHERE gender = 'M' AND pass_fail = 'P' AND class = 'senior';
```

The fastest way to access the data is to work through the low-cardinality columns with the smallest number of distinct values before the high-cardinality columns. The following sort order minimizes storage and maximizes query performance for queries that have equality restrictions on `gender`, `class`, `pass_fail`, and `name`. Specify the `ORDER BY` clause of the projection as follows:

```
ORDER BY students.gender, students.pass_fail, students.class, students.name
```

In this example, the `gender` column is represented by two RLE entries, the `pass_fail` column is represented by four entries, and the `class` column is represented by 16 entries, regardless of the cardinality of the `students` table. Vertica efficiently finds the set of rows that satisfy all the predicates, resulting in a huge reduction of search effort for RLE encoded columns that occur early in the sort order. Consequently, if you use low-cardinality columns in local predicates, as in the previous example, put those columns early in the projection sort order, in increasing order of distinct cardinality (that is, in increasing order of the number of distinct values in each column).

If you sort this table with `student.class` first, you improve the performance of queries that restrict only on the `student.class` column, and you improve the compression of the `student.class` column (which contains the largest number of distinct values), but the other columns do not compress as well. Determining which projection is better depends on the specific queries in your workload, and their relative importance.

Storage savings with compression decrease as the cardinality of the column increases; however, storage savings with compression increase as the number of bytes required to store values in that column increases.

Maximize the Advantages of RLE

To maximize the advantages of RLE encoding, use it only when the average run length of a column is greater than 10 when sorted. For example, suppose you have a table with the following columns, sorted in order of cardinality from low to high:

```
address.country, address.region, address.state, address.city, address.zipcode
```

The `zipcode` column might not have 10 sorted entries in a row with the same zip code, so there is probably no advantage to run-length encoding that column, and it could make compression worse. But there are likely to be more than 10 countries in a sorted run length, so applying RLE to the `country` column can improve performance.

Put Lower Cardinality Column First for Functional Dependencies

In general, put columns that you use for local predicates (as in the previous example) earlier in the join order to make predicate evaluation more efficient. In addition, if a lower cardinality column is uniquely determined by a higher cardinality column (like city_id uniquely determining a state_id), it is always better to put the lower cardinality, functionally determined column earlier in the sort order than the higher cardinality column.

For example, in the following sort order, the Area_Code column is sorted before the Number column in the customer_info table:

```
ORDER BY = customer_info.Area_Code, customer_info.Number, customer_info.Address
```

In the query, put the Area_Code column first, so that only the values in the Number column that start with 978 are scanned.

```
=> SELECT Address FROM customer_info WHERE Area_Code='978' AND Number='9780123457';
```

Area_code	Number	Address
508	508 012 3456 508 012 3457	1 Elm Street 1 School Street
617	617 012 3456 617 012 3457	1 Maple Avenue 1 Post Street
978	978 012 3456 978 012 3457	1 Olive Road 1 Main Street

Sort for Merge Joins

When processing a join, the Vertica optimizer chooses from two algorithms:

- **Merge join**—If both inputs are pre-sorted on the join column, the optimizer chooses a merge join, which is faster and uses less memory.
- **Hash join**—Using the hash join algorithm, Vertica uses the smaller (inner) joined table to build an in-memory hash table on the join column. A hash join has no sort requirement, but it consumes more memory because Vertica builds a hash table with the values in the inner table. The optimizer chooses a hash join when projections are not sorted on the join columns.

If both inputs are pre-sorted, merge joins do not have to do any pre-processing, making the join perform faster. Vertica uses the term sort-merge join to refer to the case when at least one of the inputs must be sorted prior to the merge join. Vertica sorts the inner input side but only if the outer input side is already sorted on the join columns.

To give the Vertica query optimizer the option to use an efficient merge join for a particular join, create projections on both sides of the join that put the join column first in their respective projections. This is primarily important to do if both tables are so large that neither table fits into memory. If all tables that a table will be joined to can be expected to fit into memory simultaneously, the benefits of merge join over hash join are sufficiently small that it probably isn't worth creating a projection for any one join column.

Sort on Columns in Important Queries

If you have an important query, one that you run on a regular basis, you can save time by putting the columns specified in the `WHERE` clause or the `GROUP BY` clause of that query early in the sort order.

If that query uses a high-cardinality column such as Social Security number, you may sacrifice storage by placing this column early in the sort order of a projection, but your most important query will be optimized.

Sort Columns of Equal Cardinality By Size

If you have two columns of equal cardinality, put the column that is larger first in the sort order. For example, a CHAR(20) column takes up 20 bytes, but an INTEGER column takes up 8 bytes. By putting the CHAR(20) column ahead of the INTEGER column, your projection compresses better.

Sort Foreign Key Columns First, From Low to High Distinct Cardinality

Suppose you have a fact table where the first four columns in the sort order make up a foreign key to another table. For best compression, choose a sort order for the fact table such that the foreign keys appear first, and in increasing order of distinct cardinality. Other factors also apply to the design of projections for fact tables, such as partitioning by a time dimension, if any.

In the following example, the table `inventory` stores inventory data, and `product_key` and `warehouse_key` are foreign keys to the `product_dimension` and `warehouse_dimension` tables:

```
=> CREATE TABLE inventory (  
  date_key INTEGER NOT NULL,  
  product_key INTEGER NOT NULL,  
  warehouse_key INTEGER NOT NULL,  
  ...  
);  
=> ALTER TABLE inventory  
  ADD CONSTRAINT fk_inventory_warehouse FOREIGN KEY(warehouse_key)  
  REFERENCES warehouse_dimension(warehouse_key);  
ALTER TABLE inventory  
  ADD CONSTRAINT fk_inventory_product FOREIGN KEY(product_key)  
  REFERENCES product_dimension(product_key);
```

The `inventory` table should be sorted by `warehouse_key` and then `product`, since the cardinality of the `warehouse_key` column is probably lower than the cardinality of the `product_key`.

Prioritizing Column Access Speed

If you measure and set the performance of storage locations within your cluster, Vertica uses this information to determine where to store columns based on their rank. For more information, see [Setting Storage Performance](#).

How Columns are Ranked

Vertica stores columns included in the projection sort order on the fastest available storage locations. Columns not included in the projection sort order are stored on slower disks.

Columns for each projection are ranked as follows:

- Columns in the sort order are given the highest priority (numbers > 1000).
- The last column in the sort order is given the rank number 1001.
- The next-to-last column in the sort order is given the rank number 1002, and so on until the first column in the sort order is given $1000 + \#$ of sort columns.
- The remaining columns are given numbers from $1000-1$, starting with 1000 and decrementing by one per column.

Vertica then stores columns on disk from the highest ranking to the lowest ranking. It places highest-ranking columns on the fastest disks and the lowest-ranking columns on the slowest disks.

Overriding Default Column Ranking

You can modify which columns are stored on fast disks by manually overriding the default ranks for these columns. To accomplish this, set the `ACCESSRANK` keyword in the column list. Make sure to use an integer that is not already being used for another column. For example, if you want to give a column the fastest access rank, use a number that is significantly higher than `1000 + the number of sort columns`. This allows you to enter more columns over time without bumping into the access rank you set.

The following example sets column `store_key`'s access rank to 1500:

```
CREATE PROJECTION retail_sales_fact_p (  
  store_key ENCODING RLE ACCESSRANK 1500,  
  pos_transaction_number ENCODING RLE,  
  sales_dollar_amount,  
  cost_dollar_amount )  
AS SELECT  
  store_key,  
  pos_transaction_number,  
  sales_dollar_amount,  
  cost_dollar_amount  
FROM store.store_sales_fact  
ORDER BY store_key  
SEGMENTED BY HASH(pos_transaction_number) ALL NODES;
```

Managing Users and Privileges

Database users should have access to only the database resources they need to perform their tasks. For example, most users should be able to read data but not modify or insert new data, while other users might need more permissive access, such as the right to create and modify schemas, tables, and views, as well as rebalance nodes on a cluster and start or stop a database. It is also possible to allow certain users to grant other users access to the appropriate database resources.

Client authentication controls what database objects users can access and change in the database. To prevent unauthorized access, a superuser limits access to what is needed, granting privileges directly to users or to roles through a series of GRANT statements. Roles can then be granted to users, as well as to other roles.

This section introduces the [privilege role model](#) in Vertica and describes how to create and manage users.

- [About Database Privileges](#)
- [About Database Roles](#)
- [GRANT Statements](#)
- [REVOKE Statements](#)

About Database Users

Every Vertica database has one or more users. When users connect to a database, they must log on with valid credentials (username and password) that a superuser defined in the database.

Database users own the objects they create in a database, such as tables, procedures, and storage locations.

Note: By default, users have the right to [create temporary tables](#) in a database.

See Also

- [Creating a Database User](#)
- [CREATE USER](#)
- [About MC Users](#)

Types of Database Users

In an Vertica database, there are three types of users:

- Database administrator (DBADMIN)
- Object owner
- Everyone else (PUBLIC)

Note: External to a Vertica database, an MC administrator can create users through the Management Console and grant them database access. See [About MC Users](#) for details.

Database Administration User

When you install a new Vertica Analytics Platform a database administration user with access to the following roles gets created:

- [DBADMIN Role](#)
- [DBDUSER Role](#)
- [PSEUDOSUPERUSER Role](#)

Access to these roles allows this user to perform all database operations. Assign a name to this user during installation using the `--dba-user` option (use `-u` for upgrades). For example:

```
--dba-user mydba
```

This example creates a database administration user called `mydba`. The username you use here must already exist on your operating system. See [Installing Vertica with the Installation Script](#)

If you do not use `--dba-user` during installation the database administrator user gets named `DBADMIN` by default.

Note: Do not confuse the `DBADMIN` user with the [DBADMIN Role](#). The `DBADMIN` role is a set of privileges you assign to a specific user based on the user's position in your organization.

The Vertica Analytics Platform Database Administration user is also called a superuser throughout the Vertica Analytics Platform documentation. Do not confuse this superuser with the Linux superuser that manages the Linux operating system.

Create a Database Administration User in the Vertica Analytics Platform

As the Database Administration user you can create other users with the same privileges:

1. Create a user:

```
=> CREATE USER DataBaseAdmin2;  
CREATE USER
```

2. Grant the appropriate roles to the new user DataBaseAdmin2:

```
=> GRANT dbduser, dbadmin, pseudosuperuser to DataBaseAdmin2;  
GRANT ROLE
```

The user DataBaseAdmin2 now has the same privileges granted to the original Database Administration user.

3. As the DataBaseAdmin2 user, enable the roles using [SET ROLE](#):

```
=> \c VMart DataBaseAdmin2;  
You are now connected to database "VMart" as user "DataBaseAdmin2".  
=> SET ROLE dbadmin, dbduser, pseudosuperuser;  
SET ROLE
```

4. Confirm the roles are enabled:

```
=> SHOW ENABLED ROLES;  
name          | setting  
-----  
enabled roles | dbduser, dbadmin, pseudosuperuser
```

See Also

- [DBADMIN Role](#)
- [PSEUDOSUPERUSER Role](#)
- [PUBLIC Role](#)

Object Owner

An object owner is the user who creates a particular database object and can perform any operation on that object. By default, only an owner (or a superuser) can act on a database object. In order to allow other users to use an object, the owner or superuser must grant privileges to those users using one of the [GRANT Statements](#).

Note: Object owners are [PUBLIC users](#) for objects that other users own.

See [About Database Privileges](#) for more information.

PUBLIC User

All non-DBA (superuser) or object owners are PUBLIC users.

Note: Object owners are PUBLIC users for objects that other users own.

Newly-created users do not have access to schema PUBLIC by default. Make sure to GRANT USAGE ON SCHEMA PUBLIC to all users you create.

See Also

- [PUBLIC Role](#)

Creating a Database User

To create a database user:

1. From vsql, connect to the database as a superuser.
2. Issue the [CREATE USER](#) statement with optional parameters.
3. Run a series of [GRANT Statements](#) to grant the new user privileges.

To create a user on MC, see [Creating an MC User](#) in Management Console

New User Privileges

By default, new database users have the right to create temporary tables in the database.

Newly-created users do not have access to schema PUBLIC by default. Make sure to `GRANT USAGE ON SCHEMA PUBLIC` to all users you create

Modifying Users

You can change information about a user, such as his or her password, by using the [ALTER USER](#) statement. If you want to configure a user to not have any password authentication, you can set the empty password "" in `CREATE USER` or `ALTER USER` statements, or omit the `IDENTIFIED BY` parameter in `CREATE USER`.

Example

The following series of commands add user Fred to a database with password 'password'. The second command grants USAGE privileges to Fred on the public schema:

```
=> CREATE USER Fred IDENTIFIED BY 'password';  
=> GRANT USAGE ON SCHEMA PUBLIC to Fred;
```

User names created with double-quotes are case sensitive. For example:

```
=> CREATE USER "FrEd1";
```

In the above example, the logon name must be an exact match. If the user name was created without double-quotes (for example, FRED1), then the user can log on as FRED1, FrEd1, fred1, and so on.

See Also

- [Granting and Revoking Privileges](#)
- [Granting Access to Database Roles](#)

Locking/unlocking a user's Database Access

A superuser can manually lock an existing database user's account with the [ALTER USER](#) statement. For example, the following command prevents user Fred from logging in to the database:

```
=> ALTER USER Fred ACCOUNT LOCK;
```

```
=> \c - Fred
FATAL 4974: The user account "Fred" is locked
HINT: Please contact the database administrator
```

To grant Fred database access, use UNLOCK syntax with the ALTER USER command:

```
=> ALTER USER Fred ACCOUNT UNLOCK;
=> \c - Fred
You are now connected as user "Fred".
```

Using CREATE USER to lock an account

Although not as common, you can create a new user with a locked account; for example, you might want to set up an account for a user who doesn't need immediate database access, as in the case of an employee who will join the company at a future date.

```
=> CREATE USER Bob ACCOUNT UNLOCK;
CREATE USER
```

CREATE USER also supports UNLOCK syntax; however, UNLOCK is the default, so you don't need to specify the keyword when you create a new user to whom you want to grant immediate database access.

Locking an account automatically

Instead of manually locking an account, a superuser can automate account locking by setting a maximum number of failed login attempts through the CREATE PROFILE statement. See Profiles.

Changing a User's Password

A superuser can change another user's database account, including reset a password, with the [ALTER USER](#) statement.

Making changes to a database user account with does not affect current sessions.

```
=> ALTER USER Fred IDENTIFIED BY 'newpassword';
```

In the above command, Fred's password is now *newpassword*.

Note: Non-DBA users can change their own passwords using the IDENTIFIED BY 'new-password' option along with the REPLACE 'old-password' clause. See [ALTER USER](#) for details.

Changing a User's MC Password

On MC, users with ADMIN or IT privileges can reset a user's non-LDAP password from the MC interface.

Non-LDAP passwords on MC are for MC access only and are not related to a user's logon credentials on the Vertica database.

1. Sign in to Management Console and navigate to **MC Settings > User management**.
2. Click to select the user to modify and click **Edit**.
3. Click **Edit password** and enter the new password twice.
4. Click **OK** and then click **Save**.

About Database Privileges

When a database object is created, such as a schema, table, or view, that object is assigned an owner—the person who executed the CREATE statement. By default, database administrators (superusers) or object owners are the only users who can do anything with the object.

In order to allow other users to use an object, or remove a user's right to use an object, the authorized user must grant another user privileges on the object.

Privileges are granted (or revoked) through a collection of GRANT/REVOKE statements that assign the privilege—a type of permission that lets users perform an action on a database object, such as:

- Create a schema
- Create a table (in a schema)
- Create a view
- View (select) data
- Insert, update, or delete table data
- Drop tables or schemas
- Run procedures

Before Vertica executes a statement, it determines if the requesting user has the necessary privileges to perform the operation.

For more information about the privileges associated with these resources, see [Privileges That Can Be Granted on Objects](#).

Note: Vertica logs information about each grant (grantor, grantee, privilege, and so on) in the `V_CATALOG.GRANTS` system table.

See Also

- [GRANT Statements](#)
- [REVOKE Statements](#)

Inherited Privileges

Inherited privileges allow you to grant privileges at the schema level. This enables privileges to be granted automatically to new tables or views in the schema. Existing tables and views are unchanged when you alter the schema to include or exclude inherited privileges. Using inherited privileges eliminates the need to apply the same privileges to each individual table or view in the schema.

To assign inherited privileges, you must be an owner of the schema or a superuser. Assign inherited privileges using the following SQL statements

- [GRANT Statements](#)
- [CREATE SCHEMA](#)
- [ALTER SCHEMA](#)
- [CREATE TABLE](#)
- [ALTER TABLE](#)
- [CREATE VIEW](#)
- [ALTER VIEW](#)

Granting Inherited Privileges from One User to Another

The following steps describe a process for user1 to enable inherited privileges to user2.

1. The database user, user1, creates a schema (schema1), and a table (table1) in schema1:

```
user1=> CREATE SCHEMA schema1;  
user1=> CREATE TABLE schema1.table1 (id int);
```

2. User user1 grants USAGE and CREATE privileges on schema1 to user2:

```
user1=> GRANT USAGE ON SCHEMA schema1 to user2;  
user1=> GRANT CREATE ON SCHEMA schema1 to user2;
```

3. The user2 user queries schema1.table1, but the query fails:

```
user2=> SELECT * FROM schema1.table1;  
ERROR 4367: Permission denied for relation table1
```

4. The user user1 grants SELECT ON SCHEMA privilege on schema1 to user2:

```
user1=> GRANT SELECT ON SCHEMA schema1 to user2;
```

5. Next, user1 uses ALTER TABLE to include SCHEMA privileges to table1:

```
user1=> ALTER TABLE schema1.table1 INCLUDE SCHEMA PRIVILEGES;
```

6. The user2 query now succeeds:

```
user2=> SELECT * FROM schema1.table1;  
id  
---  
(0 rows)
```

7. User 1 now uses ALTER SCHEMA to include privileges so that all tables created in schema1 inherit schema privileges:

```
user1=> ALTER SCHEMA schema1 DEFAULT INCLUDE PRIVILEGES;  
user1=> CREATE TABLE schema1.table2 (id int);
```

8. With Inherited Privileges enabled, user2 can query table2 without user1 having to specifically grant privileges on table2:

```
user2=> SELECT * FROM schema1.table2;  
id  
---  
(0 rows)
```

Enable or Disable Inherited Privileges at the Database Level

Use the `disableinheritedprivileges` configuration parameter to enable (0) Inherited Privileges:

```
=> ALTER DATABASE [database name] SET disableinheritedprivileges = 0;
```

Use the following configuration parameter to disable (1) Inherited Privileges:

```
=> ALTER DATABASE [database name] SET disableinheritedprivileges = 1;
```

Grant Inherited Privileges

Grant inherited privileges at the schema level. When inherited privileges is enabled, all privileges granted to the schema are automatically granted to all newly created tables or views in the schema. Existing tables or views remain unchanged when you alter the schema to include or exclude inherited privileges.

By default, inherited privileges are enabled at the database level and disabled at the schema level (unless you indicate otherwise while running `CREATE SCHEMA`). See [Enable or Disable Inherited Privileges at the Database Level](#) for more information. To apply inherited privileges, you must meet one of the following conditions:

- Be the owner of the object
- Be a superuser

Inherit Privileges on a Schema

Use the [CREATE SCHEMA](#) or [ALTER SCHEMA](#) SQL statements to apply inherited privileges to a schema. The tables and views in that schema then inherit any privileges granted to the schema by default.

This example shows how to create a new schema with inherited privileges. The `DEFAULT` parameter sets the default behavior so that all new tables and views created in this schema automatically inherit the schema's privileges:

```
=> CREATE SCHEMA s1 DEFAULT INCLUDE PRIVILEGES;
```

This example shows how to modify an existing schema to enable inherited privileges:

```
=> ALTER SCHEMA s1 DEFAULT INCLUDE PRIVILEGES;
```

Note: After enabling inherited privileges on a schema, you still must grant privileges on the schema to a user or role. From the [GRANT \(Schema\)](#) statement, use the following parameters with inherited privileges enabled:

- SELECT
- INSERT
- UPDATE

- DELETE
- REFERENCES
- TRUNCATE

The following message appears when you specify `INCLUDE PRIVILEGES` while Inherited privileges is disabled at the database level:

```
Inherited privileges are globally disabled; schema parameter is set but has no effect.
```

See [Enable or Disable Inherited Privileges at the Database Level](#) to enable Inherited Privileges at the database level.

Inherit Privileges on a Table or Flex Table

You can specify an individual table or flex table to inherit privileges from the schema. Use [CREATE TABLE](#) or [ALTER TABLE](#) SQL statements to enable inherited privileges for a table. The table-level flag takes priority over the schema flag, while the database knob takes priority over both.

This example shows creating a new table with inherited privileges:

```
=> CREATE TABLE s1.t1 ( x int) INCLUDE SCHEMA PRIVILEGES;
```

This example shows how to modify an existing table to enable inherited privileges:

```
=> ALTER TABLE s1.t1 INCLUDE SCHEMA PRIVILEGES;
```

If you run [CREATE TABLE](#), [CREATE TABLE LIKE](#), or [CREATE TABLE AS SELECT](#) in a schema with inherited privileges set, the following informational warning appears:

```
=> CREATE TABLE s1.t1 ( x int);  
WARNING: Table <table_name> will include privileges from schema <schema_name>
```

Note that this message does not appear when you add the `INCLUDE SCHEMA PRIVILEGES` statement.

Exclude Privileges on a Table

You can exclude a table in a schema with inherited privileges so that table does not inherit the schema's privileges. Use [CREATE TABLE](#) or [ALTER TABLE](#) SQL statements to exclude inherited

privileges for a table.

This example shows creating a new table and excluding schema privileges:

```
=> CREATE TABLE s1.t1 ( x int) EXCLUDE SCHEMA PRIVILEGES;
```

This example shows how to modify an existing table to exclude inherited privileges:

```
=> ALTER TABLE s1.t1 EXCLUDE SCHEMA PRIVILEGES;
```

Include Privileges on a View

You can specify a View to inherit privileges from the schema. Use [CREATE VIEW](#) or [ALTER VIEW](#) SQL statements to enable inherited privileges for a view.

This example shows creating a view with inherited privileges enabled:

```
=> CREATE VIEW view1 INCLUDE SCHEMA PRIVILEGES;
```

This example shows how to modify an existing view to enable inherited privileges:

```
=> ALTER VIEW veiw1 INCLUDE SCHEMA PRIVILEGES;
```

Exclude Privileges on a View

You can exclude a view in a schema with inherited privileges so that view does not inherit the schema's privileges. Use [CREATE VIEW](#) or [ALTER VIEW](#) SQL statements to exclude inherited privileges for a view.

This example shows creating a new view and excluding schema privileges:

```
=> CREATE VIEW view1 EXCLUDE SCHEMA PRIVILEGES;
```

This example shows how to modify an existing view to exclude inherited privileges:

```
=> ALTER VIEW view1 EXCLUDE SCHEMA PRIVILEGES;
```

Default Privileges for All Users

To set the minimum level of privilege for all users, Vertica has the special [PUBLIC Role](#), which it grants to each user automatically. This role is automatically enabled, but the database

administrator or a superuser can also grant higher privileges to users separately using GRANT statements.

The following topics discuss those higher privileges.

Default Privileges for MC Users

Privileges on Management Console (MC) are managed through roles, which determine a user's access to MC and to MC-managed Vertica databases through the MC interface. MC privileges do not alter or override Vertica privileges or roles. See [About MC Privileges and Roles](#) for details.

Privileges Required for Common Database Operations

This topic lists the required privileges for database objects in Vertica.

Unless otherwise noted, superusers can perform all of the operations shown in the following tables without any additional privilege requirements. Object owners have the necessary rights to perform operations on their own objects, by default.

Schemas

The PUBLIC schema is present in any newly-created Vertica database, and newly-created users have only USAGE privilege on PUBLIC. A database superuser must explicitly grant new users CREATE privileges, as well as grant them individual object privileges so the new users can create or look up objects in the PUBLIC schema.

Operation	Required Privileges
CREATE SCHEMA	CREATE privilege on database
DROP SCHEMA	Schema owner
ALTER SCHEMA RENAME	CREATE privilege on database

Tables

Operation	Required Privileges
CREATE TABLE	CREATE privilege on schema

Operation	Required Privileges
	<p>Note: Referencing sequences in the CREATE TABLE statement requires the following privileges:</p> <ul style="list-style-type: none"> • SELECT privilege on sequence object • USAGE privilege on sequence schema
DROP TABLE	USAGE privilege on the schema that contains the table or schema owner
TRUNCATE TABLE	USAGE privilege on the schema that contains the table or schema owner
ALTER TABLE ADD/DROP/ RENAME/ALTER-TYPE COLUMN	USAGE privilege on the schema that contains the table
ALTER TABLE ADD/DROP CONSTRAINT	USAGE privilege on the schema that contains the table
ALTER TABLE PARTITION (REORGANIZE)	USAGE privilege on the schema that contains the table
ALTER TABLE RENAME	USAGE and CREATE privilege on the schema that contains the table
ALTER TABLE SET SCHEMA	<ul style="list-style-type: none"> • CREATE privilege on new schema • USAGE privilege on the old schema
SELECT	<ul style="list-style-type: none"> • SELECT privilege on table • USAGE privilege on schema that contains the table
INSERT	<ul style="list-style-type: none"> • INSERT privilege on table • USAGE privilege on schema that contains the table
DELETE	<ul style="list-style-type: none"> • DELETE privilege on table • USAGE privilege on schema that contains the table • SELECT privilege on the referenced table when executing a DELETE statement that references table column values in a WHERE or SET clause
UPDATE	<ul style="list-style-type: none"> • UPDATE privilege on table

Operation	Required Privileges
	<ul style="list-style-type: none"> • USAGE privilege on schema that contains the table • SELECT privilege on the table when executing an UPDATE statement that references table column values in a WHERE or SET clause
REFERENCES	<ul style="list-style-type: none"> • REFERENCES privilege on table to create foreign key constraints that reference this table • USAGE privileges on schema that contains the constrained table and the source of the foreign k
ANALYZE_STATISTICS	<ul style="list-style-type: none"> • INSERT/UPDATE/DELETE privilege on table • USAGE privilege on schema that contains the table
DROP_STATISTICS	<ul style="list-style-type: none"> • INSERT/UPDATE/DELETE privilege on table • USAGE privilege on schema that contains the table
DROP_PARTITION	USAGE privilege on schema that contains the table

Views

Operation	Required Privileges
CREATE VIEW	<ul style="list-style-type: none"> • CREATE privilege on the schema to contain a view • SELECT privileges on base objects (tables/views) • USAGE privileges on schema that contains the base objects
DROP VIEW	USAGE privilege on schema that contains the view or schema owner
SELECT ... FROM VIEW	<ul style="list-style-type: none"> • SELECT privilege on view • USAGE privilege on the schema that contains the view. • View owner must have SELECT ... WITH GRANT OPTION privileges on the view's anchor tables or views if non-owner runs a SELECT query on the view.

Operation	Required Privileges
	<ul style="list-style-type: none"> View owner must have SELECT privilege on a view's base objects (table or view) if owner runs a SELECT query on the view.

Projections

Operation	Required Privileges
CREATE PROJECTION	<ul style="list-style-type: none"> SELECT privilege on anchor tables USAGE privilege on schema that contains anchor tables or schema owner CREATE privilege on schema to contain the projection <p>Note: If a projection is implicitly created with the table, no additional privilege is needed other than privileges for table creation.</p>
AUTO/DELAYED PROJECTION	<p>On projections created during INSERT..SELECT or COPY operations:</p> <ul style="list-style-type: none"> SELECT privilege on anchor tables USAGE privilege on schema that contains anchor tables
ALTER PROJECTION RENAME	USAGE and CREATE privilege on schema that contains the projection
DROP PROJECTION	USAGE privilege on schema that contains the projection or schema owner

External Procedures

Operation	Required Privileges
CREATE PROCEDURE	Superuser
DROP PROCEDURE	Superuser
EXECUTE	<ul style="list-style-type: none"> EXECUTE privilege on procedure

Operation	Required Privileges
	<ul style="list-style-type: none"> • USAGE privilege on schema that contains the procedure

Libraries

Operation	Required Privileges
<code>CREATE LIBRARY</code>	Superuser
<code>DROP LIBRARY</code>	Superuser

User-Defined Functions

The following abbreviations are used in the UDF table:

- UDF = Scalar
- UDT = Transform
- UDAnF= Analytic
- UDAF = Aggregate

Operation	Required Privileges
<code>CREATE FUNCTION (SQL)</code> <code>CREATE FUNCTION (UDF)</code> <code>CREATE TRANSFORM FUNCTION (UDF)</code> <code>CREATE ANALYTIC FUNCTION (UDAnF)</code> <code>CREATE AGGREGATE FUNCTION (UDAF)</code>	<ul style="list-style-type: none"> • CREATE privilege on schema to contain the function • USAGE privilege on base library (if applicable)
<code>DROP FUNCTION</code> <code>DROP TRANSFORM FUNCTION</code> <code>DROP ANALYTIC FUNCTION</code> <code>DROP AGGREGATE FUNCTION</code>	<ul style="list-style-type: none"> • Superuser or function owner • USAGE privilege on schema that contains the function
<code>ALTER FUNCTION (UDF or UDT) RENAME TO</code>	USAGE and CREATE privilege on schema that contains the function
<code>ALTER FUNCTION (UDF or UDT) SET SCHEMA</code>	<ul style="list-style-type: none"> • USAGE privilege on schema that currently

Operation	Required Privileges
	<p>contains the function (old schema)</p> <ul style="list-style-type: none"> • CREATE privilege on the schema to which the function will be moved (new schema)
EXECUTE (SQL/UDF/UDT/ ADAF/UDAnF) function	<ul style="list-style-type: none"> • EXECUTE privilege on function • USAGE privilege on schema that contains the function

Sequences

Operation	Required Privileges
CREATE SEQUENCE	<p>CREATE privilege on schema to contain the sequence</p> <p>Note: Referencing sequence in the CREATE TABLE statement requires SELECT privilege on sequence object and USAGE privilege on sequence schema.</p>
CREATE TABLE with SEQUENCE	<ul style="list-style-type: none"> • SELECT privilege on sequence • USAGE privilege on sequence schema
DROP SEQUENCE	<p>USAGE privilege on schema containing the sequence or schema owner</p>
ALTER SEQUENCE RENAME TO	<p>USAGE and CREATE privileges on schema</p>
ALTER SEQUENCE SET SCHEMA	<ul style="list-style-type: none"> • USAGE privilege on the schema that currently contains the sequence (old schema) • CREATE privilege on new schema to contain the sequence
CURRVAL()NEXTVAL()	<ul style="list-style-type: none"> • SELECT privilege on sequence • USAGE privilege on sequence schema

Resource Pools

Operation	Required Privileges
CREATE RESOURCE POOL	Superuser
ALTER RESOURCE POOL	<p>Superuser on the resource pool to alter:</p> <ul style="list-style-type: none"> • MAXMEMORYSIZE • PRIORITY • QUEUETIMEOUT <p>UPDATE privilege on the resource pool to alter:</p> <ul style="list-style-type: none"> • PLANNEDCONCURRENCY • SINGLEINITIATOR • MAXCONCURRENCY
SET SESSION RESOURCE_POOL	<ul style="list-style-type: none"> • USAGE privilege on the resource pool • Users can only change their own resource pool setting using ALTER USER syntax
DROP RESOURCE POOL	Superuser

Users/Profiles/Roles

Operation	Required Privileges
CREATE USER CREATE PROFILE CREATE ROLE	Superuser
ALTER USER ALTER PROFILE ALTER ROLE RENAME	Superuser
DROP USER DROP PROFILE	Superuser

Operation	Required Privileges
DROP ROLE	

Object Visibility

You can use one or a combination of vsql [\d \[pattern\]](#) meta commands and [SQL system tables](#) to view objects on which you have privileges to view.

- Use [\dn \[pattern\]](#) to view schema names and owners
- Use [\dt \[pattern\]](#) to view all tables in the database, as well as the system table [V_CATALOG.TABLES](#)
- Use [\dj \[pattern\]](#) to view projections showing the schema, projection name, owner, and node, as well as the system table [V_CATALOG.PROJECTIONS](#)

Operation	Required Privileges
Look up schema	At least one privilege on schema that contains the object
Look up Object in Schema or in System Tables	USAGE privilege on schema At least one privilege on any of the following objects: TABLE VIEW FUNCTION PROCEDURE SEQUENCE

Operation	Required Privileges
Look up Projection	At least one privilege on all anchor tables USAGE privilege on schema of all anchor table
Look up resource pool	SELECT privilege on the resource pool
Existence of object	USAGE privilege on the schema that contains the object

I/O Operations

Operation	Required Privileges
CONNECT/DISCONNECT	None
EXPORT TO Vertica	<ul style="list-style-type: none"> • SELECT privileges on the source table • USAGE privilege on source table schema • INSERT privileges for the destination table in target database • USAGE privilege on destination table schema
COPY FROM Vertica	<ul style="list-style-type: none"> • SELECT privileges on the source table • USAGE privilege on source table schema • INSERT privileges for the destination table in target

Operation	Required Privileges
	database <ul style="list-style-type: none"> • USAGE privilege on destination table schema
<code>COPY FROM file</code>	Superuser
<code>COPY FROM STDIN</code>	<ul style="list-style-type: none"> • INSERT privilege on table • USAGE privilege on schema
<code>COPY LOCAL</code>	<ul style="list-style-type: none"> • INSERT privilege on table • USAGE privilege on schema

Comments

Operation	Required Privileges
COMMENT ON { is one of }: <ul style="list-style-type: none"> • AGGREGATE FUNCTION • ANALYTIC FUNCTION • COLUMN • CONSTRAINT • FUNCTION • LIBRARY • NODE • PROJECTION • SCHEMA • SEQUENCE • TABLE • TRANSFORM FUNCTION 	Object owner or superuser

Operation	Required Privileges
<ul style="list-style-type: none">VIEW	

Transactions

Operation	Required Privileges
COMMIT	None
ROLLBACK	None
RELEASE SAVEPOINT	None
SAVEPOINT	None

Sessions

Operation	Required Privileges
SET { is one of }: <ul style="list-style-type: none">DATESTYLEESCAPE_STRING_WARNINGINTERVALSTYLELOCALEROLESEARCH_PATHSESSION AUTOCOMMITSESSION CHARACTERISTICSSESSION MEMORYCAPSESSION RESOURCE POOLSESSION RUNTIMECAP	None

Operation	Required Privileges

- [GRANT Statements](#)
- [REVOKE Statements](#)

Database Privileges

Only a database superuser can create a database. In a new database, the [PUBLIC Role](#) is granted USAGE on the automatically-created PUBLIC schema. It is up to the superuser to grant further privileges to users and roles.

The only privilege a superuser can grant on the database itself is CREATE, which allows the user to create a new schema in the database. For details on granting and revoking privileges on a database, see the [GRANT \(Database\)](#) and [REVOKE \(Database\)](#) topics in the SQL Reference Manual.

Privilege	Grantor	Description
CREATE	Superuser	Allows a user to create a schema.

Schema Privileges

By default, only a superuser and the schema owner have privileges to create objects within a schema. Additionally, only the schema owner or a superuser can drop or alter a schema. See [DROP SCHEMA](#) and [ALTER SCHEMA](#).

You must grant all new users access to the PUBLIC schema by running GRANT USAGE ON SCHEMA PUBLIC. Then grant new users CREATE privileges and privileges to individual objects in the schema. This enables new users to create or locate objects in the PUBLIC schema. Without USAGE privilege, objects in the schema cannot be used or altered, even by the object owner.

CREATE gives the schema owner or user WITH GRANT OPTION permission to create new objects in the schema, including renaming an object in the schema or moving an object into this schema.

Note: The schema owner is typically the user who creates the schema. However, a superuser can create a schema and assign ownership of the schema to a different user at creation.

All other access to the schema and its objects must be explicitly granted to users or roles by the superuser or schema owner. This prevents unauthorized users from accessing the schema and its objects. A user can be granted one of the following privileges through the GRANT statement:

Privilege	Description
CREATE	Allows the user to create new objects within the schema. This includes the ability to create a new object, rename existing objects, and move objects into the schema from other schemas.
USAGE	Permission to select, access, alter, and drop objects in the schema. The user must also be granted access to the individual objects in order to alter them. For example, a user would need to be granted USAGE on the schema and SELECT on a table to be able to select data from a table. You receive an error message if you attempt to query a table that you have SELECT privileges on, but do not have USAGE privileges for the schema that contains the table.

Note the following on error messages related to granting privileges on a schema or an object:

- You attempt to grant a privilege to a schema, but you do not have USAGE privilege for the schema. In this case, you receive an error message that the schema does not exist.
- You attempt to grant a privilege to an object within a schema, and you have USAGE privilege on the schema. You do not have privilege on the individual object within the schema. In this case, you receive an error denying permission for that object.

Schema Privileges and the Search Path

The search path determines to which schema unqualified objects in SQL statements belong.

When a user specifies an object name in a statement without supplying the schema in which the object exists (called an unqualified object name) Vertica has two different behaviors, depending on whether the object is being accessed or created.

Creating an object	Accessing/altering an object
<p>When a user creates an object—such as table, view, sequence, procedure, function—with an unqualified name, Vertica tries to create the object in the current schema (the first schema in the schema search path), returning an error if the schema does not exist or if the user does not have CREATE privileges in that schema.</p> <p>Use the SHOW search_path command to view the current search path.</p> <pre>=> SHOW search_path; name setting -----+----- search_path "\$user", public, v_catalog, v_monitor, v_internal (1 row)</pre>	<p>When a user accesses or alters an object with an unqualified name, those statements search through all schemas for a matching object, starting with the current schema, where:</p> <ul style="list-style-type: none"> • The object name in the schema matches the object name in the

Creating an object	Accessing/altering an object
<p>Note: The first schema in the search path is the current schema, and the \$user setting is a placeholder that resolves to the current user's name.</p>	<p>statement.</p> <ul style="list-style-type: none"> • The user has USAGE privileges on the schema in order to access object in it. • The user has at least one privilege on the object.

- [GRANT \(Schema\)](#)
- [REVOKE \(Schema\)](#)

Table Privileges

By default, only a superuser and the table owner (typically the person who creates a table) have access to a table. The ability to drop or alter a table is also reserved for a superuser or table owner. This privilege cannot be granted to other users.

All other users or roles (including the user who owns the schema, if he or she does not also own the table) must be explicitly granted using WITH GRANT OPTION syntax to access the table.

These are the table privileges a superuser or table owner can grant:

Privilege	Description
SELECT	Permission to run SELECT queries on the table.
INSERT	Permission to INSERT data into the table.
DELETE	Permission to DELETE data from the table, as well as SELECT privilege on the table when executing a DELETE statement that references table column values in a WHERE or SET clause.
UPDATE	Permission to UPDATE and change data in the table, as well as SELECT privilege

Privilege	Description
	on the table when executing an UPDATE statement that references table column values in a WHERE or SET clause.
REFERENCES	Permission to CREATE foreign key constraints that reference this table.

To use any of the above privileges, the user must also have USAGE privileges on the schema that contains the table. See [Schema Privileges](#) for details.

Referencing sequence in the [CREATE TABLE](#) statement requires the following privileges:

- SELECT privilege on sequence object
- USAGE privilege on sequence schema

For details on granting and revoking table privileges, see [GRANT \(Table\)](#) and [REVOKE \(Table\)](#) in the SQL Reference Manual.

Projection Privileges

Because projections are the underlying storage construct for tables, they are atypical in that they do not have an owner or privileges associated with them directly. Instead, the privileges to create, access, or alter a projection are based on the anchor tables that the projection references, as well as the schemas that contain them.

All queries in Vertica obtain data from projections directly or indirectly. In both cases, to run a query, you must have SELECT privileges on the tables that the projections reference, and USAGE privileges on all schemas that contain those tables.

You can create projections in two ways: explicitly and implicitly.

Explicit Projection Creation

To create a projection with [CREATE PROJECTION](#) or any of its variants, you must be a superuser or owner of the anchor table.

Only the anchor table owner can drop explicitly created projections. Explicitly created projections can be live aggregate projections, including Top-K projections and projections with expressions.

Implicit Projection Creation

When you insert data into a table, Vertica automatically creates a superprojection for the table.

Superprojections do not require any additional privileges to create or drop, other than privileges for table creation. Users who can create a table or drop a table can also create and drop the associated superprojection.

View Privileges

A view is a stored query that dynamically accesses and computes data from the database at execution time. Use `\dV` in `vsq` to display available views. By default, only the following users have privileges to access a view's base object:

- Superuser
- View owner—typically, the view creator

To execute a query that contains a view, you must have:

- SELECT privileges assigned with [GRANT \(View\)](#)
- USAGE privileges on the view's schema, assigned with [GRANT \(Schema\)](#).

You can assign view privileges to other users and roles using [GRANT \(View\)](#). For example:

- Assign `GRANT ALL` privileges to a user or role.

```
=> GRANT all privileges on view1 to role1 with grant option;
```

- Assign `GRANT ROLE` privileges to a specific role to provide view privileges. In the following example, privileges that are assigned to `role1` are assigned to `role2`:

```
=> CREATE ROLE role1;  
=> CREATE ROLE role2;  
=> GRANT role1 to role2;
```

See Also

[GRANT \(View\)](#)

[REVOKE \(View\)](#)

Sequence Privileges

To create a sequence, a user must have `CREATE` privileges on a schema that contains the sequence. Only the owner and superusers can initially access the sequence. All other users must be granted access to the sequence by a superuser or the owner.

Only the sequence owner (typically the person who creates the sequence) or the superuser can drop or rename a sequence, or change the schema in which the sequence resides:

- [DROP SEQUENCE](#): Only a sequence owner or schema owner can drop a sequence.
- [ALTER SEQUENCE RENAME TO](#): A sequence owner must have `USAGE` and `CREATE` privileges on the schema that contains the sequence to be renamed.
- [ALTER SEQUENCE SET SCHEMA](#): A sequence owner must have `USAGE` privilege on the schema that currently contains the sequence (old schema), as well as `CREATE` privilege on the schema where the sequence will be moved (new schema).

The following table lists the privileges that can be granted to users or roles on sequences.

The only privilege that can be granted to a user or role is `SELECT`, which allows the user to use [CURRVAL\(\)](#) and [NEXTVAL\(\)](#) on sequence and reference in table. The user or role also needs to have `USAGE` privilege on the schema containing the sequence.

Privilege	Description
<code>SELECT</code>	Permission to use CURRVAL() and NEXTVAL() on sequence and reference in table.
<code>USAGE</code>	Permissions on the schema that contains the sequence.

Note: Referencing sequence in the [CREATE TABLE](#) statement requires `SELECT` privilege on sequence object and `USAGE` privilege on sequence schema.

For details on granting and revoking sequence privileges, see [GRANT \(Sequence\)](#) and [REVOKE \(Sequence\)](#) in the SQL Reference Manual.

See Also

- [Working with Sequence Types](#)

External Procedure Privileges

Only a superuser is allowed to create or drop an external procedure.

By default, users cannot execute external procedures. A superuser must grant users and roles this right, using the `GRANT (Procedure) EXECUTE` statement. Additionally, users must have `USAGE` privileges on the schema that contains the procedure in order to call it.

Privilege	Description
EXECUTE	Permission to run an external procedure.
USAGE	Permission on the schema that contains the procedure.

For details on granting and revoking external table privileges, see [GRANT \(Procedure\)](#) and [REVOKE \(Procedure\)](#) in the SQL Reference Manual.

User-Defined Function Privileges

User-defined functions (described in [CREATE FUNCTION Statements](#)) can be created by superusers or users with `CREATE` privileges on the schema that will contain the function, as well as `USAGE` privileges on the base library (if applicable).

Users or roles other than the function owner can use a function only if they have been granted `EXECUTE` privileges on it. They must also have `USAGE` privileges on the schema that contains the function to be able to call it.

Privilege	Description
EXECUTE	Permission to call a user-defined function.
USAGE	Permission on the schema that contains the function.

- [DROP FUNCTION](#): Only a superuser or function owner can drop the function.
- [ALTER FUNCTION \(UDF or UDT\) RENAME TO](#): A superuser or function owner must have `USAGE` and `CREATE` privileges on the schema that contains the function to be renamed.
- [ALTER FUNCTION \(UDF or UDT\) SET SCHEMA](#): A superuser or function owner must have `USAGE` privilege on the schema that currently contains the function (old schema), as well as `CREATE` privilege on the schema where the function will be moved (new schema).

For details on granting and revoking user-defined function privileges, see the following topics in the SQL Reference Manual:

- [GRANT \(User Defined Extension\)](#)
- [REVOKE \(User Defined Extension\)](#)

Library Privileges

Only a superuser can load an external library using the [CREATE LIBRARY](#) statement. By default, only a superuser can create user-defined functions (UDFs) based on a loaded library. A superuser can use the `GRANT USAGE ON LIBRARY` statement to allow users to create UDFs based on classes in the library. The user must also have `CREATE` privileges on the schema that will contain the UDF.

Privilege	Description
USAGE	Permission to create UDFs based on classes in the library

Once created, only a superuser or the user who created a UDF can use it by default. Either of them can grant other users or roles the ability to call the function using the `GRANT EXECUTE ON FUNCTION` statement. See the [GRANT \(User Defined Extension\)](#) and [REVOKE \(User Defined Extension\)](#) topics in the SQL Reference Manual for more information on granting and revoking privileges on functions.

In addition to `EXECUTE` privilege, users/roles also require `USAGE` privilege on the schema in which the function resides in order to execute the function.

For more information about libraries and UDFs, see [Developing User-Defined Extensions \(UDxs\)](#) in *Extending Vertica*.

Resource Pool Privileges

Only a superuser can create, alter, or drop a resource pool.

By default, users are granted `USAGE` rights to the `GENERAL` pool, from which their queries and other statements allocate memory and get their priorities. A superuser must grant users `USAGE` rights to any additional resource pools by using the `GRANT USAGE ON RESOURCE POOL` statement. Once granted access to the resource pool, users can use the [SET SESSION RESOURCE_POOL](#) statement and the `RESOURCE POOL` clause of the [ALTER USER](#) statement to have their queries draw their resources from the new pool.

Privilege	Description
USAGE	Permission to use a resource pool.
SELECT	Permission to look up resource pool information/status in system tables.
UPDATE	Permission to adjust the tuning parameters of the pool.

For details on granting and revoking resource pool privileges, see [GRANT \(Resource Pool\)](#) and [REVOKE \(Resource Pool\)](#) in the SQL Reference Manual.

Storage Location Privileges

Users and roles without superuser privileges can copy data to and from storage locations as long as the following conditions are met, where a superuser:

1. Creates a special class of storage location ([CREATE LOCATION](#)) specifying the USAGE argument set to 'USER' , which indicates the specified area is accessible to non-superusers users.
2. Grants users or roles READ and/or WRITE access to the specified location using the [GRANT \(Storage Location\)](#) statement.

Note: GRANT/REVOKE (Storage Location) statements are applicable only to 'USER' storage locations.

Once such storage locations exist and the appropriate privileges are granted, users and roles granted READ privileges can copy data from files in the storage location into a table. Those granted WRITE privileges can export data from a table to the storage location on which they have been granted access. WRITE privileges also let users save COPY statement exceptions and rejected data files from Vertica to the specified storage location.

Only a superuser can add, alter, retire, drop, and restore a location, as well as set and measure location performance. All non-dbadmin users or roles require READ and/or WRITE permissions on the location.

Privilege	Description
READ	Allows the user to copy data from files in the storage location into a table.
WRITE	Allows the user to copy data to the specific storage location. Users with WRITE privileges can also save COPY statement exceptions and rejected data files to the specified storage location.

- [GRANT \(Storage Location\)](#)
- [Storage Management Functions](#)
- [CREATE LOCATION](#)

Role, profile, and User Privileges

Only a superuser can create, alter or drop a:

- role
- profile
- user

By default, only the superuser can grant or revoke a role to another user or role. A user or role can be given the privilege to grant and revoke a role by using the WITH ADMIN OPTION clause of the GRANT statement.

For details on granting and revoking role privileges, see [GRANT \(Role\)](#) and [REVOKE \(Role\)](#) in the SQL Reference Manual.

Metadata Privileges

A superuser has unrestricted access to all database metadata. Other users have significantly reduced access to metadata based on their privileges, as follows:

Type of Metadata	User Access
<p>Catalog objects:</p> <ul style="list-style-type: none">• Tables• Columns• Constraints• Sequences• External Procedures• Projections• ROS containers• WOS	<p>Users must possess USAGE privilege on the schema and any type of access (SELECT) or modify privilege on the object to see catalog metadata about the object. See also Schema Privileges.</p> <p>For internal objects like projections, WOS and ROS containers that don't have access privileges directly associated with them, the user must possess the requisite privileges on the associated schema and table objects instead. For example, to see whether a table has any data in the WOS, you need to have USAGE on the table schema and at least SELECT on the table itself. See also Table Privileges and Projection Privileges.</p>
<p>User sessions and functions, and system tables related to these sessions</p>	<p>Users can only access information about their own, current sessions.</p> <p>The following functions provide restricted functionality to users:</p> <ul style="list-style-type: none">• CURRENT_DATABASE• CURRENT_SCHEMA• CURRENT_USER• HAS_TABLE_PRIVILEGE

Type of Metadata	User Access
	<ul style="list-style-type: none">• SESSION_USER (same as CURRENT_USER) <p>The system table, SESSIONS, provides restricted functionality to users.</p>
Storage locations	<p>Users require READ permissions to copy data from storage locations.</p> <p>Only a superuser can add or retire storage locations.</p>

I/O Privileges

Users need no special permissions to connect to and disconnect from an Vertica database.

To [EXPORT TO](#) and [COPY FROM](#) Vertica, the user must have:

- SELECT privileges on the source table
- USAGE privilege on source table schema
- INSERT privileges for the destination table in target database
- USAGE privilege on destination table schema

To [COPY FROM STDIN](#) and use local [COPY](#) a user must have INSERT privileges on the table and USAGE privilege on schema.

Note: Only a superuser can [COPY](#) from *file*.

Comment Privileges

A comment lets you add, revise, or remove a textual message to a database object. You must be an object owner or superuser in order to [COMMENT ON](#) one of the following objects:

- [COLUMN](#)
- [CONSTRAINT](#)
- [FUNCTION](#) (including AGGREGATE and ANALYTIC)

- [LIBRARY](#)
- [NODE](#)
- [PROJECTION](#)
- [SCHEMA](#)
- [SEQUENCE](#)
- [TABLE](#)
- [TRANSFORM FUNCTION](#)
- [VIEW](#)

Other users must have VIEW privileges on an object to view its comments.

Transaction Privileges

No special permissions are required for the following database operations:

- [COMMIT](#)
- [ROLLBACK](#)
- [RELEASE SAVEPOINT](#)
- [SAVEPOINT](#)

Session Privileges

No special permissions are required for users to use the SHOW statement or any of the SET statements.

Tuning Privileges

In order to [PROFILE](#) a single SQL statement or returns a query plan's execution strategy to standard output using the [EXPLAIN](#) command, users must have the same privileges that are required for them to run the same query without the PROFILE or EXPLAIN keyword.

Granting and Revoking Privileges

To grant or revoke a privilege using one of the SQL GRANT or REVOKE statements, the user must have the following permissions for the GRANT/REVOKE statement to succeed:

- Superuser or privilege WITH GRANT OPTION
- USAGE privilege on the schema
- Appropriate privileges on the object

The syntax for granting and revoking privileges is different for each database object, such as schema, database, table, view, sequence, procedure, function, resource pool, and so on.

Normally, a superuser first [creates a user](#) and then uses GRANT syntax to define the user's privileges or roles or both. For example, the following series of statements creates user Carol and grants Carol access to the apps database in the PUBLIC schema and also lets Carol grant SELECT privileges to other users on the applog table:

```
=> CREATE USER Carol;  
=> GRANT USAGE ON SCHEMA PUBLIC to Carol;  
=> GRANT ALL ON DATABASE apps TO Carol;  
=> GRANT SELECT ON applog TO Carol WITH GRANT OPTION;
```

See [GRANT Statements](#) and [REVOKE Statements](#) in the SQL Reference Manual.

About Superuser Privileges

A superuser (DBADMIN) is the automatically-created database user who has the same name as the Linux database administrator account and who can bypass all GRANT/REVOKE authorization, as well as supersede any user that has been granted the [PSEUDOSUPERUSER](#) role.

Note: Database superusers are not the same as a Linux superuser with (root) privilege and cannot have Linux superuser privilege.

A superuser can grant privileges on all database object types to other users, as well as grant privileges to roles. Users who have been granted the role will then gain the privilege as soon as they [enable it](#).

Superusers may grant or revoke any object privilege on behalf of the object owner, which means a superuser can grant or revoke the object privilege if the object owner could have

granted or revoked the same object privilege. A superuser may revoke the privilege that an object owner granted, as well as the reverse.

Since a superuser is acting on behalf of the object owner, the GRANTOR column of [V_CATALOG.GRANTS](#) table displays the object owner rather than the superuser who issued the GRANT statement.

A superuser can also alter ownership of table and sequence objects.

[DBADMIN Role](#)

About Schema Owner Privileges

By default, the schema owner has privileges to create objects within a schema. Additionally, the schema owner can drop any object in the schema, requiring no additional privilege on the object.

The schema owner is typically the user who creates the schema.

Schema owners cannot access objects in the schema. Access to objects requires the appropriate privilege at the object level.

All other access to the schema and its objects must be explicitly granted to users or roles by a superuser or schema owner to prevent unauthorized users from accessing the schema and its objects.

See [Schema Privileges](#)

About Object Owner Privileges

The database, along with every object in it, has an owner. The object owner is usually the person who created the object, although a superuser can alter ownership of objects, such as table and sequence.

Object owners must have appropriate schema privilege to access, alter, rename, move or drop any object it owns without any additional privileges.

An object owner can also:

- **Grant privileges on their own object to other users**

The WITH GRANT OPTION clause specifies that a user can grant the permission to other users. For example, if user Bob creates a table, Bob can grant privileges on that table to users Ted, Alice, and so on.

- **Grant privileges to roles**

Users who are granted the role gain the privilege.

How to Grant Privileges

As described in [Granting and Revoking Privileges](#), specific users grant privileges using the GRANT statement with or without the optional WITH GRANT OPTION, which allows the user to grant the same privileges to other users.

- A superuser can grant privileges on all object types to other users.
- A superuser or object owner can grant privileges to roles. Users who have been granted the role then gain the privilege.
- An object owner can grant privileges on the object to other users using the optional WITH GRANT OPTION clause.
- The user needs to have USAGE privilege on schema and appropriate privileges on the object.

When a user grants an explicit list of privileges, such as `GRANT INSERT, DELETE, REFERENCES ON applog TO Bob`:

- The GRANT statement succeeds only if all the roles are granted successfully. If any grant operation fails, the entire statement rolls back.
- Vertica will return ERROR if the user does not have grant options for the privileges listed.

When a user grants ALL privileges, such as `GRANT ALL ON applog TO Bob`, the statement always succeeds. Vertica grants all the privileges on which the grantor has the WITH GRANT OPTION and skips those privileges without the optional WITH GRANT OPTION.

For example, if the user Bob has delete privileges with the optional grant option on the applog table, only DELETE privileges are granted to Bob, and the statement succeeds:

```
=> GRANT DELETE ON applog TO Bob WITH GRANT OPTION;GRANT PRIVILEGE
```

For details, see the [GRANT Statements](#) in the SQL Reference Manual.

How to Revoke Privileges

In general, **ONLY** the user who originally granted a privilege can revoke it using a REVOKE statement. That user must have superuser privilege or have the optional WITH GRANT OPTION on the privilege. The user also must have USAGE privilege on the schema and appropriate privileges on the object for the REVOKE statement to succeed.

In order to revoke a privilege, this privilege must have been granted to the specified grantee by this grantor before. If Vertica finds that to be the case, the above REVOKE statement removes the privilege (and WITH GRANT OPTION privilege, if supplied) from the grantee. Otherwise, Vertica prints a NOTICE that the operation failed, as in the following example.

```
=> REVOKE SELECT ON applog FROM Bob;  
NOTICE 0: Cannot revoke "SELECT" privilege(s) for relation "applog" that you did not grant to "Bob"  
REVOKE PRIVILEGE
```

The above REVOKE statement removes the privilege (and WITH GRANT OPTION privilege, if applicable) from the grantee or it prints a notice that the operation failed.

In order to revoke grant option for a privilege, the grantor must have previously granted the grant option for the privilege to the specified grantee. Otherwise, Vertica prints a NOTICE.

The following REVOKE statement removes the GRANT option only but leaves the privilege intact:

```
=> GRANT INSERT on applog TO Bob WITH GRANT OPTION;  
GRANT PRIVILEGE  
=> REVOKE GRANT OPTION FOR INSERT ON applog FROM Bob;  
REVOKE PRIVILEGE
```

When a user revokes an explicit list of privileges, such as GRANT INSERT, DELETE, REFERENCES ON applog TO Bob:

- The REVOKE statement succeeds only if all the roles are revoked successfully. If any revoke operation fails, the entire statement rolls back.
- Vertica returns ERROR if the user does not have grant options for the privileges listed.
- Vertica returns NOTICE when revoking privileges that this user had not been previously granted.

When a user revokes ALL privileges, such as REVOKE ALL ON applog TO Bob, the statement always succeeds. Vertica revokes all the privileges on which the grantor has the optional WITH GRANT OPTION and skips those privileges without the WITH GRANT OPTION.

For example, if the user Bob has delete privileges with the optional grant option on the applog table, only grant option is revoked from Bob, and the statement succeeds without NOTICE:

```
=> REVOKE GRANT OPTION FOR DELETE ON applog FROM Bob;
```

For details, see the [REVOKE Statements](#) in the SQL Reference Manual.

Privilege Ownership Chains

The ability to revoke privileges on objects can cascade throughout an organization. If the grant option was revoked from a user, the privilege that this user granted to other users will also be revoked.

If a privilege was granted to a user or role by multiple grantors, to completely revoke this privilege from the grantee the privilege has to be revoked by each original grantor. The only exception is a superuser may revoke privileges granted by an object owner, with the reverse being true, as well.

In the following example, the SELECT privilege on table t1 is granted through a chain of users, from a superuser through User3.

- A superuser grants User1 CREATE privileges on the schema s1:

```
=> \c - dbadminYou are now connected as user "dbadmin".
=> CREATE USER User1;
CREATE USER
=> CREATE USER User2;
CREATE USER
=> CREATE USER User3;
CREATE USER
=> CREATE SCHEMA s1;
CREATE SCHEMA
=> GRANT USAGE on SCHEMA s1 TO User1, User2, User3;
GRANT PRIVILEGE
=> CREATE ROLE reviewer;
CREATE ROLE
=> GRANT CREATE ON SCHEMA s1 TO User1;
GRANT PRIVILEGE
```

- User1 creates new table t1 within schema s1 and then grants SELECT WITH GRANT OPTION privilege on s1.t1 to User2:

```
=> \c - User1You are now connected as user "User1".
=> CREATE TABLE s1.t1(id int, sourceID VARCHAR(8));
CREATE TABLE
=> GRANT SELECT on s1.t1 to User2 WITH GRANT OPTION;
GRANT PRIVILEGE
```

- User2 grants SELECT WITH GRANT OPTION privilege on s1.t1 to User3:

```
=> \c - User2You are now connected as user "User2".
=> GRANT SELECT ON s1.t1 to User3 WITH GRANT OPTION;
GRANT PRIVILEGE
```

- User3 grants SELECT privilege on s1.t1 to the reviewer role:

```
=> \c - User3You are now connected as user "User3".
=> GRANT SELECT ON s1.t1 to reviewer;
GRANT PRIVILEGE
```

Users cannot revoke privileges upstream in the chain. For example, User2 did not grant privileges on User1, so when User1 runs the following REVOKE command, Vertica rolls back the command:

```
=> \c - User2You are now connected as user "User2".
=> REVOKE CREATE ON SCHEMA s1 FROM User1;
ROLLBACK 0: "CREATE" privilege(s) for schema "s1" could not be revoked from "User1"
```

Users can revoke privileges indirectly from users who received privileges through a cascading chain, like the one shown in the example above. Here, users can use the CASCADE option to revoke privileges from all users "downstream" in the chain. A superuser or User1 can use the CASCADE option to revoke the SELECT privilege on table s1.t1 from all users. For example, a superuser or User1 can execute the following statement to revoke the SELECT privilege from all users and roles within the chain:

```
=> \c - User1You are now connected as user "User1".
=> REVOKE SELECT ON s1.t1 FROM User2 CASCADE;
REVOKE PRIVILEGE
```

When a superuser or User1 executes the above statement, the SELECT privilege on table s1.t1 is revoked from User2, User3, and the reviewer role. The GRANT privilege is also revoked from User2 and User3, which a superuser can verify by querying the [V_CATALOG.GRANTS](#) system table.

```
=> SELECT * FROM grants WHERE object_name = 's1' AND grantee ILIKE 'User%';
grantor | privileges_description | object_schema | object_name | grantee
-----+-----+-----+-----+-----
dbadmin | USAGE                  |               | s1          | User1
dbadmin | USAGE                  |               | s1          | User2
dbadmin | USAGE                  |               | s1          | User3
(3 rows)
```

Modifying Privileges

A superuser or object owner can use one of the ALTER statements to modify a privilege, such as changing a sequence owner or table owner. Reassignment to the new owner does not transfer grants from the original owner to the new owner; grants made by the original owner are dropped.

Changing Table Ownership

As a superuser or table owner, you can reassign table ownership with [ALTER TABLE](#), as follows:

```
ALTER TABLE [schema.]table-name OWNER TO owner-name
```

Changing table ownership is useful when moving a table from one schema to another. Ownership reassignment is also useful when a table owner leaves the company or changes job responsibilities. Because you can change the table owner, the tables won't have to be completely rewritten, you can avoid loss in productivity.

Changing table ownership automatically causes the following changes:

- Grants on the table that were made by the original owner are dropped and all existing privileges on the table are revoked from the previous owner. Changes in table ownership has no effect on schema privileges.
- Ownership of dependent IDENTITY/AUTO-INCREMENT sequences are transferred with the table. However, ownership does not change for independent sequences created with [CREATE SEQUENCE](#). To transfer ownership of these sequences, use [ALTER SEQUENCE](#).
- New table ownership is propagated to its projections.

Example

In this example, user Bob connects to the database, looks up the tables, and transfers ownership of table t33 from himself to user Alice.

```
=> \c - Bob
You are now connected as user "Bob".
=> \d
Schema | Name | Kind | Owner | Comment
-----+-----+-----+-----+-----
public | applog | table | dbadmin |
public | t33 | table | Bob |
```

```
(2 rows)
=> ALTER TABLE t33 OWNER TO Alice;
ALTER TABLE
```

Notice that when Bob looks up database tables again, he no longer sees table t33.

```
=> \d
                List of tables
                List of tables
 Schema | Name | Kind | Owner | Comment
-----+-----+-----+-----+-----
 public | applog | table | dbadmin |
(1 row)
```

When user Alice connects to the database and looks up tables, she sees she is the owner of table t33.

```
=> \c - Alice
You are now connected as user "Alice".
=> \d
                List of tables
 Schema | Name | Kind | Owner | Comment
-----+-----+-----+-----+-----
 public | t33 | table | Alice |
(2 rows)
```

Either Alice or a superuser can transfer table ownership back to Bob. In the following case a superuser performs the transfer.

```
=> \c - dbadmin
You are now connected as user "dbadmin".
=> ALTER TABLE t33 OWNER TO Bob;
ALTER TABLE
=> \d
                List of tables
 Schema | Name | Kind | Owner | Comment
-----+-----+-----+-----+-----
 public | applog | table | dbadmin |
 public | comments | table | dbadmin |
 public | t33 | table | Bob |
 s1 | t1 | table | User1 |
(4 rows)
```

You can also query system table [V_CATALOG.TABLES](#) to view table and owner information. Note that a change in ownership does not change the table ID.

In the below series of commands, the superuser changes table ownership back to Alice and queries the TABLES system table.

```
=> ALTER TABLE t33 OWNER TO Alice;
ALTER TABLE
=> SELECT table_schema_id, table_schema, table_id, table_name, owner_id, owner_name FROM tables;
table_schema_id | table_schema | table_id | table_name | owner_id | owner_name
-----+-----+-----+-----+-----+-----
```

```
45035996273704968 | public      | 45035996273713634 | applog   | 45035996273704962 | dbadmin
45035996273704968 | public      | 45035996273724496 | comments | 45035996273704962 | dbadmin
45035996273730528 | s1          | 45035996273730548 | t1       | 45035996273730516 | User1
45035996273704968 | public      | 45035996273795846 | t33      | 45035996273724576 | Alice
(5 rows)
```

Now the superuser changes table ownership back to Bob and queries the TABLES table again. Nothing changes but the owner_name row, from Alice to Bob.

```
=> ALTER TABLE t33 OWNER TO Bob;
ALTER TABLE
=> SELECT table_schema_id, table_schema, table_id, table_name, owner_id, owner_name FROM tables;
  table_schema_id | table_schema |   table_id   | table_name |   owner_id   | owner_name--
-----+-----+-----+-----+-----+-----
45035996273704968 | public      | 45035996273713634 | applog     | 45035996273704962 | dbadmin
45035996273704968 | public      | 45035996273724496 | comments   | 45035996273704962 | dbadmin
45035996273730528 | s1          | 45035996273730548 | t1         | 45035996273730516 | User1
45035996273704968 | public      | 45035996273793876 | foo        | 45035996273724576 | Alice
45035996273704968 | public      | 45035996273795846 | t33        | 45035996273714428 | Bob
(5 rows)
```

[Changing Sequence Ownership](#)

Changing Sequence Ownership

The ALTER SEQUENCE command lets you change the attributes of an existing sequence. All changes take effect immediately, within the same session. Any parameters not set during an ALTER SEQUENCE statement retain their prior settings.

If you need to change sequence ownership, such as if an employee who owns a sequence leaves the company, you can do so with the following ALTER SEQUENCE syntax:

```
=> ALTER SEQUENCE sequence-name OWNER TO new-owner-name;
```

This operation immediately reassigns the sequence from the current owner to the specified new owner.

Only the sequence owner or a superuser can change ownership, and reassignment does not transfer grants from the original owner to the new owner; grants made by the original owner are dropped.

Note: Renaming a table owner transfers ownership of dependent sequence objects (associated IDENTITY/AUTO-INCREMENT sequences) but does not transfer ownership of other referenced sequences. See [Changing Table Ownership](#).

Example

The following example reassigns sequence ownership from the current owner to user Bob:

```
=> ALTER SEQUENCE sequential OWNER TO Bob;
```

See [ALTER SEQUENCE](#) in the SQL Reference Manual for details.

Viewing Privileges Granted on Objects

Vertica logs information about privileges granted on various objects, including the grantor and grantee, in the [V_CATALOG.GRANTS](#) system table. The order of columns in the table corresponds to the order in which they appear in the GRANT command. An asterisk in the output means the privilege was granted WITH GRANT OPTION.

The following command queries the GRANTS system table:

```
=> SELECT * FROM grants ORDER BY grantor, grantee;
```

grantor	privileges_description	object_schema	object_name	grantee
Bob			commentor	Alice
dbadmin	CREATE		schema2	Bob
dbadmin			commentor	Bob
dbadmin			commentor	Bob
dbadmin			logadmin	Bob
dbadmin	USAGE		general	Bob
dbadmin	INSERT, UPDATE, DELETE, REFERENCES	public	applog	Bob
dbadmin			logadmin	Ted
dbadmin	USAGE		general	Ted
dbadmin	USAGE		general	Sue
dbadmin	CREATE, CREATE TEMP		vmart	Sue
dbadmin	USAGE		public	Sue
dbadmin	SELECT*	public	applog	Sue
dbadmin	USAGE		general	Alice
dbadmin	INSERT, SELECT	public	comments	commentor
dbadmin	INSERT, SELECT	public	applog	commentor
dbadmin			logwriter	logadmin
dbadmin			logreader	logadmin
dbadmin	DELETE	public	applog	logadmin
dbadmin	SELECT	public	applog	logreader
dbadmin	INSERT	public	applog	logwriter
dbadmin	USAGE		v_internal	public
dbadmin	CREATE TEMP		vmart	public
dbadmin	USAGE		public	public
dbadmin	USAGE		v_catalog	public
dbadmin	USAGE		v_monitor	public
dbadmin	CREATE*, CREATE TEMP*		vmart	dbadmin
dbadmin	USAGE*, CREATE*		schema2	dbadmin
dbadmin	INSERT*, SELECT*, UPDATE*, DELETE*, REFERENCES*	public	comments	dbadmin
dbadmin	INSERT*, SELECT*, UPDATE*, DELETE*, REFERENCES*	public	applog	dbadmin

(30 rows)

To quickly find all of the privileges that have been granted to all users on the schema named myschema, run the following statement:

```
=> SELECT grantee, privileges_description FROM GRANTS WHERE object_name='myschema';
grantee | privileges_description
-----+-----
Bob     | USAGE, CREATE
Alice   | CREATE
(2 rows)
```

Note that the vsql commands, \dp and \z, both return similar information to GRANTS:

```
=> \dp
Access privileges for database "apps"
Privileges | Schema | Name | Grantee | Grantor |
-----+-----+-----+-----+-----+
public     | dbadmin | USAGE |         |         | v_internal
public     | dbadmin | USAGE |         |         | v_catalog
public     | dbadmin | USAGE |         |         | v_monitor
logadmin   | dbadmin |       |         |         | logreader
logadmin   | dbadmin |       |         |         | logwriter
Fred       | dbadmin | USAGE |         |         | general
Fred       | dbadmin |       |         |         | logadmin
Bob        | dbadmin | USAGE |         |         | general
dbadmin    | dbadmin | USAGE*, CREATE* |         |         | schema2
Bob        | dbadmin | CREATE |         |         | schema2
Sue        | dbadmin | USAGE |         |         | general
public     | dbadmin | USAGE |         |         | public
Sue        | dbadmin | USAGE |         |         | public
public     | dbadmin | CREATE TEMP |         |         | appdat
dbadmin    | dbadmin | CREATE*, CREATE TEMP* |         |         | appdat
Sue        | dbadmin | CREATE, CREATE TEMP |         |         | appdat
dbadmin    | dbadmin | INSERT*, SELECT*, UPDATE*, DELETE*, REFERENCES* | public | applog
logreader  | dbadmin | SELECT | public | applog
logwriter  | dbadmin | INSERT | public | applog
logadmin   | dbadmin | DELETE | public | applog
Sue        | dbadmin | SELECT* | public | applog
(22 rows)
```

See [GRANT Statements](#) in the SQL Reference Manual.

Access Policies

You can create the following access policy types to restrict access to sensitive information to only those users authorized to view it:

- [Column Access Policy](#)
- [Row Access Policy](#)

Important: If you have a table with both a row level access policy and a column level access policy, Vertica filters the row level access policy first. Then Vertica uses the column level access policy to filter the columns.

Use Cases

Column Access Policy Use Case

Base a column access policy on a user's role and the privileges granted to that role.

For example, in a healthcare organization, customer support representatives and account managers have access to the same customer table. The table contains the column SSN for storing customer Social Security numbers. Customer support representatives have only partial access, to view the last four digits. The account manager, however, must be able to view entire Social Security numbers. Therefore, the *manager* role has privileges to view all nine digits of the social security numbers.

When creating a column access policy, use expressions to specify exactly what different users or roles can access within the column.

In this case, a *manager* can access the entire SSN column, while customer support representatives can only access the last four digits:

```
=> CREATE ACCESS POLICY ON schema.customers_table
FOR COLUMN SSN
CASE
WHEN ENABLED_ROLE('manager') THEN SSN
else substr(SSN, 8, 4)
END
ENABLE;
```

Row Access Policy Use Case

You can also create a row access policy on the same table. For example, you can modify access to a customer table so a manager can view data in all rows. However, a broker can see a row only if the customer is associated with that broker:

```
=> select * from customers_table;
```

custID	password	ssn
1	secret	12345678901
2	secret	12345678902
3	secret	12345678903

(3 rows)

Each customer in the `customers_table` has an assigned broker:

```
=> select * from broker_info;
```

broker	custID
u1	1
u2	2
u3	3

Create the access policy to allow a *manager* to see all data in all rows. Limit a broker's view to only those customers to which the broker is assigned:

```
=> CREATE ACCESS POLICY ON schema.customers_table
  FOR rows
  WHERE
    ENABLED_ROLE('manager')
    or
    (ENABLED_ROLE('broker') AND customers_table.custID in (SELECT broker_info.custID FROM broker_
info
  WHERE broker = CURRENT_USER()))
  ENABLE;
```

Access Policy Creation Workflow

You can create access policies for any table type, columnar, external, or [flex](#). You can also create access policies on any column type, including joins.

If no users or roles are already created, you must create them before creating an access policy:

- [Create a User](#)
- [Create a Role](#)
- [GRANT \(Schema\)](#)
- [GRANT \(Table\)](#)
- [Grant a user access to the role](#)
- The user [enables the role](#) with the [SET ROLE](#) statement (unless the administration user assigned a [default role](#) to the user)
- Create the access policy with the [CREATE ACCESS POLICY](#) statement.

Working With Access Policies

This section describes areas that may affect how you use access policies.

Performing Operations

Having row and column access policies enabled on a table may affect the behavior when you attempt to perform the following DML operations:

- Insert
- Update
- Delete
- Merge
- Copy
- Select

Row Level Access Behavior

On tables where a row access policy is enabled, you can only perform DML operations when the condition in the Row access policy evaluates to TRUE. For example:

Table1 appears as follows:

```
A | B
---+---
1 | 1
2 | 2
3 | 3
```

Create the following row access policy on Table1:

```
=> CREATE ACCESS POLICY on table1 for ROWS
WHERE enabled_role('manager')
OR
A<2
ENABLE;
```

With this policy enabled, the following behavior exists for users who want to perform DML operations:

- A user with the manager role can perform DML on all rows in the table, because the WHERE clause in the policy evaluates to TRUE.
- Users with non-manager roles can only perform a SELECT to return data in column A that has a value of less than two. If the access policy has to read the data in the table to confirm a condition, it does not allow DML operations.

Column Level Access Behavior

On tables where a column access policy is enabled, you can perform DML operations if you can view the entire column. For example:

Table1 appears as follows:

```
A | B
---+---
1 | 1
2 | 2
3 | 3
```

Create the following column access policy on Table1:

```
=> CREATE ACCESS POLICY on Table1 FOR column A NULL::int enable;
```

In this case users cannot perform DML operations on column A.

Important: Users who can access all the rows and columns in a table with an access policy enabled can perform DML operations. Therefore, when you create an access policy, make sure you construct it in a manner that all row and column data is accessible by at least one user. This allows at least one user to perform any DML that may be required. Otherwise, you can temporarily disable the access policy to perform DML.

Schema Table and Privileges

Only dbadmin users can create access policies. If you want a user to be able to use access policies, you must first assign that user the appropriate privileges.

- Grant [schema](#) or [table](#) privileges to a table non-owner to allow that user to use the access policy.
- Revoke [schema](#) or [table](#) privileges to prohibit the user from using the access policy.

This example shows how you can create an access policy without the user being granted privilege for the public schema:

```
=> CREATE ACCESS POLICY ON public.customers_table  
FOR COLUMN SSN  
WHEN ENABLED_ROLE('operator') THEN SUBSTR(SSN, 8, 4)
```

Enable and Disable Access Policy Creation

Access policies are enabled by default for all tables in the database. To disable and enable the creation of new access policies at the database level, use the ALTER DATABASE statement.

Disable Creation of New Access Policies

```
=> ALTER DATABASE dbname SET EnableAccessPolicy=0;
```

Enable Creation of New Access Policies

```
=> ALTER DATABASE dbname SET EnableAccessPolicy=1;
```

Limitations on Creating Access Policies with Projections

You can create access policies on columns in tables that are part of a projection. However, you cannot create an access policy on an *input table* for the following projections:

- Top-K projections
- Aggregate projections
- Projections with expressions

Sometimes, a table already has an access policy and is part of a projection. In such cases, if the Vertica optimizer cannot fold (or *compress*) the query, the access query is blocked.

Query Optimization Considerations

When using access policies be aware of the following potential behaviors, and design tables optimally.

Design Tables That All Authorized Users Can Access

When Database Designer creates projections for a given table, it takes into account the access policies that apply to the current user. The set of projections that Database Designer produces for the table are optimized for that user's access privileges, and other users with similar access privileges. However, these projections might be less than optimal for users with different

access privileges. These differences might have some effect on how efficiently Vertica processes queries from those users. Therefore, when you evaluate projection designs for that table using Database Designer, design a given table so that all authorized users have optimal access.

Avoid Performance Issues Caused by Dynamic Rewrite

To enforce row-level access policies, the system dynamically rewrites user queries. Therefore, query performance may be affected by how row-level access policies are written.

For example, referring to preceding [Access Policy Use Cases](#), run the following query. Enable both the row and column access policies on the `customers_table`:

```
=> SELECT * from customers_table;
```

Vertica rewrites this query plan to:

```
=> SELECT * from (select custID, password, CASE WHEN enabled_role('manager') THEN SSN else substr
(SSN, 8, 4) end AS SSN
FROM customers_table
WHERE
enabled_role('broker')
AND
customers_table.custID IN (SELECT broker_info.custID FROM broker_info WHERE broker = current_user())
) customers_table;
```

Column Access Policy

Use the [CREATE ACCESS POLICY](#) statement to create a column access policy for a specific column in a table. Creating an access policy depends on the expressions specified when creating the policy, and also on the following:

- [Viewing a User's Role](#)
- [Granting Privileges to Roles](#)

Example

Suppose you want to prevent users from viewing a specific column in a table. This example shows how to create an access policy that masks column A in Table1.

Run the following SQL command:

```
=> SELECT * FROM Table1;
```

Table1 appears as follows:

```
A | B
---+-----
1 | one
2 | two
3 | three
4 | four
```

Create the following column access policy:

```
=> CREATE ACCESS POLICY on Table1 FOR column A NULL::int enable;
```

Re-run the SQL command:

```
=> SELECT * FROM Table1;
```

The following is returned:

```
A | B
---+-----
  | one
  | two
  | three
  | four
```

Note that no values appear in column A because the access policy prevents the return of this data (NULL::int).

Creating Column Access Policies

Creating a column access policy allows different users to run the same query and receive different results. For example, you can create an access policy authorizing access to a column of bank account numbers. You can specify that a user with the role *employee* cannot access this information. However, you do give access to a user with a *manager* role.

Conditions specified in the access policy determine whether the user can see data restricted by the policy. This example shows how you can specify that the *manager* role can view the entire Social Security number while the *operator* role can only view the last four digits. The first five digits are masked for the operator role (THEN SUBSTR (SSN, 8, 4)). The 8 indicates the operator sees data starting on the eighth character (such as 123-45-6789).

```
=> CREATE ACCESS POLICY ON customers_table
FOR COLUMN SSN
```

```
CASE  
WHEN ENABLED_ROLE('manager') THEN SSN  
WHEN ENABLED_ROLE('operator') THEN SUBSTR(SSN, 8, 4)  
ELSE NULL  
END  
ENABLE;
```

Access Policy Limitations

When you use column access policies, be aware of the following limitations:

- When using an access policy you cannot use any of the following in an expression:
 - Aggregate functions
 - Subquery
 - Analytics
 - UDT
- If the query cannot be folded by the Vertica optimizer, all functions other than SELECT are blocked. The following error message appears:

```
ERROR 0: Unable to INSERT: "Access denied due to active access policy on table <tablename> for column <columnname>
```

Note: Folding a query refers to the act of replacing deterministic expressions involving only constants, with their computed values.

- You cannot create a column access policy on temporary tables.
- It is recommended to not use a column access policy on a flex table. If you create a column access policy on a flex table, the following appears:

```
WARNING 0: Column Access Policies on flex tables may not be completely secure
```

Examples

The following examples show how to create a column access policy for various situations.

Create Access Policy in Public Schema for Column in Customer Table

```
=> CREATE ACCESS POLICY on public.customer FOR COLUMN cid length('xxxxx') enable;
```

Use Expression to Further Specify Data Access and Restrictions

In this example, a user with a *supervisor* role can see data from the `deal_size` column in the `vendor_dimension` table. However, a user assigned an *employee* role cannot.

```
=> CREATE ACCESS POLICY ON vendor_dimension FOR COLUMN deal_size  
CASE  
WHEN ENABLED_ROLE('supervisor') THEN deal_size  
WHEN ENABLED_ROLE('employee') THEN NULL  
END  
ENABLE;
```

Substitute Specific Data for Actual Data in Column

In this example, the value 1000 appears rather than the actual column data:

```
=> CREATE ACCESS POLICY on public.customer FOR COLUMN cid 1000 enable;  
  
=> SELECT * FROM customer;  
cid | dist_code  
-----+-----  
1000 | 2  
1000 | 10  
(2 rows)
```

See Also

- [CREATE ACCESS POLICY](#)
- [ALTER ACCESS POLICY](#)
- [DROP ACCESS POLICY](#)

Enable or Disable Column Access Policy

If you have dbadmin privileges, you can enable and disable an individual access policy in a table, as the following examples show.

Enable Column Access Policy

```
=> ALTER ACCESS POLICY on customer FOR column customer_key enable;
```

Disable Column Access Policy

```
=> ALTER ACCESS POLICY on customer FOR column customer_key disable;
```

Row Access Policy

Use the [CREATE ACCESS POLICY](#) statement to create a row access policy for a specific row in a table. You must use a WHERE clause to set the access policy's condition.

Example

Suppose you have a customers table but want to limit users with the broker role to being able to view only customers to which they are assigned. This example shows how to create a row access policy that allows managers to view everything and brokers to view only their customers.

Run the following SQL statement:

```
=> SELECT * FROM customers_table;
```

The customers_table appears as follows:

custID	password	SSN
1	secret	123456789

```
 2 | secret | 123456780  
 3 | secret | 123456781  
(3 rows)
```

Run the following SQL statement:

```
=> SELECT * FROM broker_info;
```

The `broker_info` table shows that each customer has an assigned broker:

```
broker | custID  
-----+-----  
 user1 |      1  
 user2 |      2  
 user3 |      3  
(3 rows)
```

Create the following access policy that only allows brokers to see customers to which they are associated:

```
=> CREATE ACCESS POLICY on customers_table for rows  
WHERE  
  ENABLED_ROLE('manager')  
  or  
  (ENABLED_ROLE('broker') AND customers_table.custID in (SELECT broker_info.custID FROM broker_info  
  WHERE broker = CURRENT_USER()))  
ENABLE;
```

As `user1`, run the following SQL command:

```
user1=> SELECT * FROM customers_table;
```

The following is returned because `user1` is associated with `custID 1`:

```
custID | password | SSN  
-----+-----+-----  
 1 | secret | 123456789  
(1 rows)
```

Creating Row Access Policies

Creating a row access policy determines what rows a user can access during a query. Row access policies include a `WHERE` clause that prompts the query to return only those rows where the condition is true. For example, a user with a `BROKER` role should only be able to

access customer information for which the user is a broker. You can write a predicate for this situation as follows:

```
WHERE ENABLED_ROLE('broker') AND customers_table.custID in (SELECT broker_info.custID FROM broker_info WHERE broker = CURRENT_USER())
```

You can use a row access policy to enforce this restriction. The following example shows how you can create a row access policy. This policy limits a user with a broker role to access information for customers whose custID in the customers_table matches the custID in the broker_info table.

```
=> CREATE ACCESS POLICY on customers_table  
for rows  
WHERE  
    ENABLED_ROLE('broker')  
    AND  
    customers_table.custID in (SELECT broker_info.custID FROM broker_info WHERE broker = CURRENT_USER  
(  
))  
enable;
```

Row Access Policy Limitations

Be aware of the following limitations when using row access policies:

- You can only have one row access policy per table. If you need to add more later, place the policies in a single `WHERE` predicate and use [ALTER ACCESS POLICY](#) to enable the new condition.
- You cannot use row access policies on:
 - Tables with aggregate projections
 - Temporary tables
 - System tables. If you try to create a row access policy on a system table the following message appears:

```
=> ROLLBACK 0: Access policy cannot be created on system table <system table name>
```

- Views
- When a row access policy exists on a table, you cannot create directed queries on that table.

Examples

The following examples show you can create a row access policy:

Create Access Policy in for specific row in Customer Table

```
=> CREATE ACCESS POLICY on customer FOR ROWS where cust_id > 3 enable;
```

See Also

- [CREATE ACCESS POLICY](#)
- [ALTER ACCESS POLICY](#)
- [DROP ACCESS POLICY](#)

Enable or Disable Row Access Policy

If you have dbadmin privileges, you can enable and disable individual row access policies in a table, as the following examples show:

Enable Row Access Policy

```
=> ALTER ACCESS POLICY on customer FOR rows enable;
```

Disable Row Access Policy

```
=> ALTER ACCESS POLICY on customer FOR rows disable;
```

About Database Roles

To make managing permissions easier, use roles. A role is a collection of privileges that a superuser can grant to (or revoke from) one or more users or other roles. Using roles avoids having to manually grant sets of privileges user by user. For example, several users might be assigned to the administrator role. You can grant or revoke privileges to or from the administrator role, and all users with access to that role are affected by the change.

Note: Users must first enable a role before they gain all of the privileges that have been granted to it. See [Enabling Roles](#).

Role Hierarchies

You can also use roles to build hierarchies of roles; for example, you can create an administrator role that has privileges granted non-administrator roles as well as to the privileges granted directly to the administrator role. See also [Role Hierarchy](#).

Roles do not supersede manually-granted privileges, so privileges directly assigned to a user are not altered by roles. Roles just give additional privileges to the user.

Creating and Using a Role

Using a role follows this general flow:

1. A superuser creates a role using the [CREATE ROLE](#) statement.
2. A superuser or object owner grants privileges to the role using one of the GRANT statements.
3. A superuser or users with administrator access to the role grant users and other roles access to the role.
4. Users granted access to the role use the [SET ROLE](#) command to enable that role and gain the role's privileges.

You can do steps 2 and 3 in any order. However, granting access to a role means little until the role has privileges granted to it.

Tip: You can query the V_CATALOG system tables [ROLES](#), [GRANTS](#), and [USERS](#) to see any directly-assigned roles; however, these tables do not indicate whether a role is available to a user when roles could be available through other roles (indirectly). See the [HAS_ROLE\(\)](#) function for additional information.

Roles on Management Console

When users sign in to the Management Console (MC), what they can view or do is governed by MC roles. For details, see [About MC Users](#) and [About MC Privileges and Roles](#).

Types of Database Roles

Vertica has the following pre-defined roles:

- [PUBLIC](#)
- [PSEUDOSUPERUSER](#)
- [DBADMIN](#)
- [DBDUSER](#)
- [SYSMONITOR](#)

You cannot drop or rename predefined roles, however, you can grant to, or revoke from, predefined roles except to/from PUBLIC. You can also grant predefined roles to other roles and users.

Individual privileges may be granted to/revoked from predefined roles. See the SQL Reference Manual for all of the GRANT and REVOKE statements.

DBADMIN Role

Every database has the special DBADMIN role. A superuser (or someone with the [PSEUDOSUPERUSER Role](#)) can grant this role to or revoke this role from any user or role.

Users who enable the DBADMIN role gain these privileges:

- Create or drop users
- Create or drop schemas
- Create or drop roles
- Grant roles to other users
- View all system tables
- View and terminate user sessions
- Access to all data created by any user

The DBADMIN role does NOT allow users to:

- Start and stop a database
- Set configuration parameters

Note: A user with a DBADMIN role must have the ADMIN OPTION enabled to be able to grant a DBADMIN or PSEUDOSUPERUSER role to another user. . For more information see [GRANT \(Role\)](#).

You cannot assign additional roles to the DBADMIN role:

```
=> CREATE ROLE appviewer;  
CREATE ROLE  
=> GRANT appviewer TO dbadmin;  
ROLLBACK 2347: Cannot alter predefined role "dbadmin"
```

You can, however, grant the DBADMIN role to other roles to augment a set of privileges. See [Role Hierarchy](#) for more information.

View a List of Database Superusers

To see who is a superuser, run the `vsq! \du` command. In this example, only `dbadmin` is a superuser.

```
=> \du  
List of users  
User name | Is Superuser  
-----+-----  
dbadmin   | t  
Fred      | f  
Bob       | f  
Sue       | f  
Alice     | f  
User1     | f  
User2     | f  
User3     | f  
u1        | f  
u2        | f  
(10 rows)
```

See Also

[Database Administration User](#)

DBDUSER Role

The DBDUSER role is predefined, and allows non-DBADMIN users to access Database Designer [functions](#). This role must be explicitly granted by a superuser or DBADMIN user.

Note: Non-DBADMIN users with the DBDUSER role cannot run Database Designer through Administration Tools. Only [DBADMIN](#) users can run Administration Tools.

You cannot assign any additional privileges to the DBDUSER role, but you can grant the DBDUSER role to other roles to augment a set of privileges.

After you are granted the DBDUSER role, you must enable it before you can run Database Designer using command-line functions. For more information, see [About Running Database Designer Programmatically](#).

Important: When you create a DBADMIN user or grant the DBDUSER role, make sure to associate a resource pool with that user to manage resources during Database Designer runs. Multiple users can run Database Designer concurrently without interfering with each other or using up all the cluster resources. When a user runs Database Designer, either using the Administration Tools or programmatically, its execution is mostly contained by the user's resource pool, but may spill over into some system resource pools for less-intensive tasks.

PSEUDOSUPERUSER Role

The special PSEUDOSUPERUSER role is automatically created in each database. A superuser (or someone with the PSEUDOSUPERUSER role) can perform grant and revoke on this role. The PSEUDOSUPERUSER cannot revoke or change any superuser privileges.

Users with the PSEUDOSUPERUSER role are entitled to complete administrative privileges, including the ability to:

- Create schemas
- Create and grant privileges to roles
- Bypass all GRANT/REVOKE authorization
- Set user account's passwords
- Lock and unlock user accounts

- Create or drop a UDF library
- Create or drop a UDF function
- Create or drop an external procedure
- Add or edit comments on nodes
- Create or drop password profiles

You cannot revoke any of these privileges from a PSEUDOSUPERUSER.

You can assign additional privileges to the PSEUDOSUPERUSER role, but you cannot assign any additional roles; for example, the following is not allowed:

```
=> CREATE ROLE appviewer;  
CREATE ROLE  
=> GRANT appviewer TO pseudosuperuser;  
ROLLBACK 2347: Cannot alter predefined role "pseudosuperuser"
```

PUBLIC Role

By default, every database has the special PUBLIC role. Vertica grants this role to each user automatically, and it is automatically enabled. You grant privileges to this role that every user should have by default. You can also grant access to roles to PUBLIC, which allows any user to access the role using the [SET ROLE](#) statement.

Note: The PUBLIC role can never be dropped, nor can it be revoked from users or roles.

Privileges created using the WITH GRANT OPTION cannot be granted to a Public Role:

```
=> CREATE TABLE t1(a int);  
CREATE TABLE  
=> GRANT SELECT on t1 to PUBLIC with grant option;  
ROLLBACK 3484: Grant option for a privilege cannot be granted to  
"public"
```

For more information see [How to Grant Privileges](#).

Example

In the following example, if the superuser hadn't granted INSERT privileges on the table publicdata to the PUBLIC group, the INSERT statement executed by user bob would fail:

```
=> CREATE TABLE publicdata (a INT, b VARCHAR);
CREATE TABLE
=> GRANT INSERT, SELECT ON publicdata TO PUBLIC;
GRANT PRIVILEGE
=> CREATE PROJECTION publicdataproj AS (SELECT * FROM publicdata);
CREATE PROJECTION

dbadmin=> \c - bob
You are now connected as user "bob".

=> INSERT INTO publicdata VALUES (10, 'Hello World');
OUTPUT
-----
      1
(1 row)
```

See Also

[PUBLIC User](#)

SYSMONITOR Role

An organization's database administrator may have many responsibilities outside of maintaining Vertica as a DBADMIN user. In this case, as the DBADMIN you may want to delegate some Vertica administrative tasks to another Vertica user.

The DBADMIN can assign a delegate the SYSMONITOR role to grant access to system tables without granting full [DBADMIN](#) access.

The SYSMONITOR role provides the following privileges.

- View all system tables that are marked as monitorable. You can see a list of all the monitorable tables by issuing the statement:

```
=> select * from system_tables where is_monitorable='t';
```

- If `WITH ADMIN OPTION` was included when granting SYSMONITOR to the user or role, that user or role can then grant SYSMONITOR privileges to other users and roles.

Grant a SYSMONITOR Role

To grant a user or role the SYSMONITOR role, you must be one of the following:

- a DBADMIN user
- a user assigned the SYSMONITOR who has the ADMIN OPTION

Use the [GRANT \(Role\)](#) SQL statement to assign a user the SYSMONITOR role. This example shows how to grant the SYSMONITOR role to user1 and includes administration privileges by using the WITH ADMIN OPTION parameter. The ADMIN OPTION grants the SYSMONITOR role administrative privileges.

```
=> GRANT SYSMONITOR TO user1 WITH ADMIN OPTION;
```

This example shows how to revoke the ADMIN OPTION from the SYSMONITOR role for user1:

```
=> REVOKE ADMIN OPTION for SYSMONITOR FROM user1;
```

Use CASCADE to revoke ADMIN OPTION privileges for all users assigned the SYSMONITOR role:

```
=> REVOKE ADMIN OPTION for SYSMONITOR FROM PUBLIC CASCADE;
```

Example

This example shows how to:

- Create a user
- Create a role
- Grant SYSMONITOR privileges to the new role
- Grant the role to the user

```
=> CREATE USER user1;  
=> CREATE ROLE monitor;  
=> GRANT SYSMONITOR to monitor;  
=> GRANT monitor to user1;
```

Assign SYSMONITOR Privileges

This example uses the user and role created in the Grant SYSMONITOR Role example and shows how to:

- Create a table called `personal_data`
- Log in as `user1`
- Grant `user1` the monitor role. (You already granted the monitor `SYSMONITOR` privileges in the Grant a `SYSMONITOR` Role example.)
- Run a `SELECT` statement as `user1`

The results of the operations are based on the privilege already granted to `user1`.

```
=> CREATE TABLE personal_data (SSN varchar (256));
=> \c -user1;
user1=> SET ROLE monitor;
user1=> SELECT COUNT(*) FROM TABLES;
COUNT
-----
1
(1 row)
```

Because you assigned the `SYSMONITOR` role, `user1` can see the number of rows in the `Tables` system table. In this simple example, there is only one table (`personal_data`) in the database so the `SELECT COUNT` returns one row. In actual conditions, the `SYSMONITOR` role would see all the tables in the database.

Check if a Table is Accessible by `SYSMONITOR`

Use the following command to check if a system table can be accessed by a user assigned the `SYSMONITOR` role:

```
=> select table_name, is_monitorable from system_tables where table_
name='<table_name>';
```

Example

This example checks whether the `current_session` system table is accessible by the `SYSMONITOR`:

```
=> select table_name, is_monitorable from system_tables where table_
name='current_session';
table_name      | is_monitorable
-----
current_session | t
```

The `t` in the `is_monitorable` column indicates the `current_session` system table is accessible by the `SYSMONITOR`.

Default Roles for Database Users

By default, no roles (other than the default [PUBLIC Role](#)) are enabled at the start of a user session.

```
=> SHOW ENABLED_ROLES;
  name      | setting
-----+-----
enabled roles |
(1 row)
```

A superuser can set one or more default roles for a user, which are automatically enabled at the start of the user's session. Setting a default role is a good idea if users normally rely on the privileges granted by one or more roles to carry out the majority of their tasks. To set a default role, use the `DEFAULT ROLE` parameter of the [ALTER USER](#) statement as superuser:

```
=> \c vmart apps
You are now connected to database "apps" as user "dbadmin".
=> ALTER USER Bob DEFAULT ROLE logadmin;
ALTER USER
=> \c - Bob;
You are now connected as user "Bob"
=> SHOW ENABLED_ROLES;
  name      | setting
-----+-----
enabled roles | logadmin
(1 row)
```

Notes

- Only roles that the user already has access to can be made default.
- Unlike granting a role, setting a default role or roles overwrites any previously-set defaults.
- To clear any default roles for a user, use the keyword `NONE` as the role name in the `DEFAULT ROLE` argument.
- Default roles only take effect at the start of a user session. They do not affect the roles enabled in the user's current session.
- Avoid giving users default roles that have administrative or destructive privileges (the [PSEUDOSUPERUSER](#) role or `DROP` privileges, for example). By forcing users to explicitly enable these privileges, you can help prevent accidental data loss.

Using Database Roles

There are several steps to using roles:

1. A superuser creates a role using the [CREATE ROLE](#) statement.
2. A superuser or object owner grants privileges to the role.
3. A superuser or users with administrator access to the role grant users and other roles access to the role.
4. Users granted access to the role run the [SET ROLE](#) command to make that role active and gain the role's privileges.

You can do steps 2 and 3 in any order. However, granting access to a role means little until the role has privileges granted to it.

Tip: Query system tables [ROLES](#), [GRANTS](#), and [USERS](#) to see any directly-assigned roles. Because these tables do not indicate whether a role is available to a user when roles could be available through other roles (indirectly), see the [HAS_ROLE\(\)](#) function for additional information.

See Also

- [About MC Privileges and Roles](#)

Role Hierarchy

In addition to granting roles to users, you can also grant roles to other roles. This lets you build hierarchies of roles, with more privileged roles (an administrator, for example) being assigned all of the privileges of lesser-privileged roles (a user of a particular application), in addition to the privileges you assign to it directly. By organizing your roles this way, any privilege you add to the application role (reading or writing to a new table, for example) is automatically made available to the more-privileged administrator role.

Example

The following example creates two roles, assigns them privileges, then assigns them to a new administrative role.

1. Create new table applog:

```
=> CREATE TABLE applog (id int, sourceID VARCHAR(32), data TIMESTAMP, event VARCHAR(256));
```

2. Create a new role called logreader:

```
=> CREATE ROLE logreader;
```

3. Grant the logreader role read-only access on the applog table:

```
=> GRANT SELECT ON applog TO logreader;
```

4. Create a new role called logwriter:

```
=> CREATE ROLE logwriter;
```

5. Grant the logwriter write access on the applog table:

```
=> GRANT INSERT ON applog to logwriter;
```

6. Create a new role called logadmin, which will rule the other two roles:

```
=> CREATE ROLE logadmin;
```

7. Grant the logadmin role privileges to delete data:

```
=> GRANT DELETE ON applog to logadmin;
```

8. Grant the logadmin role privileges to have the same privileges as the logreader and logwriter roles:

```
=> GRANT logreader, logwriter TO logadmin;
```

9. Create new user Bob:

```
=> CREATE USER Bob;
```

10. Give Bob logadmin privileges:

```
=> GRANT logadmin TO Bob;
```

The user Bob can now enable the logadmin role, which also includes the logreader and logwriter roles. Note that Bob cannot enable either the logreader or logwriter role directly. A user can only enable explicitly-granted roles.

Hierarchical roles also works with administrative access to a role:

```
=> GRANT logreader, logwriter TO logadmin WITH ADMIN OPTION;  
GRANT ROLE  
=> GRANT logadmin TO Bob;  
=> \c - bob; -- connect as Bob  
You are now connected as user "Bob".  
=> SET ROLE logadmin; -- Enable logadmin role  
SET  
=> GRANT logreader TO Alice;  
GRANT ROLE
```

Note that the user Bob only has administrative access to the logreader and logwriter roles through the logadmin role. He doesn't have administrative access to the logadmin role, since it wasn't granted to him with the optional WITH ADMIN OPTION argument:

```
=> GRANT logadmin TO Alice;  
WARNING: Some roles were not granted  
GRANT ROLE
```

For Bob to be able to grant the logadmin role, a superuser would have had to explicitly grant him administrative access.

See Also

- [About MC Privileges and Roles](#)

Creating Database Roles

A superuser creates a new role using the [CREATE ROLE](#) statement. Only a superuser can create or drop roles.

```
=> CREATE ROLE administrator;  
CREATE ROLE
```

The newly-created role has no privileges assigned to it, and no users or other roles are initially granted access to it. A superuser must [grant privileges](#) and [access](#) to the role.

Deleting Database Roles

A superuser can delete a role with the [DROP ROLE](#) statement.

Note that if any user or other role has been assigned the role you are trying to delete, the `DROP ROLE` statement fails with a dependency message.

```
=> DROP ROLE administrator;
NOTICE:  User Bob depends on Role administrator
ROLLBACK:  DROP ROLE failed due to dependencies
DETAIL:   Cannot drop Role administrator because other objects depend on it
HINT:     Use DROP ROLE ... CASCADE to remove granted roles from the dependent users/roles
```

Supply the optional `CASCADE` parameter to drop the role and its dependencies.

```
=> DROP ROLE administrator CASCADE;
DROP ROLE
```

Granting Privileges to Roles

A superuser or owner of a schema, table, or other database object can assign privileges to a role, just as they would assign privileges to an individual user by using the `GRANT` statements described in the [SQL Reference Manual](#). See [About Database Privileges](#) for information about which privileges can be granted.

Granting a privilege to a role immediately affects active user sessions. When you grant a new privilege, it becomes immediately available to every user with the role active.

Example

The following example creates two roles and assigns them different privileges on a single table called `applog`.

1. Create a table called `applog`:

```
=> CREATE TABLE applog (id int, sourceID VARCHAR(32), data TIMESTAMP, event VARCHAR(256));
```

2. Create a new role called `logreader`:

```
=> CREATE ROLE logreader;
```

3. Assign read-only privileges to the logreader role on table applog:

```
=> GRANT SELECT ON applog TO logreader;
```

4. Create a role called logwriter:

```
=> CREATE ROLE logwriter;
```

5. Assign write privileges to the logwriter role on table applog:

```
=> GRANT INSERT ON applog TO logwriter;
```

See the [SQL Reference Manual](#) for the different GRANT statements.

Revoking Privileges From Roles

Use one of the REVOKE statements to revoke a privilege from a role.

```
=> REVOKE INSERT ON applog FROM logwriter;  
REVOKE PRIVILEGE
```

Revoking a privilege immediately affects any user sessions that have the role active. When you revoke a privilege, it is immediately removed from users that rely on the role for the privilege.

See the [SQL Reference Manual](#) for the different REVOKE statements.

Granting Access to Database Roles

A pseudosuperuser or dbadmin user can assign any role to a user or to another role using the GRANT command. The simplest form of this command is:

```
GRANT role [, ...] TO { user | role } [, ...]
```

Vertica returns a NOTICE if you grant a role to a user who has already been granted that role. For example:

```
=> GRANT commenter to Bob;  
NOTICE 4622: Role "commenter" was already granted to user "Bob"
```

See [GRANT \(Role\)](#) in the SQL Reference Manual for details.

Example

The following example shows how to create a role called `commenter` and grant that role to user Bob:

1. Create a table called `comments`.

```
=> CREATE TABLE comments (id INT, comment VARCHAR);
```

2. Create a role called `commenter`.

```
=> CREATE ROLE commenter;
```

3. Grant privileges to the `commenter` role on the `comments` table.

```
=> GRANT INSERT, SELECT ON comments TO commenter;
```

4. Grant the `commenter` role to user Bob.

```
=> GRANT commenter TO Bob;
```

Before being able to access the role and its associated privileges, Bob must enable the newly-granted role to himself.

1. Connect to the database as user Bob.

```
=> \c - Bob
```

2. Enable the role.

```
=> SET ROLE commenter;
```

3. Insert some values into the `comments` table.

```
=> INSERT INTO comments VALUES (1, 'Hello World');
```

Based on the privileges granted to Bob by the `commenter` role, Bob can insert and query the `comments` table.

4. Query the `comments` table.

```
=> SELECT * FROM comments;
 id | comment
-----+-----
  1 | Hello World
(1 row)
```

5. Commit the transaction.

```
=> COMMIT;
```

Note that Bob does not have proper permissions to drop the table.

```
=> DROP TABLE comments;ROLLBACK 4000: Must be owner of relation comments
```

See Also

- [Granting Database Access to MC Users](#)

Revoking Access From Database Roles

A superuser can revoke any role from a user or from another role using the REVOKE command. The simplest form of this command is:

```
REVOKE role [, ...] FROM { user | role | PUBLIC } [, ...]
```

See [REVOKE \(Role\)](#) in the SQL Reference Manual for details.

Example

To revoke access from a role, use the REVOKE (Role) statement:

1. Connect to the database as a superuser:

```
\c - dbadmin
```

2. Revoke the commenter role from user Bob:

```
=> REVOKE commenter FROM bob;
```

Granting Administrative Access to a Role

A superuser can assign a user or role administrative access to a role by supplying the optional `WITH ADMIN OPTION` argument to the `GRANT` statement. Administrative access allows the user to grant and revoke access to the role for other users (including granting them administrative access). Giving users the ability to grant roles lets a superuser delegate role administration to other users.

Example

The following example demonstrates granting the user bob administrative access to the commenter role, then connecting as bob and granting a role to another user.

1. Connect to the database as a superuser (or a user with administrative access):

```
=> \c - dbadmin
```

2. Grant administrative options on the commenter role to Bob

```
=> GRANT commenter TO Bob WITH ADMIN OPTION;
```

3. Connect to the database as user Bob

```
=> \c - Bob
```

4. As user Bob, grant the commenter role to Alice:

```
=> GRANT commenter TO Alice;
```

Users with administrative access to a role can also grant other users administrative access:

```
=> GRANT commenter TO alice WITH ADMIN OPTION;  
GRANT ROLE
```

As with all user privilege models, database superusers should be cautious when granting any user a role with administrative privileges. For example, if the database superuser grants two users a role with administrative privileges, both users can revoke the role of the other user. This example shows granting the `appadmin` role (with administrative privileges) to users `bob` and `alice`. After each user has been granted the `appadmin` role, either user can connect as the other will full privileges.

```
=> GRANT appadmin TO bob, alice WITH ADMIN OPTION;  
GRANT ROLE  
=> \connect - bob  
You are now connected as user "bob".  
=> REVOKE appadmin FROM alice;  
REVOKE ROLE
```

Revoking Administrative Access From a Role

A superuser can revoke administrative access from a role using the `ADMIN OPTION` parameter with the `REVOKE` statement. Giving users the ability to revoke roles lets a superuser delegate role administration to other users.

Example

The following example demonstrates revoking administrative access from Alice for the commenter role.

1. Connect to the database as a superuser (or a user with administrative access)

```
\c - dbadmin
```

2. Issue the `REVOKE` command with `ADMIN OPTION` parameters:

```
=> REVOKE ADMIN OPTION FOR commenter FROM alice;
```

Enabling Roles

By default, roles aren't enabled automatically for a user account. (See [Default Roles for Database Users](#) for a way to make roles enabled automatically.) Users must explicitly enable a role using the `SET ROLE` statement. When users enable a role in their session, they gain all of the privileges assigned to that role. Enabling a role does not affect any other roles that the users have active in their sessions. They can have multiple roles enabled simultaneously, gaining the combined privileges of all the roles they have enabled, plus any of the privileges that have been granted to them directly.

```
=> SELECT * FROM applog;  
ERROR: permission denied for relation applog  
  
=> SET ROLE logreader;
```

```
SET
```

```
=> SELECT * FROM applog;
```

id	sourceID	data	event
1	Loader	2011-03-31 11:00:38.494226	Error: Failed to open source file
2	Reporter	2011-03-31 11:00:38.494226	Warning: Low disk space on volume /scratch-a

(2 rows)

You can enable all of the roles available to your user account using the **SET ROLE ALL** statement.

```
=> SET ROLE ALL;SET  
=> SHOW ENABLED_ROLES;
```

name	setting
enabled roles	logreader, logwriter

(1 row)

See Also

- [Viewing a User's Role](#)

Disabling Roles

To disable all roles, use the **SET ROLE NONE** statement:

```
=> SET ROLE NONE;  
=> SHOW ENABLED_ROLES;  
name | setting  
-----+-----  
enabled roles |  
(1 row)
```

Viewing Enabled and Available Roles

You can list the roles you have enabled in your session using the **SHOW ENABLED ROLES** statement:

```
=> SHOW ENABLED_ROLES;  
name | setting  
-----+-----
```

```
enabled roles | logreader  
(1 row)
```

You can find the roles available to your account using the `SHOW AVAILABLE ROLES` statement:

```
Bob=> SHOW AVAILABLE_ROLES;  
      name      |      setting  
-----+-----  
available roles | logreader, logwriter  
(1 row)
```

Viewing Named Roles

To view the names of all roles users can access, along with any roles that have been assigned to those roles, query the [V_CATALOG.ROLES](#) system table.

```
=> SELECT * FROM roles;  
      role_id      |      name      |      assigned_roles  
-----+-----+-----  
45035996273704964 | public        |  
45035996273704966 | dbduser       |  
45035996273704968 | dbadmin       | dbduser*  
45035996273704972 | pseudosuperuser | dbadmin*  
45035996273704974 | logreader     |  
45035996273704976 | logwriter     |  
45035996273704978 | logadmin      | logreader, logwriter  
(7 rows)
```

Note: An asterisk (*) in the output means that role was granted WITH ADMIN OPTION.

Viewing a User's Role

The [HAS_ROLE\(\)](#) function lets you see if a role has been granted to a user.

Non-superusers can check their own role membership using `HAS_ROLE('role_name')`, but only a superuser can look up other users' memberships using the `user_name` parameter. Omitting the `user_name` parameter will return role results for the superuser who is calling the function.

How to View a User's Role

In this example, user Bob wants to see if he's been assigned the logwriter command. The output returns Boolean value `t` for true, denoting that Bob is assigned the specified logwriter role:

```
Bob=> SELECT HAS_ROLE('logwriter');
HAS_ROLE
-----
t
(1 row)
```

In this example, a superuser wants to verify that the logadmin role has been granted to user Ted:

```
dbadmin=> SELECT HAS_ROLE('Ted', 'logadmin');
```

The output returns boolean value *t* for true, denoting that Ted is assigned the specified logadmin role:

```
HAS_ROLE
-----
t
(1 row)
```

Note that if a superuser omits the `user_name` argument, the function looks up that superuser's role. The following output indicates that this superuser is not assigned the logadmin role:

```
dbadmin=> SELECT HAS_ROLE('logadmin');
HAS_ROLE
-----
f
(1 row)
```

Output of the function call with user Alice indicates that she is not granted the logadmin role:

```
dbadmin=> SELECT HAS_ROLE('Alice', 'logadmin');
HAS_ROLE
-----
f
(1 row)
```

To view additional information about users, roles and grants, you can also query the following system tables in the `V_CATALOG` schema to show directly-assigned roles:

- [ROLES](#)
- [GRANTS](#)
- [USERS](#)

Note that the system tables do not indicate whether a role is available to a user when roles could be available through other roles (indirectly). You need to call the `HAS_ROLE()` function for that information.

Users

This command returns all columns from the USERS system table:

```
=> SELECT * FROM users;
-[ RECORD 1 ]
-----+-----
user_id      | 45035996273704962
user_name    | dbadmin
is_super_user | t
profile_name | default
is_locked    | f
lock_time    |
resource_pool | general
memory_cap_kb | unlimited
temp_space_cap_kb | unlimited
run_time_cap | unlimited
all_roles    | dbadmin*, pseudosuperuser*default_roles
              | dbadmin*, pseudosuperuser*
```

Note: An asterisk (*) in table output for all_roles and default_roles columns indicates a role granted WITH ADMIN OPTION.

Roles

The following command returns all columns from the ROLES system table:

```
=> SELECT * FROM roles;
  role id      | name      | assigned_roles
-----+-----+-----
45035996273704964 | public   |
45035996273704964 | dbduser  |
45035996273704964 | dbadmin  | dbduser*
45035996273704964 | pseudosuperuser | dbadmin*
```

Grants

The following command returns all columns from the GRANTS system table:

```
=> SELECT * FROM grants;
 grantor | privileges_description | object_schema | object_name | grantee
-----+-----+-----+-----+-----
dbadmin | USAGE                  |                | public      | public
dbadmin | USAGE                  |                | v_internal  | public
dbadmin | USAGE                  |                | v_catalog   | public
dbadmin | USAGE                  |                | v_monitor   | public
(4 rows)
```

Viewing User Roles on Management Console

You can see an MC user's roles and database resources through the **MC Settings > User management** page on the Management Console interface. For more information, see [About MC Privileges and Roles](#).

Using the Administration Tools

The Vertica Administration tools allow you to easily perform administrative tasks. You can perform most Vertica database administration tasks with Administration Tools.

Run Administration Tools using the Database Administrator account on the Administration host, if possible. Make sure that no other Administration Tools processes are running.

If the Administration host is unresponsive, run Administration Tools on a different node in the cluster. That node permanently takes over the role of Administration host.

Any user can view the man page available for admintools. Enter the following:

```
man admintools
```

Running Administration Tools

As dbadmin user, you can run administration tools. The syntax follows:

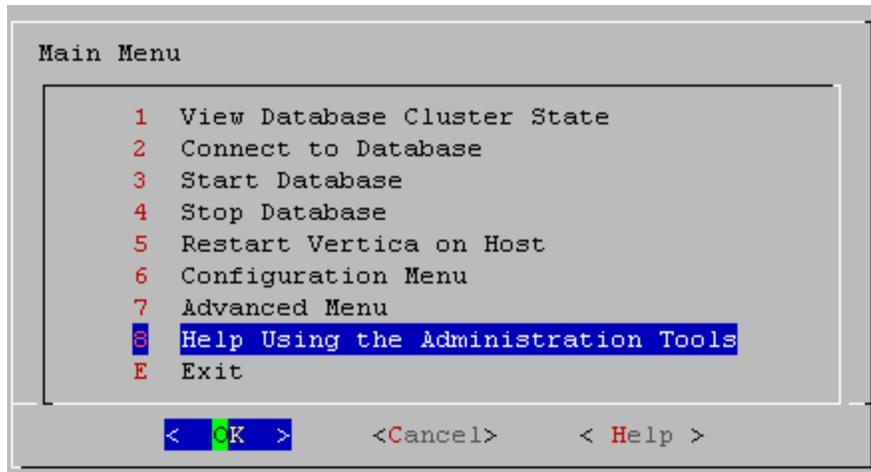

```
/opt/vertica/bin/admintools [--debug ][  
  { -h | --help }  
  | { -a | --help_all }  
  | { -t | --tool } name_of_tool [ options ]  
]
```

Options

<code>--debug</code>	If you include the debug option, Vertica logs debug information. Note: You can specify the debug option with or without naming a specific tool. If you specify debug with a specific tool, Vertica logs debug information during tool execution. If you do not specify a tool, Vertica logs debug information when you run tools through the admintools user interface.
<code>-h</code> <code>--help</code>	Outputs abbreviated help.
<code>-a</code> <code>--help_all</code>	Outputs verbose help, which lists all command-line sub-commands and options.
<code>{ -t --tool } <i>name_of_tool</i></code>	Specifies the tool to run, where <i>name_of_tool</i> is one of the tools described in the help output, and <i>options</i> are one or more

[options]	comma-delimited tool arguments. Note: Enter <code>admintools -h</code> to see the list of tools available. Enter <code>admintools -t name_of_tool --help</code> to review a specific tool's options.
-----------	--

An unqualified `admintools` command displays the Main Menu dialog box.

If you are unfamiliar with this type of interface, read [Using the Administration Tools Interface](#)

First Login as Database Administrator

The first time you log in as the Database Administrator and run the Administration Tools, the user interface displays.

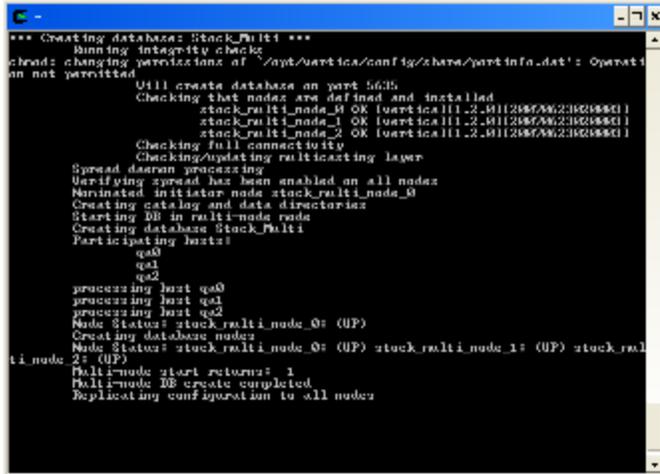

1. In the end-user license agreement (EULA) window, type `accept` to proceed.

A window displays, requesting the location of the license key file you downloaded from the Micro Focus Web site. The default path is `/tmp/vlicense.dat`.

2. Type the absolute path to your license key (for example, `/tmp/vlicense.dat`) and click **OK**.

Between Dialogs

While the Administration Tools are working, you see the command line processing in a window similar to the one shown below. Do not interrupt the processing.

```
*** Creating database: Stock_Multi ***
Running integrity check
Thread: changing permissions of /opt/vertica/config/share/partinfo.dat: Operation not permitted.
Will create database on port 5438.
Checking that nodes are defined and installed
stock_multi_node_0 OK [vertica11.2.011288736238288801]
stock_multi_node_1 OK [vertica11.2.011288736238288801]
stock_multi_node_2 OK [vertica11.2.011288736238288801]
Checking full connectivity
Checking/updating replicating layer
Spread daemon processing
Verifying spread has been enabled on all nodes
Nominated initiator node stock_multi_node_0
Creating catalog and data directories
Starting DB in multi-node mode
Creating database Stock_Multi
Participating hosts:
  qe0
  qe1
  qe2
processing host qe0
processing host qe1
processing host qe2
Node Status: stock_multi_node_0: (UP)
Creating database nodes
Node Status: stock_multi_node_0: (UP) stock_multi_node_1: (UP) stock_multi_node_2: (UP)
Multi-node start returns: 1
Multi-node DB create completed
Replicating configuration to all nodes
```

Using the Administration Tools Interface

The Vertica Administration Tools are implemented using Dialog, a graphical user interface that works in terminal (character-cell) windows. The interface responds to mouse clicks in some terminal windows, particularly local Linux windows, but you might find that it responds only to keystrokes. Thus, this section describes how to use the Administration Tools using only keystrokes.

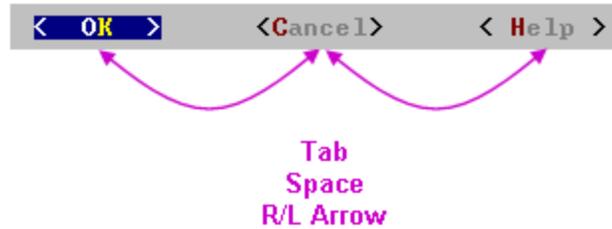

Note: This section does not describe every possible combination of keystrokes you can use to accomplish a particular task. Feel free to experiment and to use whatever keystrokes you prefer.

Enter [Return]

In all dialogs, when you are ready to run a command, select a file, or cancel the dialog, press the **Enter** key. The command descriptions in this section do not explicitly instruct you to press Enter.

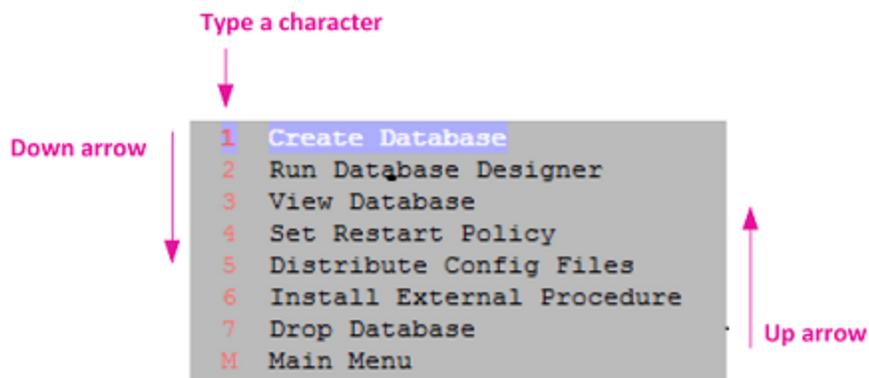

OK - Cancel - Help

The OK, Cancel, and Help buttons are present on virtually all dialogs. Use the tab, space bar, or right and left arrow keys to select an option and then press Enter. The same keystrokes apply to dialogs that present a choice of Yes or No.

Menu Dialogs

Some dialogs require that you choose one command from a menu. Type the alphanumeric character shown or use the up and down arrow keys to select a command and then press Enter.

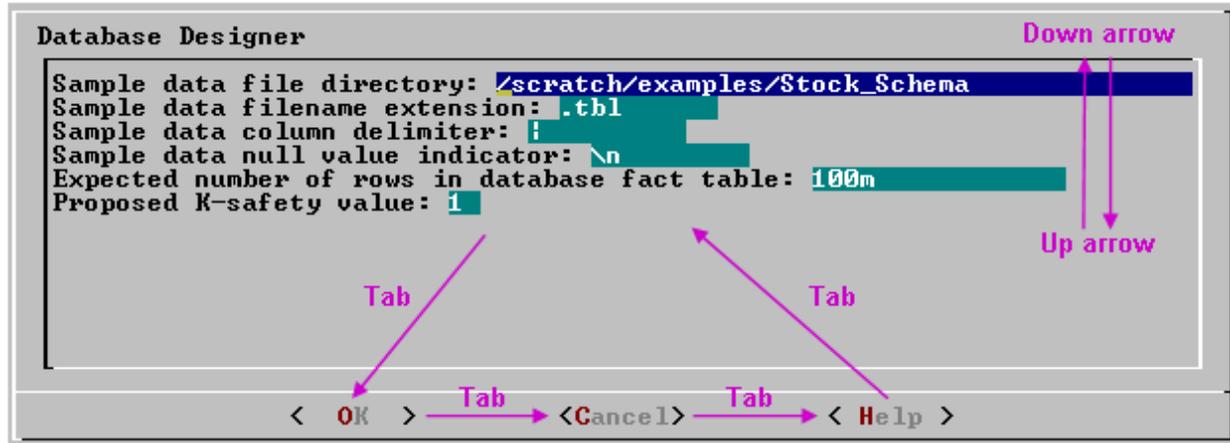

List Dialogs

In a list dialog, use the up and down arrow keys to highlight items, then use the space bar to select the items (which marks them with an X). Some list dialogs allow you to select multiple items. When you have finished selecting items, press Enter.

Form Dialogs

In a form dialog (also referred to as a dialog box), use the tab key to cycle between **OK**, **Cancel**, **Help**, and the form field area. Once the cursor is in the form field area, use the up and down arrow keys to select an individual field (highlighted) and enter information. When you have finished entering information in all fields, press Enter.

Help Buttons

Online help is provided in the form of text dialogs. If you have trouble viewing the help, see [Notes for Remote Terminal Users](#).

K-Safety Support in Administration Tools

The Administration Tools allow certain operations on a K-Safe database, even if some nodes are unresponsive.

The database must have been marked as K-Safe using the [MARK_DESIGN_KSAFE](#) function.

The following management functions within the Administration Tools are operational when some nodes are unresponsive.

Note: Vertica users can perform much of the below functionality using the Management Console interface. See [Management Console and Administration Tools](#) for details.

- View database cluster state
- Connect to database
- Start database (including manual recovery)
- Stop database
- Replace node (assuming node that is down is the one being replaced)
- View database parameters
- Upgrade license key

The following operations work with unresponsive nodes; however, you might have to repeat the operation on the failed nodes after they are back in operation:

- Distribute config files
- Install external procedure
- (Setting) database parameters

The following management functions within the Administration Tools require that all nodes be UP in order to be operational:

- Create database
- Run the Database Designer
- Drop database
- Set restart policy
- Roll back database to Last Good Epoch

Notes for Remote Terminal Users

The appearance of the graphical interface depends on the color and font settings used by your terminal window. The screen captures in this document were made using the default color and font settings in a PuTTY terminal application running on a Windows platform.

Note: If you are using a remote terminal application, such as PuTTY or a Cygwin bash shell, make sure your window is at least 81 characters wide and 23 characters high.

If you are using PuTTY, you can make the Administration Tools look like the screen captures in this document:

1. In a PuTTY window, right click the title area and select Change Settings.
2. Create or load a saved session.
3. In the Category dialog, click Window > Appearance.
4. In the Font settings, click the Change... button.
5. Select Font: Courier New: Regular Size: 10
6. Click Apply.

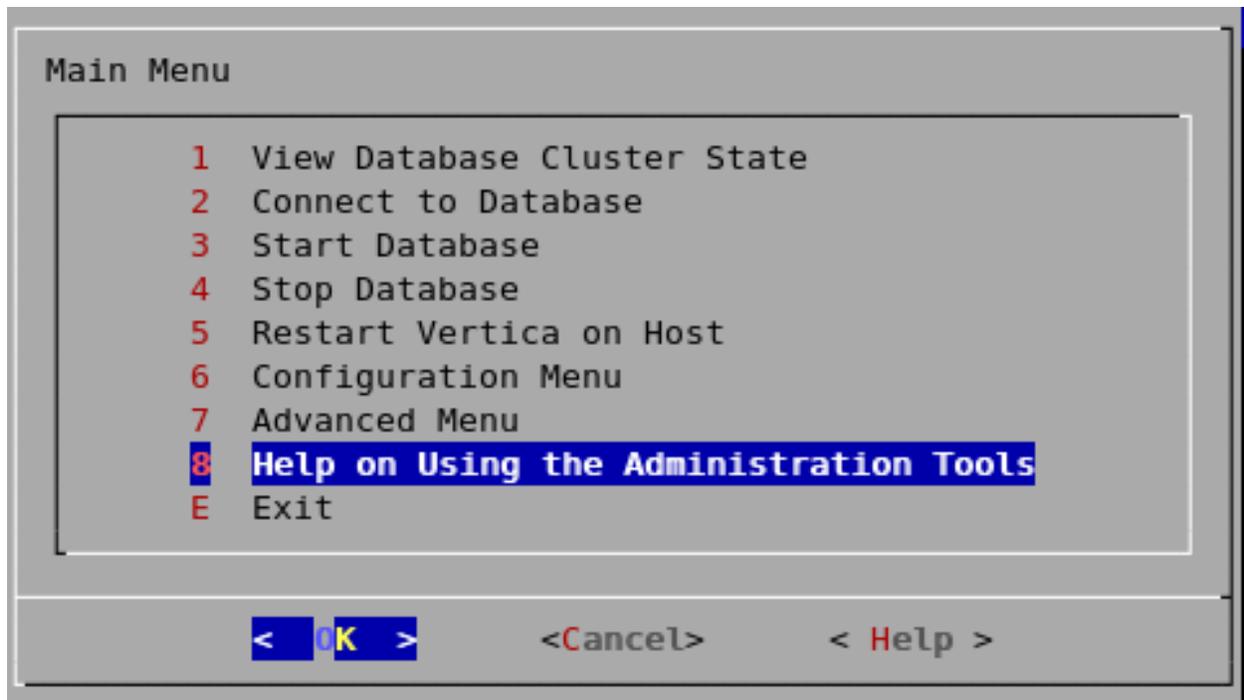

Repeat these steps for each existing session that you use to run the Administration Tools.

You can also change the translation to support UTF-8:

1. In a PuTTY window, right click the title area and select Change Settings.
2. Create or load a saved session.
3. In the Category dialog, click Window > Translation.
4. In the "Received data assumed to be in which character set" drop-down menu, select UTF-8.
5. Click Apply.

Using Administration Tools Help

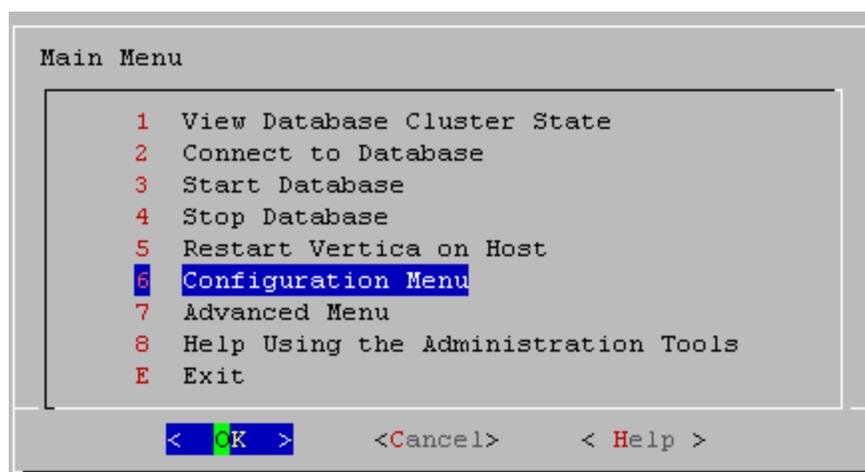

The **Help on Using the Administration Tools** command displays a help screen about using the Administration Tools.

Most of the online help in the Administration Tools is context-sensitive. For example, if you use up/down arrows to select a command, press tab to move to the Help button, and press return, you get help on the selected command.

In a Menu Dialog

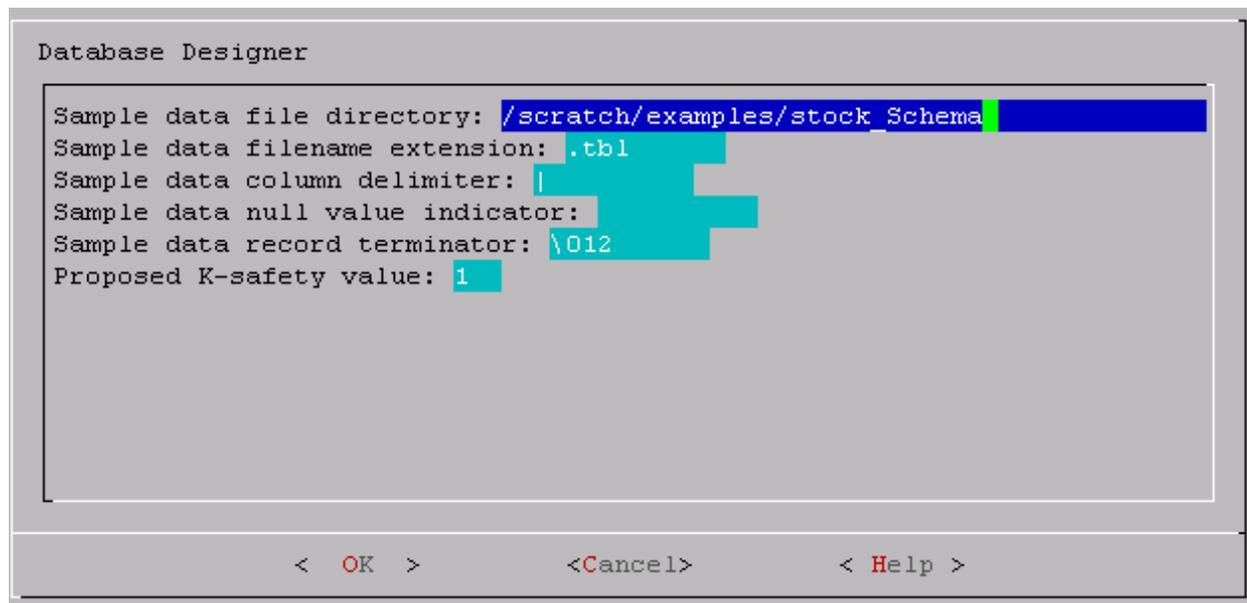

1. Use the up and down arrow keys to choose the command for which you want help.

2. Use the Tab key to move the cursor to the Help button.
3. Press Enter (Return).

In a Dialog Box

1. Use the up and down arrow keys to choose the field on which you want help.

2. Use the Tab key to move the cursor to the Help button.
3. Press Enter (Return).

Scrolling

Some help files are too long for a single screen. Use the up and down arrow keys to scroll through the text.

Password Authentication

When you create a new user with the [CREATE USER](#) command, you can configure the password or leave it empty. You cannot bypass the password if the user was created with a password configured. You can change a user's password using the [ALTER USER](#) command.

See [Security and Authentication](#) for more information about controlling database authorization through passwords.

Tip: Unless the database is used solely for evaluation purposes, Micro Focus recommends that all database users have encrypted passwords.

Distributing Changes Made to the Administration Tools Metadata

Administration Tools-specific metadata for a failed node will fall out of synchronization with other cluster nodes if you make the following changes:

- Modify the restart policy
- Add one or more nodes
- Drop one or more nodes.

When you restore the node to the database cluster, you can use the Administration Tools to update the node with the latest Administration Tools metadata:

1. Log on to a host that contains the metadata you want to transfer and start the Administration Tools. (See [Using the Administration Tools](#).)
2. On the **Main Menu** in the Administration Tools, select **Configuration Menu** and click **OK**.
3. On the **Configuration Menu**, select **Distribute Config Files** and click **OK**.
4. Select **AdminTools Meta-Data**.

The Administration Tools metadata is distributed to every host in the cluster.

5. [Restart the database](#).

Administration Tools and Management Console

You can perform most database administration tasks using the Administration Tools, but you have the additional option of using the more visual and dynamic Management Console.

The following table compares the functionality available in both interfaces. Continue to use Administration Tools and the command line to perform actions not yet supported by Management Console.

Vertica Functionality	Management Console	Administration Tools
Use a Web interface for the administration of Vertica	Yes	No
Manage/monitor one or more databases and clusters through a UI	Yes	No
Manage multiple databases on different clusters	Yes	Yes
View database cluster state	Yes	Yes
View multiple cluster states	Yes	No
Connect to the database	Yes	Yes
Start/stop an existing database	Yes	Yes
Stop/restart Vertica on host	Yes	Yes
Kill an Vertica process on host	No	Yes
Create one or more databases	Yes	Yes
View databases	Yes	Yes
Remove a database from view	Yes	No
Drop a database	Yes	Yes
Create a physical schema design (Database Designer)	Yes	Yes
Modify a physical schema design (Database Designer)	Yes	Yes
Set the restart policy	No	Yes
Roll back database to the Last Good Epoch	No	Yes
Manage clusters (add, replace, remove hosts)	Yes	Yes
Rebalance data across nodes in the database	Yes	Yes

Vertica Functionality	Management Console	Administration Tools
Configure database parameters dynamically	Yes	No
View database activity in relation to physical resource usage	Yes	No
View alerts and messages dynamically	Yes	No
View current database size usage statistics	Yes	No
View database size usage statistics over time	Yes	No
Upload/upgrade a license file	Yes	Yes
Warn users about license violation on login	Yes	Yes
Create, edit, manage, and delete users/user information	Yes	No
Use LDAP to authenticate users with company credentials	Yes	Yes
Manage user access to MC through roles	Yes	No
Map Management Console users to an Vertica database	Yes	No
Enable and disable user access to MC and/or the database	Yes	No
Audit user activity on database	Yes	No
Hide features unavailable to a user through roles	Yes	No
Generate new user (non-LDAP) passwords	Yes	No

Management Console Provides some, but Not All of the Functionality Provided By the Administration Tools. MC Also Provides Functionality Not Available in the Administration Tools.

- [Monitoring Vertica Using Management Console](#)

Administration Tools Reference

With Vertica Administration Tools, you can perform the following tasks:

- [View the database cluster state](#)
- [Connect to the database](#)
- [Start the database](#)
- [Stop the database](#)
- [Write scripts](#)

Viewing Database Cluster State

This tool shows the current state of the nodes in the database.

1. On the Main Menu, select **View Database Cluster State**, and click **OK**.
The normal state of a running database is ALL UP. The normal state of a stopped database is ALL DOWN.

DB	Host	State
Clickstream_Schema	ALL	DOWN
CreditHistory_Schema	ALL	DOWN
Retail_Schema	ALL	DOWN
Stock_Schema	ALL	UP
Telecom_Schema	ALL	DOWN

2. If some hosts are UP and some DOWN, restart the specific host that is down using **Restart Vertica on Host** from the Administration Tools, or you can start the database as described in [Starting and Stopping the Database](#) (unless you have a known node failure and want to continue in that state.)

DB	Host	State
Clickstream_Schema	ALL	DOWN
CreditHistory_Schema	ALL	DOWN
Retail_Schema	ALL	DOWN
Stock_Schema	host01	UP
Stock_Schema	host02	UP
Stock_Schema	host03	DOWN
Stock_Schema	host04	UP
Telecom_Schema	ALL	DOWN

Nodes shown as INITIALIZING or RECOVERING indicate that [Failure Recovery](#) is in progress.

Nodes in other states (such as `NEEDS_CATCHUP`) are transitional and can be ignored unless they persist.

See Also

- [Advanced Menu Options](#)

Connecting to the Database

This tool connects to a running database with `vsq`. You can use the Administration Tools to connect to a database from any node within the database while logged in to any user account with access privileges. You cannot use the Administration Tools to connect from a host that is not a database node. To connect from other hosts, run `vsq` as described in [Connecting from the Command Line](#).

1. On the Main Menu, click **Connect to Database**, and then click **OK**.
2. Supply the database password if asked:

```
Password:
```

When you create a new user with the [CREATE USER](#) command, you can configure the password or leave it empty. You cannot bypass the password if the user was created with a password configured. You can change a user's password using the [ALTER USER](#) command.

The Administration Tools connect to the database and transfer control to `vsq`.

```
Welcome to vsq, the Vertica Analytic Database interactive terminal.  
Type: \h or \? for help with vsq commands  
      \g or terminate with semicolon to execute query  
      \q to quit  
  
=>
```

See [Using vsq](#) for more information.

Note: After entering your password, you may be prompted to change your password if it has expired. See [Implementing Client Authentication](#) for details of password security.

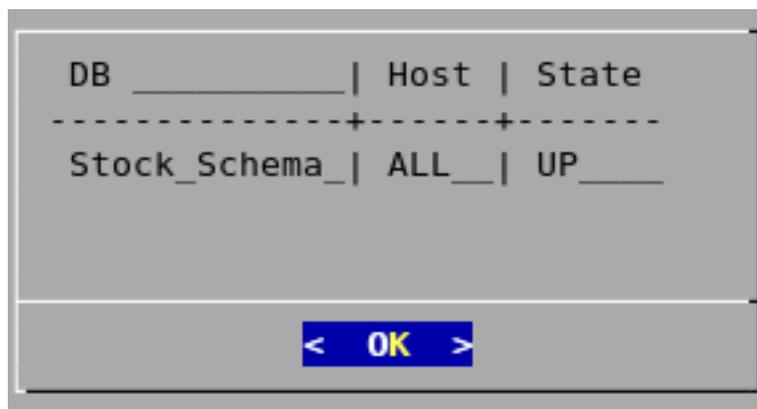

See Also

- [CREATE USER](#)
- [ALTER USER](#)

Restarting Vertica on Host

This tool restarts the Vertica process on one or more nodes in a running database. Use this tool when a cluster host reboots while the database is running. The spread daemon starts automatically but the Vertica process does not, so the node does not automatically rejoin the cluster.

1. On the Main Menu, select **View Database Cluster State**, and click **OK**.
2. If one or more nodes are down, select **Restart Vertica on Host**, and click **OK**.
3. Select the database that contains the host that you want to restart, and click **OK**.
4. Select the Host to restart, and click **OK**.
5. Select **View Database Cluster State** again to verify all nodes are up.

Configuration Menu Item

The Configuration Menu includes:

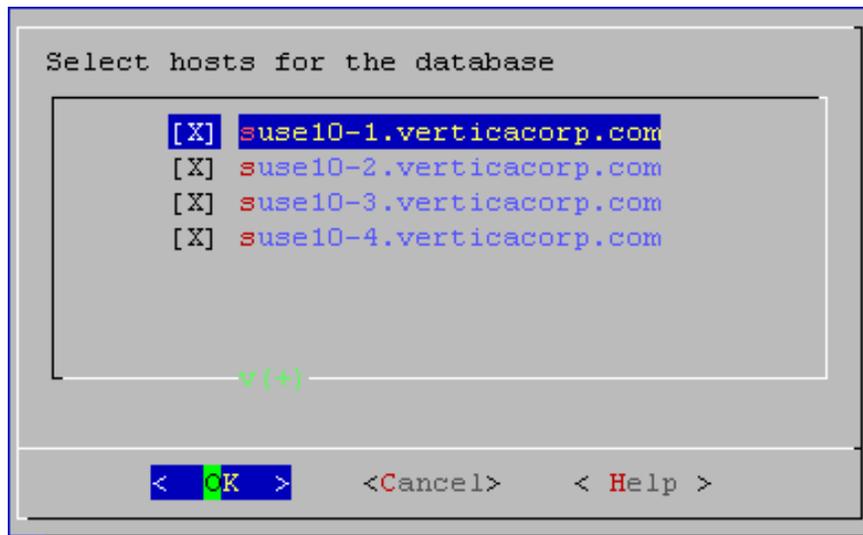

Creating a Database

1. On the **Configuration Menu**, click **Create Database** and then click **OK**.
2. Enter the name of the database and an optional comment. Click **OK**.
3. Enter a password. See [Creating a Database Name and Password](#) for rules.

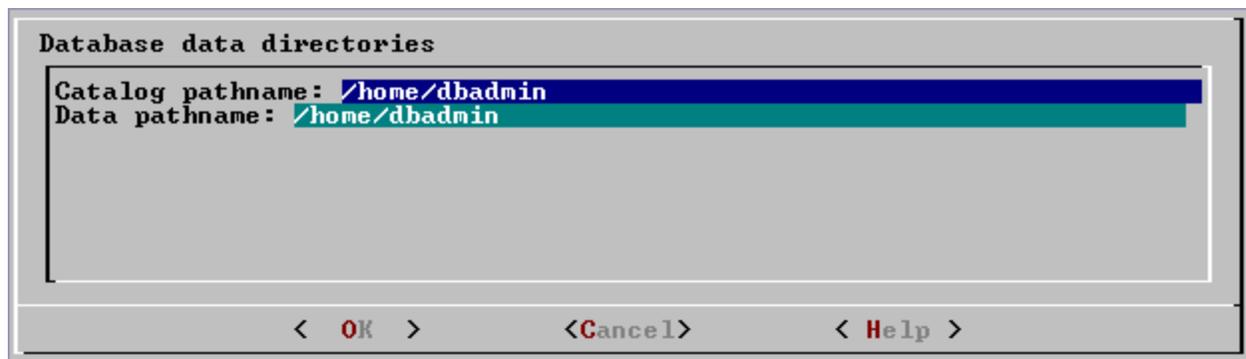

If you do not enter a password, you are prompted to indicate whether you want to enter a password. Click **Yes** to enter a password or **No** to create a database without a superuser password.

Caution: If you do not enter a password at this point, superuser password is set to empty. Unless the database is for evaluation or academic purposes, Micro Focus strongly recommends that you enter a superuser password.

4. If you entered a password, enter the password again.
5. Select the hosts to include in the database. The hosts in this list are the ones that were specified at installation time (`install_vertica -s`).

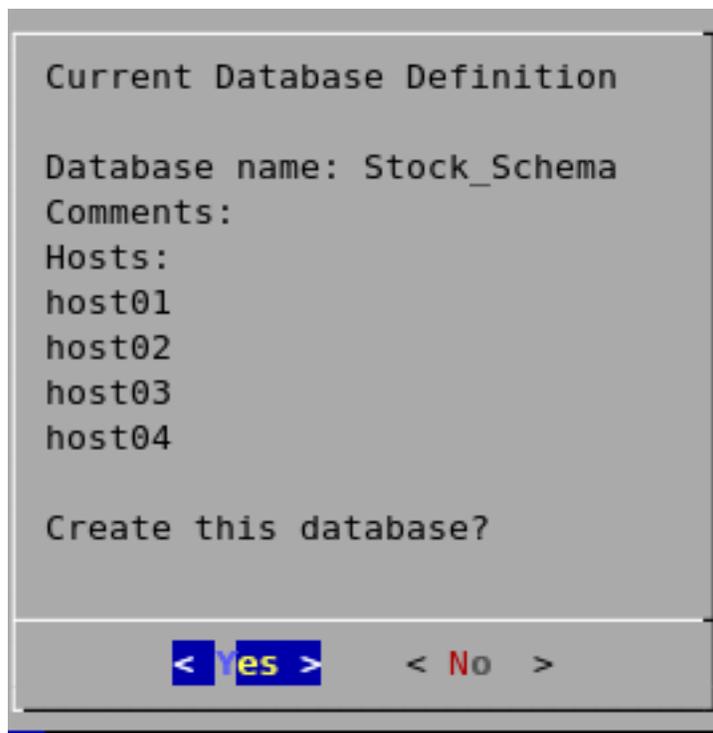

6. Specify the directories in which to store the catalog and data files.

Note: Catalog and data paths must contain only alphanumeric characters and cannot have leading space characters. Failure to comply with these restrictions could result in database creation failure.

Note: Do not use a shared directory for more than one node. Data and catalog directories must be distinct for each node. Multiple nodes must not be allowed to write to the same data or catalog directory.

7. Check the current database definition for correctness, and click Yes to proceed.

8. A message indicates that you have successfully created a database. Click **OK**.

Dropping a Database

This tool drops an existing database. Only the Database Administrator is allowed to drop a database.

1. [Stop the database](#).
2. On the **Configuration Menu**, click **Drop Database** and then click **OK**.
3. Select the database to drop and click **OK**.
4. Click **Yes** to confirm that you want to drop the database.
5. Type **yes** and click **OK** to reconfirm that you really want to drop the database.
6. A message indicates that you have successfully dropped the database. Click **OK**.

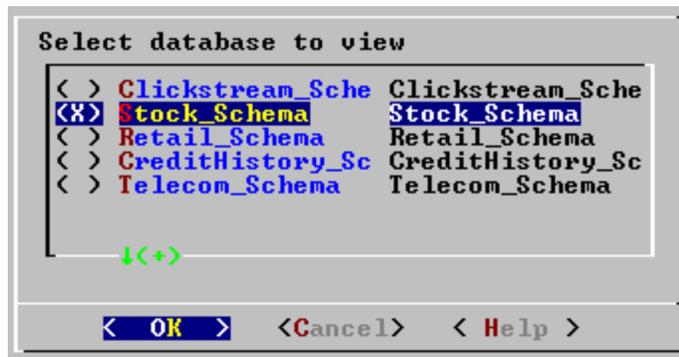

When Vertica drops the database, it also automatically drops the node definitions that refer to the database . The following exceptions apply:

- Another database uses a node definition. If another database refers to any of these node definitions, none of the node definitions are dropped.
- A node definition is the only node defined for the host. (Vertica uses node definitions to locate hosts that are available for database creation, so removing the only node defined for a host would make the host unavailable for new databases.)

Viewing a Database

This tool displays the characteristics of an existing database.

1. On the **Configuration Menu**, select **View Database** and click **OK**.
2. Select the database to view.

3. Vertica displays the following information about the database:

- The name of the database.
- The name and location of the log file for the database.
- The hosts within the database cluster.
- The value of the restart policy setting.

Note: This setting determines whether nodes within a K-Safe database are restarted when they are rebooted. See [Setting the Restart Policy](#).

- The database port.
- The name and location of the catalog directory.

Setting the Restart Policy

The Restart Policy enables you to determine whether or not nodes in a K-Safe database are automatically restarted when they are rebooted. Since this feature does not automatically restart nodes if the entire database is DOWN, it is not useful for databases that are not K-Safe.

To set the Restart Policy for a database:

1. Open the Administration Tools.
2. On the Main Menu, select **Configuration Menu**, and click **OK**.
3. In the Configuration Menu, select **Set Restart Policy**, and click **OK**.
4. Select the database for which you want to set the Restart Policy, and click **OK**.
5. Select one of the following policies for the database:
 - **Never** — Nodes are never restarted automatically.
 - **K-Safe** — Nodes are automatically restarted if the database cluster is still UP. This is the default setting.
 - **Always** — Node on a single node database is restarted automatically.

Note: Always does not work if a single node database was not shutdown cleanly or crashed.

6. Click **OK**.

Best Practice for Restoring Failed Hardware

Following this procedure will prevent Vertica from misdiagnosing missing disk or bad mounts as data corruptions, which would result in a time-consuming, full-node recovery.

If a server fails due to hardware issues, for example a bad disk or a failed controller, upon repairing the hardware:

1. Reboot the machine into runlevel 1, which is a root and console-only mode.

Runlevel 1 prevents network connectivity and keeps Vertica from attempting to reconnect to the cluster.

2. In runlevel 1, validate that the hardware has been repaired, the controllers are online, and any RAID recover is able to proceed.

Note: You do not need to initialize RAID recover in runlevel 1; simply validate that it can recover.

3. Once the hardware is confirmed consistent, only then reboot to runlevel 3 or higher.

At this point, the network activates, and Vertica rejoins the cluster and automatically recovers any missing data. Note that, on a single-node database, if any files that were associated with a projection have been deleted or corrupted, Vertica will delete all files associated with that projection, which could result in data loss.

Installing External Procedure Executable Files

1. Run the Administration Tools.

```
$ /opt/vertica/bin/adminTools
```

2. On the AdminTools **Main Menu**, click **Configuration Menu**, and then click **OK**.
3. On the **Configuration Menu**, click **Install External Procedure** and then click **OK**.
4. Select the database on which you want to install the external procedure.
5. Either select the file to install or manually type the complete file path, and then click **OK**.
6. If you are not the superuser, you are prompted to enter your password and click **OK**.

The Administration Tools automatically create the `<database_catalog_path>/procedures` directory on each node in the database and installs the external procedure in these directories for you.

7. Click **OK** in the dialog that indicates that the installation was successful.

Advanced Menu Options

This Advanced Menu includes:

Rolling Back the Database to the Last Good Epoch

Vertica provides the ability to roll the entire database back to a specific epoch primarily to assist in the correction of human errors during data loads or other accidental corruptions. For example, suppose that you have been performing a bulk load and the cluster went down during a particular [COPY](#) command. You might want to discard all epochs back to the point at which the previous COPY command committed and run the one that did not finish again. You can determine that point by examining the log files (see [Monitoring the Log Files](#)).

1. On the Advanced Menu, select **Roll Back Database to Last Good Epoch**.
2. Select the database to roll back. The database must be stopped.
3. Accept the suggested restart epoch or specify a different one.
4. Confirm that you want to discard the changes after the specified epoch.

The database restarts successfully.

Important: The default value of `HistoryRetentionTime` is 0, which means that Vertica only keeps historical data when nodes are down. This settings prevents the use of the Administration Tools 'Roll Back Database to Last Good Epoch' option because the AHM remains close to the current epoch. Vertica cannot roll back to an epoch that precedes the AHM.

If you rely on the Roll Back option to remove recently loaded data, consider setting a day-wide window for removing loaded data. For example:

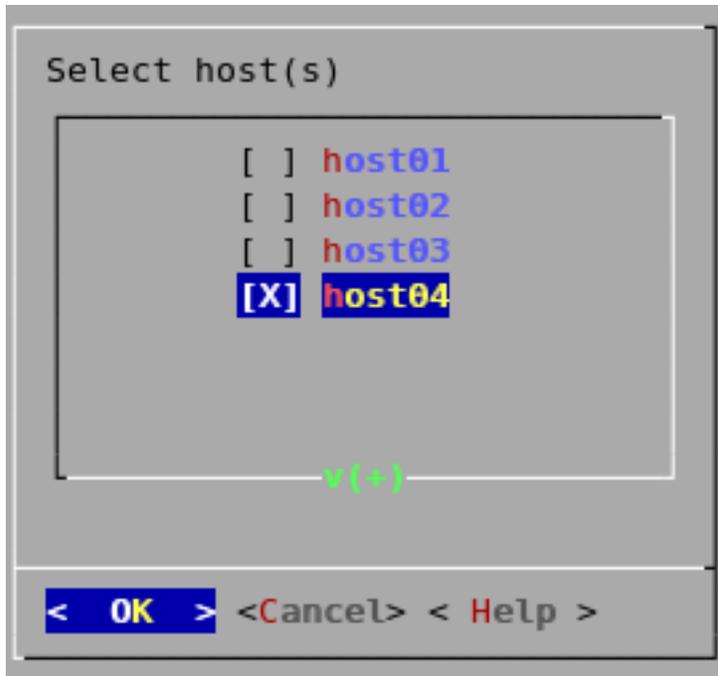

```
=> ALTER DATABASE mydb SET HistoryRetentionTime = 86400;
```

Stopping Vertica on Host

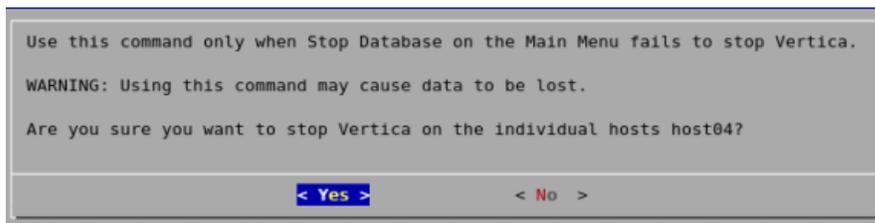

This command attempts to gracefully shut down the Vertica process on a single node.

Caution: Do not use this command to shut down the entire cluster. Instead, [stop the database](#) to perform a clean shutdown that minimizes data loss.

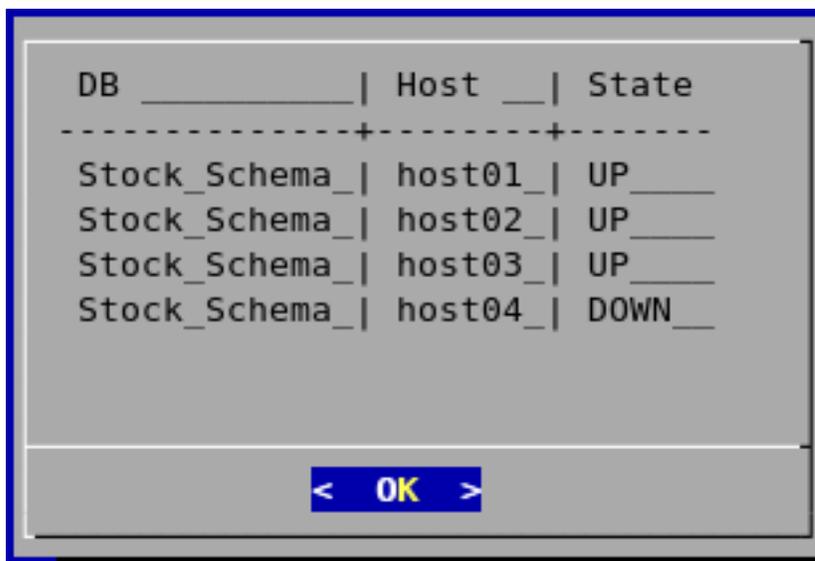

1. On the Advanced Menu, select **Stop Vertica on Host** and click **OK**.
2. Select the hosts to stop.

3. Confirm that you want to stop the hosts.

If the command succeeds [View Database Cluster State](#) shows that the selected hosts are DOWN.

DB _____	Host ____	State
Stock_Schema_	host01_	UP_____
Stock_Schema_	host02_	UP_____
Stock_Schema_	host03_	UP_____
Stock_Schema_	host04_	DOWN_____

< OK >

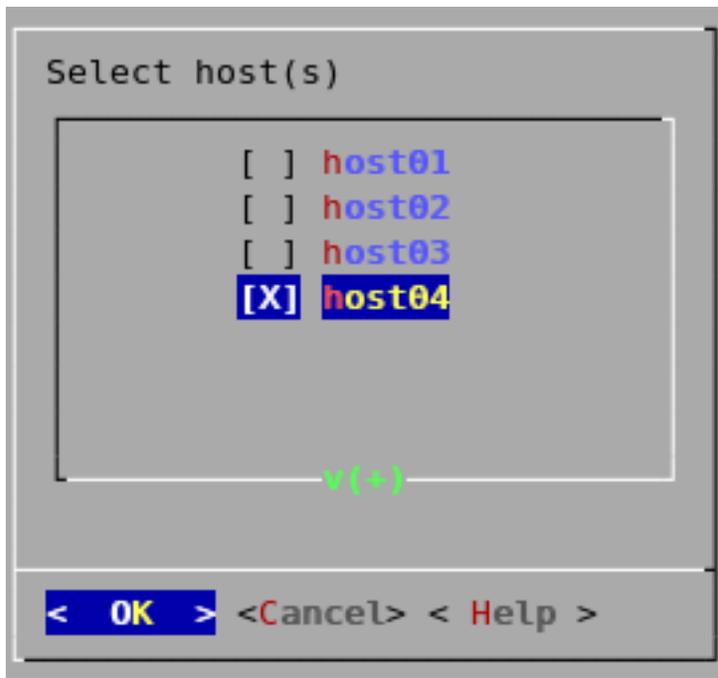

If the command fails to stop any selected nodes, proceed to [Killing Vertica Process on Host](#).

Killing the Vertica Process on Host

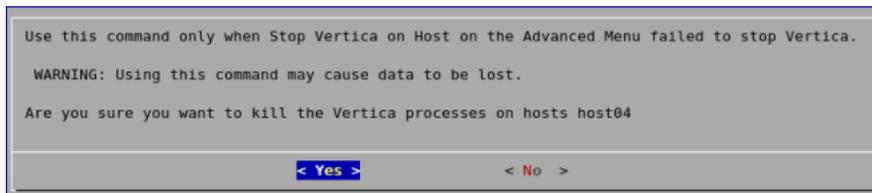

This command sends a kill signal to the Vertica process on a node.

Caution: Use this command only after you tried to [stop the database](#) and [stop Vertica on a node](#) and both were unsuccessful.

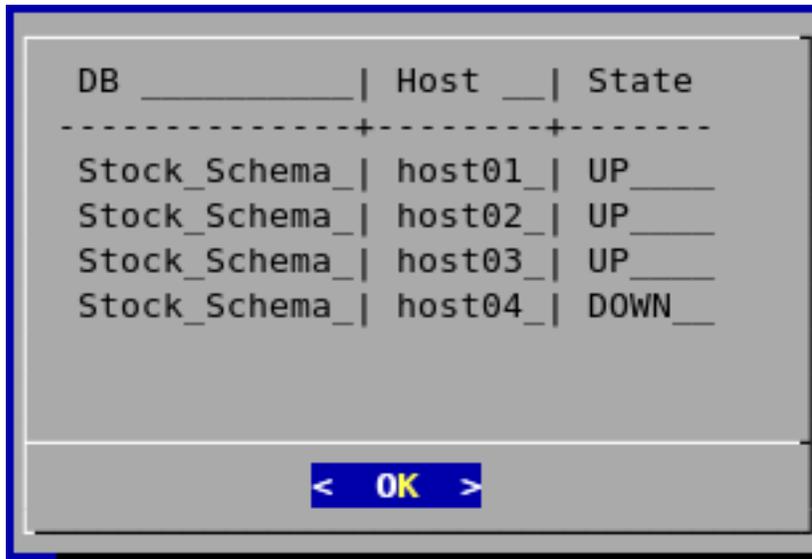

1. On the Advanced menu, select **Kill Vertica Process on Host** and click **OK**.
2. Select the hosts on which to kills the Vertica process.

3. Confirm that you want to stop the processes.

4. If the command succeeds, [View Database Cluster State](#) shows that the selected hosts are DOWN.

DB _____	Host ___	State
Stock_Schema_	host01_	UP_____
Stock_Schema_	host02_	UP_____
Stock_Schema_	host03_	UP_____
Stock_Schema_	host04_	DOWN____

< OK >

Upgrading a Vertica License Key

The following steps are for licensed Vertica users. Completing the steps copies a license key file into the database. See [Managing Licenses](#) for more information.

1. On the Advanced menu select **Upgrade License Key** . Click **OK**.
2. Select the database for which to upgrade the license key.
3. Enter the absolute pathname of your downloaded license key file (for example, /tmp/vlicense.dat). Click **OK**.
4. Click OK when you see a message indicating that the upgrade succeeded.

Note: If you are using Vertica Community Edition, follow the instructions in [Vertica License Renewals or Upgrades](#) for instructions to upgrade to a Vertica Premium Edition license key.

Managing Clusters

Cluster Management lets you add, replace, or remove hosts from a database cluster. These processes are usually part of a larger process of [adding](#), [removing](#), or [replacing](#) a database node.

Note: View the database state to verify that it is running. See [View Database Cluster State](#). If the database isn't running, restart it. See [Start the Database](#).

Using Cluster Management

To use Cluster Management:

1. From the **Main Menu**, select **Advanced Menu**, and then click **OK**.
2. In the **Advanced Menu**, select **Cluster Management**, and then click **OK**.
3. Select one of the following, and then click **OK**.
 - **Add Hosts to Database:** See [Adding Hosts to a Database](#).
 - **Re-balance Data:** See [Rebalancing Data](#).
 - **Replace Host:** See [Replacing Hosts](#).
 - **Remove Host from Database:** See [Removing Hosts from a Database](#).

Using Administration Tools

The **Help Using the Administration Tools** command displays a help screen about using the Administration Tools.

Most of the online help in the Administration Tools is context-sensitive. For example, if you use the up/down arrows to select a command, press tab to move to the Help button, and press return, you get help on the selected command.

Administration Tools Metadata

The Administration Tools configuration data (metadata) contains information that databases need to start, such as the hostname/IP address of each participating host in the database cluster.

To facilitate hostname resolution within the Administration Tools, at the command line, and inside the installation utility, Vertica enforces all hostnames you provide through the Administration Tools to use IP addresses:

- **During installation**

Vertica immediately converts any hostname you provide through command line options `--hosts`, `--add-hosts` or `--remove-hosts` to its IP address equivalent.

- If you provide a hostname during installation that resolves to multiple IP addresses (such as in multi-homed systems), the installer prompts you to choose one IP address.
- Vertica retains the name you give for messages and prompts only; internally it stores these hostnames as IP addresses.

- **Within the Administration Tools**

All hosts are in IP form to allow for direct comparisons (for example db = database = database.example.com).

- **At the command line**

Vertica converts any hostname value to an IP address that it uses to look up the host in the configuration metadata. If a host has multiple IP addresses that are resolved, Vertica tests each IP address to see if it resides in the metadata, choosing the first match. No match indicates that the host is not part of the database cluster.

Metadata is more portable because Vertica does not require the names of the hosts in the cluster to be exactly the same when you install or upgrade your database.

Writing Administration Tools Scripts

You can invoke most Administration Tools from the command line or a shell script.

Syntax

```
/opt/vertica/bin/admintools {  
  { -h | --help }  
  | { -a | --help_all }  
  | { [--debug] { -t | --tool } toolname [ tool-args ] }  
}
```

Note: For convenience, add `/opt/vertica/bin` to your search path.

Parameters

-h -help	Outputs abbreviated help.
-a	Outputs verbose help, which lists all command-line sub-commands

<code>-help_all</code>	and options.
<code>[debug] { -t -tool } toolname [args]</code>	Specifies the tool to run, where <i>toolname</i> is one of the tools listed in the help output described below, and <i>args</i> is one or more comma-delimited <i>toolname</i> arguments. If you include the debug option, Vertica logs debug information during tool execution.

Tools

To return a list of all available tools, enter `admintools -h` at a command prompt.

Note: To create a database or password, see [Creating a Database Name and Password](#) for naming rules.

To display help for a specific tool and its options or commands, qualify the specified tool name with `--help` or `-h`, as shown in the example below:

```
$ admintools -t connect_db --help
Usage: connect_db [options]

Options:
  -h, --help            show this help message and exit
  -d DB, --database=DB  Name of database to connect
  -p DBPASSWORD, --password=DBPASSWORD
                        Database password in single quotes
```

To list all available tools and their commands and options in individual help text, enter `admintools -a`.

```
$ admintools -a
Usage:
  adminTools [-t | --tool] toolName [options]
Valid tools are:
  command_host
  connect_db
  create_db
  database_parameters
  db_add_node
  db_remove_node
  db_replace_node
  db_status
  distribute_config_files
  drop_db
  host_to_node
  install_package
  install_procedure
  kill_host
  kill_node
```

```
license_audit  
list_allnodes  
list_db  
list_host  
list_node  
list_packages  
logrotate  
node_map  
rebalance_data  
restart_db  
restart_node  
return_epoch  
set_restart_policy  
set_ssl_params  
show_active_db  
start_db  
stop_db  
stop_host  
stop_node  
uninstall_package  
upgrade_license_key  
view_cluster
```

Usage: command_host [options]

Options:

```
-h, --help          show this help message and exit  
-c CMD, --command=CMD  
                    Command to run
```

Usage: connect_db [options]

Options:

```
-h, --help          show this help message and exit  
-d DB, --database=DB Name of database to connect  
-p DBPASSWORD, --password=DBPASSWORD  
                    Database password in single quotes
```

Usage: create_db [options]

Options:

```
-h, --help          show this help message and exit  
-D DATA, --data_path=DATA  
                    Path of data directory[optional] if not using compat21  
-c CATALOG, --catalog_path=CATALOG  
                    Path of catalog directory[optional] if not using  
                    compat21  
--compat21         (deprecated) Use Vertica 2.1 method using node names  
                    instead of hostnames  
-d DB, --database=DB Name of database to be created  
-l LICENSEFILE, --license=LICENSEFILE  
                    Database license [optional]  
-p DBPASSWORD, --password=DBPASSWORD  
                    Database password in single quotes [optional]  
-P POLICY, --policy=POLICY  
                    Database restart policy [optional]  
-s NODES, --hosts=NODES  
                    comma-separated list of hosts to participate in  
                    database
```

```
--skip-fs-checks      Skip file system checks while creating a database (not
                      recommended).
-----
Usage: database_parameters [options]

Options:
-h, --help            show this help message and exit
-d DB, --database=DB  Name of database
-P PARAMETER, --parameter=PARAMETER
                      Database parameter
-c COMPONENT, --component=COMPONENT
                      Component[optional]
-s SUBCOMPONENT, --subcomponent=SUBCOMPONENT
                      Sub Component[optional]
-p PASSWORD, --password=PASSWORD
                      Database password[optional]
-----
Usage: db_add_node [options]

Options:
-h, --help            show this help message and exit
-d DB, --database=DB  Name of database to be restarted
-s HOSTS, --hosts=HOSTS
                      Comma separated list of hosts to add to database
-p DBPASSWORD, --password=DBPASSWORD
                      Database password in single quotes
-a AHOSTS, --add=AHOSTS
                      Comma separated list of hosts to add to database
-i, --noprompts       do not stop and wait for user input(default false)
--compat21            (deprecated) Use Vertica 2.1 method using node names
                      instead of hostnames
--skip-fs-checks     Skip file system checks while adding nodes (not
                      recommended).
-----
Usage: db_remove_node [options]

Options:
-h, --help            show this help message and exit
-d DB, --database=DB  Name of database to be modified
-s HOSTS, --hosts=HOSTS
                      Name of the host to remove from the db
-p DBPASSWORD, --password=DBPASSWORD
                      Database password in single quotes
-i, --noprompts       do not stop and wait for user input (default false)
--compat21            (deprecated) Use Vertica 2.1 method using node names
                      instead of hostnames
-----
Usage: db_replace_node [options]

Options:
-h, --help            show this help message and exit
-d DB, --database=DB  Name of database to be restarted
-o ORIGINAL, --original=ORIGINAL
                      Name of host you wish to replace
-n NEWHOST, --new=NEWHOST
                      Name of the replacement host
-p DBPASSWORD, --password=DBPASSWORD
                      Database password in single quotes
-i, --noprompts       do not stop and wait for user input(default false)
--skip-fs-checks     Skip file system checks while replacing nodes (not
```

```
recommended).
-----
Usage: db_status [options]

Options:
  -h, --help          show this help message and exit
  -s STATUS, --status=STATUS
                      Database status UP,DOWN or ALL(list running dbs -
                      UP,list down dbs - DOWN list all dbs - ALL
-----
Usage: distribute_config_files
Sends admintools.conf from local host to all other hosts in the cluster

Options:
  -h, --help          show this help message and exit
-----
Usage: drop_db [options]

Options:
  -h, --help          show this help message and exit
  -d DB, --database=DB Database to be dropped
-----
Usage: host_to_node [options]

Options:
  -h, --help          show this help message and exit
  -s HOST, --host=HOST comma separated list of hostnames which is to be
                      converted into its corresponding nodenames
  -d DB, --database=DB show only node/host mapping for this database.
-----
Usage: admintools -t install_package --package PACKAGE -d DB -p PASSWORD

Examples:
admintools -t install_package -d mydb -p 'mypasswd' --package default
# (above) install all default packages that aren't currently installed

admintools -t install_package -d mydb -p 'mypasswd' --package default --force-reinstall
# (above) upgrade (re-install) all default packages to the current version

admintools -t install_package -d mydb -p 'mypasswd' --package hcat
# (above) install package hcat

See also: admintools -t list_packages

Options:
  -h, --help          show this help message and exit
  -d DBNAME, --dbname=DBNAME
                      database name
  -p PASSWORD, --password=PASSWORD
                      database admin password
  -P PACKAGE, --package=PACKAGE
                      specify package or 'all' or 'default'
  --force-reinstall  Force a package to be re-installed even if it is
                      already installed.
-----
Usage: install_procedure [options]

Options:
  -h, --help          show this help message and exit
  -d DBNAME, --database=DBNAME
```

```

        Name of database for installed procedure
-f PROCPATH, --file=PROCPATH
        Path of procedure file to install
-p OWNERPASSWORD, --password=OWNERPASSWORD
        Password of procedure file owner
-----
Usage: kill_host [options]

Options:
-h, --help          show this help message and exit
-s HOSTS, --hosts=HOSTS
                    comma-separated list of hosts on which the vertica
                    process is to be killed using a SIGKILL signal
--compat21          (deprecated) Use Vertica 2.1 method using node names
                    instead of hostnames
-----
Usage: kill_node [options]

Options:
-h, --help          show this help message and exit
-s HOSTS, --hosts=HOSTS
                    comma-separated list of hosts on which the vertica
                    process is to be killed using a SIGKILL signal
--compat21          (deprecated) Use Vertica 2.1 method using node names
                    instead of hostnames
-----
Usage: license_audit --dbname DB_NAME [OPTIONS]
Runs audit and collects audit results.

Options:
-h, --help          show this help message and exit
-d DATABASE, --database=DATABASE
                    Name of the database to retrieve audit results
-p PASSWORD, --password=PASSWORD
                    Password for database admin
-q, --quiet          Do not print status messages.
-f FILE, --file=FILE Output results to FILE.
-----
Usage: list_allnodes [options]

Options:
-h, --help          show this help message and exit
-----
Usage: list_db [options]

Options:
-h, --help          show this help message and exit
-d DB, --database=DB Name of database to be listed
-----
Usage: list_host [options]

Options:
-h, --help          show this help message and exit
-----
Usage: list_node [options]

Options:
-h, --help          show this help message and exit
-n NODENAME, --node=NODENAME
                    Name of the node to be listed
```

```
-----
Usage: admintools -t list_packages [OPTIONS]

Examples:
admintools -t list_packages                # lists all available packages
admintools -t list_packages --package all  # lists all available packages
admintools -t list_packages --package default # list all packages installed by default
admintools -t list_packages -d mydb --password 'mypasswd' # list the status of all packages in mydb

Options:
-h, --help          show this help message and exit
-d DBNAME, --dbname=DBNAME
                    database name
-p PASSWORD, --password=PASSWORD
                    database admin password
-P PACKAGE, --package=PACKAGE
                    specify package or 'all' or 'default'
-----

Usage: logrotate [options]

Options:
-h, --help          show this help message and exit
-d DBNAME, --dbname=DBNAME
                    database name
-r ROTATION, --rotation=ROTATION
                    set how often the log is rotated.[
                    daily|weekly|monthly ]
-s MAXLOGSZ, --maxsize=MAXLOGSZ
                    set maximum log size before rotation is forced.
-k KEEP, --keep=KEEP set # of old logs to keep
-----

Usage: node_map [options]

Options:
-h, --help          show this help message and exit
-d DB, --database=DB List only data for this database.
-----

Usage: rebalance_data [options]

Options:
-h, --help          show this help message and exit
-d DBNAME, --dbname=DBNAME
                    database name
-k KSAFETY, --ksafety=KSAFETY
                    specify the new k value to use
-p PASSWORD, --password=PASSWORD
--script            Don't re-balance the data, just provide a script for
                    later use.
-----

Usage: restart_db [options]

Options:
-h, --help          show this help message and exit
-d DB, --database=DB Name of database to be restarted
-e EPOCH, --epoch=EPOCH
                    Epoch at which the database is to be restarted. If
                    'last' is given as argument the db is restarted from
                    the last good epoch.
-p DBPASSWORD, --password=DBPASSWORD
                    Database password in single quotes
```

```
--timeout=NONINTERACTIVE_TIMEOUT
        set a timeout (in seconds) to wait for actions to
        complete ('never') will wait forever (implicitly sets
        -i)
-i, --noprompts      do not stop and wait for user input(default false)
-----
Usage: restart_node [options]

Options:
-h, --help          show this help message and exit
-s NODES, --hosts=NODES
                    comma-separated list of hosts to be restarted
-d DB, --database=DB Name of database whose node is to be restarted
-p DBPASSWORD, --password=DBPASSWORD
                    Database password in single quotes
--timeout=NONINTERACTIVE_TIMEOUT
        set a timeout (in seconds) to wait for actions to
        complete ('never') will wait forever (implicitly sets
        -i)
-i, --noprompts    do not stop and wait for user input(default false)
-F, --force        force the node to start and auto recover if necessary
--compat21         (deprecated) Use Vertica 2.1 method using node names
                    instead of hostnames
-----
Usage: return_epoch [options]

Options:
-h, --help          show this help message and exit
-d DB, --database=DB Name of database
-----
Usage: set_restart_policy [options]

Options:
-h, --help          show this help message and exit
-d DB, --database=DB Name of database for which to set policy
-p POLICY, --policy=POLICY
                    Restart policy: ('never', 'ksafe', 'always')
-----
Usage: set_ssl_params [options]

Options:
-h, --help          show this help message and exit
-d DB, --database=DB Name of database whose parameters will be set
-k KEYFILE, --ssl-key-file=KEYFILE
                    Path to SSL private key file
-c CERTFILE, --ssl-cert-file=CERTFILE
                    Path to SSL certificate file
-a CAFILE, --ssl-ca-file=CAFILE
                    Path to SSL CA file
-p DBPASSWORD, --password=DBPASSWORD
                    Database password in single quotes
-----
Usage: show_active_db [options]

Options:
-h, --help          show this help message and exit
-----
Usage: start_db [options]

Options:
```

```
-h, --help          show this help message and exit
-d DB, --database=DB  Name of database to be started
-p DBPASSWORD, --password=DBPASSWORD
                    Database password in single quotes
--timeout=NONINTERACTIVE_TIMEOUT
                    set a timeout (in seconds) to wait for actions to
                    complete ('never') will wait forever (implicitly sets
                    -i)
-i, --noprompts     do not stop and wait for user input(default false)
-F, --force         force the database to start at an epoch before data
                    consistency problems were detected.
-U, --unsafe        Start database unsafely, skipping recovery. Use under
                    support guidance only.
```

Usage: stop_db [options]

Options:

```
-h, --help          show this help message and exit
-d DB, --database=DB  Name of database to be stopped
-p DBPASSWORD, --password=DBPASSWORD
                    Database password in single quotes
-F, --force         Force the databases to shutdown, even if users are
                    connected.
--timeout=NONINTERACTIVE_TIMEOUT
                    set a timeout (in seconds) to wait for actions to
                    complete ('never') will wait forever (implicitly sets
                    -i)
-i, --noprompts     do not stop and wait for user input(default false)
```

Usage: stop_host [options]

Options:

```
-h, --help          show this help message and exit
-s HOSTS, --hosts=HOSTS
                    comma-separated list of hosts on which the vertica
                    process is to be killed using a SIGTERM signal
--compat21          (deprecated) Use Vertica 2.1 method using node names
                    instead of hostnames
```

Usage: stop_node [options]

Options:

```
-h, --help          show this help message and exit
-s HOSTS, --hosts=HOSTS
                    comma-separated list of hosts on which the vertica
                    process is to be killed using a SIGTERM signal
--compat21          (deprecated) Use Vertica 2.1 method using node names
                    instead of hostnames
```

Usage: uninstall_package [options]

Options:

```
-h, --help          show this help message and exit
-d DBNAME, --dbname=DBNAME
                    database name
-p PASSWORD, --password=PASSWORD
                    database admin password
-P PACKAGE, --package=PACKAGE
                    specify package or 'all' or 'default'
```

```
-----  
Usage: upgrade_license_key --database mydb --license my_license.key  
upgrade_license_key --install --license my_license.key  
  
Updates the vertica license.  
  
Without '--install', updates the license used by the database and  
the admintools license cache.  
  
With '--install', updates the license cache in admintools that  
is used for creating new databases.  
  
Options:  
-h, --help          show this help message and exit  
-d DB, --database=DB  Name of database. Cannot be used with --install.  
-l LICENSE, --license=LICENSE  
                    Required - path to the license.  
-i, --install        When option is included, command will only update the  
                    admintools license cache. Cannot be used with  
                    --database.  
-p PASSWORD, --password=PASSWORD  
                    Database password.  
-----  
Usage: view_cluster [options]  
  
Options:  
-h, --help          show this help message and exit  
-x, --xexpand        show the full cluster state, node by node  
-d DB, --database=DB  filter the output for a single database
```

Operating the Database

This topic explains how to start and stop your Vertica database, and how to use the database index tool:

- [Starting the Database](#)
- [Stopping the Database](#)
- [CRC and Sort Order Check](#)

Start the Database

You can start a database through one of the following:

- [Management Console](#)
- Administration Tools interface
- Command line

Administration Tools

1. Open the Administration Tools and select [View Database Cluster State](#) to make sure that all nodes are down and that no other database is running.
2. Open the Administration Tools. See [Using the Administration Tools](#) for information about accessing the Administration Tools.
3. On the **Main Menu**, select **Start Database**, and then select **OK**.
4. Select the database to start, and then click **OK**.

Caution: You should start only one database at a time. If you start more than one database at any time, the results can be unpredictable. Users might encounter resource conflicts or perform operations on the wrong database.

5. Enter the database password and click **OK**.

6. When prompted that the database started successfully, click **OK**.
7. Check the log files to make sure that no startup problems occurred.

Command Line

You can start a database with the [command line tool](#) `start_db`:

```
$ /opt/vertica/bin/admintools -t start_db -d db-name  
[-p password] [-F]
```

Option	Description
<code>-p</code> <code>--password</code>	Required only during database creation, when you install a new license. If the license is valid, the option <code>-p</code> (or <code>--password</code>) is not required to start the database and is silently ignored. This is by design, as the database can only be started by the user who (as part of the <code>verticadba</code> UNIX user group) initially created the database or who has root or su privileges. If the license is invalid, Vertica uses the <code>-p password</code> argument to attempt to upgrade the license with the license file stored in <code>/opt/vertica/config/share/license.key</code> .
<code>-F</code> <code>--force</code>	Forces the database to start at an epoch that precedes detection of data consistency problems

Following is an example of using `start_db` on a standalone node:

```
$ /opt/vertica/bin/admintools -t start_db -d VMart  
Info:  
no password specified, using none  
Node Status: v_vmart_node0001: (DOWN)  
Node Status: v_vmart_node0001: (UP)  
Database VMart started successfully
```

Stopping the Database

There are many occasions when you must stop a database, for example, before an upgrade or performing various maintenance tasks. You can stop a running database through one of the following:

- [Management Console](#)
- [Administration Tools interface](#)
- [Command line](#)

You cannot stop a running database if any users are connected or Database Designer is building or deploying a database design.

Note: If the Tuple Mover is doing a Moveout operation then the database cannot stop until the Moveout is complete. If the database is not stopping after you issue a stop command then you can verify a Moveout operation is preventing the database from stopping by looking at the Vertica log file. See [Monitoring Log Files](#) for details on locating and viewing the Vertica log. Tuple Mover operations that are in progress display an INFO message: [Session] <INFO> closeAndWaitAllSessions: waiting for session to end. The database will stop after the Moveout completes, you do not need to take additional action other than waiting.

Administration Tools

To stop a running database with admintools:

1. [Verify that all cluster nodes are up](#). If any nodes are down, [identify and restart them](#).
2. Close all user sessions:
 - Identify all users with active sessions by querying the [SESSIONS](#) system table. Notify users of the impending shutdown and request them to shut down their sessions.
 - Prevent users from starting new sessions by temporarily resetting configuration parameter [MaxClientSessions](#) to 0:

```
=> ALTER DATABASE mydb SET MaxClientSessions = 0;
```

- Close all remaining user sessions with Vertica functions [CLOSE_SESSION](#) and [CLOSE_ALL_SESSIONS](#).

Note: You can also force a database shutdown and block new sessions with the function [SHUTDOWN](#).

3. Open Vertica [Administration Tools](#).
4. From the Main Menu:
 - Select Stop Database
 - Click **OK**
5. Select the database to stop and click **OK**.
6. Enter the password (if asked) and click **OK**.
7. When prompted that database shutdown is complete, click **OK**.

Command Line

You can stop a database with the [command line tool](#) `stop_db`:

```
$ /opt/vertica/bin/admintools -t stop_db -d db-name  
[-p password] [-F]
```

Use the option `-F` (or `--force`) to override all user connections and force a shutdown.

CRC and Sort Order Check

As a superuser, you can run the Index tool on a Vertica database to perform two tasks:

- Run a per-block cyclic redundancy check (CRC) on data storage to verify data integrity.
- Check that the sort order in ROS containers is correct.

If the database is down, invoke the Index tool from the Linux command line. If the database is up, invoke it as a SQL statement from vsql:

Operation	Database Down	Database Up
Run CRC	<code>/opt/vertica/bin/vertica -D catalog-path -v</code>	<code>select run_index_tool ('checkcrc'); select run_index_tool ('checkcrc', 'true');</code>
Check sort order	<code>/opt/vertica/bin/vertica -D catalog-path -I</code>	<code>select run_index_tool ('checksort'); select run_index_tool ('checksort', 'true');</code>

If you run the Index tool in vsql as a SQL statement, you can specify that it analyze all cluster nodes by setting the optional Boolean parameter to `true` (1). If this parameter is omitted, the Index tool runs only on the current node.

If invoked from the command line, the Index tool runs only on the current node. However, the Index tool can run on multiple nodes simultaneously. Invoke the Index tool binary from the `/opt/vertica/bin` directory.

Viewing Results

The Index tool writes summary information about its operation to standard output; detailed information on results is logged in one of two locations, depending on the environment where you invoke the tool:

- **Invoked from the command-line:** Results written to `indextool.log` file in the database catalog directory.
- **Invoked from vsql:** Results written to `vertica.log` on the current node.

Privileges

Restricted to superusers.

Running a Cyclic Redundancy Check

The Index tool can run a cyclic redundancy check (CRC) on each block of existing data storage to check the data integrity of ROS data blocks.

Running the Tool

You can invoke the Index tool from the command line or from `vsql`, depending on whether the database is up or down:

- **If the database is down:**

Invoke the Index tool from the Linux command line. For example:

```
dbadmin@localhost bin]$ /opt/vertica/bin/vertica -D /home/dbadmin/VMart/v_vmart_node0001_catalog -v
```

The Index tool writes summary information about its operation to standard output, and logs detailed information in `indextool.log` in the database catalog directory.

- **If the database is up:**

Invoke the Index tool it as a SQL statement from `vsql` with the argument `checkcrc`. To run the index tool on all nodes, also set the tool's optional Boolean parameter to `true`. If this parameter is omitted, the Index tool runs only on the current node. For example, the following SQL statement runs a CRC on all cluster nodes:

```
select run_index_tool ('checkcrc', 'true');
```

The Index tool writes summary information about its operation to standard output, and logs detailed information in `vertica.log` on the current node.

Handling CRC Errors

Vertica evaluates the CRC values in each ROS data block each time it fetches data disk to process a query. If CRC errors occur while fetching data, the following information is written to the `vertica.log` file:

```
CRC Check Failure Details:File Name:  
File Offset:  
Compressed size in file:  
Memory Address of Read Buffer:  
Pointer to Compressed Data:  
Memory Contents:
```

The Event Manager is also notified of CRC errors, so you can use an SNMP trap to capture CRC errors:

```
"CRC mismatch detected on file <file_path>. File may be corrupted. Please check hardware and drivers."
```

If you run a query from `vsq`, ODBC, or JDBC, the query returns a `FileColumnReader ERROR`. This message indicates that a specific block's CRC does not match a given record as follows:

```
hint: Data file may be corrupt. Ensure that all hardware (disk and memory) is working properly.  
Possible solutions are to delete the file <pathname> while the node is down, and then allow the node  
to recover, or truncate the table data.code: ERRCODE_DATA_CORRUPTED
```

Checking Sort Order

If ROS data is not sorted correctly in the projection's order, query results that rely on sorted data will be incorrect. You can use the Index tool to check the ROS sort order if you suspect or detect incorrect query results. The Index tool evaluates each ROS row to determine whether it is sorted correctly. If the check locates a row that is not in order, it writes an error message to the log file with the row number and contents of the unsorted row.

Running the Tool

You can invoke the Index tool from the command line or from `vsq`, depending on whether the database is up or down:

- **If the database is down:**

Invoke the Index tool from the Linux command line. For example:

```
$ /opt/vertica/bin/vertica -D /home/dbadmin/VMart/v_vmart_node0001_catalog -I
```

The Index tool writes summary information about its operation to standard output, and logs detailed information in `indextool.log` in the database catalog directory.

- **If the database is up:**

Invoke the Index tool from `vsq` as a SQL statement with the argument `checksort`. To run the index tool on all nodes, also set the tool's optional Boolean parameter to `true`. If this parameter is omitted, the Index tool runs only on the current node.

For example, the following SQL statement runs a CRC on all cluster nodes:

```
select run_index_tool ('checksort', 'true');
```

The Index tool writes summary information about its operation to standard output, and logs detailed information in `vertica.log` on the current node.

Reviewing Errors

1. Open the `indextool.log` file. For example:

```
$ cd VMart/v_check_node0001_catalog
```

2. Look for error messages that include an OID number and the string `Sort Order Violation`. For example:

```
<INFO> ...on oid 45035996273723545: Sort Order Violation:
```

3. Find detailed information about the sort order violation string by running `grep` on `indextool.log`. For example, the following command returns the line before each string (`-B1`), and the four lines that follow (`-A4`):

```
[15:07:55][vertica-s1]: grep -B1 -A4 'Sort Order Violation:' /my_host/databases/check/v_check_node0001_catalog/indextool.log  
2012-06-14 14:07:13.686 unknown:0x7fe1da7a1950 [EE] <INFO> An error occurred when running index tool thread on oid 45035996273723537:
```

```
Sort Order Violation:
Row Position: 624
Column Index: 0
Last Row: 2576000
This Row: 2575000
--
2012-06-14 14:07:13.687 unknown:0x7fe1dafa2950 [EE] <INFO> An error occurred when running index
tool thread on oid 45035996273723545:
Sort Order Violation:
Row Position: 3
Column Index: 0
Last Row: 4
This Row: 2
--
```

4. Find the projection where a sort order violation occurred by querying the `storage_containers` system table. Use a `storage_oid` equal to the OID value listed in `indextool.log`. For example:

```
=> select * from storage_containers where storage_oid = 45035996273723545;
```

Managing Tables

You can create two types of tables in Vertica, columnar and flexible. You can create both types as persistent or temporary. You can also create views that query a specific set of table columns.

Creating Tables

CREATE TABLE creates a table in the Vertica logical schema. For example:

```
CREATE TABLE vendor_dimension (  
  vendor_key      INTEGER      NOT NULL PRIMARY KEY,  
  vendor_name     VARCHAR(64),  
  vendor_address  VARCHAR(64),  
  vendor_city     VARCHAR(64),  
  vendor_state    CHAR(2),  
  vendor_region   VARCHAR(32),  
  deal_size       INTEGER,  
  last_deal_update DATE  
);
```

Table Data Storage

Unlike traditional databases that store data in tables, Vertica physically stores table data in projections, which are collections of table columns. Projections store data in a format that optimizes query execution. Similar to materialized views, they store result sets on disk rather than compute them each time they are used in a query.

In order to query or perform any operation on a Vertica table, the table must have one or more projections associated with it. For more information, see [Physical Schema](#) in Vertica Concepts.

See Also

- [Altering Table Definitions](#)
- [Creating Temporary Tables](#)
- [Creating a Table from Other Tables](#)
- [Creating External Tables](#)

Creating Temporary Tables

`CREATE TEMPORARY TABLE` creates a table whose data persists only during the current session. Temporary table data is never visible to other sessions.

By default, all temporary table data is transaction-scoped—that is, the data is discarded when a `COMMIT` statement ends the current transaction. If `CREATE TEMPORARY TABLE` includes the parameter `ON COMMIT PRESERVE ROWS`, table data is retained until the current session ends.

Temporary tables can be used to divide complex query processing into multiple steps. Typically, a reporting tool holds intermediate results while reports are generated—for example, the tool first gets a result set, then queries the result set, and so on.

When you create a temporary table, Vertica automatically generates a default projection for it. For more information, see [Auto-Projections](#).

Global versus Local Tables

`CREATE TEMPORARY TABLE` can create tables at two scopes, global and local, through the keywords `GLOBAL` and `LOCAL`, respectively:

Global temporary tables	Vertica creates global temporary tables in the public schema. Definitions of these tables are visible to all sessions, and persist across sessions until they are explicitly dropped. Multiple users can access the table concurrently. Table data is session-scoped, so it is visible only to the session user, and is discarded when the session ends.
Local temporary tables	Vertica creates local temporary tables in the <code>V_TEMP_SCHEMA</code> namespace and inserts them transparently into the user's search path. These tables are visible only to the session where they are created. When the session ends, Vertica automatically drops the table and its data.

Data Retention

You can specify whether temporary table data is transaction- or session-scoped:

- **ON COMMIT DELETE ROWS** (default): Vertica automatically removes all table data when each transaction ends.
- **ON COMMIT PRESERVE ROWS**: Vertica preserves table data across transactions in the current session. Vertica automatically truncates the table when the session ends.

Note: If you create a temporary table with `ON COMMIT PRESERVE ROWS`, you cannot add projections for that table if it contains data. You must first remove all data from that table with `TRUNCATE TABLE`.

You can create projections for temporary tables created with `ON COMMIT DELETE ROWS`, whether populated with data or not. However, `CREATE PROJECTION` ends any transaction where you might have added data, so projections are always empty.

ON COMMIT DELETE ROWS

By default, Vertica removes all data from a temporary table, whether global or local, when the current transaction ends.

For example:

```
=> CREATE TEMPORARY TABLE tempDelete (a int, b int);
CREATE TABLE
=> INSERT INTO tempDelete VALUES(1,2);
OUTPUT
-----
      1
(1 row)

=> SELECT * FROM tempDelete;
 a | b
---+---
 1 | 2
(1 row)

=> COMMIT;
COMMIT

=> SELECT * FROM tempDelete;
 a | b
---+---
(0 rows)
```

If desired, you can use `DELETE` within the same transaction multiple times, in order to refresh table data repeatedly.

ON COMMIT PRESERVE ROWS

You can specify that a temporary table retain data across transactions in the current session, by defining the table with the keywords `ON COMMIT PRESERVE ROWS`. Vertica automatically removes all data from the table only when the current session ends.

For example:

```
=> CREATE TEMPORARY TABLE tempPreserve (a int, b int) ON COMMIT PRESERVE ROWS;
CREATE TABLE
=> INSERT INTO tempPreserve VALUES (1,2);
  OUTPUT
-----
      1
(1 row)

VMart=> COMMIT;
COMMIT
VMart=> SELECT * FROM tempPreserve;
  a | b
---+---
  1 | 2
(1 row)

=> INSERT INTO tempPreserve VALUES (3,4);
  OUTPUT
-----
      1
(1 row)

VMart=> COMMIT;
COMMIT
VMart=> SELECT * FROM tempPreserve;
  a | b
---+---
  1 | 2
  3 | 4
(2 rows)
```

Creating a Table from Other Tables

You can create a table from other tables in two ways:

- [Replicate an existing table](#) through `CREATE TABLE...LIKE`.
- [Create a table from a query](#) through `CREATE TABLE...AS`.

Replicating a Table

You can create a table from an existing one using `CREATE TABLE` with the `LIKE` clause:

```
CREATE TABLE [schema.]table-name LIKE [schema.]existing-table
...[ {INCLUDING | EXCLUDING} PROJECTIONS ]
...[ Load-method ]
...[ {INCLUDE | EXCLUDE} [SCHEMA] PRIVILEGES ]
```

Creating a table with LIKE replicates the source table definition and any storage policy associated with it. CREATE TABLE . . . LIKE copies all table constraints except foreign key constraints. It does not copy table data or expressions on columns and constraints.

Including Projections

You can qualify the LIKE clause with INCLUDING PROJECTIONS or EXCLUDING PROJECTIONS, which specify whether to copy projections from the source table:

- EXCLUDING PROJECTIONS (default): Do not copy projections from the source table.
- INCLUDING PROJECTIONS: Copy current projections from the source table. INCLUDING PROJECTIONS also copies all table constraints except foreign key constraints. If the table is associated with a storage policy, the policy association is also replicated. Vertica names the new projections according to Vertica [naming conventions](#), which avoids name conflicts with existing objects.

Specifying a Load Method

You can qualify the LIKE clause with a load method, one of the following:

- AUTO (default): Initially loads data into WOS, suitable for smaller bulk loads.
- DIRECT: Loads data directly into ROS containers, suitable for large (>100 MB) bulk loads.
- TRICKLE: Loads data only into WOS, suitable for frequent incremental loads.

For details, see [Choosing a Load Method](#) in the Administrator's Guide.

Including Schema Privileges

You can specify default inheritance of schema privileges for the new table:

- EXCLUDE [SCHEMA] PRIVILEGES (default) disables inheritance of privileges from the schema
- INCLUDE [SCHEMA] PRIVILEGES grants the table the same privileges granted to its schema

For more information see [Grant Inherited Privileges](#).

Restrictions

The following restrictions apply to the source table:

- It cannot have out-of-date projections.
- It cannot be a temporary table.

Example

1. Create the table states:

```
=> CREATE TABLE states (  
    state char(2) NOT NULL, bird varchar(20), tree varchar (20), tax float, stateDate char  
(20))  
    PARTITION BY state;
```

2. Populate the table with data:

```
INSERT INTO states VALUES ('MA', 'chickadee', 'american_elm', 5.675, '07-04-1620');  
INSERT INTO states VALUES ('VT', 'Hermit_Thrasher', 'Sugar_Maple', 6.0, '07-04-1610');  
INSERT INTO states VALUES ('NH', 'Purple_Finch', 'White_Birch', 0, '07-04-1615');  
INSERT INTO states VALUES ('ME', 'Black_Cap_Chickadee', 'Pine_Tree', 5, '07-04-1615');  
INSERT INTO states VALUES ('CT', 'American_Robin', 'White_Oak', 6.35, '07-04-1618');  
INSERT INTO states VALUES ('RI', 'Rhode_Island_Red', 'Red_Maple', 5, '07-04-1619');
```

3. View the table contents:

```
=> SELECT * FROM states;
```

state	bird	tree	tax	stateDate
VT	Hermit_Thrasher	Sugar_Maple	6	07-04-1610
CT	American_Robin	White_Oak	6.35	07-04-1618
RI	Rhode_Island_Red	Red_Maple	5	07-04-1619
MA	chickadee	american_elm	5.675	07-04-1620
NH	Purple_Finch	White_Birch	0	07-04-1615
ME	Black_Cap_Chickadee	Pine_Tree	5	07-04-1615

(6 rows)

4. Create a sample projection and refresh:

See Also

- [Creating Tables](#)
- [Creating Temporary Tables](#)
- [Creating External Tables](#)
- [Creating a Table from a Query](#)

Creating a Table from a Query

CREATE TABLE can specify an AS clause, to create a table from a query, as follows:

```
CREATE [TEMPORARY] TABLE [schema.]table-name
... [ ( column-name-list ) ]
... [ Load-method ]
... [ {INCLUDE | EXCLUDE} [SCHEMA] PRIVILEGES ]
AS [ /*+ hint[, hint] */ ] [ AT epoch ] query [ ENCODED BY column-ref-list ]
```

Vertica creates a table from the query results and loads the result set into it. For example:

```
=> CREATE TABLE cust_basic_profile AS SELECT
    customer_key, customer_gender, customer_age, marital_status, annual_income, occupation
    FROM customer_dimension WHERE customer_age>18 AND customer_gender !='';
CREATE TABLE
=> SELECT customer_age, annual_income, occupation FROM cust_basic_profile
    WHERE customer_age > 23 ORDER BY customer_age;
customer_age | annual_income |      occupation
-----+-----+-----
      24 |      469210 | Hairdresser
      24 |      140833 | Butler
      24 |      558867 | Lumberjack
      24 |      529117 | Mechanic
      24 |      322062 | Acrobat
      24 |      213734 | Writer
      ...
```

AS Clause Options

You can qualify the AS clause with one or both of the following hints:

- A load method hint: [AUTO](#), [DIRECT](#), or [TRICKLE](#)

Note: The `CREATE TABLE` statement can also specify a load method. However, this load method applies to load operations only after the table is created.

- [LABEL](#): Assigns a label to a statement to identify it for profiling and debugging. See [Labeling the AS Clause](#) below.

You can also specify that the query return historical data with `AT epoch`, where *epoch* is one of the following:

- `EPOCH LATEST`: Return data from the latest committed DML transaction.
- `EPOCH integer`: Return data from the *integer*-specified epoch.
- `TIME 'timestamp'`: Return data from the *timestamp*-specified epoch.

Note: These options are invalid for external tables.

Labeling the AS Clause

You can embed a [LABEL](#) hint in an AS clause in two places:

- Immediately after the keyword `AS`:

```
CREATE TABLE myTable AS /*+LABEL myLabel*/...
```

- In the `SELECT` statement:

```
CREATE TABLE myTable AS SELECT /*+LABEL myLabel*/
```

If the AS clause contains a `LABEL` hint in both places, the first label has precedence.

Note: Labels are invalid for external tables.

Specifying a Load Method

You can qualify the AS clause with one of these load method hints:

- [AUTO](#)
- [DIRECT](#)
- [TRICKLE](#)

Vertica applies the load hint to the data that is loaded into the new table. You can also specify a load method in the `CREATE TABLE` statement, which is saved to the table schema. However, the load method applies only to load operations after the table is created.

In the following example, table `bar` is created and loaded from table `foo` with a `CREATE TABLE AS` statement. The `CREATE` statement is qualified with the load method `DIRECT`, which is saved to `bar`'s schema definition. The load method specifies that all future load operations are written to ROS. The `CREATE` statement's `AS` clause also contains the load method hint `/*+DIRECT*/`, which specifies to load the data queried from `foo` into ROS:

```
=> SELECT * FROM foo;
 col1 | col2 | col3
-----+-----
    4 |    5 |    6
    1 |    2 |    3
(2 rows)

=> CREATE TABLE bar DIRECT AS SELECT /*+DIRECT*/ * FROM foo;
CREATE TABLE
dbadmin=> SELECT EXPORT_TABLES ('', 'bar');
                                EXPORT_TABLES
-----
CREATE TABLE public.bar
(
  col1 int,
  col2 int,
  col3 int
) DIRECT ;
(1 row)
```

For details, see [Choosing a Load Method](#).

Note: Load methods cannot be specified for external tables.

Loading Historical Data

You can qualify a `CREATE TABLE AS` query with the option, with `AT epoch`. `AT epoch` specifies to return historical data, where `epoch` is one of the following:

- `EPOCH LATEST`: Return data from the latest committed DML transaction.
- `EPOCH integer`: Return data from the `integer`-specified epoch.

- `TIME 'timestamp'`: Return data from the *timestamp*-specified epoch.

For details, see [Historical Queries](#) in Analyzing Data.

Note: This option is invalid for external tables.

Zero-Width Column Handling

If the query returns a column with zero width, Vertica automatically converts it to a `VARCHAR(80)` column. For example:

```
=> CREATE TABLE example AS SELECT '' AS X;
CREATE TABLE
=> SELECT EXPORT_TABLES ('', 'example');
          EXPORT_TABLES
-----
CREATE TEMPORARY TABLE public.example
(
  X varchar(80)
);
```

Requirements and Restrictions

- If you create a temporary table from a query, you must specify `ON COMMIT PRESERVE ROWS` in order to load the result set into the table. Otherwise, Vertica creates an empty table.
- If the query output has expressions other than simple columns, such as constants or functions, you must specify an alias for that expression, or list all columns in the column name list.

- [Creating Tables](#)
- [Creating Temporary Tables](#)
- [Creating External Tables](#)
- [Replicating a Table](#)

Creating External Tables

You create an external table using the `CREATE EXTERNAL TABLE AS COPY` statement. You cannot create temporary external tables. For the syntax details to create an external table, see the [CREATE EXTERNAL TABLE](#) statement in the SQL Reference Manual.

Note: Each table can have a maximum of 1600 columns.

Required Permissions for External Tables

You must be a database superuser to create external tables.

Permission requirements to use (`SELECT` from) external tables differ from those of other tables. By default, once external tables exist, you must also be a database superuser to access them through a `SELECT` statement.

To allow users without superuser access to query external tables, an administrator must create a 'user' storage location and grant those users read access to the location. See [CREATE LOCATION](#), and [GRANT \(Storage Location\)](#). This location must be a parent of the path used in the `COPY` statement when creating the external table.

COPY Statement Definition

When you create an external table, table data is not added to the database, and no projections are created. Instead, Vertica performs a syntactic check of the `CREATE EXTERNAL TABLE . . .` statement, and stores the table name and `COPY` statement definition in the catalog. When a `SELECT` query references an external table, Vertica parses and executes the stored `COPY` statement to obtain the referenced data. Successfully returning data from an external table requires that the `COPY` definition be correct, and that other dependencies, such as files, nodes, and other resources are accessible and available at query-time.

If the maximum length of a column is smaller than the actual data, such as a `VARCHAR` that is too short, Vertica truncates the data and logs the event.

When using the [COPY parameter](#) on any node, confirm that the source file definition is identical on all nodes. Specifying different external files can produce inconsistent results.

For more information about checking the validity of the external table `COPY` definition, see [Validating External Tables](#).

NOT NULL Constraints

Do not specify a NOT NULL column constraint, unless you are certain that the external data does not contain NULL values. Otherwise, you may see unexpected query results. For example, a SELECT statement for an external table with a NOT NULL constraint will reject a column value if it is not NULL.

Canceling the Create Query

Canceling a CREATE EXTERNAL TABLE AS COPY statement can cause unpredictable results. If you enter a query to create an external table, and it is incorrect (for example, you inadvertently specify the wrong external location), wait for the query to complete. When the external table exists, use [DROP TABLEs](#) definition.

Developing User-Defined Load (UDL) Functions for External Tables

You can create external tables with your own load functions. For more information about developing user-defined load functions, see [User Defined Load \(UDL\)](#) and the extended [COPY](#) syntax in the SQL Reference Manual.

Examples

Examples of external table definitions:

```
=> CREATE EXTERNAL TABLE ext1 (x integer) AS COPY FROM '/tmp/ext1.dat' DELIMITER ',';
=> CREATE EXTERNAL TABLE ext1 (x integer) AS COPY FROM 'hdfs:///dat/ext1.dat';
=> CREATE EXTERNAL TABLE ext1 (x integer) AS COPY FROM '/tmp/ext1.dat.bz2' BZIP DELIMITER ',';
=> CREATE EXTERNAL TABLE ext1 (x integer, y integer) AS COPY (x as '5', y) FROM '/tmp/ext1.dat.bz2'
BZIP DELIMITER ',';
```

To allow users without superuser access to use these tables, create a location for 'user' usage and grant access to it. This example shows granting access to a user named Bob to any external table whose data is located under /tmp (including in subdirectories to any depth):

```
=> CREATE LOCATION '/tmp' ALL NODES USAGE 'user';
=> GRANT ALL ON LOCATION '/tmp' to Bob;
```

See Also

- [COPY](#)
- [CREATE EXTERNAL TABLE AS COPY](#)

Validating External Tables

When you create an external table, Vertica validates the syntax of the `CREATE EXTERNAL TABLE AS COPY FROM` statement. For example, if you omit a required keyword in the statement (such as `FROM`), creating the external table fails:

```
VMart=> create external table ext (ts timestamp,d varchar) as copy '/home/dbadmin/designer.log';  
ERROR 2778: COPY requires a data source; either a FROM clause or a WITH SOURCE for a user-defined  
source
```

Checking other components of the `COPY` definition (such as path statements and node availability) does not occur until a `SELECT` query references the external table.

To validate an external table definition, run a `SELECT` query that references the external table. Check that the returned query data is what you expect. If the query does not return data correctly, check the `COPY` exception and rejected data log files.

Since the `COPY` definition determines what occurs when you query an external table, `COPY` statement errors can reveal underlying problems. For more information about `COPY` exceptions and rejections, see [Capturing Load Rejections and Exceptions](#).

Setting Maximum Exceptions

Querying external table data with an incorrect `COPY FROM` statement definition can potentially result in many rejected rows. To limit the number of rejections, Vertica sets the maximum number of retained rejections with the `ExternalTablesExceptionsLimit` configuration parameter. The default value is 100. Setting the `ExternalTablesExceptionsLimit` to `-1` removes the limit, but is not recommended.

If `COPY` errors reach the maximum number of rejections, the external table query continues, but `COPY` generates a warning in the `vertica.log`, and does not report subsequent rejected rows.

Note: Using the `ExternalTablesExceptionsLimit` configuration parameter differs from the `COPY` statement `REJECTMAX` parameter. The `REJECTMAX` value controls how many rejected rows to permit before causing the load to fail. If `COPY` encounters a number of rejected rows equal to or greater than `REJECTMAX`, `COPY` aborts execution. A `vertica.log` warning is not generated if `COPY` exceeds `REJECTMAX`.

Working with External Tables

After creating external tables, you access them as any other table. However, you cannot perform `UPDATE`, `INSERT`, or `DELETE` operations on external tables.

Managing Resources for External Tables

External tables require minimal additional resources. When you use a select query for an external table, Vertica uses a small amount of memory when reading external table data, since the table contents are not part of your database and are parsed each time the external table is used.

Vertica Does Not Back Up External Tables

Since the data in external tables is managed outside of Vertica, only the external table definitions, not the data files, are included in database backups. Arrange for a separate backup process for your external table data.

Using Sequences and Identity Columns in External Tables

The `COPY` statement definition for external tables can include identity columns and sequences. Whenever a select statement queries the external table, sequences and identity columns are re-evaluated. This results in changing the external table column values, even if the underlying external table data remains the same.

Viewing External Table Definitions

When you create an external table, Vertica stores the `COPY` definition statement in the `table_definition` column of the `v_catalog.tables` system table.

1. To list all tables, use a `select * query`, as shown:

```
select * from v_catalog.tables where table_definition <> '';
```

2. Use a query such as the following to list the external table definitions (`table_definition`):

```
select table_name, table_definition from v_catalog.tables;
table_name | table_definition
-----+-----
t1         | COPY          FROM 'TMPDIR/external_table.dat' DELIMITER ','
t1_copy   | COPY          FROM 'TMPDIR/external_table.dat' DELIMITER ','
t2         | COPY FROM 'TMPDIR/external_table2.dat' DELIMITER ','
(3 rows)
```

External Table DML Support

Following are examples of supported queries, and others that are not:

Supported	Unsupported
<code>SELECT * FROM external_table;</code>	<code>DELETE FROM external_table WHERE x = 5;</code>
<code>SELECT * FROM external_table where col1=4;</code>	<code>INSERT INTO external_table SELECT * FROM ext;</code>
<code>DELETE FROM internal_table WHERE id IN (SELECT x FROM external_table);</code>	
<code>INSERT INTO internal_table SELECT * FROM external_table;</code>	<code>SELECT * FROM external_table FOR UPDATE;</code>

Using External Table Values

Following is a basic example of how you could use the values of an external table.

1. Create and display the contents of a file with some integer values:

```
[dbadmin@localhost ~]$ more ext.dat1
2
3
4
5
6
```

```
7  
8  
10  
11  
12
```

2. Create an external table pointing at ext.dat :

```
VMart=> create external table ext (x integer) as copy from '/home/dbadmin/ext.dat';  
CREATE TABLE
```

3. Select the table contents:

```
VMart=> select * from ext;  
x  
----  
1  
2  
3  
4  
5  
6  
7  
8  
10  
11  
12  
(11 rows)
```

4. Perform evaluation on some external table contents:

```
VMart=> select ext.x, ext.x + ext.x as double_x from ext where x > 5;  
x | double_x  
----+-----  
6 |      12  
7 |      14  
8 |      16  
10 |     20  
11 |     22  
12 |     24  
(6 rows)
```

5. Create a second table (second), also with integer values:

```
VMart=> create table second (y integer);  
CREATE TABLE
```

6. Populate the table with some values:

```
VMart=> copy second from stdin;Enter data to be copied followed by a newline.  
End with a backslash and a period on a line by itself.  
>> 1  
>> 1  
>> 3  
>> 4  
>> 5  
>> \.
```

7. Join the external table (ext) with the table created in Vertica, called second:

```
VMart=> select * from ext join second on x=y;  
 x | y  
----  
 1 | 1  
 1 | 1  
 3 | 3  
 4 | 4  
 5 | 5  
(5 rows)
```

Using External Tables

External tables let you query data stored in files accessible to the Vertica database, but not managed by it. Creating external tables supplies read-only access through SELECT queries. You cannot modify external tables through DML commands, such as INSERT, UPDATE, DELETE, and MERGE.

Using CREATE EXTERNAL TABLE AS COPY Statement

You create external tables with the CREATE EXTERNAL TABLE AS COPY... statement, shown in this basic example:

```
CREATE EXTERNAL TABLE tbl(i INT) AS COPY (i) FROM 'path1' ON v_vmart_node0001, 'path2' ON v_vmart_  
node0002;
```

For more details on the supported options to create an external table, see the [CREATE EXTERNAL TABLE](#) statement in the SQL Reference Manual.

The data you specify in the FROM clause of a CREATE EXTERNAL TABLE AS COPY statement can reside in one or more files or directories, and on one or more nodes. After successfully creating an external table, Vertica stores the table name and its COPY definition. Each time a select query references the external table, Vertica parses the COPY statement definition again to access the data. Here is a sample select statement:

```
SELECT * FROM tbl WHERE i > 10;
```

Storing Vertica Data in External Tables

While there are many requirements for you to use external table data, one reason is to store infrequently-accessed Vertica data on low-cost external media. If external storage is a goal at your site, the process to accomplish that requires exporting the older data to a text file, creating a bzip or gzip file of the export data, and saving the compressed file on an NFS disk. You can then create an external table to access the data any time it is required.

Calculating Exact Row Count for External Tables

To calculate the exact number of rows in an external table, use [ANALYZE_EXTERNAL_ROW_COUNT](#). The Optimizer uses this count to optimize for queries that access external tables.

In particular, if an external table participates in a join, the Optimizer can now identify the smaller table to be used as the inner input to the join, resulting in better query performance.

Using External Tables with User-Defined Load (UDL) Functions

You can also use external tables in conjunction with the UDL functions that you create. For more information about using UDLs, see [User Defined Load \(UDL\)](#) in Extending Vertica.

Organizing External Table Data

If the data you store in external tables changes regularly (for instance, each month in the case of storing recent historical data), your COPY definition statement can use wildcards to make parsing the stored COPY statement definition more dynamic. For instance, if you store monthly data on an NFS mount, you could organize monthly files within a top-level directory for a calendar year, such as:

```
/2012/monthly_archived_data/
```

In this case, the external table COPY statement will include a wildcard definition such as the following:

```
CREATE TABLE archive_data (...) AS COPY FROM '/nfs_name/2012/monthly_archived_data/*'
```

Whenever a Vertica query references the external table `months`, and Vertica parses the `COPY` statement, all stored data tables in the top-level `monthly_archived_data` directory are made accessible to the query.

Managing Table Columns

After you define a table, you can use `ALTER TABLE` to modify existing table columns. You can perform the following operations on a column:

- [Rename it](#).
- [Change its data type](#).
- [Set its default value](#).
- [Add](#) and [remove](#) constraints.

Renaming Columns

You rename a column with `ALTER TABLE` as follows:

```
ALTER TABLE [schema.]table-name RENAME [ COLUMN ] column-name TO new-column-name
```

The following example renames a column in the `Retail.Product_Dimension` table from `Product_description` to `Item_description`:

```
=> ALTER TABLE Retail.Product_Dimension  
    RENAME COLUMN Product_description TO Item_description;
```

If you rename a column that is referenced by a view, the column does not appear in the result set of the view even if the view uses the wild card (*) to represent all columns in the table. Recreate the view to incorporate the column's new name.

Changing a Column Data Type

You can change a table column's data type with `ALTER TABLE` as long as the change complies with the requirements and restrictions cited below.

Supported Data Type Conversions

You can change a column's data type if doing so does not require storage reorganization. After you modify a column's data type, data that you load conforms to the new definition.

Vertica supports conversion between the following data types:

Data Types	Notes
Binary types	Expansion and contraction allowed. Conversion not allowed between BINARY and VARBINARY types.
Character types	All conversions allowed, including between CHAR and VARCHAR
Exact numeric types	INTEGER, INT, BIGINT, TINYINT, INT8, SMALLINT, and all NUMERIC values of scale ≤ 18 and precision 0 are interchangeable. For NUMERIC data types, you cannot alter scale, but you can change the precision in the ranges (0-18), (19-37), and so on.

You can expand columns within the same class of data type. This is useful for storing longer strings in a column. Vertica validates the data before it performs the conversion. In general, you can also reduce column widths within the data type class, as long as existing column data is no greater than the new width. For details, see [Reducing Column Width](#).

Unsupported Data Type Conversions

Vertica does not allow data type conversion on types that require storage reorganization:

- Boolean type conversion to other types
- DATE/TIME type conversion
- Approximate numeric type conversions
- Between BINARY and VARBINARY types

You also cannot change a column's data type if the column is one of the following:

- Primary key
- Foreign key

- Included in the SEGMENTED BY clause of any projection for that table.

You can work around some of these restrictions. For details, see [Working With Column Data Conversions](#).

Reducing Column Width

In general, Vertica supports reductions to column widths within the data type class, as long as existing column data is no greater than the new width. Otherwise, Vertica returns an error and the conversion fails. For example, if you try to convert a column from `varchar(25)` to `varchar(10)` Vertica allows the conversion as long as all column data is no more than 10 characters.

In the following example, columns `y` and `z` are initially defined as `VARCHAR` data types, and loaded with values `12345` and `654321`, respectively. The attempt to reduce column `z`'s width to 5 fails because it contains six-character data. The attempt to reduce column `y`'s width to 5 succeeds because its content conforms with the new width:

```
=> CREATE TABLE t (x int, y VARCHAR, z VARCHAR);
CREATE TABLE
=> CREATE PROJECTION t_p1 AS SELECT * FROM t SEGMENTED BY hash(x) ALL NODES;
CREATE PROJECTION
=> INSERT INTO t values(1,'12345','654321');
OUTPUT
-----
      1
(1 row)

=> SELECT * FROM t;
 x |  y  |  z
---+-----+-----
  1 | 12345 | 654321
(1 row)

=> ALTER TABLE t ALTER COLUMN z SET DATA TYPE char(5);
ROLLBACK 2378: Cannot convert column "z" to type "char(5)"
HINT: Verify that the data in the column conforms to the new type
=> ALTER TABLE t ALTER COLUMN y SET DATA TYPE char(5);
ALTER TABLE
```

Purging Historical Data

You cannot reduce a column's width if Vertica retains any historical data that exceeds the new width. To reduce the column width, first remove that data from the table:

1. Advance the AHM to an epoch more recent than the historical data that needs to be removed from the table.
2. Purge the table of all historical data that precedes the AHM with the function `PURGE_TABLE`.

For example, given the previous example, you can update the data in column `t.z` as follows:

```
=> UPDATE t SET z = '54321';
OUTPUT
-----
      1
(1 row)

=> SELECT * FROM t;
 x | y | z
-----+-----
 1 | 12345 | 54321
(1 row)
```

Although no data in column `z` now exceeds 5 characters, Vertica retains the history of its earlier data, so attempts to reduce the column width to 5 return an error:

```
=> ALTER TABLE t ALTER COLUMN z SET DATA TYPE char(5);
ROLLBACK 2378: Cannot convert column "z" to type "char(5)"
HINT: Verify that the data in the column conforms to the new type
```

You can reduce the column width by purging the table's historical data as follows:

```
=> SELECT MAKE_AHM_NOW();
      MAKE_AHM_NOW
-----
AHM set (New AHM Epoch: 6350)
(1 row)

=> SELECT PURGE_TABLE('t');
                                     PURGE_TABLE
-----
Task: purge operation
(Table: public.t) (Projection: public.t_p1_b0)
(Table: public.t) (Projection: public.t_p1_b1)

(1 row)

=> ALTER TABLE t ALTER COLUMN z SET DATA TYPE char(5);
ALTER TABLE
```

Working With Column Data Conversions

Vertica conforms to the SQL standard by disallowing certain data conversions for table columns. However, you sometimes need to work around this restriction when you convert data

from a non-SQL database. The following examples describe one such workaround, using the following table:

```
=> CREATE TABLE sales(id INT, price VARCHAR) UNSEGMENTED ALL NODES;
CREATE TABLE
=> INSERT INTO sales VALUES (1, '$50.00');
OUTPUT
-----
      1
(1 row)

=> INSERT INTO sales VALUES (2, '$100.00');
OUTPUT
-----
      1
(1 row)

=> COMMIT;
COMMIT

=> SELECT * FROM SALES;
 id | price
-----+-----
  1 | $50.00
  2 | $100.00
(2 rows)
```

To convert the price column's existing data type from VARCHAR to NUMERIC, complete these steps:

1. [Add a new column for temporary use](#). Assign the column a NUMERIC data type, and derive its default value from the existing price column.
2. [Drop the original price column](#).
3. [Rename the new column to the original column](#).

Add a new column for temporary use

1. Add a column `temp_price` to table `sales`. You can use the new column temporarily, setting its data type to what you want (NUMERIC), and deriving its default value from the `price` column. Cast the default value for the new column to a NUMERIC data type and query the table:

```
=> ALTER TABLE sales ADD COLUMN temp_price NUMERIC(10,2) DEFAULT
SUBSTR(sales.price, 2)::NUMERIC;
ALTER TABLE

=> SELECT * FROM SALES;
 id | price | temp_price
```

```
-----+-----+-----  
1 | $50.00 | 50.00  
2 | $100.00 | 100.00  
(2 rows)
```

2. Use `ALTER TABLE` to drop the default expression from the new column `temp_price`. Vertica retains the values stored in this column:

```
=> ALTER TABLE sales ALTER COLUMN temp_price DROP DEFAULT;  
ALTER TABLE
```

Drop the original price column

Drop the extraneous `price` column. Before doing so, you must first advance the AHM to purge historical data that would otherwise prevent the drop operation:

1. Advance the AHM:

```
=> SELECT MAKE_AHM_NOW();  
MAKE_AHM_NOW  
-----  
AHM set (New AHM Epoch: 6354)  
(1 row)
```

2. Drop the original price column:

```
=> ALTER TABLE sales DROP COLUMN price CASCADE;  
ALTER COLUMN
```

Rename the new column to the original column

You can now rename the `temp_price` column to `price`:

1. Use `ALTER TABLE` to rename the column:

```
=> ALTER TABLE sales RENAME COLUMN temp_price to price;
```

2. Query the sales table again:

```
=> SELECT * FROM sales;  
id | price  
-----  
1 | 50.00
```

```
2 | 100.00  
(2 rows)
```

Changing Column Types in External Tables

Data from external tables is not stored in Vertica, so Vertica cannot validate any changes that you make in column data types. Vertica checks external table definitions only when it tries to read table data. If external column data is incompatible with the data type that is declared in the Vertica table, Vertica returns an error.

For example:

```
=> CREATE EXTERNAL TABLE t (a char(10), b binary(20)) AS COPY FROM '...';  
=> ALTER TABLE t ALTER COLUMN a SET DATA TYPE long varchar(1000000);  
ALTER TABLE  
=> ALTER TABLE t ALTER COLUMN b SET DATA TYPE long varbinary(1000000);  
ALTER TABLE
```

If you convert a column to a size that is too small for the data, Vertica truncates the data during the read. For example, if you convert a column from `varchar(25)` to `varchar(10)` and the column holds a 20-character string, Vertica reads the first ten and logs a truncation event.

Defining Column Values

You can define a column so Vertica automatically sets its value from an expression through one of the following clauses:

<code>DEFAULT <i>expression</i></code>	<p>Sets the default column values immediately in the following cases:</p> <ul style="list-style-type: none">• Adding a column with a DEFAULT expression to an existing table. Vertica populates the new column with its default values when it is added to the table. <p>Note: Altering an existing table column to specify a DEFAULT expression has no effect on existing values in that column. Vertica applies the DEFAULT expression only on new rows when they are added to the table, through load operations such as INSERT and COPY. To refresh the</p>
--	--

	<p>entire column with its DEFAULT expression, update the column as follows:</p> <pre>UPDATE table-name SET column-name=DEFAULT;</pre> <ul style="list-style-type: none">• Executing a table load operation such as INSERT. Vertica populates columns with default values in the new rows. Values in existing rows, including columns with DEFAULT expressions, remain unchanged.• Executing UPDATE on a table and setting default column to DEFAULT. See the example below.
<p>SET USING <i>expression</i></p>	<p>Sets the column value only when the function REFRESH_COLUMNS is invoked. This approach is especially useful for large denormalized (flattened) tables, where multiple columns get their values by querying other tables. For details, see Flattened Tables.</p> <p>In general, REFRESH_COLUMNS must be explicitly invoked by the user. One exception applies: when you use ALTER TABLE . . . ALTER COLUMN to apply SET USING to an existing column, or modify an existing SET USING expression. In this case, the DDL operation automatically invokes REFRESH_COLUMNS on the column, using UPDATE mode. After the refresh operation is complete, the DDL operation auto-commits the updates and returns. If the refresh operation fails, Vertica rolls back the entire DDL operation. Execution time can be significant if the refresh operation involves a large data set.</p>

Supported Expressions

DEFAULT and SET USING generally support the same expressions. These include:

- Queries (see [Flattened Tables](#))
- Other columns in the same table
- [Literals](#) (constants)
- All [operators](#) supported by Vertica

- The following categories of functions:
 - [Null-handling](#)
 - [User-defined scalar](#)
 - [System information](#)
 - [String](#)
 - [Mathematical](#)
 - [Formatting](#)

Expression Restrictions

The following restrictions apply to `DEFAULT` and `SET USING` expressions:

- The return value data type must match or be cast to the column data type.
- The expression must return a value that conforms to the column bounds. For example, a column that is defined as a `VARCHAR(1)` cannot be set to a default string of `abc`.
- The expression cannot specify correlated sub-queries.
- In a temporary table, `DEFAULT` and `SET USING` do not support sub-queries. If you try to create a temporary table with `DEFAULT` or `SET USING` using subquery expressions, Vertica returns an error.
- A column's `SET USING` expression cannot specify another column in the same table that also sets its value with `SET USING`. Similarly, a column's `DEFAULT` expression cannot specify another column in the same table that also sets its value with `DEFAULT`, or whose value is automatically set to a [sequence](#). However, a column's `SET USING` expression can specify another column that sets its value with `DEFAULT`.

Note: You can set a column's `DEFAULT` expression from another column in the same table that sets its value with `SET USING`. However, the `DEFAULT` column is typically set to `NULL`, as it is only set on load operations that initially set the `SET USING` column to `NULL`.

DEFAULT Restrictions

`DEFAULT` expressions cannot specify volatile functions with `ALTER TABLE...ADD COLUMN`. To specify volatile functions, use `CREATE TABLE` or `ALTER TABLE...ALTER COLUMN` statements.

SET USING Restrictions

The following restrictions apply to SET USING expressions:

- Volatile functions are not allowed.
- The expression cannot specify a sequence.
- You cannot modify SET USING data directly with DML operations such as COPY, INSERT, UPDATE, or MERGE. SET USING columns can only be updated by calling [REFRESH_COLUMNS](#). Attempts to modify SET USING columns return an error.
- Vertica limits the use of several meta-functions that copy table data: [COPY_TABLE](#), [COPY_PARTITIONS_TO_TABLE](#), [MOVE_PARTITIONS_TO_TABLE](#), and [SWAP_PARTITIONS_BETWEEN_TABLES](#). The following table describes these limitations:

SET USING columns in...	Limitation
Source and target table	All functions allowed only if each SET USING column in source table has an identical match in the target table
Source table only	<p>Allowed functions:</p> <ul style="list-style-type: none"> ■ COPY_TABLE ■ COPY_PARTITIONS_TO_TABLE ■ MOVE_PARTITIONS_TO_TABLE <p>Disallowed: SWAP_PARTITIONS_BETWEEN_TABLES</p> <p>The same set of restrictions apply if the target table is new.</p>
Target table only	No functions allowed.

Important: Several restrictions apply to Vertica's ability to refresh a SET USING column with [REFRESH_COLUMNS](#). For details, see [REFRESH_COLUMNS](#).

DEFAULT USING Columns and Restrictions

A column can specify both DEFAULT and SET USING constraints, as follows:

```
column-name data-type DEFAULT default-expr SET USING using-expr
```

Typically, both constraints specify the same expression. In this case, you can define the column as follows:

```
column-name data-type DEFAULT USING expression
```

DEFAULT USING columns support the same expressions as SET USING columns, and are subject to the same [restrictions](#).

Examples

Default column value derived from another column

1. Create a sample table called `t` with `timestamp`, `integer`, and `varchar(10)` columns:

```
=> CREATE TABLE t (a TIMESTAMP, b INT, c VARCHAR(10));
CREATE TABLE
=> INSERT INTO t VALUES ('2012-05-14 10:39:25', 2, 'MA');
OUTPUT
-----
      1
(1 row)
```

2. Use `ALTER TABLE` to add a fourth column that extracts the month from the timestamp value in column `a`:

```
=> ALTER TABLE t ADD COLUMN d INTEGER DEFAULT EXTRACT(MONTH FROM a);
ALTER TABLE
```

3. Verify this change:

```
select export_tables('', 't');
                                export_tables
-----
CREATE TABLE public.t
(
  a timestamp,
  b int,
  c varchar(10),
  d int DEFAULT date_part('month', t.a)
);
```

4. Query table `t`:

```
=> select * from t;
      a          | b | c | d
-----+-----+-----+-----
2012-05-14 10:39:25 | 2 | MA | 5
(1 row)
```

Column d returns integer 5 (month of May).

Default column value derived from user-defined scalar function

This example shows a user-defined scalar function that adds two integer values. The function is called `add2ints` and takes two arguments.

1. Develop and deploy the function, as described in [Scalar Functions \(UDSFs\)](#).
2. Create a sample table, `t1`, with two integer columns:

```
=> CREATE TABLE t1 ( x int, y int );  
CREATE TABLE
```

3. Insert some values into `t1`:

```
=> insert into t1 values (1,2);  
OUTPUT  
-----  
      1  
(1 row)  
=> insert into t1 values (3,4);  
OUTPUT  
-----  
      1  
(1 row)
```

4. Use `ALTER TABLE` to add a column to `t1`, with the default column value derived from the UDSF `add2ints`:

```
alter table t1 add column z int default add2ints(x,y);  
ALTER TABLE
```

5. List the new column:

```
select z from t1;  
z  
----  
  3  
  7  
(2 rows)
```

Table with a `SET USING` column that queries another table for its values

1. Define tables `t1` and `t2`. Column `t2.b` is defined to get its data from column `t1.b`, through the query in its `SET USING` clause:

```
=> CREATE TABLE t1 (a INT PRIMARY KEY ENABLED, b INT);
CREATE TABLE

=> CREATE TABLE t2 (a INT, alpha VARCHAR(10), b INT SET USING (SELECT t1.b FROM t1 WHERE
t1.a=t2.a))
ORDER BY a SEGMENTED BY HASH(a) ALL NODES;
CREATE TABLE
```

Important: The definition for table t2 includes `SEGMENTED BY` and `ORDER BY` clauses that exclude `SET USING` column b. If these clauses are omitted, Vertica creates an [auto-projection](#) for this table that specifies column b in its `SEGMENTED BY` and `ORDER BY` clauses. Inclusion of a `SET USING` column in any projection's segmentation or sort order prevents function `REFRESH_COLUMNS` from populating this column. Instead, it returns with an error.

For details on this and other restrictions, see [REFRESH_COLUMNS](#).

2. Populate the tables with data:

```
=> INSERT INTO t1 VALUES(1,11);
=> INSERT INTO t1 VALUES(2,22);
=> INSERT INTO t1 VALUES(3,33);
=> INSERT INTO t1 VALUES(4,44);
=> INSERT INTO t2 VALUES(1, 'aa');
=> INSERT INTO t2 VALUES(2, 'bb');
=> COMMIT;
COMMIT
```

3. View the data in table t2: Column in `SET USING` column b is empty, pending invocation of Vertica function `REFRESH_COLUMNS`:

```
=> SELECT * FROM t2;
 a | alpha | b
---+-----+---
 1 | aa    |
 2 | bb    |
(2 rows)
```

4. Refresh the column data in table t2 by calling function `REFRESH_COLUMNS`:

```
=> SELECT REFRESH_COLUMNS ('t2','b', 'REBUILD');
REFRESH_COLUMNS
-----
refresh_columns completed
(1 row)
```

In this example, `REFRESH_COLUMNS` is called with the optional argument `REBUILD`. This argument specifies to replace all data in `SET USING` column b. It is generally good practice

to call `REFRESH_COLUMNS` with `REBUILD` on any new `SET USING` column. For details, see [REFRESH_COLUMNS](#).

5. View data in refreshed column `b`, whose data is obtained from table `t1` as specified in the column's `SET USING` query:

```
=> SELECT * FROM t2 ORDER BY a;  
a | alpha | b  
-----  
1 | aa    | 11  
2 | bb    | 22  
(2 rows)
```

Altering Table Definitions

Using `ALTER TABLE` syntax, you can respond to your evolving database schema requirements. The ability to change the definition of existing database objects facilitates ongoing maintenance. Furthermore, most of these options are both fast and efficient for large tables, because they consume fewer resources and less storage than having to stage data in a temporary table.

`ALTER TABLE` lets you perform the following table-level changes:

- [Add](#) and [drop](#) table columns.
- [Rename a table](#).
- [Add](#) and [drop](#) constraints.
- [Alter key constraint enforcement](#).
- [Move a table to a new schema](#).
- [Change a table owner](#).
- [Change and reorganize table partitions](#).

`ALTER TABLE` has an `ALTER COLUMN` clause that lets you modify column definitions—for example, change their name or data type. For column-level changes, see [Managing Table Columns](#).

Exclusive ALTER TABLE Clauses

The following ALTER TABLE clauses are exclusive: you cannot combine them with another ALTER TABLE clause:

- ADD COLUMN
- RENAME COLUMN
- SET SCHEMA
- PARTITION BY
- REORGANIZE
- REMOVE PARTITIONING
- RENAME [TO]
- OWNER TO

Note: You can use the ADD constraints and DROP constraints clauses together.

Using Consecutive ALTER TABLE Commands

With the exception of performing a table rename, complete ALTER TABLE statements consecutively. For example, to add multiple columns to a table, issue consecutive ALTER TABLE ADD COLUMN statements.

External Table Restrictions

Not all ALTER TABLE options pertain to external tables. For instance, you cannot add a column to an external table, but you can rename the table:

```
=> ALTER TABLE mytable RENAME TO mytable2;  
ALTER TABLE
```

Restoring to an Earlier Epoch

If you restore the database to an epoch that precedes changes to the table definition, the restore operation reverts the table to the earlier definition. For example, if you change a column's data type from CHAR(8) to CHAR(16) in epoch 10, and then restore the database from epoch 5, the column reverts to CHAR(8) data type.

Adding Table Columns

You add a column to a persistent table with the `ALTER TABLE` clause `ADD COLUMN`:

```
ALTER TABLE
...
ADD COLUMN column-name datatype
    [column-constraint]
    [ENCODING encoding-type]
    [RESTRICT | CASCADE]
    [PROJECTIONS (projection-name [,...]) ]
```

Note: Before you can add columns to a table, all superprojections that are anchored to it must be up to date.

Default Add Operations

When you update a table with a new columns, Vertica always executes the following actions:

- Refreshes existing rows with their default values. For example, if you set a column's default expression to `CURRENT_TIMESTAMP`, Vertica updates all rows with the current timestamp.
- Adds the column to all superprojections that are anchored to the updated table.

Table Locking

When you use `ADD COLUMN` to alter a table, Vertica takes an O lock on the table until the operation completes. The lock prevents `DELETE`, `UPDATE`, `INSERT`, and `COPY` statements from accessing the table. The lock also blocks `SELECT` statements issued at `SERIALIZABLE` isolation level, until the operation completes.

If you use `CASCADE`, Vertica also takes O locks on all anchor tables of any pre-join projections associated with the target table. Consequently, `SELECT` statements issued on those tables at `SERIALIZABLE` isolation level are blocked until the operation completes.

Adding a column to a table does not affect K-safety of the physical schema design.
You can add columns when nodes are down.

Using the PROJECTIONS Option to Add New Columns to Projections

When you add a new column to a table, you can use the PROJECTIONS option to simultaneously add the new column to one or more existing projections.

Note: The PROJECTIONS option accepts the base name of a projection. When you specify the base name, Vertica updates the projection along with any buddy projections.

The following example creates a table and projection, and adds a new column to the table and to the projection.

1. Create a sample table and add content.

```
=> CREATE TABLE t1 (col1 int, col2 int, col3 int);  
=> INSERT INTO t1 VALUES (1, 2, 3);  
=> INSERT INTO t1 VALUES (4, 5, 6);
```

2. Create a projection.

```
=> CREATE PROJECTION myproj (col1) AS SELECT col1 FROM t1;
```

3. Add a new column to the table, simultaneously adding the column to the existing projection.

```
=> ALTER TABLE t1 ADD COLUMN newcol INT PROJECTIONS(myproj);
```

4. Check that the new column is included in the projection.

```
=> SELECT table_name, table_column_name, projection_name FROM projection_columns WHERE  
projection_name LIKE 'myproj%';
```

table_name	table_column_name	projection_name
t1	col1	myproj_b0
t1	col1	myproj_b1
t1	newcol	myproj_b0
t1	newcol	myproj_b1

(4 rows)

The following example adds a new column and defines the column with a column-constraint DEFAULT expression. (For details about expressions, see [Defining Column Values](#).) When you include a DEFAULT expression, the columns that you reference in the expression must have already been included in the existing projection. If the columns from the table you are altering are referenced in the expression, but were not included in the existing projection, Vertica rolls back. The following example illustrates.

1. Create two tables and add content.

```
=> CREATE TABLE dimension (pk INT, val INT, colx INT);
=> CREATE TABLE fact (pk INT, fk INT, cols INT);
=> INSERT INTO dimension VALUES (1, 2, 3);
=> INSERT INTO fact VALUES (4, 5, 6);
```

2. Create a projection that includes the pk column from the table fact.

```
=> CREATE PROJECTION fact_pk AS SELECT pk FROM fact;
```

3. Attempt to add a new column to the table fact. Note that the sample references the column fact.fk, which is not included in the existing projection. Vertica rolls back.

```
=> ALTER TABLE fact ADD COLUMN val INT
  DEFAULT (SELECT val FROM dimension WHERE dimension.pk = fact.fk) PROJECTIONS (fact_pk);
ROLLBACK 7871: Projection "public.fact_pk_b0" refers to column "fk" referenced in the added
column's default expression
```

What follows is the same example, but in this case the projection includes both columns.

1. Create a sample table and add content.

```
=> CREATE TABLE t1 (col1 int, col2 int, col3 int);
=> INSERT INTO t1 VALUES (1, 2, 3);
=> INSERT INTO t1 VALUES (4, 5, 6);
```

2. Create a projection that includes both the pk and fk columns from the table fact.

```
=> CREATE PROJECTION fact_pk AS SELECT pk, fk FROM fact;
```

3. Add the new column using a column-constraint DEFAULT expression.

```
=> ALTER TABLE fact ADD COLUMN val INT
  DEFAULT (SELECT val FROM dimension WHERE dimension.pk = fact.fk) PROJECTIONS (fact_pk);
```

4. Check that the new column val is included in the projection.

```
=> SELECT table_name, table_column_name, projection_name FROM projection_columns WHERE  
projection_name LIKE 'fact_pk%';
```

table_name	table_column_name	projection_name
fact	pk	fact_pk_b0
fact	pk	fact_pk_b1
fact	fk	fact_pk_b0
fact	fk	fact_pk_b1
fact	val	fact_pk_b0
fact	val	fact_pk_b1

Updating Associated Table Views

Adding new columns to a table that has an associated view does not update the view's result set, even if the view uses a wildcard (*) to represent all table columns. To incorporate new columns, you must [recreate the view](#).

Dropping Table Columns

When an ALTER TABLE statement includes a DROP COLUMN clause to drop a column, Vertica drops the specified column from the table and the ROS containers that correspond to the dropped column.

The syntax looks like this:

```
ALTER TABLE [schema.]table-name DROP [ COLUMN ] column-name [ CASCADE | RESTRICT ]
```

After a DROP COLUMN operation completes, data backed up from the current epoch onward recovers without the column. Data recovered from a backup that precedes the current epoch re-add the table column. Because drop operations physically purge object storage and catalog definitions (table history) from the table, AT EPOCH (historical) queries return nothing for the dropped column.

The altered table retains its object ID.

Note: Drop column operations can be fast because these catalog-level changes do not require data reorganization, so Vertica can quickly reclaim disk storage.

Restrictions

- You cannot drop or alter a primary key column or a column that participates in the table partitioning clause.

- You cannot drop the first column of any projection sort order, or columns that participate in a projection segmentation expression.
- All nodes must be up.
- You cannot drop a column associated with an access policy. Attempts to do so produce the following error:
ERROR 6482: Failed to parse Access Policies for table "t1"

Using CASCADE to Force a Drop

If the table column to drop has dependencies, you must qualify the `DROP COLUMN` clause with the `CASCADE` option. For example, the target column might be specified in a projection sort order. In this and other cases, `DROP COLUMN . . CASCADE` handles the dependency by reorganizing catalog definitions or dropping a projection. In all cases, `CASCADE` performs the minimal reorganization required to drop the column.

Use `CASCADE` to drop a column with the following dependencies:

Dropped column dependency	CASCADE behavior
Any constraint	Vertica drops the column when a FOREIGN KEY constraint depends on a UNIQUE or PRIMARY KEY constraint on the referenced columns.
Specified in projection sort order	Vertica truncates projection sort order up to and including the projection that is dropped without impact on physical storage for other columns and then drops the specified column. For example if a projection's columns are in sort order (a,b,c), dropping column b causes the projection's sort order to be just (a), omitting column (c).
Specified in one of the following: <ul style="list-style-type: none"> • Pre-join projection • Projection segmentation expression 	<p>In both cases, the column to drop is integral to the projection definition. If possible, Vertica drops the projections as long as doing so does not compromise K-safety; otherwise, the transaction rolls back.</p> <p>For example, a table has multiple projections, where one projection's segmentation clause specifies the target column. Vertica tries to drop this projection, unless doing so violates K-safety. In this case, the transaction rolls back.</p>

Dropped column dependency	CASCADE behavior
Referenced as default value of another column	See Dropping a Column Referenced as Default , below.

Dropping a Column Referenced as Default

You might want to drop a table column that is referenced by another column as its default value. For example, the following table is defined with two columns, a and b;, where b gets its default value from column a:

```
=> CREATE TABLE x (a int) UNSEGMENTED ALL NODES;  
CREATE TABLE  
=> ALTER TABLE x ADD COLUMN b int DEFAULT a;  
ALTER TABLE
```

In this case, dropping column a requires the following procedure:

1. Remove the default dependency through ALTER COLUMN. .DROP DEFAULT:

```
=> ALTER TABLE x ALTER COLUMN b DROP DEFAULT;
```

2. Create a replacement superprojection for the target table if one or both of the following conditions is true:
 - The target column is the table's first sort order column. If the table has no explicit sort order, the default table sort order specifies the first table column as the first sort order column. In this case, the new superprojection must specify a sort order that excludes the target column.
 - If the table is segmented, the target column is specified in the segmentation expression. In this case, the new superprojection must specify a segmentation expression that excludes the target column.

Given the previous example, table x has a default sort order of (a,b). Because column a is the table's first sort order column, you must create a replacement superprojection that is sorted on column b:

```
=> CREATE PROJECTION x_p1 as select * FROM x ORDER BY b UNSEGMENTED ALL NODES;
```

3. Run `START_REFRESH`:

```
=> SELECT START_REFRESH();
          START_REFRESH
-----
Starting refresh background process.

(1 row)
```

4. Run `MAKE_AHM_NOW`:

```
=> SELECT MAKE_AHM_NOW();
          MAKE_AHM_NOW
-----
AHM set (New AHM Epoch: 1231)

(1 row)
```

5. Drop the column:

```
=> ALTER TABLE x DROP COLUMN a CASCADE;
```

Vertica implements the `CASCADE` directive as follows:

- Drops the original superprojection for table `x` (`x_super`).
- Updates the replacement superprojection `x_p1` by dropping column `a`.

Examples

The following series of commands successfully drops a `BYTEA` data type column:

```
=> CREATE TABLE t (x BYTEA(65000), y BYTEA, z BYTEA(1));
CREATE TABLE
=> ALTER TABLE t DROP COLUMN y;
ALTER TABLE
=> SELECT y FROM t;
ERROR 2624: Column "y" does not exist
=> ALTER TABLE t DROP COLUMN x RESTRICT;
ALTER TABLE
=> SELECT x FROM t;
ERROR 2624: Column "x" does not exist
=> SELECT * FROM t;
  z
---
(0 rows)
=> DROP TABLE t CASCADE;
DROP TABLE
```

The following series of commands tries to drop a FLOAT(8) column and fails because there are not enough projections to maintain K-safety.

```
=> CREATE TABLE t (x FLOAT(8),y FLOAT(08));  
CREATE TABLE  
=> ALTER TABLE t DROP COLUMN y RESTRICT;  
ALTER TABLE  
=> SELECT y FROM t;  
ERROR 2624: Column "y" does not exist  
=> ALTER TABLE t DROP x CASCADE;  
ROLLBACK 2409: Cannot drop any more columns in t  
=> DROP TABLE t CASCADE;
```

Altering Constraint Enforcement

To alter how Vertica enforces constraints, use the [ALTER TABLE](#) clause ALTER CONSTRAINT. You must qualify this clause with the keyword ENABLED or DISABLED:

- ENABLED automatically enforces a primary key, unique key or check constraint.
- DISABLED prevents automatic enforcement of a primary key, unique key or check constraint.

For more information on automatic constraint enforcement, see [Enforcing Primary Key, Unique Key, and Check Constraints Automatically](#)

If you disable automatic enforcement of primary or unique key constraints, you can instead run [ANALYZE_CONSTRAINTS](#) to verify that columns have unique values after running a DML command or bulk loading. In the case of check constraints, you can use ANALYZE_CONSTRAINTS to validate check constraint conditions.

See [About Constraints](#) for general information about constraints.

Renaming Tables

The ALTER TABLE RENAME TO statement lets you rename one or more tables. Renaming tables does not change the table OID.

You rename multiple tables by supplying two comma-delimited lists. Vertica maps the names according to their order in the two lists. Only the first list can qualify table names with a schema. For example:

```
=> ALTER TABLE S1.T1, S1.T2 RENAME TO U1, U2;
```

The `RENAME TO` parameter is applied atomically : all tables are renamed, or none of them. For example, if the number of tables to rename does not match the number of new names, none of the tables is renamed.

Note: Renaming a table referenced by a view causes the view to fail, unless you create another table with the previous name to replace the renamed table.

Using Rename to Swap Tables Within a Schema

You can use `ALTER TABLE RENAME TO` to swap tables within the same schema, without actually moving data. You cannot swap tables across schemas.

To swap tables within a schema (example statement is split to explain steps):

1. Enter the names of the tables to swap, followed by a new temporary table placeholder (temps):

```
=> ALTER TABLE T1, T2, temps
```

2. Use the `RENAME TO` clause to swap the tables: T1 to temps, T2 to T1, and temps to T2:

```
RENAME TO temps, T1, T2;
```

Moving Tables to Another Schema

The `ALTER TABLE` clause `SET SCHEMA` moves a table from one schema to another. Vertica automatically moves all projections that are anchored to the source table to the destination schema.

Moving a table across schemas requires that you have `USAGE` privileges on the current schema and `CREATE` privileges on destination schema. You can move only one table between schemas at a time. You cannot move temporary tables across schemas.

Name Conflicts

If a table of the same name or any of the projections that you want to move already exist in the new schema, the statement rolls back and does not move either the table or any projections.

To work around name conflicts:

1. Rename any conflicting table or projections that you want to move.
2. Run the `ALTER TABLE SET SCHEMA` statement again.

Note: Vertica lets you move system tables to system schemas. Moving system tables could be necessary to support designs created through the Database Designer.

Example

The following example moves table T1 from schema S1 to schema S2. All projections that are anchored on table T1 automatically move to schema S2:

```
=> ALTER TABLE S1.T1 SET SCHEMA S2;
```

Changing Table Ownership

As a superuser or table owner, you can reassign table ownership with `ALTER TABLE`, as follows:

```
ALTER TABLE [schema.]table-name OWNER TO owner-name
```

Changing table ownership is useful when moving a table from one schema to another. Ownership reassignment is also useful when a table owner leaves the company or changes job responsibilities. Because you can change the table owner, the tables won't have to be completely rewritten, you can avoid loss in productivity.

Changing table ownership automatically causes the following changes:

- Grants on the table that were made by the original owner are dropped and all existing privileges on the table are revoked from the previous owner. Changes in table ownership has no effect on schema privileges.
- Ownership of dependent `IDENTITY/AUTO-INCREMENT` sequences are transferred with the table. However, ownership does not change for independent sequences created with `CREATE SEQUENCE`. To transfer ownership of these sequences, use `ALTER SEQUENCE`.
- New table ownership is propagated to its projections.

Example

In this example, user Bob connects to the database, looks up the tables, and transfers ownership of table t33 from himself to user Alice.

```
=> \c - Bob
You are now connected as user "Bob".
=> \d
 Schema | Name | Kind | Owner | Comment
-----+-----+-----+-----+-----
 public | applog | table | dbadmin |
 public | t33   | table | Bob    |
(2 rows)
=> ALTER TABLE t33 OWNER TO Alice;
ALTER TABLE
```

Notice that when Bob looks up database tables again, he no longer sees table t33.

```
=> \d
          List of tables
          List of tables
 Schema | Name | Kind | Owner | Comment
-----+-----+-----+-----+-----
 public | applog | table | dbadmin |
(1 row)
```

When user Alice connects to the database and looks up tables, she sees she is the owner of table t33.

```
=> \c - Alice
You are now connected as user "Alice".
=> \d
          List of tables
 Schema | Name | Kind | Owner | Comment
-----+-----+-----+-----+-----
 public | t33  | table | Alice |
(2 rows)
```

Either Alice or a superuser can transfer table ownership back to Bob. In the following case a superuser performs the transfer.

```
=> \c - dbadmin
You are now connected as user "dbadmin".
=> ALTER TABLE t33 OWNER TO Bob;
ALTER TABLE
=> \d
          List of tables
 Schema | Name | Kind | Owner | Comment
-----+-----+-----+-----+-----
 public | applog | table | dbadmin |
 public | comments | table | dbadmin |
 public | t33   | table | Bob    |
 s1    | t1    | table | User1  |
```

(4 rows)

You can also query system table [V_CATALOG.TABLES](#) to view table and owner information. Note that a change in ownership does not change the table ID.

In the below series of commands, the superuser changes table ownership back to Alice and queries the TABLES system table.

```
=> ALTER TABLE t33 OWNER TO Alice;
ALTER TABLE
=> SELECT table_schema_id, table_schema, table_id, table_name, owner_id, owner_name FROM tables;
table_schema_id | table_schema | table_id | table_name | owner_id | owner_name
-----+-----+-----+-----+-----+-----
45035996273704968 | public | 45035996273713634 | applog | 45035996273704962 | dbadmin
45035996273704968 | public | 45035996273724496 | comments | 45035996273704962 | dbadmin
45035996273730528 | s1 | 45035996273730548 | t1 | 45035996273730516 | User1
45035996273704968 | public | 45035996273795846 | t33 | 45035996273724576 | Alice
(5 rows)
```

Now the superuser changes table ownership back to Bob and queries the TABLES table again. Nothing changes but the owner_name row, from Alice to Bob.

```
=> ALTER TABLE t33 OWNER TO Bob;
ALTER TABLE
=> SELECT table_schema_id, table_schema, table_id, table_name, owner_id, owner_name FROM tables;
table_schema_id | table_schema | table_id | table_name | owner_id | owner_name--
-----+-----+-----+-----+-----+-----
45035996273704968 | public | 45035996273713634 | applog | 45035996273704962 | dbadmin
45035996273704968 | public | 45035996273724496 | comments | 45035996273704962 | dbadmin
45035996273730528 | s1 | 45035996273730548 | t1 | 45035996273730516 | User1
45035996273704968 | public | 45035996273793876 | foo | 45035996273724576 | Alice
45035996273704968 | public | 45035996273795846 | t33 | 45035996273714428 | Bob
(5 rows)
```

[Changing Sequence Ownership](#)

Working with Sequence Types

Vertica supports these types of incrementing values:

- **Auto-increment or Identity column:** The Auto-increment and Identity types are identical. They are basic incrementing numeric column types that the database increments automatically.
- **Named sequences:** A named sequence is a database object that generates unique numbers in ascending or descending sequential order.

You define Auto-increment and Identity sequences through [column constraints](#) in the [CREATE TABLE](#) statement. These sequences are incremented each time a row is added to the table. Both of these sequence object types are table-dependent and do not persist independently. Vertica does not roll back an identity value even if a transaction that tries to insert a value is not committed. The [LAST_INSERT_ID](#) function returns the last value generated for an auto-increment or identity column.

Each type of sequence value has a set of properties. A named sequence has the most properties, and an Auto-increment sequence the least. The following table lists the differences between the three sequence values:

Behavior	Named Sequence	Identity	Auto-increment
Default cache value 250K	X	X	X
Set initial cache	X	X	X
Define start value	X	X	X
Specify increment unit	X	X	X
Exists as an independent object	X		
Exists only as part of table		X	X
Create as column constraint		X	X
Requires name	X		
Use in expressions	X		
Unique across tables	X		

Behavior	Named Sequence	Identity	Auto-increment
Change parameters	X		
Move to different schema	X		
Set to increment or decrement	X		
Grant privileges to object	X		
Specify minimum value	X		
Specify maximum value	X		

Note: While sequence object values are guaranteed to be unique, they are not guaranteed to be contiguous. Since sequences are not necessarily contiguous, you may interpret the returned values as missing. For example, two nodes can increment a sequence at different rates. The node with a heavier processing load increments the sequence, but the values are not contiguous with those being incremented on a node with less processing.

Using Named Sequences

You use named sequences most often when an application requires a unique identifier in a table or an expression. Once a named sequence returns a value, it never returns that same value again in the same session. Named sequences are independent objects. While you can use their values in tables, they are not subordinate to the tables in which you use the named sequences.

This section includes:

- [Creating and Instantiating Named Sequences](#)
- [Distributing Named Sequences](#)
- [Altering Sequences](#)
- [Changing Sequence Ownership](#)
- [Dropping Sequences](#)

Creating and Instantiating Named Sequences

You create a named sequence with `CREATE SEQUENCE`. The statement requires only a sequence name; all other parameters are optional.

The following example creates an ascending named sequence, `my_seq`, starting at the value 100:

```
=> create sequence my_seq START 100;  
CREATE SEQUENCE
```

After creating a sequence, call the function `NEXTVAL` at least once in a session to create a cache for the sequence and its initial value. Subsequently, use `NEXTVAL` to increment the sequence value. Call the function `CURRVAL` to get the current value.

The following call to `NEXTVAL` instantiates the newly-created `my_seq` sequence and sets its first number:

```
=> SELECT NEXTVAL('my_seq');  
nextval  
-----  
      100  
(1 row)
```

If you call `CURRVAL` before `NEXTVAL`, the system returns an error:

```
dbt=> SELECT CURRVAL('my_seq');  
ERROR 4700: Sequence my_seq has not been accessed in the session
```

You can use a sequence as part of creating a table. The sequence must already exist, and have been instantiated using the `NEXTVAL` statement.

Update sequence number values by calling the `NEXTVAL` function, which increments/decrements the current sequence and returns the next value. Use `CURRVAL` to return the current value. These functions can also be used in `INSERT` and `COPY` expressions.

The following example shows creation of a simple table including a named sequence. Table creation is followed by an insert into the table using the sequence as the default value for the column `ID`:

```
CREATE TABLE customer2(  
  ID INTEGER DEFAULT NEXTVAL('my_seq'),  
  lname VARCHAR(25),  
  fname VARCHAR(25),  
  membership_card INTEGER  
);  
INSERT INTO customer2 VALUES (default, 'Carr', 'Mary', 87432);
```

Now query the table you just created. The column named ID has been incremented by (1) again to 104:

```
SELECT * FROM customer2;
 ID | lname | fname | membership_card
-----+-----+-----+-----
 104 | Carr  | Mary  |                87432
(1 row)
```

Using Named Sequence Functions

When you create a named sequence object, you can also specify its increment or decrement value. The default is 1.

Use these functions with named sequences:

- **NEXTVAL** advances the sequence and returns the next value. The value is incremented for ascending sequences and decremented for descending. The first time you call NEXTVAL after creating a named sequence, the function sets up the default or specified amount of cache on each cluster node. From its cache store, each node returns either the default sequence value, or a start number you specified with CREATE SEQUENCE.
- **CURRVAL** returns the last value that the previous invocation of NEXTVAL returned in the current session. If there were no calls to NEXTVAL after creating a sequence, the CURRVAL function returns an error:

```
dbt=> create sequence seq2;
CREATE SEQUENCE
dbt=> select currval('seq2');
ERROR 4700: Sequence seq2 has not been accessed in the session
```

Using DDL Statements with Named Sequences

The table that follows lists the statements you use specifically for named sequences.

Use this statement...	To...
CREATE SEQUENCE	Create a named sequence object.
ALTER SEQUENCE	Alter named sequence parameters, rename a sequence within a schema, or move a named sequence between schemas.
DROP SEQUENCE	Remove a named sequence object.
GRANT SEQUENCE	Grant user privileges to a named sequence object. See also Sequence Privileges .

Distributing Named Sequences

When you create a named sequence, the CACHE parameter determines the number of sequence values each node maintains during a session. The default cache value is 250K, so each node reserves 250,000 values per session for each sequence. The default cache size provides an efficient means for large insert or copy operations. Specifying a smaller number of cache values can impact performance of large loads, since Vertica must create a new set of cache values whenever more are required. Getting more cache for a new set of sequence values requires Vertica to perform a catalog lock. Such locks can adversely affect database performance, since some activities, such as data inserts, cannot occur until Vertica releases the lock.

By default, when the cache is initially empty, the initiator node requests and reserves cache for all nodes in a cluster. You can change this default so that each node requests its own cache. To change the default, set the parameter ClusterSequenceCacheMode to 0. For information on how Vertica requests and distributes cache among all nodes in a cluster, refer to [How Vertica Allots Cache for Sequencing](#).

Effects of Distributed Sessions

Vertica distributes a session across all nodes. After you create a named sequence, the first time any cluster node executes a NEXTVAL () statement within a query, the node requests its own cache of sequence values. The node then maintains that set of values for the current session. Other nodes executing a NEXTVAL () statement create and maintain their own cache of sequence values.

During a session, nodes can increment sequence values from NEXTVAL () statements at different rates. This behavior results in the sequences from a NEXTVAL statement on one node not being sequential with sequence values from another node. Each sequence is guaranteed to be unique, but can be out of order with a NEXTVAL statement executed on another node. Regardless of the number of calls to NEXTVAL and CURRVAL, Vertica increments a sequence only once per row. If multiple calls to NEXTVAL occur in the same row, the statement returns the same value.

If sequences are used in join statements, Vertica increments a sequence once for each composite row output by the join.

Calculating Named Sequences

Vertica calculates the current value of a sequence as follows:

- At the end of every statement, the state of all sequences used in the session is returned to the initiator node.
- The initiator node calculates the maximum CURRVAL of each sequence across all states on all nodes.
- This maximum value is used as CURRVAL in subsequent statements until another NEXTVAL is invoked.

Losing Sequence Values

Sequence values in cache can be lost in the following situations:

- If a statement fails after NEXTVAL is called (thereby consuming a sequence value from the cache), the value is lost.
- If a disconnect occurs (for example, dropped session), any remaining values in cache that have not been returned through NEXTVAL are lost.
- When the initiator node distributes a new block of cache to each node where one or more nodes has not used up its current cache allotment. For information on this scenario, refer to [How Vertica Allots Cache for Sequencing](#).

To recover lost sequence values, you can run an [ALTER SEQUENCE](#) command to define a new sequence number generator, which resets the counter to the correct value in the next session.

Altering Sequences

The **ALTER SEQUENCE** statement lets you change the attributes of a previously-defined named sequence. Changes take effect in the next database session. Any parameters not specifically set in the ALTER SEQUENCE command retain their previous settings.

The ALTER SEQUENCE statement lets you rename an existing sequence, or the schema of a sequence, but you cannot combine either of these changes with any other optional parameters.

Note: Using ALTER SEQUENCE to set a START value below the CURRVAL can result in duplicate keys.

Examples

The following example modifies an ascending sequence called `my_seq` to start at 105:

```
=>ALTER SEQUENCE my_seq RESTART WITH 105;
```

The following example moves a sequence from one schema to another:

```
=>ALTER SEQUENCE [public.]my_seq SET SCHEMA vmart;
```

The following example renames a sequence in the Vmart schema:

```
=>ALTER SEQUENCE [vmart.]my_seq RENAME TO serial;
```

Remember that changes occur only after you start a new database session. For example, if you create a named sequence `my_sequence`, starting at value 10, each time you call `NEXTVAL()`, you increment the value by 1, as in the following series of commands:

```
=>CREATE SEQUENCE my_sequence START 10;
=>SELECT NEXTVAL('my_sequence');
  nextval
-----
      10
(1 row)
=>SELECT NEXTVAL('my_sequence');
  nextval
-----
      11
(1 row)
```

Next, issue the ALTER SEQUENCE statement to assign a new value starting at 50:

```
=>ALTER SEQUENCE my_sequence RESTART WITH 50;
```

When you call the NEXTVAL function, the sequence is incremented again by 1 value:

```
=>SELECT NEXTVAL('my_sequence');
NEXTVAL
-----
      12
(1 row)
```

The sequence starts at 50 only after restarting the database session:

```
=>SELECT NEXTVAL('my_sequence');
NEXTVAL
-----
      50
(1 row)
```

Changing Sequence Ownership

The ALTER SEQUENCE command lets you change the attributes of an existing sequence. All changes take effect immediately, within the same session. Any parameters not set during an ALTER SEQUENCE statement retain their prior settings.

If you need to change sequence ownership, such as if an employee who owns a sequence leaves the company, you can do so with the following ALTER SEQUENCE syntax:

```
=> ALTER SEQUENCE sequence-name OWNER TO new-owner-name;
```

This operation immediately reassigns the sequence from the current owner to the specified new owner.

Only the sequence owner or a superuser can change ownership, and reassignment does not transfer grants from the original owner to the new owner; grants made by the original owner are dropped.

Note: Renaming a table owner transfers ownership of dependent sequence objects (associated IDENTITY/AUTO-INCREMENT sequences) but does not transfer ownership of other referenced sequences. See [Changing Table Ownership](#).

Example

The following example reassigns sequence ownership from the current owner to user Bob:

```
=> ALTER SEQUENCE sequential OWNER TO Bob;
```

See [ALTER SEQUENCE](#) in the SQL Reference Manual for details.

Dropping Sequences

Use `DROP SEQUENCE` to remove a named sequence. You cannot drop a sequence in if any of the following conditions is true:

- Other objects depend on the sequence. `DROP SEQUENCE` does not support cascade operations.
- A column's `DEFAULT` expression references the sequence. Before dropping the sequence, you must remove all column references to it.

Example

The following command drops the sequence named `my_sequence`:

```
=> DROP SEQUENCE my_sequence;
```

Using `AUTO_INCREMENT` and `IDENTITY` Sequences

You can define a column that automatically increments its value as new rows are added, with options `AUTO_INCREMENT` or `IDENTITY`. See `CREATE TABLE` [Column-Constraint](#) for syntax options.

While sequence object values are guaranteed to be unique, they are not guaranteed to be contiguous. Since sequences are not necessarily contiguous, you may interpret the returned values as missing. For example, two nodes can increment a sequence at different rates. The node with a heavier processing load increments the sequence, but the values are not contiguous with those being incremented on a node with less processing.

`IDENTITY` and `AUTO_INCREMENT` can take between 0 and three arguments, which Vertica parses as follows:

# arguments	Description
None	Specifies starting column values at 1. Values increment by 1, but values are not guaranteed to be contiguous. Your number of nodes and cache impact sequence values. Setting cache to 1 (no cache) can ensure contiguous values.
1	Specifies cache size, an integer value ≥ 1 that determines how many unique numbers each node is allocated per session:

	<p>IDENTITY(<i>cache</i>)</p> <p>Default: 250,000</p>
2 or 3	<p>Set as follows:</p> <p>IDENTITY (<i>start</i>, <i>increment</i>[, <i>cache</i>])</p> <ul style="list-style-type: none"> • <i>start</i>: The first value of the IDENTITY column <p>Default: 1</p> <ul style="list-style-type: none"> • <i>increment</i>: How much to increment the value from the previous row's value. <p>Default: 1</p> <ul style="list-style-type: none"> • <i>cache</i>: Integer value ≥ 1 that specifies how many unique numbers each node caches per session <ul style="list-style-type: none"> • Default: 250,000

Note: The *increment* value is the minimum increment. For example, setting an increment value of 3 guarantees that values returned increment by at least 3. However, the values returned may not be contiguous, unless you have set the cache value to 1 (no cache).

The following restrictions apply to IDENTITY and AUTO_INCREMENT sequences:

- You can set this constraint on only one table column.
- IDENTITY and AUTO_INCREMENT values are never rolled back, even if a transaction that tries to insert a value into a table is not committed.
- You cannot change the value of an IDENTITY or AUTO_INCREMENT column in an existing table.

Examples

The following example shows how you can use the IDENTITY column-constraint to create a table with an ID column. The ID column has an initial value of 1. It is incremented by 1 every time a row is inserted.

```
=> CREATE TABLE Premium_Customer(
  ID IDENTITY(1,1),
  lname VARCHAR(25),
```

```
    fname VARCHAR(25),
    store_membership_card INTEGER
  );
=> INSERT INTO Premium_Customer (lname, fname, store_membership_card )
VALUES ('Gupta', 'Saleem', 475987);
```

Confirm the row you added and see the ID value:

```
=> SELECT * FROM Premium_Customer;
 ID | lname | fname | store_membership_card
-----+-----+-----+-----
  1 | Gupta | Saleem |                475987
(1 row)
```

Now add another row:

```
=> INSERT INTO Premium_Customer (lname, fname, store_membership_card)
VALUES ('Lee', 'Chen', 598742);
```

Calling the `LAST_INSERT_ID` function returns value 2 because you previously inserted a new customer (Chen Lee), and this value is incremented each time a row is inserted:

```
=> SELECT LAST_INSERT_ID();
 last_insert_id
-----
                2
(1 row)
```

View all the ID values in the `Premium_Customer` table:

```
=> SELECT * FROM Premium_Customer;
 ID | lname | fname | store_membership_card
-----+-----+-----+-----
  1 | Gupta | Saleem |                475987
  2 | Lee   | Chen   |                598742
(2 rows)
```

The next examples illustrate the three valid ways to use `IDENTITY` arguments. (Note that these examples are valid for the `AUTO_INCREMENT` argument also.) The first example uses a cache of 100, and the defaults for start value (1) and increment value (1):

```
=> CREATE TABLE t1(x IDENTITY(100), y INT);
```

The second example specifies the start and increment values as 1, and defaults to a cache value of 250,000:

```
=> CREATE TABLE t2(y IDENTITY(1,1), x INT);
```

The third example specifies start and increment values of 1, and a cache value of 100:

```
=> CREATE TABLE t3(z IDENTITY(1,1,100), zx INT);
```

Using a Named Sequence with an AUTO_INCREMENT or IDENTITY Column

A table can contain only one AUTO_INCREMENT or IDENTITY column. A table with an AUTO_INCREMENT or IDENTITY column can also contain a named sequence. In the following example, table test2 contains a named sequence (my_seq), and an auto_increment value for the column last):

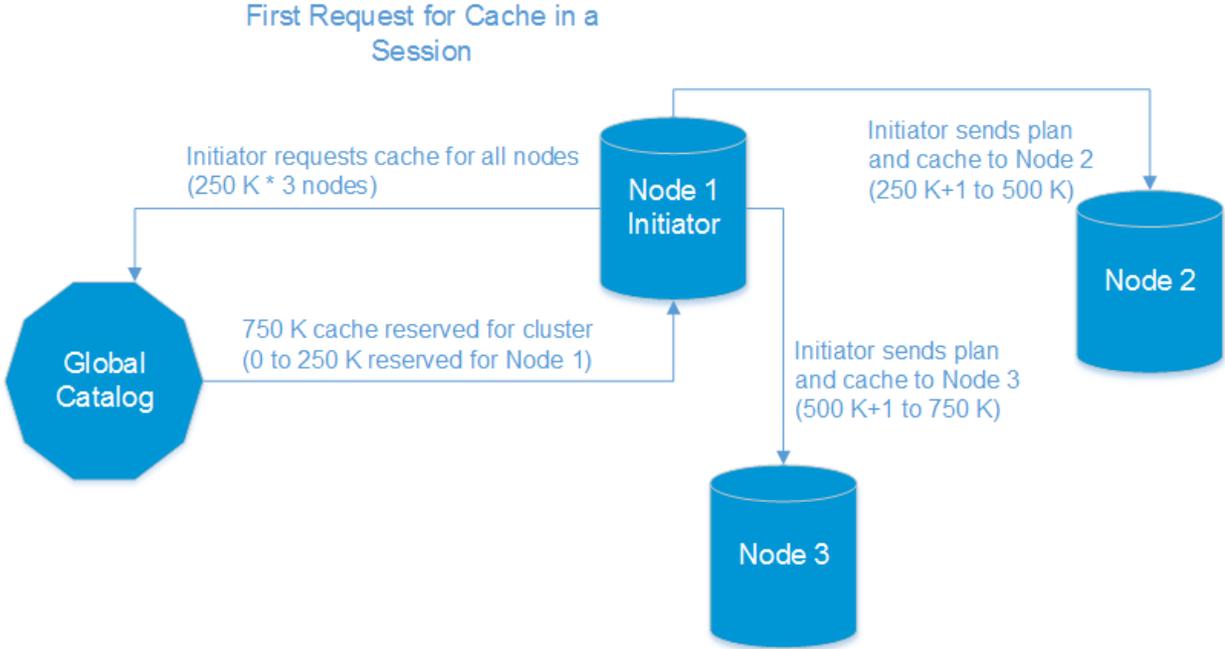

```
VMart=> CREATE TABLE test2 (id INTEGER NOT NULL UNIQUE,  
    middle INTEGER DEFAULT NEXTVAL('my_seq'),  
    next INT, last AUTO_INCREMENT);  
CREATE TABLE
```

How Vertica Allots Cache for Sequencing

Vertica caching is similar for all types of sequences, including named sequences, identity sequences, and auto-increment sequences. To allot cache among the nodes in a cluster using named sequences, Vertica uses the following process.

1. By default, when a session begins, an initiator node requests cache for itself and all other nodes in a cluster.
2. The initiator distributes the cache to other nodes when it distributes the execution plan.
3. Because the initiator requests a block of cache for all nodes, only the initiator locks the global catalog for the cache request.

This approach is optimal for large INSERT-SELECT and COPY operations. The following figure shows the initiator request for cache (with 250-K cache default).

Nodes run out of cache at different times. While executing the same query, nodes individually request additional cache as needed.

For new queries in the same session, the initiator might have an empty cache if it used all of its cache to execute the previous query execution. In this case, the initiator requests cache for all nodes.

You can change how Vertica initially allots cache by setting the configuration parameter `ClusterSequenceCacheMode` to 0 (disabled). When this parameter is set to 0, all nodes in the cluster request their own cache and catalog lock. However, for initial large INSERT-SELECT and COPY operations, when the cache is empty for all nodes, each node requests cache at the same time. These multiple requests result in multiple simultaneous locks on the global catalog, which can adversely affect performance. For this reason, `ClusterSequenceCacheMode` should remain set to its default value of 1 (enabled).

The following example compares how different settings of `ClusterSequenceCacheMode` affect cache allotment for sequence processing. The example assumes a three-node cluster, the default 250 K cache allotment for each node, and sequence ID values that are sequential (incrementing by 1).

Workflow step	<code>ClusterSequenceCacheMode = 1</code>	<code>ClusterSequenceCacheMode = 0</code>
1	Cache is empty for all nodes. Initiator node requests block of 250 K	Cache is empty for all nodes. Each node, including initiator,

Workflow step	ClusterSequenceCacheMode = 1	ClusterSequenceCacheMode = 0
	cache equal to for each node.	requests its own 250 K cache.
2	<p>Each node has cache:</p> <ul style="list-style-type: none"> • Node 1: 0–250 K • Node 2: 250 K + 1 to 500 K • Node 3: 500 K + 1 to 750 K <p>Each node begins to use its cache allotment as it does its work.</p>	
3	<p>Initiator node and node 3 run out of cache.</p> <p>Node 2 only uses 250 K +1 to 400 K, 100 K of cache remains from 400 K +1 to 500 K.</p>	
4	<p>Executing same statement:</p> <ul style="list-style-type: none"> • As individual nodes run out of cache, they individually request a new cache allotment. • If node 2 never uses its cache allotment, the 100-K unused cache becomes a gap in sequence IDs. <p>Executing new statement in same session, if initiator node cache is empty:</p> <ul style="list-style-type: none"> • Initiator node again requests and distributes cache for all nodes. • Nodes receive new cache before their previous allotment is totally used, leaving a gap in the sequence IDs. 	<p>Executing same or new statement:</p> <ul style="list-style-type: none"> • As individual nodes run out of cache, they individually request a new cache allotment. • If node 2 never uses its cache allotment, the 100 K unused cache becomes a gap in sequence IDs.

Merging Table Data

MERGE statements can perform [update](#) and [insert](#) operations on a target table based on the results of a join with a source data set. The join can match a source row with only one target row; otherwise, Vertica returns an error.

MERGE has the following syntax:

```
MERGE INTO target-table USING source-dataset ON join-condition  
      matching-clause[ matching-clause ]
```

Merge operations have at least three components:

- The target table on which to perform update and insert operations. MERGE takes an X (exclusive) lock on the target table until the merge operation is complete.
- [Join to another data set](#), one of the following: a table, view, or subquery result set.
- One or both matching clauses: **WHEN MATCHED THEN UPDATE SET** and **WHEN NOT MATCHED THEN INSERT**.

Basic MERGE Example

In this example, a merge operation involves two tables:

- `visits_daily` logs daily restaurant traffic, and is updated with each customer visit. Data in this table is refreshed every 24 hours.
- `visits_history` stores the history of customer visits to various restaurants, accumulated over an indefinite time span.

Each night, you merge the daily visit count from `visits_daily` into `visits_history`. The merge operation modifies the target table in two ways:

- Updates existing customer data.
- Inserts new rows of data for first-time customers.

One MERGE statement executes both operations as a single (upsert) transaction.

Source and Target Tables

The source and target tables `visits_daily` and `visits_history` are defined as follows:

```
CREATE TABLE public.visits_daily
(
  customer_id int,
  location_name varchar(20),
  visit_time time(0) DEFAULT (now())::timetz(6)
);

CREATE TABLE public.visits_history
(
  customer_id int,
  location_name varchar(20),
  visit_count int
);
```

Table `visits_history` contains rows of three customers who between them visited two restaurants, Etoile and LaRosa:

```
=> SELECT * FROM visits_history ORDER BY customer_id, location_name;
 customer_id | location_name | visit_count
-----+-----+-----
          1001 | Etoile       |           2
          1002 | La Rosa     |           4
          1004 | Etoile       |           1
(3 rows)
```

By close of business, table `visits_daily` contains three rows of restaurant visits:

```
=> SELECT * FROM visits_daily ORDER BY customer_id, location_name;
 customer_id | location_name | visit_time
-----+-----+-----
          1001 | Etoile       | 18:19:29
          1003 | Lux Cafe     | 08:07:00
          1004 | La Rosa     | 11:49:20
(3 rows)
```

Table Data Merge

The following MERGE statement merges `visits_daily` data into `visits_history`:

- For matching customers, MERGE updates the occurrence count.
- For non-matching customers, MERGE inserts new rows.

```
=> MERGE INTO visits_history h USING visits_daily d
  ON (h.customer_id=d.customer_id AND h.location_name=d.location_name)
  WHEN MATCHED THEN UPDATE SET visit_count = h.visit_count + 1
  WHEN NOT MATCHED THEN INSERT (customer_id, location_name, visit_count)
  VALUES (d.customer_id, d.location_name, 1);
OUTPUT
-----
      3
(1 row)
```

MERGE returns the number of rows updated and inserted. In this case, the returned value specifies three updates and inserts:

- Customer 1001's third visit to Etoile
- New customer 1003's first visit to new restaurant Lux Cafe
- Customer 1004's first visit to La Rosa

If you now query table `visits_history`, the result set shows the merged (updated and inserted) data. Updated and new rows are highlighted:

```
=> SELECT * FROM visits_history ORDER BY customer_id, location_name
  customer_id | location_name | visit_count
-----+-----+-----
  1001 | Etoile | 3
  1002 | La Rosa | 4
  1003 | Lux Cafe | 1
  1004 | Etoile | 1
  1004 | La Rosa | 1
(5 rows)
```

MERGE Source Options

A MERGE operation joins the target table to one of the following data sources:

- Another table
- View
- Subquery result set

Merging from Table and View Data

You merge data from one table into another as follows:

```
MERGE INTO target-table USING { source-table | source-view } join-condition  
  matching-clause[ matching-clause ]
```

If you specify a view, Vertica expands the view name to the query that it encapsulates, and uses the result set as the merge source data.

For example, the VMart table `public.product_dimension` contains current and discontinued products. You can move all discontinued products into a separate table `public.product_dimension_discontinued`, as follows:

```
=> CREATE TABLE public.product_dimension_discontinued (  
  product_key int,  
  product_version int,  
  sku_number char(32),  
  category_description char(32),  
  product_description varchar(128));  
  
=> MERGE INTO product_dimension_discontinued tgt  
  USING product_dimension src ON tgt.product_key = src.product_key  
    AND tgt.product_version = src.product_version  
  WHEN NOT MATCHED AND src.discontinued_flag='1' THEN INSERT VALUES  
    (src.product_key,  
     src.product_version,  
     src.sku_number,  
     src.category_description,  
     src.product_description);  
  
OUTPUT  
-----  
  1186  
(1 row)
```

Source table `product_dimension` uses two columns, `product_key` and `product_version`, to identify unique products. The `MERGE` statement joins the source and target tables on these columns in order to return single instances of non-matching rows. The `WHEN NOT MATCHED` clause includes a [filter](#) (`src.discontinued_flag='1'`), which reduces the result set to include only discontinued products. The remaining rows are inserted into target table `product_dimension_discontinued`.

Merging from a Subquery Result Set

You can merge into a table the result set that is returned by a subquery, as follows:

```
MERGE INTO target-table USING (subquery) sq-alias join-condition  
  matching-clause[ matching-clause ]
```

For example, the VMart table `public.product_dimension` is defined as follows (DDL truncated):

```
CREATE TABLE public.product_dimension  
(  
  product_key int NOT NULL,  
  product_version int NOT NULL,
```

```
product_description varchar(128),
sku_number char(32),
...
)
ALTER TABLE public.product_dimension
ADD CONSTRAINT C_PRIMARY PRIMARY KEY (product_key, product_version) DISABLED;
```

Columns `product_key` and `product_version` comprise the table's primary key. You can modify this table so it contains a single column that concatenates the values of these two columns. This column can be used to uniquely identify each product, while also maintaining the original values from `product_key` and `product_version`.

You populate the new column with a `MERGE` statement that queries the other two columns:

```
=> ALTER TABLE public.product_dimension ADD COLUMN product_ID numeric(8,2);
ALTER TABLE

=> MERGE INTO product_dimension tgt
  USING (SELECT (product_key||'.0'||product_version)::numeric(8,2) AS pid, sku_number
  FROM product_dimension) src
  ON tgt.product_key||'.0'||product_version::numeric=src.pid
  WHEN MATCHED THEN UPDATE SET product_ID = src.pid;
OUTPUT
-----
 60000
(1 row)
```

The following query verifies that the new column values correspond to the values in `product_key` and `product_version`:

```
=> SELECT product_ID, product_key, product_version, product_description
FROM product_dimension
WHERE category_description = 'Medical'
AND product_description ILIKE '%diabetes%'
AND discontinued_flag = 1 ORDER BY product_ID;
product_ID | product_key | product_version | product_description
-----+-----+-----+-----
 5836.02 | 5836 | 2 | Brand #17487 diabetes blood testing kit
14320.02 | 14320 | 2 | Brand #43046 diabetes blood testing kit
18881.01 | 18881 | 1 | Brand #56743 diabetes blood testing kit
(3 rows)
```

MERGE Matching Clauses

`MERGE` supports one instance of the following matching clauses:

- [WHEN MATCHED THEN UPDATE SET](#)
- [WHEN NOT MATCHED THEN INSERT](#)

Each matching clause can specify an additional filter, as described in [Update and Insert Filters](#).

WHEN MATCHED THEN UPDATE SET

Updates all target table rows that are joined to the source table, typically with data from the source table:

```
WHEN MATCHED [ AND update-filter ] THEN UPDATE  
  SET { target-column = expression }[,...]
```

Vertica can execute the join only on unique values in the source table's join column. If the source table's join column contains more than one matching value, the MERGE statement returns with a run-time error.

WHEN NOT MATCHED THEN INSERT

WHEN NOT MATCHED THEN INSERT inserts into the target table a new row for each source table row that is excluded from the join:

```
WHEN NOT MATCHED [ AND insert-filter ] THEN INSERT  
  [ ( column-list ) ] VALUES ( values-list )
```

column-list is a comma-delimited list of one or more target columns in the target table, listed in any order. MERGE maps *column-list* columns to *values-list* values in the same order, and each column-value pair must be [compatible](#). If you omit *column-list*, Vertica maps *values-list* values to columns according to column order in the table definition.

For example, given the following source and target table definitions:

```
CREATE TABLE t1 (a int, b int, c int);  
CREATE TABLE t2 (x int, y int, z int);
```

The following WHEN NOT MATCHED clause implicitly sets the values of the target table columns a, b, and c in the newly inserted rows:

```
MERGE INTO t1 USING t2 ON t1.a=t2.x  
  WHEN NOT MATCHED THEN INSERT VALUES (t2.x, t2.y, t2.z);
```

In contrast, the following WHEN NOT MATCHED clause excludes columns t1.b and t2.y from the merge operation. The WHEN NOT MATCHED clause explicitly pairs two sets of columns from the target and source tables: t1.a to t2.x, and t1.c to t2.z. Vertica sets excluded column t1.b. to null:

```
MERGE INTO t1 USING t2 ON t1.a=t2.x  
  WHEN NOT MATCHED THEN INSERT (a, c) VALUES (t2.x, t2.z);
```

Update and Insert Filters

Each WHEN MATCHED and WHEN NOT MATCHED clause in a MERGE statement can optionally specify an update filter and insert filter, respectively:

```
WHEN MATCHED AND update-filter THEN UPDATE ...  
WHEN NOT MATCHED AND insert-filter THEN INSERT ...
```

Vertica also supports Oracle syntax for specifying update and insert filters:

```
WHEN MATCHED THEN UPDATE SET column-updates WHERE update-filter  
WHEN NOT MATCHED THEN INSERT column-values WHERE insert-filter
```

Each filter can specify multiple conditions. Vertica handles the filters as follows:

- An update filter is applied to the set of matching rows in the target table that are returned by the MERGE join. For each row where the update filter evaluates to true, Vertica updates the specified columns.
- An insert filter is applied to the set of source table rows that are excluded from the MERGE join. For each row where the insert filter evaluates to true, Vertica adds a new row to the target table with the specified values.

For example, given the following data in tables t11 and t22:

```
=> SELECT * from t11 ORDER BY pk;  
pk | col1 | col2 | SKIP_ME_FLAG  
-----  
1 | 2 | 3 | t  
2 | 3 | 4 | t  
3 | 4 | 5 | f  
4 | | 6 | f  
5 | 6 | 7 | t  
6 | | 8 | f  
7 | 8 | | t  
(7 rows)  
  
=> SELECT * FROM t22 ORDER BY pk;  
pk | col1 | col2  
-----  
1 | 2 | 4  
2 | 4 | 8  
3 | 6 |  
4 | 8 | 16  
(4 rows)
```

You can merge data from table t11 into table t22 with the following MERGE statement, which includes update and insert filters:

```
=> MERGE INTO t22 USING t11 ON ( t11.pk=t22.pk )
  WHEN MATCHED
    AND t11.SKIP_ME_FLAG=FALSE AND (
      COALESCE (t22.col1<>t11.col1, (t22.col1 is null)<>(t11.col1 is null))
    )
  THEN UPDATE SET col1=t11.col1, col2=t11.col2
  WHEN NOT MATCHED
    AND t11.SKIP_ME_FLAG=FALSE
  THEN INSERT (pk, col1, col2) VALUES (t11.pk, t11.col1, t11.col2);
OUTPUT
-----
      3
(1 row)

=> SELECT * FROM t22 ORDER BY pk;
pk | col1 | col2
-----+-----+-----
  1 |    2 |    4
  2 |    4 |    8
  3 |    4 |    5
  4 |     |    6
  6 |     |    8
(5 rows)
```

Vertica uses the update and insert filters as follows:

- Evaluates all matching rows against the update filter conditions. Vertica updates each row where the following two conditions both evaluate to true:
 - Source column `t11.SKIP_ME_FLAG` is set to false.
 - The `COALESCE` function evaluates to true.
- Evaluates all non-matching rows in the source table against the insert filter. For each row where column `t11.SKIP_ME_FLAG` is set to false, Vertica inserts a new row in the target table.

MERGE Optimization

You can improve MERGE performance in several ways:

- [Design projections for optimal MERGE performance.](#)
- [Facilitate creation of optimized query plans.](#)
- Use source tables that are smaller than target tables.

Projections for MERGE Operations

The Vertica query optimizer automatically chooses the best projections to implement a merge operation. A good projection design strategy provides projections that help the query optimizer avoid extra sort and data transfer operations, and facilitate MERGE performance.

Tip: You can rely on Database Designer to generate projections that address merge requirements. You can then [customize these projections](#) as needed.

For example, the following MERGE statement fragment joins source and target tables `tgt` and `src`, respectively, on columns `tgt.a` and `src.b`:

```
=> MERGE INTO tgt USING src ON tgt.a = src.b ...
```

Vertica can use a local merge join if projections for tables `tgt` and `src` use one of the following projection designs, where inputs are presorted by projection `ORDER BY` clauses:

- Replicated projections are sorted on:
 - Column `a` for table `tgt`
 - Column `b` for table `src`
- Segmented projections are [identically segmented](#) on:
 - Column `a` for table `tgt`
 - Column `b` for table `src`
 - Corresponding segmented columns

Optimizing MERGE Query Plans

Vertica prepares an optimized query plan if the following conditions are all true:

- The MERGE statement contains both matching clauses `WHEN MATCHED THEN UPDATE SET` and `WHEN NOT MATCHED THEN INSERT`. If the MERGE statement contains only one matching clause, it uses a non-optimized query plan.
- The MERGE statement excludes [update and insert filters](#).

- The target table join column has a unique or primary key constraint. This requirement does not apply to the source table join column.
- Both matching clauses specify all columns in the target table.
- Both matching clauses specify identical source values.

For details on evaluating an [EXPLAIN](#)-generated query plan, see [MERGE Path](#).

The examples that follow use a simple schema to illustrate some of the conditions under which Vertica prepares or does not prepare an optimized query plan for MERGE:

```
CREATE TABLE target(a INT PRIMARY KEY, b INT, c INT) ORDER BY b,a;
CREATE TABLE source(a INT, b INT, c INT) ORDER BY b,a;
INSERT INTO target VALUES(1,2,3);
INSERT INTO target VALUES(2,4,7);
INSERT INTO source VALUES(3,4,5);
INSERT INTO source VALUES(4,6,9);
COMMIT;
```

Optimized MERGE statement

Vertica can prepare an optimized query plan for the following MERGE statement because:

- The target table's join column `t.a` has a primary key constraint.
- All columns in the target table (`a, b, c`) are included in the UPDATE and INSERT clauses.
- The UPDATE and INSERT clauses specify identical source values: `s.a`, `s.b`, and `s.c`.

```
MERGE INTO target t USING source s ON t.a = s.a
  WHEN MATCHED THEN UPDATE SET a=s.a, b=s.b, c=s.c
  WHEN NOT MATCHED THEN INSERT(a,b,c) VALUES(s.a, s.b, s.c);
```

```
OUTPUT
-----
2
(1 row)
```

The output value of 2 indicates success and denotes the number of rows updated/inserted from the source into the target.

Non-optimized MERGE statement

In the next example, the MERGE statement runs without optimization because the source values in the UPDATE/INSERT clauses are not identical. Specifically, the UPDATE clause includes constants for columns `s.a` and `s.c` and the INSERT clause does not:

```
MERGE INTO target t USING source s ON t.a = s.a
  WHEN MATCHED THEN UPDATE SET a=s.a + 1, b=s.b, c=s.c - 1
```

```
WHEN NOT MATCHED THEN INSERT(a,b,c) VALUES(s.a, s.b, s.c);
```

To make the previous MERGE statement eligible for optimization, rewrite the statement so that the source values in the UPDATE and INSERT clauses are identical:

```
MERGE INTO target t USING source s ON t.a = s.a  
  WHEN MATCHED THEN UPDATE SET a=s.a + 1, b=s.b, c=s.c -1  
  WHEN NOT MATCHED THEN INSERT(a,b,c) VALUES(s.a + 1, s.b, s.c - 1);
```

MERGE Restrictions

The following restrictions apply to updating and inserting table data with [MERGE](#).

Constraint Enforcement

MERGE respects all enforced constraints in the target table. If the merge operation attempts to copy values that violate those constraints, MERGE returns with an error and rolls back the merge operation.

Caution: If you run MERGE multiple times using the same target and source table, each iteration is liable to introduce duplicate values into the target columns and return with an error.

Columns Prohibited from Merge

The following columns cannot be specified in a merge operation; attempts to do so return with an error:

- [Identity/auto-increment](#) columns, or columns whose default value is set to a [named sequence](#).
- Vmap columns such as `__raw__` in flex tables.

Removing Table Data

Vertica provides several ways to remove data from a table:

Delete operation	Description
DROP TABLE	Permanently removes a table and its definition, optionally removes associated views and projections.
DELETE	Marks rows with delete vectors and stores them so data can be rolled back to a previous epoch. The data must be purged to reclaim disk space. See Purging Deleted Data .
TRUNCATE TABLE	Removes all storage and history associated with a table. The table structure is preserved for future use. The results of this command cannot be rolled back.
DROP_PARTITION	Removes one partition from a partitioned table. Each partition contains a related subset of data in the table. Partitioned data can be dropped efficiently, and provides query performance benefits. See Using Table Partitions .

Delete Operations Compared

The following table summarizes differences between various delete operations.

Operations and options	Performance	Auto commits	Saves history
DELETE FROM <i>table</i>	Normal	No	Yes
DELETE FROM <i>temp-table</i>	High	No	No
DELETE FROM <i>table</i> <i>where-clause</i>	Normal	No	Yes
DELETE FROM <i>temp-table</i> <i>where-clause</i>	Normal	No	Yes
DELETE FROM <i>temp-table</i> <i>where-clause</i> ON COMMIT PRESERVE ROWS	Normal	No	Yes
DELETE FROM <i>temp-table</i> <i>where-clause</i> ON COMMIT DELETE ROWS	High	Yes	No
DROP <i>table</i>	High	Yes	No
TRUNCATE <i>table</i>	High	Yes	No
TRUNCATE <i>temp-table</i>	High	Yes	No

Operations and options	Performance	Auto commits	Saves history
SELECT DROP_PARTITION (...)	High	Yes	No

Choosing the Best Delete Operation

The following table can help you decide which delete operation is best:

If you want to...	Use...
Delete both table data and definitions and start from scratch.	DROP TABLE
Quickly drop data while preserving table definitions, and reload data.	TRUNCATE TABLE
Regularly perform bulk delete operations.	DROP_PARTITION
Perform occasional small deletes or updates with the option to roll back or review history. See also: Best Practices for DELETE and UPDATE .	DELETE

Best Practices for DELETE and UPDATE

Vertica is optimized for query-intensive workloads, so DELETE and UPDATE queries might not achieve the same level of performance as other queries. DELETE and UPDATE operations go to the WOS by default, but if the data is sufficiently large and would not fit in memory, Vertica automatically switches to using the ROS. See [Using INSERT, UPDATE, and DELETE](#).

The topics that follow discuss best practices when using DELETE and UPDATE operations in Vertica.

DELETE and UPDATE Performance Considerations

To improve the performance of your DELETE and UPDATE queries, consider the following issues:

- **Query performance after large deletes**—A large number of (unpurged) deleted rows can negatively affect query performance.

To eliminate rows that have been deleted from the result, a query must do extra processing. If 10% or more of the total rows in a table have been deleted, the performance of a query on the table degrades. However, your experience may vary depending on the size of the table, the table definition, and the query. If a table has a large number of deleted rows, consider purging those rows to improve performance. For more information on purging, see [Purging Deleted Data](#).

- **Recovery performance**—Recovery is the action required for a cluster to restore K-safety after a crash. Large numbers of deleted records can degrade the performance of a recovery. To improve recovery performance, purge the deleted rows. For more information on purging, see [Purging Deleted Data](#).
- **Concurrency**—DELETE and UPDATE take exclusive locks on the table. Only one DELETE or UPDATE transaction on a table can be in progress at a time and only when no loads (or INSERTs) are in progress. DELETES and UPDATES on different tables can be run concurrently.

For detailed tips about improving DELETE and UPDATE performance, see [DELETE and UPDATE Optimization](#).

Caution: Vertica does not remove deleted data immediately but keeps it as history for the purposes of historical query. A large amount of history can result in slower query

performance. For information about how to configure the appropriate amount of history to retain, see [Purging Deleted Data](#).

DELETE and UPDATE Optimization

The process of optimizing DELETE and UPDATE queries is the same for both operations. Some simple steps can increase the query performance by tens to hundreds of times. The following sections describe several ways to improve projection design and improve DELETE and UPDATE queries to significantly increase DELETE and UPDATE performance.

Note: For large bulk deletion, Vertica recommends using [Partitioned Tables](#) where possible because they provide the best DELETE performance and improve query performance.

Projection Column Requirements for Optimized Deletes

When all columns required by the DELETE or UPDATE predicate are present in a projection, the projection is optimized for DELETES and UPDATES. DELETE and UPDATE operations on such projections are significantly faster than on non-optimized projections.

For example, consider the following table and projections:

```
CREATE TABLE t (a INTEGER, b INTEGER, c INTEGER);  
CREATE PROJECTION p1 (a, b, c) AS SELECT * FROM t ORDER BY a;  
CREATE PROJECTION p2 (a, c) AS SELECT a, c FROM t ORDER BY c, a;
```

In the following query, both p1 and p2 are eligible for DELETE and UPDATE optimization because column a is available:

```
DELETE from t WHERE a = 1;
```

In the following example, only projection p1 is eligible for DELETE and UPDATE optimization because the b column is not available in p2:

```
DELETE from t WHERE b = 1;
```

Optimized Deletes in Subqueries

To be eligible for DELETE optimization, all target table columns referenced in a DELETE or UPDATE statement's WHERE clause must be in the projection definition.

For example, the following simple schema has two tables and three projections:

```
CREATE TABLE tb1 (a INT, b INT, c INT, d INT);  
CREATE TABLE tb2 (g INT, h INT, i INT, j INT);
```

The first projection references all columns in `tb1` and sorts on column `a`:

```
CREATE PROJECTION tb1_p AS SELECT a, b, c, d FROM tb1 ORDER BY a;
```

The buddy projection references and sorts on column `a` in `tb1`:

```
CREATE PROJECTION tb1_p_2 AS SELECT a FROM tb1 ORDER BY a;
```

This projection references all columns in `tb2` and sorts on column `i`:

```
CREATE PROJECTION tb2_p AS SELECT g, h, i, j FROM tb2 ORDER BY i;
```

Consider the following DML statement, which references `tb1.a` in its `WHERE` clause. Since both projections on `tb1` contain column `a`, both are eligible for the optimized `DELETE`:

```
DELETE FROM tb1 WHERE tb1.a IN (SELECT tb2.i FROM tb2);
```

Restrictions

Optimized `DELETE`s are not supported under the following conditions:

- With replicated projections if subqueries reference the target table. For example, the following syntax is not supported:

```
DELETE FROM tb1 WHERE tb1.a IN (SELECT e FROM tb2, tb2 WHERE tb2.e = tb1.e);
```

- With subqueries that do not return multiple rows. For example, the following syntax is not supported:

```
DELETE FROM tb1 WHERE tb1.a = (SELECT k from tb2);
```

Projection Sort Order for Optimizing Deletes

Design your projections so that frequently-used `DELETE` or `UPDATE` predicate columns appear in the sort order of all projections for large `DELETE`s and `UPDATE`s.

For example, suppose most of the `DELETE` queries you perform on a projection look like the following:

```
DELETE from t where time_key < '1-1-2007'
```

To optimize the DELETES, make `time_key` appear in the ORDER BY clause of all your projections. This schema design results in better performance of the DELETE operation.

In addition, add additional sort columns to the sort order such that each combination of the sort key values uniquely identifies a row or a small set of rows. For more information, see [Combine RLE and Sort Order](#). To analyze projections for sort order issues, use the [EVALUATE_DELETE_PERFORMANCE](#) function.

Purging Deleted Data

In Vertica, delete operations do not remove rows from physical storage. [DELETE](#) marks rows as deleted, as does [UPDATE](#), which combines delete and insert operations. In both cases, Vertica retains discarded rows as historical data, which remains accessible to historical queries until it is purged.

The cost of retaining historical data is twofold:

- Disk space is allocated to deleted rows and delete markers.
- Typical (non-historical) queries must read and skip over deleted data, which can impact performance.

A purge operation permanently removes historical data from physical storage and frees disk space for reuse. Only historical data that precedes the Ancient History Mark (AHM) is eligible to be purged.

You can purge data in two ways:

- [Set a purge policy](#).
- [Manually purge data](#).

In both cases, Vertica purges all historical data up to and including the AHM epoch and resets the AHM.

Caution: Large delete and purge operations can take a long time to complete, so use them sparingly. If your application requires deleting data on a regular basis, such as by month or year, consider designing tables that take advantage of [table partitioning](#). If partitioning is not suitable, consider [rebuilding the table](#).

Setting a Purge Policy

The preferred method for purging data is to establish a policy that determines which deleted data is eligible to be purged. Eligible data is automatically purged when the Tuple Mover performs mergeout operations.

Vertica provides two methods for determining when deleted data is eligible to be purged:

- Specifying the time for which delete data is saved
- Specifying the number of epochs that are saved

Specifying the Time for Which Delete Data Is Saved

Specifying the time for which delete data is saved is the preferred method for determining which deleted data can be purged. By default, Vertica saves historical data only when nodes are down.

To change the specified time for saving deleted data, use the `HistoryRetentionTime` [configuration parameter](#):

```
=> ALTER DATABASE mydb SET HistoryRetentionTime = {seconds | -1};
```

In the above syntax:

- `seconds` is the amount of time (in seconds) for which to save deleted data.
- `-1` indicates that you do not want to use the `HistoryRetentionTime` configuration parameter to determine which deleted data is eligible to be purged. Use this setting if you prefer to use the other method (`HistoryRetentionEpochs`) for determining which deleted data can be purged.

The following example sets the history epoch retention level to 240 seconds:

```
=> ALTER DATABASE mydb SET HistoryRetentionTime = 240;
```

Specifying the Number of Epochs That Are Saved

Unless you have a reason to limit the number of epochs, Micro Focus recommends that you specify the time over which delete data is saved.

To specify the number of historical epoch to save through the `HistoryRetentionEpochs` configuration parameter:

1. Turn off the `HistoryRetentionTime` configuration parameter:

```
=> ALTER DATABASE mydb SET HistoryRetentionTime = -1;
```

2. Set the history epoch retention level through the `HistoryRetentionEpochs` configuration parameter:

```
=> ALTER DATABASE mydb SET HistoryRetentionEpochs = {num_epochs | -1};
```

- `num_epochs` is the number of historical epochs to save.
- `-1` indicates that you do not want to use the `HistoryRetentionEpochs` configuration parameter to trim historical epochs from the epoch map. By default, `HistoryRetentionEpochs` is set to `-1`.

The following example sets the number of historical epochs to save to 40:

```
=> ALTER DATABASE mydb SET HistoryRetentionEpochs = 40;
```

Modifications are immediately implemented across all nodes within the database cluster. You do not need to restart the database.

Note: If both `HistoryRetentionTime` and `HistoryRetentionEpochs` are specified, `HistoryRetentionTime` takes precedence.

See [Epoch Management Parameters](#) for additional details.

Disabling Purge

If you want to preserve all historical data, set the value of both historical epoch retention parameters to `-1`, as follows:

```
=> ALTER DATABASE mydb SET HistoryRetentionTime = -1;  
=> ALTER DATABASE mydb SET HistoryRetentionEpochs = -1;
```

Manually Purging Data

You manually purge deleted data as follows:

1. Determine the point in time to which you want to purge deleted data.
2. Set the ancient history mark (AHM) to this point in time using one of the following functions:
 - `SET_AHM_TIME` sets the AHM to the epoch that includes the specified `TIMESTAMP` value on the initiator node.
 - `SET_AHM_EPOCH` sets the AHM to the specified epoch.

- [GET_AHM_TIME](#) returns a `TIMESTAMP` value representing the AHM.
- [GET_AHM_EPOCH](#) returns the number of the epoch in which the AHM is located.
- [MAKE_AHM_NOW](#) sets the AHM to the greatest allowable value. This lets you purge all deleted data.

When you use `SET_AHM_TIME` or `GET_AHM_TIME`, keep in mind that the timestamp you specify is mapped to an epoch, which by default has a three-minute granularity. Thus, if you specify an AHM time of `2008-01-01 00:00:00.00`, the resulting purge might permanently remove as much as the first three minutes of 2008, or fail to remove the last three minutes of 2007.

Note: The system prevents you from setting the AHM beyond the point where it prevents recovery in the event of node failure.

3. Purge deleted data from the desired projections with one of the following functions:
 - [PURGE](#) purges all projections in the physical schema.
 - [PURGE_TABLE](#) purges all projections anchored to the specified table.
 - [PURGE_PROJECTION](#) purges the specified projection.
 - [PURGE_PARTITION](#) purges a specified partition.
4. The tuple mover performs a mergeout operation to purge the data. Vertica periodically invokes the tuple mover to perform mergeout operations, as configured by [tuple mover parameters](#). You can manually invoke the tuple mover by calling the function `DO_TM_TASK`.

Caution: Manual purge operations can take a long time.

Truncating Tables

`TRUNCATE TABLE` removes all storage associated with the target table and its projections. Vertica preserves the table and the projection definitions. If the truncated table has out-of-date projections, those projections are cleared and marked up-to-date when `TRUNCATE TABLE` returns.

`TRUNCATE TABLE` commits the entire transaction after statement execution, even if truncating the table fails. You cannot roll back a `TRUNCATE TABLE` statement.

Use `TRUNCATE TABLE` for testing purposes. You can use it to remove all data from a table and load it with fresh data, without recreating the table and its projections.

Table Locking

`TRUNCATE TABLE` takes an O (owner) lock on the table until the truncation process completes. The savepoint is then released. If the operation cannot obtain an [O lock](#) on the target table, Vertica tries to close any internal [tuple mover](#) (TM) sessions that are running on that table. If successful, the operation can proceed. Explicit TM operations that are running in user sessions do not close. If an explicit TM operation is running on the table, the operation proceeds only when the TM operation is complete.

Restrictions

- You cannot truncate an external table.
- You can truncate the fact table of a pre-join projection. However, you cannot truncate the dimension table of the same pre-join projection. If a table acts as a dimension table in any pre-join projections, you must drop those projections before you can execute `TRUNCATE TABLE` on the dimension table.

Examples

```
=> INSERT INTO sample_table (a) VALUES (3);
=> SELECT * FROM sample_table;
a
---
3
(1 row)

=> TRUNCATE TABLE sample_table;
TRUNCATE TABLE
=> SELECT * FROM sample_table;
a
---
(0 rows)
```

Rebuilding Tables

You can reclaim disk space on a large scale by rebuilding tables, as follows:

1. Create a table with the same (or similar) definition as the table to rebuild.
2. Create projections for the new table.
3. Copy data from the target table into the new one with `INSERT . . SELECT`.
4. Drop the old table and its projections.

Note: Rather than dropping the old table, you can rename it and use it as a backup copy. Before doing so, verify that you have sufficient disk space for both the new and old tables.

5. Rename the new table with `ALTER TABLE . . RENAME`, using the name of the old table.

Caution: When you rebuild a table, Vertica purges the table of all delete vectors that precede the AHM. This prevents historical queries on any older epoch.

Projection Considerations

- You must have enough disk space to contain the old and new projections at the same time. If necessary, you can drop some of the old projections before loading the new table. You must, however, retain at least one superprojection of the old table (or two buddy superprojections to maintain K-safety) until the new table is loaded. (See [Prepare Disk Storage Locations](#) in Installing Vertica for disk space requirements.)
- You can specify different names for the new projections or use `ALTER TABLE . . RENAME` to change the names of the old projections.
- The relationship between tables and projections does not depend on object names. Instead, it depends on object identifiers that are not affected by rename operations. Thus, if you rename a table, its projections continue to work normally.

Dropping Tables

`DROP TABLE` drops a table from the database catalog. If any projections are associated with the table, `DROP TABLE` returns an error message unless it also includes the `CASCADE` option. One exception applies: the table only has an [auto-generated superprojection](#) (auto-projection) associated with it.

Using CASCADE

In the following example, `DROP TABLE` tries to remove a table that has several projections associated with it. Because it omits the `CASCADE` option, Vertica returns an error:

```
=> DROP TABLE d1;
NOTICE: Constraint - depends on Table d1
NOTICE: Projection d1p1 depends on Table d1
NOTICE: Projection d1p2 depends on Table d1
NOTICE: Projection d1p3 depends on Table d1
NOTICE: Projection f1d1p1 depends on Table d1
NOTICE: Projection f1d1p2 depends on Table d1
NOTICE: Projection f1d1p3 depends on Table d1
ERROR: DROP failed due to dependencies: Cannot drop Table d1 because other objects depend on it
HINT: Use DROP ... CASCADE to drop the dependent objects too.
=> DROP TABLE d1 CASCADE;
DROP TABLE
=> CREATE TABLE mytable (a INT, b VARCHAR(256));
CREATE TABLE
=> DROP TABLE IF EXISTS mytable;
DROP TABLE
=> DROP TABLE IF EXISTS mytable; -- Doesn't exist
NOTICE: Nothing was dropped
DROP TABLE
```

The next attempt includes the `CASCADE` option and succeeds:

```
=> DROP TABLE d1 CASCADE;
DROP TABLE
=> CREATE TABLE mytable (a INT, b VARCHAR(256));
CREATE TABLE
=> DROP TABLE IF EXISTS mytable;
DROP TABLE
=> DROP TABLE IF EXISTS mytable; -- Doesn't exist
NOTICE: Nothing was dropped
DROP TABLE
```

Using IF EXISTS

In the following example, `DROP TABLE` includes the option `IF EXISTS`. This option specifies not to report an error if one or more of the tables to drop does not exist. This clause is useful in SQL scripts—for example, to ensure that a table is dropped before you try to recreate it:

```
=> DROP TABLE IF EXISTS mytable;
DROP TABLE
=> DROP TABLE IF EXISTS mytable; -- Table doesn't exist
NOTICE: Nothing was dropped
DROP TABLE
```

Dropping and Restoring View Tables

Views that reference a table that is dropped and then replaced by another table with the same name continue to function and use the contents of the new table. The new table must have the same column definitions.

Managing Client Connections

You can limit the number of active concurrent sessions a user can open to the server. Limiting user sessions lets you better manage sessions and prevents excessive server communication.

You can define connection limits at three levels: user level, for an individual node or entire cluster.

You can use the following parameters to close a session that has been idle for a period of time:

- `IDLESESSIONTIMEOUT`: Sets how much time can elapse before a session times out.
- `DEFAULTIDLESESSIONTIMEOUT`— A configuration parameter that sets the default timeout value for users who do not have `idlesessiontimeout` set. See [Security Parameters](#).

The `IDLESESSIONTIMEOUT` parameter applies only to sessions that are idle, not to sessions where query execution is in progress. An idle session is one that has no queries running. If a client is slow or unresponsive during query execution, that time does not apply to timeout. For example, if you are doing a streaming batch insert, the time that it takes to perform this operation is not counted towards timeout.

Use Cases

A user executes a query, and for some reason the query takes an unusually long time to finish (for example, because of server traffic or query complexity). In this case, the user may mistakenly think the query failed and opens another session to run the same query. Now, two sessions are running the same query, using an extra connection.

To prevent this situation, limit the number of sessions a user can run by creating or modifying a user and setting `MAXCONNECTIONS`. For example:

```
=> CREATE USER u1 MAXCONNECTIONS 10 ON NODE;
```

Another issue setting client connections prevents is when a user connects to the server many times. Too many user connections exhausts the number of allowable connections set with the `MaxClientSessions` parameter (see [Managing Sessions](#)).

Note: No user can have a `MAXCONNECTIONS` limit greater than the `MaxClientSessions` setting.

Manage Client Sessions

After setting a user's connection limits, you can manage the client sessions by monitoring changes to the user's connection parameters. Also be aware that behavior changes can occur with client connection limits when a node:

- Is removed
- Is added
- Goes down
- Comes up

Client Connection Changes

When you modify a user's client connection parameters, be aware that:

- Changing a user's MAXCONNECTIONS setting only affects new connections.
- Changing a user's connection mode from DATABASE to NODE does not affect current sessions. All new sessions are reserved on the invoking node rather than the entire cluster.
- Changing a user's connection mode from NODE to DATABASE does not affect current sessions. New connection requests are reserved on the entire cluster.

Node Going Up or Down

In terms of honoring connection limits, no significant impact exists when nodes go down or come up in between connection requests. No special actions are needed to handle this.

However, note the following:

- If a node goes down, its active session exits and other nodes in the cluster also drop their sessions. This frees up connections. The query may hang in which case the blocked sessions are reasonable and as expected.

User-Defined Session Timeout

As the DBADMIN, you can set a user's idle session timeout with IDLESESSIONTIMEOUT. A user can edit the session timeout value as follows:

```
=> SET SESSION IDLESESSIONTIMEOUT 'interval';
```

In the user role, you can only lower the IDLESESSIONTIMEOUT value. If you attempt to increase the value, the following error message appears:

```
ERROR 0: New idlesessiontimeout 00:12 would exceed user limit of 00:10
```

Run the following query to see the current IDLESESSIONTIMEOUT value:

```
=> SHOW IDLESESSIONTIMEOUT;
name | idlesessiontimeout
-----+-----
user1 | 00:08
```

Set the DEFAULTIDLESESSIONTIMEOUT configuration parameter as the default session timeout value:

```
=> ALTER DATABASE <dbname> SET DEFAULTIDLESESSIONTIMEOUT = interval;
```

This value applies to users who do not have an IDLESESSIONTIMEOUT value set.

In the user role, you can lower the idle timeout for a specific session as follows:

```
=> SET SESSION IDLESESSIONTIMEOUT 'interval';
```

Close a Session for a User

If necessary, you can manually close a user session with [CLOSE_USER_SESSIONS](#):

```
=> SELECT CLOSE_USER_SESSIONS ('user-name');
          close_user_sessions
-----
Session close command sent. Check v_monitor.session for progress
```

Set Client Connection Limits

Setting a user's client connection limits allows you to control how many simultaneous sessions a user can run. This prevents Vertica from exhausting the allowable concurrent connections set by `MaxClientSessions` and improves the usability of the system.

MaxClientSessions Limits

Client connection limits cannot be higher than the limits set in `MaxClientSessions`. Therefore:

- If you need to increase a user's allowed concurrent connections, check to see if `MaxClientSessions` needs to be increased first.
- If you decrease `MaxClientSessions`, the database uses the lesser of the two connection values between `MaxClientSessions` and the user-level connection limit set with `MAXCONNECTIONS`.

Set Connection Limits for a User

Set connection limits for a user as follows:

```
=> CREATE USER user1 MAXCONNECTIONS 10 ON NODE IDLESESSIONTIMEOUT '10 mins';
```

This example limits `user1` to ten concurrent connections on an individual node. An idle session for the user times out after ten minutes. For more information see [CREATE USER](#).

You can also modify an existing user to add connection limits with [ALTER USER](#).

```
=> ALTER USER user2 MAXCONNECTIONS 5 ON DATABASE;
```

View User Connection Limits and Session Timeouts

See the [USERS](#) table to determine if a user has connection limits and session timeouts implemented.

```
=> SELECT user_name, max_connections, connection_limit_mode, idle_session_timeout FROM users;  
user_name | max_connections | connection_limit_mode | idle_session_timeout
```

max1	10	node	00:10
max2	5	database	unlimited

IDLESESSIONTIMEOUT

When setting the IDLESESSIONTIMEOUT value, be aware that a system is considered idle when it is waiting for instructions from the client.

The system starts tracking the timeout value from the point the server starts waiting for any type of message. For example, if the server receives a parse and is waiting for a bind, the time spent waiting is considered idle time and IDLESESSIONTIMEOUT starts.

When you change a user's IDLESESSIONTIMEOUT value, the new value affects only those sessions started after the update.

Working with Projections

Unlike traditional databases that store data in tables, Vertica physically stores table data in projections, which are collections of table columns.

Projections store data in a format that optimizes query execution. Similar to materialized views, they store result sets on disk rather than compute them each time they are used in a query. Vertica automatically refreshes these result sets with updated or new data.

Projections can be generally classified in two ways:

- [How projection data is distributed](#) on the cluster. A projection can be defined to divide its data into multiple segments, or maintain all projection data as a single unsegmented unit.
- [How much data a projection contains, and the nature of that data](#). For example, each table Vertica requires a superprojection, which contains all table columns. You can also create query-specific projections, which contain only the subset of table columns to process a given query.

For more general information about Vertica projections, see [Physical Schema](#) in Vertica Concepts.

Projection Naming

Vertica identifies projections according to the following conventions, where *proj-basename* is the name assigned to this projection by [CREATE PROJECTION](#).

Unsegmented Projections

Unsegmented projections conform to the following naming conventions:

<i>table-name_</i> super	Identifies the auto projection that Vertica automatically creates when you initially load data into an unsegmented table, where <i>table-basename</i> is the table name specified in CREATE TABLE . The auto projection is always a superprojection. For example: <pre>store.customer_dimension_super</pre>
-----------------------------	---

<i>proj-basename</i> [_unseg]	<p>Identifies an unsegmented projection. If <i>proj-basename</i> is identical to the anchor table name, Vertica appends the string <code>_unseg</code> to the projection name. If the projection is copied on all nodes, this projection name maps to all instances.</p> <p>For example:</p> <pre>store.customer_dimension_unseg</pre>
----------------------------------	--

Segmented Projections

Segmented projections conform to the following naming convention:

<i>proj-basename_</i> <i>boffset</i>	<p>Identifies buddy projections for a segmented projection, where <i>offset</i> identifies the projection's node location relative to all other buddy projections. All buddy projections share the same project base name.</p> <p>For example:</p> <pre>store.store_orders_fact_b0 store.store_orders_fact_b1</pre> <p>One exception applies: Vertica uses the following convention to name live aggregate projections:</p> <ul style="list-style-type: none">• <i>proj-basename</i>• <i>proj-basename_b1</i>• ...
---	--

Projections of Copied Tables

Vertica creates projections for tables that you create from existing tables with [CREATE TABLE LIKE...INCLUDING PROJECTIONS](#).

The following table describes the algorithm that Vertica uses to assign base names to the new projections:

Source projection name	Target		
	Schema	Table	Projection base name
<i>string</i>	Same	Different	<i>tgtTableName_string</i>
<i>string</i>	Different	Same	<i>string</i>
<i>string</i>	Different	Different	<i>tgtTableName_string</i>
<i>srcTableName_string</i>	Same	Different	<i>tgtTableName_string</i>
<i>srcTableName_string</i>	Different	Different	<i>tgtTableName_string</i>

For example, given the following table and its segmented projections:

Table name	Projection names
public.T1	T1_b0 T1_b1
	T1_proj1_b0 T1_proj1_b1
	proj2_b0 proj2_b1

The following CREATE TABLE . . . LIKE statements copy table public.T1 and its projections to tables public.T2 and private.T1:

```
CREATE TABLE public.T2 LIKE public.T1 INCLUDING PROJECTIONS;
CREATE TABLE private.T1 LIKE public.T1 INCLUDING PROJECTIONS;
```

For each new table, Vertica copies the public.T1 projections as follows:

New table name	Copied projection names
public.T2	T2_b0 T2_b1
	T2_proj1_b0 T2_proj1_b1
	T2_proj2_b0 T2_proj2_b1
private.T1	T1_b0 T1_b1
	T1_proj1_b0 T1_proj1_b1
	proj2_b0 proj2_b1

Auto-Projections

Auto-projections are superprojections that Vertica automatically generates for tables, both temporary and persistent. The following rules apply to all auto-projections:

- Vertica creates the auto-projection in the same schema as the table.
- Auto-projections conform to encoding, sort order, segmentation, and K-safety as specified in the table's creation statement.
- If the table creation statement contains an `AS SELECT` clause, Vertica uses some properties of the projection definition's underlying query.

Auto-Projection Triggers

The conditions for creating auto-projections differ, depending on whether the table is temporary or persistent:

Table type	Auto-projection trigger
Temporary	<code>CREATE TEMPORARY TABLE</code> statement unless it includes <code>NO PROJECTION</code> .
Persistent	<code>CREATE TABLE</code> statement contains one of these clauses: <ul style="list-style-type: none">• <code>AS SELECT</code>• <code>ENCODED BY</code>• <code>ORDER BY</code>• <code>SEGMENTED BY / UNSEGMENTED</code>• <code>KSAFE</code> If none of these conditions is true, Vertica automatically creates a superprojection (if one does not already exist) only when you first load data into the table with <code>INSERT</code> or <code>COPY</code> .

Default Segmentation and Sort Order

If `CREATE TABLE` or `CREATE TEMPORARY TABLE` omits a segmentation (`SEGMENTED BY` or `UNSEGMENTED`) or `ORDER BY` clause, Vertica segments and sorts auto-projections according to the table's manner of creation:

- If `CREATE [TEMPORARY] TABLE` contains an `AS SELECT` clause, and the query output is segmented, the auto-projection uses the same segmentation. If the result set is already sorted, the projection uses the same sort order.
- In all other cases, Vertica evaluates table column constraints to determine how to sort and segment the projection, as shown below:

Constraints	Sorted by:	Segmented by:
Primary key	Primary key	Primary key
Primary and foreign keys	<ol style="list-style-type: none"> 1. Foreign keys 2. Primary key 	Primary key
Foreign keys only	<ol style="list-style-type: none"> 1. Foreign keys 2. Remaining columns excluding <code>LONG data types</code>, in the order specified by <code>CREATE TABLE</code>. 	<p>All columns excluding <code>LONG data types</code>, up to the limit set in configuration parameter <code>MaxAutoSegColumns</code> (by default 32).</p> <p>Vertica orders segmentation according to data type size, as follows:</p>
None	All columns excluding <code>LONG data types</code> , in the order specified by <code>CREATE TABLE</code> .	<ol style="list-style-type: none"> 1. Small (< 8 byte) data type columns 2. Large (>8 byte) data type columns

Unsegmented Projections

In many cases, dimension tables are relatively small, so you do not need to segment them. Accordingly, you should design a K-safe database so projections for its dimension tables are

replicated without segmentation on all cluster nodes. You create unsegmented projections with a `CREATE PROJECTION` statement that includes the clause `UNSEGMENTED ALL NODES`. This clause specifies to create identical instances of the projection on all cluster nodes.

The following example shows how to create an unsegmented projection for the table `store.store_dimension`:

```
=> CREATE PROJECTION store.store_dimension_proj (storekey, name, city, state)
      AS SELECT store_key, store_name, store_city, store_state
      FROM store.store_dimension
      UNSEGMENTED ALL NODES;
CREATE PROJECTION
```

Vertica uses the same name to identify all instances of the unsegmented projection—in this example, `store.store_dimension_proj`. The keyword `ALL NODES` specifies to replicate the projection on all nodes:

```
=> \dj store.store_dimension_proj
      List of projections
Schema | Name | Owner | Node | Comment
-----+-----+-----+-----+-----
store | store_dimension_proj | dbadmin | v_vmart_node0001 |
store | store_dimension_proj | dbadmin | v_vmart_node0002 |
store | store_dimension_proj | dbadmin | v_vmart_node0003 |
(3 rows)
```

For more information about projection name conventions, see [Projection Naming](#).

Segmented Projections

You typically create segmented projections for large fact tables. Vertica splits segmented projections into chunks (segments) of similar size and distributes these segments evenly across the cluster. System K-safety determines how many duplicates (*buddies*) of each segment are created and maintained on different nodes.

You create segmented projections with a `CREATE PROJECTION` statement that includes a `SEGMENTED BY clause`.

The following `CREATE PROJECTION` statement creates projection `public.employee_dimension_super`. It specifies to include all columns in table `public.employee_dimension`. The hash segmentation clause invokes the Vertica `HASH` function to segment projection data on the column `employee_key`; it also includes the `ALL NODES` clause, which specifies to distribute projection data evenly across all nodes in the cluster:

```
=> CREATE PROJECTION public.employee_dimension_super
      AS SELECT * FROM public.employee_dimension
      ORDER BY employee_key
```

```
SEGMENTED BY hash(employee_key) ALL NODES;
```

If the database is K-safe, Vertica creates multiple buddies for this projection and distributes them on different nodes across the cluster. In this case, database K-safety is set to 1, so Vertica creates two buddies for this projection. It uses the projection name `employee_dimension_super` as the basename for the two buddy identifiers it creates—in this example, `employee_dimension_super_b0` and `employee_dimension_super_b1`:

```
=> SELECT projection_name FROM projections WHERE projection_basename='employee_dimension_super';
      projection_name
-----
employee_dimension_super_b0
employee_dimension_super_b1
(2 rows)
```

K-Safe Database Projections

K-safety is implemented differently for segmented and unsegmented projections, as described below. Examples assume database K-safety is set to 1 in a 3-node database, and uses projections for two tables:

- `store.store_orders_fact` is a large fact table. The projection for this table should be segmented. Vertica distributes projection segments uniformly across the cluster.
- `store.store_dimension` is a smaller dimension table. The projection for this table should be unsegmented. Vertica copies a complete instance of this projection on each cluster node.

Segmented Projections

In a K-safe database, the database requires K+1 instances, or buddies, of each projection segment. For example, if database K-safety is set to 1, the database requires two instances, or buddies, of each projection segment.

You can set K-safety on individual segmented projections through the [CREATE PROJECTION](#) option `KSAFE`. Projection K-safety must be equal to or greater than database K-safety. If you omit setting `KSAFE`, the projection obtains K-safety from the database.

The following [CREATE PROJECTION](#) defines a segmented projection for the fact table `store.store_orders_fact`:

```
=> CREATE PROJECTION store.store_orders_fact
      (prodkey, ordernum, storekey, total)
      AS SELECT product_key, order_number, store_key, quantity_ordered*unit_price
      FROM store.store_orders_fact
      SEGMENTED BY HASH(product_key, order_number) ALL NODES KSAFE 1;
CREATE PROJECTION
```

The following keywords in the `CREATE PROJECTION` statement pertain to setting projection K-safety:

<code>SEGMENTED BY</code>	Specifies how to segment projection data for distribution across the cluster. In this example, the segmentation expression specifies Vertica's built-in HASH function.
<code>ALL NODES</code>	Specifies to distribute projection segments across all cluster nodes.
<code>K-SAFE 1</code>	Sets K-safety to 1. Vertica creates two projection buddies with these identifiers: <ul style="list-style-type: none">• <code>store.store_orders_fact_b0</code>• <code>store.store_orders_fact_b1</code>

Unsegmented Projections

In a K-safe database, unsegmented projections must be replicated on all nodes. Thus, the `CREATE PROJECTION` statement for an unsegmented projection must include the segmentation clause `UNSEGMENTED ALL NODES`. This instructs Vertica to create identical instances (buddies) of the projection on all cluster nodes. If you create an unsegmented projection on a single node, Vertica regards it unsafe and does not use it.

The following example shows how to create an unsegmented projection for the table `store.store_dimension`:

```
=> CREATE PROJECTION store.store_dimension_proj (storekey, name, city, state)
      AS SELECT store_key, store_name, store_city, store_state
      FROM store.store_dimension
      UNSEGMENTED ALL NODES;
CREATE PROJECTION
```

Vertica uses the same name to identify all instances of the unsegmented projection—in this example, `store.store_dimension_proj`. The keyword `ALL NODES` specifies to replicate the projection on all nodes:

```
=> \dj store.store_dimension_proj
List of projections
Schema | Name | Owner | Node | Comment
-----+-----+-----+-----+-----
store | store_dimension_proj | dbadmin | v_vmart_node0001 |
store | store_dimension_proj | dbadmin | v_vmart_node0002 |
store | store_dimension_proj | dbadmin | v_vmart_node0003 |
(3 rows)
```

For more information about projection name conventions, see [Projection Naming](#).

Refreshing Projections

[CREATE PROJECTION](#) does not load data into physical storage. If the anchor tables already contain data, run [START_REFRESH](#) to update the projection. Depending on how much data is in the tables, updating a projection can be time consuming. When a projection is up-to-date, however, it is updated automatically as part of [COPY](#), [DELETE](#), [INSERT](#), [MERGE](#), or [UPDATE](#) statements.

Monitoring Projection Refresh on Buddy Projections

Vertica refreshes projections only after you create a buddy projection. If you run [START_REFRESH](#) after creating a projection, Vertica returns this message:

```
Starting refresh background process
```

However, the refresh begins only after you create buddy projections.

To confirm whether a refresh operation is complete, review the `vertica.log` file. [GET_PROJECTIONS](#) also provides the final status of the projection refresh:

```
=> SELECT GET_PROJECTIONS('customer_dimension');
GET_PROJECTIONS
-----
Current system K is 1.
# of Nodes: 3.
Table public.customer_dimension has 2 projections.

Projection Name: [Segmented] [Seg Cols] [# of Buddies] [Buddy Projections] [Safe] [UptoDate] [Stats]
-----
public.customer_dimension_unseg [Segmented: No] [Seg Cols: ] [K: 2] [public.customer_dimension_unseg]
[Safe: Yes] [UptoDate: Yes] [Stats: Yes]
```

```
public.customer_dimension_DBD_1_rep_VMartDesign_node0001 [Segmented: No] [Seg Cols: ] [K: 2]  
[public.customer_dimension_DBD_1_rep_VMartDesign_node0001] [Safe: Yes] [UptoDate: Yes] [Stats: Yes]
```

(1 row)

Dropping Projections

Projections can be dropped explicitly through the [DROP PROJECTION](#) statement. They are also implicitly dropped when you drop their anchor table.

Using Table Partitions

Data partitioning is [defined as a table property](#), and is implemented on all projections of that table. On all load, refresh, and recovery operations, the Vertica Tuple Mover automatically partitions data into separate ROS containers. Each ROS container contains data for a single partition; depending on space requirements, a partition can span multiple ROS containers.

For example, it is common to partition data by time slices. If a table contains decades of data, you can partition it by year. If the table contains only one year of data, you can partition it by month.

Logical divisions of data can significantly improve query execution. For example, if you query a table on a column that is in the table's partition clause, the query optimizer can quickly isolate the relevant ROS containers (see [Eliminating Partitions](#)).

Partitions can also facilitate DML operations. For example, given a table that is partitioned by months, you might drop all data for the oldest month when a new month begins. In this case, Vertica can easily identify the ROS containers that store the partition data to drop. For further details on partitions and using them, see this article, [FAQ: Vertica Partitions](#).

Defining Partitions

You can specify partitioning for a table when you initially define the table with [CREATE TABLE](#). Alternatively, you can specify partitioning for an existing table by modifying its definition with [ALTER TABLE](#). In the first case, Vertica automatically partitions data with each load operation. In the second case, you must explicitly repartition existing data with the Vertica function [PARTITION_TABLE](#).

A table definition specifies partitioning through a `PARTITION BY` clause:

```
PARTITION BY expression
```

where *expression* resolves to a value derived from one or more table columns.

Partitioning a New Table

The following `CREATE TABLE` statement creates the `trade` table, which partitions data into separate years:

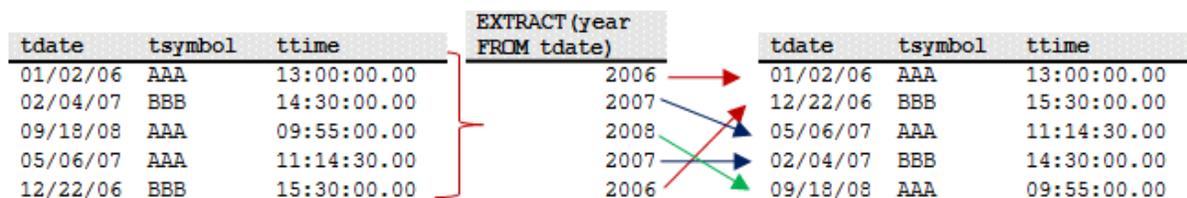

```
=> CREATE TABLE trade (  
    tdate DATE NOT NULL,
```

```

    tsymbol VARCHAR(8) NOT NULL,
    ttime TIME)
PARTITION BY EXTRACT (year FROM tdate);
CREATE TABLE
CREATE PROJECTION trade_p (tdate, tsymbol, ttime) AS
SELECT * FROM trade
ORDER BY tdate, tsymbol, ttime UNSEGMENTED ALL NODES;
INSERT INTO trade VALUES ('01/02/08' , 'AAA' , '13:00:00');
INSERT INTO trade VALUES ('02/04/09' , 'BBB' , '14:30:00');
INSERT INTO trade VALUES ('09/18/10' , 'AAA' , '09:55:00');
INSERT INTO trade VALUES ('05/06/09' , 'AAA' , '11:14:30');
INSERT INTO trade VALUES ('12/22/08' , 'BBB' , '15:30:00');

```

As new data is inserted into the table, Vertica implements its `PARTITION BY` clause as follows:

Partitioning an Existing Table

Use the `ALTER TABLE` statement to partition or repartition an existing table, as specified by the `PARTITION BY` clause. On executing this statement, Vertica immediately drops any existing partition keys.

For example, the following statements create the unpartitioned `trade` table, alter the table to add a constraint, and then insert data:

```

=> CREATE TABLE public.employee_dim(
    employee_key int NOT NULL,
    employee_gender varchar(8),
    courtesy_title varchar(8),
    employee_first_name varchar(64),
    employee_middle_initial varchar(8),
    employee_last_name varchar(64),
    employee_age int,
    hire_date date,
    employee_street_address varchar(256),
    employee_city varchar(64) NOT NULL,
    employee_state char(2),
    employee_region char(32) NOT NULL,
    job_title varchar(64),
    reports_to int,
    salaried_flag int,
    annual_salary int,
    hourly_rate float,

```

```
vacation_days int
);
CREATE TABLE
=> ALTER TABLE public.employee_dim ADD CONSTRAINT C_PRIMARY PRIMARY KEY (employee_key) ENABLED;
ALTER TABLE
=> INSERT INTO employee_dim SELECT * from employee_dimension;
OUTPUT
-----
10000
(1 row)
```

You can view how Vertica distributes the newly loaded data in various ROS containers across the cluster nodes, by querying the system table [STORAGE_CONTAINERS](#):

```
=> SELECT node_name, projection_name, storage_type, total_row_count FROM storage_containers
WHERE projection_name ilike '%employee_dim_b%' ORDER BY projection_name;
node_name      | projection_name | storage_type | total_row_count
-----|-----|-----|-----
v_vmart_node0001 | employee_dim_b0 | ROS          | 3347
v_vmart_node0002 | employee_dim_b0 | ROS          | 3321
v_vmart_node0003 | employee_dim_b0 | ROS          | 3332
v_vmart_node0001 | employee_dim_b1 | ROS          | 3332
v_vmart_node0002 | employee_dim_b1 | ROS          | 3347
v_vmart_node0003 | employee_dim_b1 | ROS          | 3321
(6 rows)
```

The following statement partitions the table on column `employee_region`:

```
=> ALTER TABLE employee_dim PARTITION BY employee_region;
=> NOTICE 4954: The new partitioning scheme will produce 6 partitions
WARNING 4493: Queries using table "employee_dim" may not perform optimally since the data may not be
repartitioned in accordance with the new partition expression
HINT: Use "ALTER TABLE public.employee_dim REORGANIZE;" to repartition the data
ALTER TABLE
```

The partition clause omits the keyword `REORGANIZE`, so table data remains unpartitioned. If you query the `STORAGE_CONTAINERS` table again, Vertica returns the same or similar results as before. Vertica repartitions table data only when it executes a mergeout operation. You can initiate a mergeout with functions [DO_TM_TASK](#) or [PARTITION_TABLE](#), or with an `ALTER TABLE . . . REORGANIZE` statement:

```
=> SELECT PARTITION_TABLE('employee_dim');
PARTITION_TABLE
-----
Task: partition operation
(Table: public.employee_dim) (Projection: public.employee_dim_b0)
(Table: public.employee_dim) (Projection: public.employee_dim_b1)
(1 row)
```

Now when you query the `STORAGE_CONTAINERS` table, the results confirm that `employee_dim` data is repartitioned into logical divisions among ROS containers. The following query joins `STORAGE_CONTAINERS` with system table [PARTITIONS](#). The truncated output below shows

how Vertica redistributes the repartitioned data. The data is now ordered by partition keys (East, Midwest, etc.) within each projection buddy (employee_dim_b0 and employee_dim_b1):

```
=> SELECT c.projection_name,
       p.partition_key,
       c.node_name,
       c.storage_type,
       c.total_row_count ROS_rows
FROM STORAGE_CONTAINERS c JOIN PARTITIONS p ON c.projection_name=p.projection_name
WHERE c.projection_name LIKE '%employee_dim%' ORDER BY c.projection_name, p.partition_key;
```

projection_name	partition_key	node_name	storage_type	ROS_rows
employee_dim_b0	East	v_vmart_node0002	ROS	745
employee_dim_b0	East	v_vmart_node0002	ROS	557
...

```

Caution: If you repartition a table without specifying REORGANIZE, Vertica stores new data according to the new partition expression, while existing data storage remains unchanged. Until you explicitly partition all table data, using either with ALTER TABLE . . . REORGANIZE statement, or with PARTITION_TABLE, query performance, DROP_PARTITION, and node recovery can be adversely affected.

Partitioning Best Practices

Recommendations

Minimize number of partitions

Vertica supports up to 1024 ROS containers per partition. In general, a ROS contains only one partition (although a partition can [sometimes span multiple ROS containers](#)). Each partition typically spans multiple ROS containers. Be aware that any delete operation requires Vertica to open all ROS containers, so a large number of partitions can adversely affect performance.

In practice, it is highly unlikely that you will approach this maximum. For optimal performance, Vertica recommends that the number of partitions range between 10 and 20, and not exceed more than 50. This range is typically compatible with most business requirements.

Avoid partitioning by LONG data types

For maximum performance, do not partition table data on LONG VARBINARY and LONG VARCHAR columns.

Tip: Partitioning by Year and Month

To partition by both year and month, the partition clause should pad the month out to two digits with an expression like this:

```
PARTITION BY EXTRACT(year FROM tdate)*100 + EXTRACT(month FROM tdate)
```

This expression formats partition keys as follows:

```
201101  
201102  
201103  
...  
201111  
201112
```

Comparing Partitioning and Segmentation

In Vertica, partitioning and segmentation are separate concepts and achieve different goals to localize data:

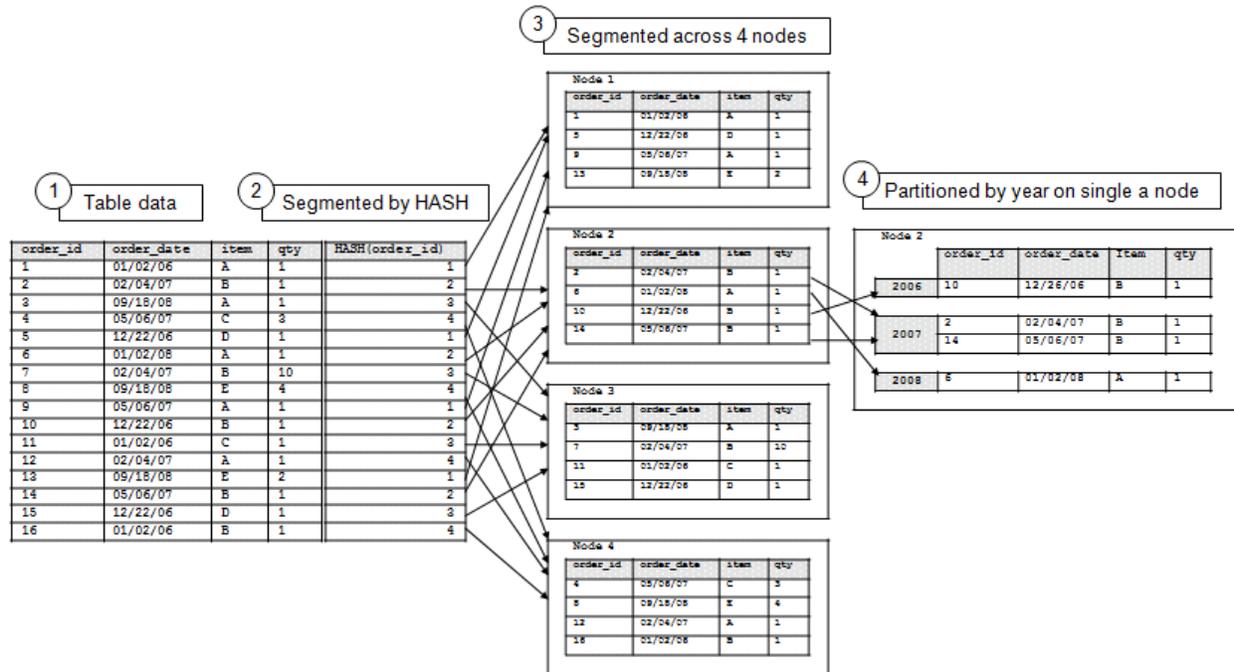

- **Segmentation** refers to organizing and distributing data across cluster nodes for fast data purges and query performance. Segmentation aims to distribute data evenly across multiple database nodes so all nodes participate in query execution. You specify segmentation with the `CREATE PROJECTION` statement's `hash segmentation clause`.
- **Partitioning** specifies how to organize data within individual nodes for distributed computing. Node partitions let you easily identify data you wish to drop and help reclaim disk space. You specify partitioning with the `CREATE TABLE` statement's `PARTITION BY` clause.

For example: partitioning data by year makes sense for retaining and dropping annual data. However, segmenting the same data by year would be inefficient, because the node holding data for the current year would likely answer far more queries than the other nodes.

The following diagram illustrates the flow of segmentation and partitioning on a four-node database cluster:

1. Example table data
2. Data segmented by `HASH(order_id)`
3. Data segmented by hash across four nodes
4. Data partitioned by year on a single node

While partitioning occurs on all four nodes, the illustration shows partitioned data on one node for simplicity.

Managing Partitions

Vertica provides various options to let you manage and monitor the partitions you create.

PARTITION_TABLE Function

The function [PARTITION_TABLE](#) physically separates partitions into separate containers. Only ROS containers with more than one distinct value participate in the split.

The following example creates a simple table states and partitions the data by state:

```
=> CREATE TABLE states (year INTEGER NOT NULL, state VARCHAR NOT NULL) PARTITION BY state;  
=> CREATE PROJECTION states_p (state, year) AS  
    SELECT * FROM states ORDER BY state, year UNSEGMENTED ALL NODES;
```

Run `PARTITION_TABLE` to partition the table `states`:

```
=> SELECT PARTITION_TABLE('states');  
           PARTITION_TABLE  
-----  
Task: partition operation  
(Table: public.states) (Projection: public.states_p)  
(1 row)
```

PARTITIONS System Table

You can display partition metadata, one row per partition key, per ROS container, by querying the [PARTITIONS](#) system table.

Given the unsegmented projection `states_p` replicated across three nodes, the following query on the `PARTITIONS` table returns twelve rows, representing twelve ROS containers:

```
=> SELECT PARTITION_KEY, ROS_ID, ROS_SIZE_BYTES, ROS_ROW_COUNT, NODE_NAME FROM partitions WHERE  
PROJECTION_NAME='states_p' order by ROS_ID;  
PARTITION_KEY | ROS_ID | ROS_SIZE_BYTES | ROS_ROW_COUNT | NODE_NAME  
-----  
VT | 45035996281231297 | 95 | 14 | v_vmart_node0001  
PA | 45035996281231309 | 92 | 11 | v_vmart_node0001  
NY | 45035996281231321 | 90 | 9 | v_vmart_node0001  
MA | 45035996281231333 | 96 | 15 | v_vmart_node0001  
VT | 49539595902704977 | 95 | 14 | v_vmart_node0002  
PA | 49539595902704989 | 92 | 11 | v_vmart_node0002  
NY | 49539595902705001 | 90 | 9 | v_vmart_node0002  
MA | 49539595902705013 | 96 | 15 | v_vmart_node0002  
VT | 54043195530075651 | 95 | 14 | v_vmart_node0003  
PA | 54043195530075663 | 92 | 11 | v_vmart_node0003  
NY | 54043195530075675 | 90 | 9 | v_vmart_node0003  
MA | 54043195530075687 | 96 | 15 | v_vmart_node0003  
(12 rows)
```

Restrictions

You cannot use volatile functions in a `PARTITION BY` expression. For example, the value of `TIMESTAMP_TZ` depends on user settings.

Eliminating Partitions

If the ROS containers of partitioned tables are not needed, Vertica can eliminate the containers from being processed during query execution. To eliminate ROS containers, Vertica compares query predicates to partition-related metadata.

Each ROS partition expression column maintains the minimum and maximum values of data stored in that ROS, and Vertica uses those min/max values to potentially eliminate ROS containers from query planning. Partitions that cannot contain matching values are not scanned. For example, if a ROS does not contain data that satisfies a given query predicate, the optimizer eliminates (prunes) that ROS from the query plan. After non-participating ROS containers have been eliminated, queries that use partitioned tables run more quickly.

Note: Partition pruning occurs at query run time and requires a query predicate on the partitioning column.

Assume a table that is partitioned by year (2007, 2008, 2009) into three ROS containers, one for each year. Given the following series of commands, the two ROS containers that contain data for 2007 and 2008 fall outside the boundaries of the requested year (2009) and get eliminated.

```
=> CREATE TABLE ... PARTITION BY EXTRACT(year FROM date);  
=> SELECT ... WHERE date = '12-2-2009';
```

date	amount	date	amount	date	amount
11/11/09	6	03/13/08	96	07/12/07	43
06/05/09	12	04/21/08	17	03/02/07	45
...
12/02/09	8	12/02/08	7	12/02/07	68
Min: 01/01/09 Max: 12/31/09		Min: 01/01/08 Max: 12/31/08		Min: 01/01/07 Max: 12/31/07	

Making Past Partitions Eligible for Elimination

The following procedure lets you make past partitions eligible for elimination. The easiest way to guarantee that all ROS containers are eligible is to:

1. Create a fact table with the same projections as the existing table.
2. Use `INSERT . . SELECT` to populate the new table.
3. Drop the original table and rename the new table.

If the disk lacks enough space for a second copy of the fact table, follow this procedure:

1. Verify that the Tuple Mover finished all post-upgrade work—for example, when the following command shows no mergeout activity:

```
=> SELECT * FROM TUPLE_MOVER_OPERATIONS;
```

2. Identify which partitions need to be merged to get the ROS minimum/maximum values:

```
=> SELECT DISTINCT table_schema, projection_name, partition_key  
FROM partitions p LEFT OUTER JOIN vs_ros_min_max_values v  
ON p.ros_id = v.delid  
WHERE v.min_value IS null;
```

3. Insert a record into each partition that has ineligible ROS containers, and commit.
4. Delete each inserted record and commit again.

At this point, the Tuple Mover automatically merges ROS containers from past partitions.

Verifying the ROS Merge

1. Query the `TUPLE_MOVER_OPERATIONS` table:

```
=> SELECT * FROM TUPLE_MOVER_OPERATIONS;
```

2. Check for any partitions that need to be merged:

```
=> SELECT DISTINCT table_schema, projection_name, partition_key  
FROM partitions p LEFT OUTER JOIN vs_ros_min_max_values v  
ON p.ros_id = v.rosid  
WHERE v.min_value IS null;
```

Examples

Assume a table that is partitioned by time and will use queries that restrict data on time.

```
=> CREATE TABLE time ( tdate DATE NOT NULL, tnum INTEGER)
    PARTITION BY EXTRACT(year FROM tdate);
=> CREATE PROJECTION time_p (tdate, tnum) AS
=> SELECT * FROM time ORDER BY tdate, tnum UNSEGMENTED ALL NODES;
```

Note: Projection sort order has no effect on partition elimination.

```
=> INSERT INTO time VALUES ('03/15/04' , 1);
=> INSERT INTO time VALUES ('03/15/05' , 2);
=> INSERT INTO time VALUES ('03/15/06' , 3);
=> INSERT INTO time VALUES ('03/15/06' , 4);
```

The data inserted in the previous series of commands are loaded into three ROS containers, one per year, as that is how the data is partitioned:

```
=> SELECT * FROM time ORDER BY tnum;
  tdate  | tnum
-----+-----
2004-03-15 |    1  --ROS1 (min 03/01/04, max 03/15/04)
2005-03-15 |    2  --ROS2 (min 03/15/05, max 03/15/05)
2006-03-15 |    3  --ROS3 (min 03/15/06, max 03/15/06)
2006-03-15 |    4  --ROS3 (min 03/15/06, max 03/15/06)
(4 rows)
```

Here's what happens when you query the `time` table:

- In this query, Vertica can eliminate ROS2 because it is only looking for year 2004:

```
=> SELECT COUNT(*) FROM time WHERE tdate = '05/07/2004';
```

- In the next query, Vertica can eliminate both ROS1 and ROS3:

```
=> SELECT COUNT(*) FROM time WHERE tdate = '10/07/2005';
```

- The following query has an additional predicate on the `tnum` column for which no minimum/maximum values are maintained. In addition, the use of logical operator OR is not supported, so no ROS elimination occurs:

```
=> SELECT COUNT(*) FROM time WHERE tdate = '05/07/2004' OR tnum = 7;
```

Dropping Partitions

Use the [DROP_PARTITION](#) function to drop a partition. Typically, this is a fast operation that discards all ROS containers that contain data for the partition. If the WOS contains table data,

DROP_PARTITION first forces a moveout operation.

Tip: When a ROS container has data for a single partition, you can discard that storage location with [DROP_LOCATION](#) after dropping that partition.

Dropping Partitions Due to Space Constraints

If your hardware has fixed disk space, you might need to configure a regular process to roll out old data by dropping partitions.

For example, if you have only enough space to store data for a fixed number of days, configure Vertica to drop the partition with the oldest date. To do so, create a time-based job scheduler, such as `cron`, to drop the partition on a regular basis during low-load periods.

If the ingest rate for data has peaks and valleys, you can use two techniques to manage how you drop partitions:

- Set up a process to check the disk space on a regular (daily) basis. If the percentage of used disk space exceeds a certain threshold—for example, 80%—drop the oldest partition.
- Add an artificial column in a partition that increments based on a metric like row count. For example, that column might increment each time that the row count increases by 100 rows. Set up a process that queries that column on a regular (daily) basis. If the value in the new column exceeds a certain threshold—for example, 100—drop the oldest partition, and set the column value back to 0.

Table Locks

DROP_PARTITION acquires an exclusive [O lock](#) on the target table to block any DML operation (DELETE, UPDATE, INSERT, or COPY) that might affect table data. The lock also blocks SELECT statements that are issued at [SERIALIZABLE](#) isolation level.

If the operation cannot obtain an [O lock](#) on the target table, Vertica tries to close any internal [tuple mover](#) (TM) sessions that are running on that table. If successful, the operation can proceed. Explicit TM operations that are running in user sessions do not close. If an explicit TM operation is running on the table, the operation proceeds only when the TM operation is complete.

Examples

Using the example schema in [Defining Partitions](#), the following command explicitly drops the 2009 partition key from table `trade`:

```
SELECT DROP_PARTITION('trade', 2009);
      DROP_PARTITION
-----
Partition dropped
(1 row)
```

Here, the partition key is specified:

```
SELECT DROP_PARTITION('trade', EXTRACT('year' FROM '2009-01-01'::date));
      DROP_PARTITION
-----
Partition dropped
(1 row)
```

The following example creates a table called `dates` and partitions the table by year:

```
CREATE TABLE dates (year INTEGER NOT NULL,
                    month VARCHAR(8) NOT NULL)
PARTITION BY year * 12 + month;
```

The following statement drops the partition using a constant for Oct 2010 ($2010*12 + 10 = 24130$):

```
SELECT DROP_PARTITION('dates', '24130');
      DROP_PARTITION
-----
Partition dropped
(1 row)
```

Alternatively, the expression can be placed in line: `SELECT DROP_PARTITION('dates', 2010*12 + 10);`

The following command first reorganizes the data if it is unpartitioned and then explicitly drops the 2009 partition key from table `trade`:

```
SELECT DROP_PARTITION('trade', 2009, false, true);
      DROP_PARTITION
-----
Partition dropped
(1 row)
```

Archiving Partitions

You can move partitions from one table to another with the Vertica function [MOVE_PARTITIONS_TO_TABLE](#). This function is useful for archiving old partitions, as part of the following procedure:

1. [Identify the partitions to archive, and move them to a temporary staging table](#) with `MOVE_PARTITIONS_TO_TABLE`.
2. [Back up the staging table](#).
3. [Drop the staging table](#).

You can retrieve and restore archived partitions at any time, as described in [Restoring Archived Partitions](#).

For general information about moving partitions, see [MOVE_PARTITIONS_TO_TABLE](#).

Move Partitions to Staging Tables

You archive historical data by identifying the partitions you wish to remove from a table. You then move each partition (or group of partitions) to a temporary staging table.

Before calling `MOVE_PARTITIONS_TO_TABLE`, you must:

- Drop any pre-join projections associated with the source table.
- Refresh all out-of-date projections.

The following recommendations apply to staging tables:

- To facilitate the backup process, create a unique schema for the staging table of each archiving operation.
- Specify new names for staging tables. This ensures that they do not contain partitions from previous move operations.

If the table does not exist, Vertica creates a table from the source table's definition, by calling `CREATE TABLE` with `LIKE` and `INCLUDING PROJECTIONS` clause. The new table inherits ownership from the source table. For details, see [Replicating a Table](#).

- Use staging names that enable other users to easily identify partition contents. For example, if a table is partitioned by dates, use a name that specifies a date or date range.

In the following example, `MOVE_PARTITIONS_TO_TABLE` specifies to move a single partition to the staging table `partn_backup.tradfes_200801`.

```
=> SELECT MOVE_PARTITIONS_TO_TABLE (  
      'prod_trades',  
      '200801',  
      '200801',  
      'partn_backup.tradfes_200801');  
MOVE_PARTITIONS_TO_TABLE  
-----  
1 distinct partition values moved at epoch 15.  
(1 row)
```

Back Up the Staging Table

After you create a staging table, you archive it through an object-level backup using a `vbr` configuration file. For detailed information, see [Backing Up and Restoring the Database](#).

Important: Vertica recommends performing a full database backup before the object-level backup, as a precaution against data loss. You can only restore object-level backups to the original database.

Drop the Staging Tables

After the backup is complete, you can drop the staging table as described in [Dropping Tables](#).

Restoring Archived Partitions

You can restore partitions that you previously moved to an intermediate table, archived as an object-level backup, and then dropped.

Note: Restoring an archived partition requires that the original table definition has not changed since the partition was archived and dropped. If you have changed the table definition, you can only restore an archived partition using `INSERT/SELECT` statements, which are not described here.

These are the steps to restoring archived partitions:

1. Restore the backup of the intermediate table you saved when you moved one or more partitions to archive (see [Archiving Partitions](#)).
2. Move the restored partitions from the intermediate table to the original table.
3. Drop the intermediate table.

Swapping Partitions

`SWAP_PARTITIONS_BETWEEN_TABLES` combines the operations of `DROP_PARTITION` and `MOVE_PARTITIONS_TO_TABLE` as a single transaction. `SWAP_PARTITIONS_BETWEEN_TABLES` is useful if you regularly load partitioned data from one table into another and need to refresh partitions in the second table.

For example, you might have a table of revenue that is partitioned by date, and you routinely move data into it from a staging table. Occasionally, the staging table contains data for dates that are already in the target table. In this case, you must first remove partitions from the target table for those dates, then replace them with the corresponding partitions from the staging table. You can accomplish both tasks with a single call to `SWAP_PARTITIONS_BETWEEN_TABLES`.

By wrapping the drop and move operations within a single transaction, `SWAP_PARTITIONS_BETWEEN_TABLES` maintains integrity of the swapped data. If any task in the swap operation fails, the entire operation fails and is rolled back.

Examples

In the following example, `SWAP_PARTITIONS_BETWEEN_TABLES` drops from table `member_info` all partitions in range specified by partition keys `2008` and `2009`. It replaces the dropped partitions with the corresponding partitions in source table `customer_info`:

```
=> SELECT SWAP_PARTITIONS_BETWEEN_TABLES('customer_info',2008,2009,'member_info');
          SWAP_PARTITIONS_BETWEEN_TABLES
-----
1 partition values from table customer_info and 2 partition values from table
member_info are swapped at epoch 1250.
```

See Also

[Tutorial for Swapping Partitions](#)

Tutorial for Swapping Partitions

The following example shows how to create two partitioned tables and then swap certain partitions between the tables.

Both tables have the same definition and have partitions for various year values. You swap the partitions where `year = 2008` and `year = 2009`. Both tables have at least two rows that will be swapped.

1. Create the `customer_info` table:

```
=> CREATE TABLE customer_info (  
    customer_id INT PRIMARY KEY NOT NULL,  
    first_name VARCHAR(25),  
    last_name VARCHAR(35),  
    city VARCHAR(25),  
    year INT NOT NULL)  
ORDER BY last_name  
PARTITION BY year;
```

2. Insert data into the `customer_info` table:

```
=> INSERT INTO customer_info VALUES (1, 'Joe', 'Smith', 'Denver', 2008);  
=> INSERT INTO customer_info VALUES (2, 'Bob', 'Jones', 'Boston', 2008);  
=> INSERT INTO customer_info VALUES (3, 'Silke', 'Muller', 'Frankfurt', 2007);  
=> INSERT INTO customer_info VALUES (4, 'Simone', 'Bernard', 'Paris', 2014);  
=> INSERT INTO customer_info VALUES (5, 'Vijay', 'Kumar', 'New Delhi', 2010);
```

3. View the table data:

```
=> SELECT * FROM customer_info;  
customer_id | first_name | last_name | city    | year  
-----+-----+-----+-----+-----  
1 | Joe      | Smith    | Denver  | 2008  
2 | Bob      | Jones    | Boston  | 2008  
3 | Silke    | Muller   | Frankfurt | 2007  
4 | Simone   | Bernard  | Paris   | 2014  
5 | Vijay    | Kumar    | New Delhi | 2010
```

4. Create a second table, `member_info`, that has the same definition as `customer_info`:

```
=> CREATE TABLE member_info (  
    customer_id INT PRIMARY KEY NOT NULL,  
    first_name VARCHAR(25),  
    last_name VARCHAR(35),  
    city VARCHAR(25),  
    year INT NOT NULL)  
ORDER BY last_name  
PARTITION BY year;
```

5. Insert data into the member_info table:

```
=> INSERT INTO member_info VALUES (1, 'Jane', 'Doe', 'Miami', 2001);  
=> INSERT INTO member_info VALUES (2, 'Mike', 'Brown', 'Chicago', 2014);  
=> INSERT INTO member_info VALUES (3, 'Patrick', 'OMalley', 'Dublin', 2008);  
=> INSERT INTO member_info VALUES (4, 'Ana', 'Lopez', 'Madrid', 2009);  
=> INSERT INTO member_info VALUES (5, 'Mike', 'Green', 'New York', 2008);
```

6. View the data in the member_info table:

```
=> SELECT * FROM member_info;  
customer_id | first_name | last_name | city | year  
-----+-----+-----+-----+-----  
1 | Jane      | Doe      | Miami | 2001  
2 | Mike     | Brown   | Chicago | 2014  
3 | Patrick  | OMalley | Dublin | 2008  
4 | Ana     | Lopez  | Madrid | 2009  
5 | Mike     | Green   | New York | 2008
```

7. To swap the partitions, run the SWAP_PARTITIONS_BETWEEN_TABLES function:

```
=> SELECT SWAP_PARTITIONS_BETWEEN_TABLES('customer_info',2008,2009,'member_info');
```

8. To verify that the partitions have been swapped, query the contents of both tables, and confirm the following results:

- After the swap, the rows in both tables whose year values are 2008 or 2009 have moved to the other table.
- The partitions that contain the rows for Ana Lopez, Mike Green, and Patrick OMalley moved from member_info to customer_info.
- The partition that contains the rows for Joe Smith and Bob Jones moved from customer_info to member_info.

```
=> SELECT * FROM customer_info;  
customer_id | first_name | last_name | city | year  
-----+-----+-----+-----+-----
```

```
4 | Simone | Bernard | Paris | 2014
5 | Vijay | Kumar | New Delhi | 2010
3 | Silke | Muller | Frankfurt | 2007
4 | Ana | Lopez | Madrid | 2009
5 | Mike | Green | New York | 2008
3 | Patrick | OMalley | Dublin | 2008

=> SELECT * FROM member_info;
customer_id | first_name | last_name | city | year
-----+-----+-----+-----+-----
2 | Bob | Jones | Boston | 2008
1 | Joe | Smith | Denver | 2008
2 | Mike | Brown | Chicago | 2014
1 | Jane | Doe | Miami | 2001
```

Handling Multiple Partitions in One ROS Container

Occasionally, a ROS container contains rows that belong to more than one partition. For example, in some cases refresh and recovery operations can generate ROS containers with mixed partitions. In general, Vertica segregates data from different partitions in different ROS containers, but exceptions can occur. This is generally true only in a database that was created with an early version of Vertica.

If a ROS container has data from multiple partitions, [DROP_PARTITION](#) executes as follows:

1. If the ROS contains table data, forces a moveout operation.
2. Divides the ROS container data among two containers:
 - One container holds the data that belongs to the partition to drop.
 - The second container holds the remaining partitions
3. Drops the specified partition.

About Constraints

Constraints specify rules on what values can go into a column. Examples of constraints:

- Primary key
- Foreign key
- Unique
- Check
- Not NULL

Using constraints can help you maintain data integrity in one or more columns. Do not define constraints on columns unless you expect to keep the data consistent.

Vertica can use constraints to perform optimizations (such as the optimized MERGE) that assume the data is consistent.

Adding Constraints

Add constraints on one or more table columns using the following SQL commands:

- [CREATE TABLE](#): Add a constraint on one or more columns.
- [ALTER TABLE](#): Add or drop a constraint on one or more columns.

Vertica recommends naming a constraint but it is optional; if you specify the `CONSTRAINT` keyword, you must give a name for the constraint.

The examples that follow illustrate several ways of adding constraints. For additional details, see:

- [Primary Key Constraints](#)
- [Foreign Key Constraints](#)
- [Unique Constraints](#)
- [Not NULL Constraints](#)
- [Check constraints](#)

Adding Column Constraints with CREATE TABLE

There are several ways to add a constraint on a column using `CREATE TABLE`:

- On the column definition using the `CONSTRAINT` keyword, which requires that you assign a constraint name, in this example, `dim1PK`:

```
CREATE TABLE dim1 ( c1 INTEGER CONSTRAINT dim1PK PRIMARY KEY,  
                    c2 INTEGER  
                    );
```

- On the column definition, omitting the `CONSTRAINT` keyword. When you omit the `CONSTRAINT` keyword, you cannot specify a constraint name:

```
CREATE TABLE dim1 ( c1 INTEGER PRIMARY KEY,  
                    c2 INTEGER
```

```
);
```

- After the column definition, using the `CONSTRAINT` keyword and assigning a name, in this example, `dim1PK`:

```
CREATE TABLE dim1 ( c1 INTEGER,  
                    c2 INTEGER,  
                    CONSTRAINT dim1pk PRIMARY KEY(c1)  
);
```

- After the column definition, omitting the `CONSTRAINT` keyword:

```
CREATE TABLE dim1 ( c1 INTEGER,  
                    c2 INTEGER,  
                    PRIMARY KEY(c1)  
);
```

Adding Two Constraints on a Column

To add more than one constraint on a column, specify the constraints one after another when you create the table column. For example, the following statement enforces both not NULL and unique constraints on the `customer_key` column, indicating that the column values cannot be NULL and must be unique:

```
CREATE TABLE test1 ( id INTEGER NOT NULL UNIQUE,  
                    ...  
);
```

Adding a Foreign Key Constraint on a Column

There are four ways to add a foreign key constraint on a column using `CREATE TABLE`. The `FOREIGN KEY` keywords are not valid *on* the column definition, only *after* the column definition:

- On the column definition, use the `CONSTRAINT` and `REFERENCES` keywords and name the constraint, in this example, `fact1dim1PK`. This example creates a column with a named foreign key constraint referencing the table (`dim1`) with the primary key (`c1`):

```
CREATE TABLE fact1 ( c1 INTEGER CONSTRAINT fact1dim1FK REFERENCES dim1(c1),  
                    c2 INTEGER  
);
```

- On the column definition, omit the **CONSTRAINT** keyword and use the **REFERENCES** keyword with the table name and column:

```
CREATE TABLE fact1 ( c1 INTEGER REFERENCES dim1(c1),  
c2 INTEGER  
);
```

- After the column definition, use the **CONSTRAINT**, **FOREIGN KEY**, and **REFERENCES** keywords and name the constraint:

```
CREATE TABLE fact1 ( c1 INTEGER,  
c2 INTEGER,  
CONSTRAINT fk1 FOREIGN KEY(c1) REFERENCES dim1(c1)  
);
```

- After the column definition, omitting the **CONSTRAINT** keyword:

```
CREATE TABLE fact1 ( c1 INTEGER,  
c2 INTEGER,  
FOREIGN KEY(c1) REFERENCES dim1(c1)  
);
```

Each of the following **ALTER TABLE** statements adds a foreign key constraint on an existing column, with and without using the **CONSTRAINT** keyword:

```
ALTER TABLE fact2  
ADD CONSTRAINT fk1 FOREIGN KEY (c1) REFERENCES dim2(c1);
```

or

```
ALTER TABLE fact2 ADD FOREIGN KEY (c1) REFERENCES dim2(c1);
```

For additional details, see [Foreign Key Constraints](#).

Adding Multicolumn Constraints

The following example defines a primary key constraint on multiple columns by first defining the table columns (**c1** and **c2**), and then specifying both columns in a **PRIMARY KEY** clause:

```
CREATE TABLE dim ( c1 INTEGER,  
c2 INTEGER,  
PRIMARY KEY (c1, c2)  
);
```

To specify multicolumn (compound) primary keys, the following example uses CREATE TABLE to define the columns. After creating the table, ALTER TABLE defines the compound primary key and names it dim2PK:

```
CREATE TABLE dim2 ( c1 INTEGER,  
  c2 INTEGER,  
  c3 INTEGER NOT NULL,  
  c4 INTEGER UNIQUE  
);  
ALTER TABLE dim2  
  ADD CONSTRAINT dim2PK PRIMARY KEY (c1, c2);
```

In the next example, you define a compound primary key as part of the CREATE TABLE statement. Then you specify the matching foreign key constraint to table dim2 using CREATE TABLE and ALTER TABLE:

```
CREATE TABLE dim2 ( c1 INTEGER,  
  c2 INTEGER,  
  c3 INTEGER NOT NULL,  
  c4 INTEGER UNIQUE,  
  PRIMARY KEY (c1, c2)  
);  
CREATE TABLE fact2 (  
  c1 INTEGER,  
  c2 INTEGER,  
  c3 INTEGER NOT NULL,  
  c4 INTEGER UNIQUE  
);  
ALTER TABLE fact2  
  ADD CONSTRAINT fact2FK FOREIGN KEY (c1, c2) REFERENCES dim2(c1, c2);
```

Specify a foreign key constraint using a reference to the table that contains the primary key. In the ADD CONSTRAINT clause, the REFERENCES column names are optional. The following ALTER TABLE statement is equivalent to the previous ALTER TABLE statement:

```
ALTER TABLE fact2 ADD CONSTRAINT fact2FK FOREIGN KEY (c1, c2) REFERENCES dim2;
```

Adding Constraints on Tables with Existing Data

When you add a constraint on a column with existing data, Vertica:

- Verifies the validity of the column values only if you are adding a primary key, unique key, or check constraint enabled for automatic enforcement.
- Does *not* verify the validity of column values for other constraint types.

If your data does not conform to the declared non-enabled constraints, your queries could yield unexpected results.

Use [ANALYZE_CONSTRAINTS](#) to check for constraint violations in your column. If you find violations, use the ALTER COLUMN SET/DROP parameters of the [ALTER TABLE](#) statement to apply or remove a constraint on an existing column.

Note: You can configure your system to automatically enforce primary key, unique key and check constraints during DML. For information on automatic enforcement, see [Enforcing Primary Key, Unique Key, and Check Constraints Automatically](#).

Altering Column Constraints

The following example uses [ALTER TABLE](#) to add column b with not NULL and default 5 constraints to a table test6:

```
CREATE TABLE test6 (a INT);  
ALTER TABLE test6 ADD COLUMN b INT DEFAULT 5 NOT NULL;
```

Use ALTER TABLE with the ALTER COLUMN and SET NOT NULL clauses to add the constraint on column a in table test6:

```
ALTER TABLE test6 ALTER COLUMN a SET NOT NULL;
```

Use the SET NOT NULL or DROP NOT NULL clause to add or remove a not NULL column constraint:

```
=> ALTER TABLE T1 ALTER COLUMN x SET NOT NULL;  
=> ALTER TABLE T1 ALTER COLUMN x DROP NOT NULL;
```

Use these clauses so that the column has the proper constraints when you have added or removed a primary key constraint on a column. You can also use them any time you want to add or remove the NOT NULL constraint.

Note: A PRIMARY KEY constraint includes a NOT NULL constraint. However, if you drop the PRIMARY KEY constraint on a column, the NOT NULL constraint remains on that column.

Enforcing Constraints

Check constraints are enforced by default unless you disable individual constraints when you create or alter the constraint, or set the parameter EnableNewCheckConstraintsByDefault to 0 (disabled). See [check constraints](#) for more information.

To maximize query performance, Vertica checks for primary key and foreign key violations when loading into the fact table of a pre-join projection. For more details, see [Enforcing Primary Key and Foreign Key Constraints](#).

Vertica checks for not NULL constraint violations when loading data, but it does not check for unique constraint violations for constraints that are not enabled.

To validate table data on constraints that are not enabled, load data without committing it by using the [COPY](#) with the NO COMMIT option. Then perform a post-load check using the [ANALYZE_CONSTRAINTS](#) function. If constraint violations are found, you can roll back the load because you have not committed it. For more details, see [Detecting Constraint Violations with ANALYZE_CONSTRAINTS](#).

Note: Vertica enforces check constraints automatically by default. You can also enforce primary key and unique key constraints automatically. See [Enforcing Primary Key, Unique Key, and Check Constraints Automatically](#).

- [ALTER TABLE](#)
- [CREATE TABLE](#)
- [COPY](#)
- [ANALYZE_CONSTRAINTS](#)

Primary Key Constraints

A primary key (PK) is a single column or combination of columns (called a *compound key*) that uniquely identifies each row in a table. A primary key constraint contains unique, non-null values.

When you apply the primary key constraint, the NOT NULL and unique constraints are added implicitly. You do not need to specify them when you create the column. However, if you remove the primary key constraint, the NOT NULL constraint continues to apply to the column. To remove the NOT NULL constraint after removing the primary key constraint, use the ALTER COLUMN DROP NOT NULL parameter of the [ALTER TABLE](#) statement (see [Dropping Constraints](#)).

The following example shows how you can add a primary key constraint on the `employee_id` field:

```
CREATE TABLE employees (employee_id INTEGER PRIMARY KEY);
```

Alternatively, you can add a primary key constraint after the column is created:

```
CREATE TABLE employees (employee_id INTEGER);  
ALTER TABLE employees  
  ADD PRIMARY KEY (employee_id);
```

Note: If you specify a primary key constraint using ALTER TABLE, the system returns the following message, which is informational only. The primary key constraint is added to the designated column.

```
WARNING 2623: Column "employee_id" definition changed to NOT NULL
```

You can also use primary keys to constrain more than one column:

```
CREATE TABLE employees (employee_id INTEGER,  
  employee_gender CHAR(1),  
  PRIMARY KEY (employee_id, employee_gender)  
);
```

When you enable automatic enforcement of primary or unique key constraints, Vertica applies enforcement for:

- INSERT
- UPDATE
- MERGE
- COPY
- COPY_PARTITIONS_TO_TABLE
- MOVE_PARTITIONS_TO_TABLE
- SWAP_PARTITIONS_BETWEEN_TABLES

Alternatively, rather than automatic enforcement, you can use ANALYZE_CONSTRAINTS to validate primary and unique key constraints after issuing these statements. For more information on enabling and disabling primary key constraints, refer to [Enforcing Primary Key, Unique Key, and Check Constraints Automatically](#).

Foreign Key Constraints

A foreign key (FK) is a column that is used to join a table to other tables to ensure referential integrity of the data. A foreign key constraint requires that a column contain only values from the primary key column on a specific dimension table.

You can create a foreign key constraint in the [CREATE TABLE](#) statement, or you can define a foreign key constraint using [ALTER TABLE](#).

A column with a foreign key constraint can contain NULL values if it does not also have a [not NULL](#) constraint, even though the NULL value does not appear in the dimension table's primary key column. This allows rows to be inserted into the table even if the foreign key is not yet known.

You can add a foreign key constraint by referencing the table that contains the primary key. The columns in the referenced table do not need to be specified explicitly.

Examples

Create a table called `inventory` to store inventory data:

```
CREATE TABLE inventory (  
  date_key INTEGER NOT NULL,  
  product_key INTEGER NOT NULL,  
  warehouse_key INTEGER NOT NULL,  
  ...  
);
```

Create a table called `warehouse` to store warehouse information:

```
CREATE TABLE warehouse (  
  warehouse_key INTEGER NOT NULL PRIMARY KEY,  
  warehouse_name VARCHAR(20),  
  ...  
);
```

To ensure referential integrity between the `inventory` and `warehouse` tables, define a foreign key constraint called `fk_inventory_warehouse` on the `inventory` table that references the `warehouse` table:

```
ALTER TABLE inventory  
  ADD CONSTRAINT fk_inventory_warehouse FOREIGN KEY(warehouse_key)  
  REFERENCES warehouse(warehouse_key);
```

In this example, the `inventory` table is the *referencing* table and the `warehouse` table is the *referenced* table.

You can also create the foreign key constraint in the CREATE TABLE statement that creates the inventory table, eliminating the need for the ALTER TABLE statement. If you do not specify one or more columns, the PRIMARY KEY of the referenced table is used:

```
CREATE TABLE inventory (  
  date_key INTEGER NOT NULL,  
  product_key INTEGER NOT NULL,  
  warehouse_key INTEGER NOT NULL REFERENCES warehouse(warehouse_key),  
  ...  
);
```

A foreign key can also constrain and reference multiple columns. The following example uses CREATE TABLE to add a foreign key constraint to a pair of columns:

```
CREATE TABLE t1 ( c1 INTEGER PRIMARY KEY,  
  c2 INTEGER,  
  c3 INTEGER,  
  FOREIGN KEY (c2, c3) REFERENCES other_table (c1, c2)  
);
```

The following two examples use ALTER TABLE to add a foreign key constraint to a pair of columns. When you use the CONSTRAINT keyword, you must specify a constraint name:

```
ALTER TABLE t ADD FOREIGN KEY (a, b) REFERENCES other_table(c, d);  
ALTER TABLE t ADD CONSTRAINT fk_cname FOREIGN KEY (a, b) REFERENCES other_table(c, d);
```

Note: The FOREIGN KEY keywords are valid only after the column definition, not *on* the column definition.

Unique Constraints

Unique constraints ensure that the data contained in a column or a group of columns is unique with respect to all rows in the table.

How to Verify Unique Constraints

Vertica allows you to add a (non-enabled) unique constraint to a column. You can then insert data into that column, regardless of whether that constraint is not unique with respect to other values in that column. If your data does not conform to the declared non-enabled constraints, your queries could yield unexpected results.

You can use [ANALYZE_CONSTRAINTS](#) to check for constraint violations, or you can enable automatic enforcement of unique key constraints. For more information on enabling and disabling unique key constraints, refer to [Enforcing Primary Key, Unique Key, and Check Constraints Automatically](#).

Add Unique Column Constraints

There are several ways to add a unique constraint on a column. If you use the `CONSTRAINT` keyword, you must specify a constraint name. The following example adds a `UNIQUE` constraint on the `product_key` column and names it `product_key_UK`:

```
CREATE TABLE product (product_key INTEGER NOT NULL CONSTRAINT product_key_UK UNIQUE,  
    ...  
);
```

Vertica recommends naming constraints, but it is optional:

```
CREATE TABLE product (product_key INTEGER NOT NULL UNIQUE,  
    ...  
);
```

You can specify the constraint after the column definition, with and without naming it:

```
CREATE TABLE product (product_key INTEGER NOT NULL,  
    ...,  
    CONSTRAINT product_key_uk UNIQUE (product_key)  
);  
CREATE TABLE product (  
    product_key INTEGER NOT NULL,  
    ...,  
    UNIQUE (product_key)  
);
```

You can also use `ALTER TABLE` to specify a unique constraint. This example names the constraint `product_key_UK`:

```
ALTER TABLE product ADD CONSTRAINT product_key_UK UNIQUE (product_key);
```

You can use `CREATE TABLE` and `ALTER TABLE` to specify unique constraints on multiple columns. If a unique constraint refers to a group of columns, separate the column names using commas. The column listing specifies that the combination of values in the indicated columns is unique across the whole table, though any one of the columns need not be (and ordinarily isn't) unique:

```
CREATE TABLE dim1 (c1 INTEGER,  
    c2 INTEGER,  
    c3 INTEGER,  
    UNIQUE (c1, c2)  
);
```

Check Constraints

A *check constraint* specifies a SQL predicate (Boolean expression) that is evaluated independently on each row of a table. The predicate cannot access data stored in other tables or database objects, such as sequences. It also cannot access data in other rows of the current table.

As with other constraints, check constraints help ensure data integrity. By default, Vertica automatically enforces check constraints. You have the option of turning this feature off for specific constraints when you create or alter them. You can also set the configuration parameter `EnableNewCheckConstraintsByDefault` to 0 (disabled), which automatically disables all check constraints that you subsequently create or alter. You can override this parameter by explicitly enabling a specific constraint.

For more information on enabling and disabling constraints, refer to [Enforcing Primary Key, Unique Key, and Check Constraints Automatically](#).

The following examples show how you can use check constraints:

Add a constraint named `smp1check` to the column `n1` without specifically enabling or disabling the constraint:

```
=> CREATE TABLE checksample (n1 int CONSTRAINT smp1check CHECK(n1<50),n2 int, n3 int);
```

Add a constraint in the disabled state:

```
=> CREATE TABLE checksample2 (n1 int CONSTRAINT smp1check2 CHECK(n1<50) DISABLED,n2 int, n3 int);
```

Use `ALTER TABLE` to add a constraint to an existing table:

```
=> ALTER TABLE checksample ADD CONSTRAINT smp1check2 CHECK(n2<100);
```

Use `ALTER TABLE` to disable an existing constraint:

```
=> ALTER TABLE checksample ALTER CONSTRAINT smp1check2 DISABLED;
```

When you enable automatic enforcement of check constraints, Vertica applies enforcement for:

- INSERT
- UPDATE
- MERGE

- COPY
- COPY_PARTITIONS_TO_TABLE (Vertica enforces check constraints on the target table.)
- MOVE_PARTITIONS_TO_TABLE (Vertica enforces check constraints on the target table.)
- SWAP_PARTITIONS_BETWEEN_TABLES (Vertica enforces check constraints on both tables.)

Alternatively, rather than automatic enforcement, you can use ANALYZE_CONSTRAINTS to validate constraints after issuing these statements. ANALYZE_CONSTRAINTS reports all constraint violations. For more information on enabling and disabling check constraints, refer to [Enforcing Primary Key, Unique Key, and Check Constraints Automatically](#)

Allowed Syntax for Check Constraint Predicates

A check constraint predicate can include:

- Arithmetic and concatenated string operators
- Logical operators — Such as AND, OR, NOT
- WHERE prepositions — Such as CASE, IN, LIKE, BETWEEN, IS (NOT) NULL
- Calls to certain types of functions — Immutable SQL macros, immutable build-in SQL functions (for example, length()) and user-defined scalar functions that are marked as immutable in the component factory.

The following examples show you how you can define hypothetical check constraints on a table. The examples assume that the table contains the referenced attributes (column names), defined as appropriate types. (The last one is an unnamed check constraint.)

```
CONSTRAINT chk_pos_quant CHECK (quantity > 0)
CONSTRAINT chk_pqe CHECK (price*quantity = extended_price)
CONSTRAINT size_sml CHECK (size in ('small', 'medium', 'large', 'x- large'))
CHECK (regexp_like(dept_name, '^[a-z]+$', 'i') OR (dept_name = 'inside sales'))
```

Restrictions on Check Constraints

A check constraint expression must evaluate to a Boolean value. However, Vertica does not support implicit conversion to a Boolean value. For example, Vertica would return an error for the following (invalid) check constraint:

```
CHECK (1) -- produces an error  
CHECK ('hello') -- produces an error
```

You must always enclose a check constraint in parentheses:

```
check (quantity > 0)
```

A check constraint expression cannot include any of the following elements:

- Subqueries — `CHECK (dept_id in (SELECT id FROM dept))`
- Aggregates — `CHECK (quantity < sum(quantity)/2)`
- Window functions — `CHECK (RANK() over () < 3)`
- SQL meta-functions — `CHECK (START_REFRESH('') = 0)`
- References to the epoch column
- References to other tables or objects (for example, sequences), or system context
- Invocation of functions that are not immutable in time and space

Check Constraints and Nulls

If a check constraint expression evaluates to an unknown for a given row because a column within the expression contains a null, the row passes the constraint condition. Vertica evaluates the predicate and considers it satisfied if it resolves to either true or unknown. For example, `check (quantity > 0)` passes validation if `quantity` is null. This result differs from how a `WHERE` clause would work. With a `WHERE` clause, the row would not be included in the result set.

You can prohibit nulls in a check constraint by explicitly including a null check in the check constraint expression. For example, `CHECK (quantity IS NOT NULL AND (quantity > 0))`. You could alternatively include a not null constraint separate from the check constraint.

Check Constraints and SQL Macros

A check constraint can call a SQL macro (a function written in SQL) if the macro is immutable. An *immutable macro* always returns the same value for a given set of arguments.

When you include a macro, Vertica determines if it is immutable. If it is not, Vertica rolls back the DDL statement.

This example shows you can create a macro name, `mycompute`, and then use it within a check constraint expression:

```
=> CREATE OR REPLACE FUNCTION mycompute(j int, name1 varchar)
RETURN int AS BEGIN RETURN (j + length(name1)); END;

=> ALTER TABLE sampletable
ADD CONSTRAINT chk_compute
CHECK(mycompute(weekly_hours, name1)<50);
```

Check Constraints and User-Defined Extensions (UDxs)

A check constraint can call user-defined scalar function (UDSFs), but not other kinds of UDxs. To use a UDSF, you must first mark it as immutable in the UDx factory.

If you use a UDSF within a check constraint, you must verify that the immutable tag on the referenced functions is correct and that the constraint handles null values properly. Otherwise, the check constraint may not work as you intended. In addition, Vertica evaluates the predicate of an enabled check constraint on every row that is loaded or updated. For performance reasons, you may want to avoid invoking a computationally expensive check constraint.

To view a sample UDSF that you can use within a check constraint, refer to [C++ Example: Calling a UDSF from a Check Constraint](#).

Dropping a Check Constraint

Use `ALTER TABLE` with the `DROP CONSTRAINT` option to explicitly drop a constraint.

If you drop a table that includes check constraints, Vertica automatically deletes all check constraints associated with the table. The `CASCADE` option is not needed.

If you drop a table column (or function object):

- If you do not specify the `CASCADE` option, Vertica returns an error if any check constraint references the column. Vertica returns the error even if the constraint is disabled.
- If you specify `CASCADE`, Vertica drops check constraints (both enabled and disabled) along with the table column (or function object).

If you rename a table column, Vertica updates the constraint predicate to use the new name.

Not NULL Constraints

A not NULL constraint specifies that a column *cannot* contain a null value. This means that new rows cannot be inserted or updated unless you specify a value for this column.

You can apply the not NULL constraint when you create a column in a new table, and when you add a column to an existing table ([ALTER TABLE . .ADD COLUMN](#)). You can also add or drop the not NULL constraint on an existing column:

- ALTER TABLE *t* ALTER COLUMN *x* SET NOT NULL
- ALTER TABLE *t* ALTER COLUMN *x* DROP NOT NULL

Important: Using the [SET | DROP] NOT NULL clause does not validate whether column data conforms to the NOT NULL constraint. Use [ANALYZE_CONSTRAINTS](#) to check for constraint violations in a table.

The not NULL constraint is implicitly applied to a column when you add the PRIMARY KEY (PK) constraint. When you designate a column as a primary key, you do not need to specify the not NULL constraint.

However, if you remove the primary key constraint, the not NULL constraint still applies to the column. Use the ALTER COLUMN . .DROP NOT NULL clause of the [ALTER TABLE](#) statement to drop the not NULL constraint after dropping the primary key constraint.

The following statement enforces a not NULL constraint on the `customer_key` column, specifying that the column cannot accept NULL values.

```
CREATE TABLE customer (customer_key INTEGER NOT NULL,  
    ...  
);
```

Dropping Constraints

To drop named constraints, use the [ALTER TABLE](#) command.

The following example drops the constraint fact2fk:

```
=> ALTER TABLE fact2 DROP CONSTRAINT fact2fk;
```

To drop constraints that you did not assign a name to, query the system table [TABLE_CONSTRAINTS](#), which returns both system-generated and user-named constraint names. For example:

```
=> SELECT * FROM TABLE_CONSTRAINTS;
```

If you do not specify a constraint name, Vertica assigns a constraint name that is unique to that table. In the following output, note the system-generated constraint name C_PRIMARY and the user-defined constraint name fk_inventory_date:

```
-[ RECORD 1 ]-----+-----  
constraint_id      | 45035996273707984  
constraint_name    | C_PRIMARY  
constraint_schema_id | 45035996273704966  
constraint_key_count | 1  
foreign_key_count  | 0  
table_id          | 45035996273707982  
foreign_table_id   | 0  
constraint_type    | p  
-[ ... ]-----+-----  
-[ RECORD 9 ]-----+-----  
constraint_id      | 45035996273708016  
constraint_name    | fk_inventory_date  
constraint_schema_id | 0  
constraint_key_count | 1  
foreign_key_count  | 1  
table_id          | 45035996273708014  
foreign_table_id   | 45035996273707994  
constraint_type    | f
```

Once you know the name of the constraint, you can then drop it using the [ALTER TABLE](#) command. (If you do not know the table name, use `table_id` to retrieve `table_name` from the [ALL_TABLES](#) table.)

Remove NOT NULL Constraints

When a column is a primary key and you drop the primary key constraint, the column retains the NOT NULL constraint. To specify that the column now can contain NULL values, use `[DROP`

NOT NULL] to remove the NOT NULL constraint.

Remove (Drop) a NOT NULL constraint on the column using [DROP NOT NULL]:

```
ALTER TABLE T1 ALTER COLUMN x DROP NOT NULL;
```

Important: Using the [SET | DROP] NOT NULL clause does not validate whether the column data conforms to the NOT NULL constraint. Use [ANALYZE_CONSTRAINTS](#) to check for constraint violations in a table.

Limitations of Dropping Constraints

- You cannot drop a primary key constraint if another table has a foreign key constraint that references the primary key.
- If you drop a primary or foreign key constraint, the system does not automatically drop the not NULL constraint on a column. You need to manually drop this constraint if you no longer want it.
- If you drop an enabled primary or unique key constraint, the system drops the associated projection if one was automatically created.

[ALTER TABLE](#)

Enforcing Primary Key and Foreign Key Constraints

Enforcing (Non-Enabled) Primary Key Constraints

Unless you enable enforcement of primary key constraints, Vertica does not enforce the uniqueness of primary key values when they are loaded into a table. Thus, a key enforcement error can occur unless one dimension row uniquely matches each foreign key value when the table is joined to a dimension table during a query:

Note: Consider using sequences or auto-incrementing columns for primary key columns, which guarantees uniqueness and avoids the constraint enforcement problem and associated overhead. For more information, see [Using Sequences](#).

For information on automatic enforcement of primary key constraints during DML, see [Enforcing Primary Key, Unique Key, and Check Constraints Automatically](#).

Foreign Key Constraint Violations

A table's foreign key constraints are not enforced during data load. Thus, it is possible to load data that causes a constraint violation. Subsequently, a constraint violation error can occur when:

- An inner join query is processed.
- An outer join is treated as an inner join due to the presence of foreign key.

Detecting Constraint Violations Before You Commit Data

To detect constraint violations, you can load data without committing it using the [COPY](#) statement with the NO COMMIT option, and then perform a post-load check using the [ANALYZE_CONSTRAINTS](#) function. If constraint violations exist, you can roll back the load because you have not committed it. For more details, see [Detecting Constraint Violations with ANALYZE_CONSTRAINTS](#).

You can also configure your system to automatically enforce primary key, unique key, and check constraints during DML. For information on automatic enforcement, see [Enforcing Primary Key, Unique Key, and Check Constraints Automatically](#).

Enforcing Primary Key, Unique Key, and Check Constraints Automatically

When you create a new constraint with [CREATE TABLE](#) or [ALTER TABLE](#), you can specify whether the constraint will be automatically enforced. You can also alter a constraint with [ALTER TABLE](#) (using the `ALTER CONSTRAINT` parameter) and specify whether it will be automatically enforced. You enable or disable individual constraints specifically using the `ENABLED` or `DISABLED` options.

In addition, you can create multi-column constraints with [CREATE TABLE](#) or [ALTER TABLE](#). All primary key and unique key constraints are defined at the table level. Check constraints are defined at the column or table level.

By checking any system table with an `is_enabled` column, you can confirm whether a primary key, unique key, or check constraint is currently enabled. The system tables that include an `is_enabled` column are [CONSTRAINT_COLUMNS](#), [TABLE_CONSTRAINTS](#), and [PRIMARY_KEYS](#).

Automatic enforcement applies to current table content and content you later add to the table.

- **Enabling a Constraint on an Empty Table** — If you create an enabled constraint on an empty table, the constraint is enforced on any content you later add to that table.
- **Enabling a Constraint on a Populated Table** — If you use [ALTER TABLE](#) to either enable an existing constraint or add a new constraint that is enabled, the constraint is immediately enforced for the current content, and is enforced for content you subsequently add to the table.

Important: If validation of the current content fails, Vertica completely rolls back the [ALTER TABLE](#) DDL statement that caused the failure.

If you do not specify the `ENABLED` or `DISABLED` option when you create a constraint, the system relies on the setting of the configuration parameter for the respective constraint:

- **EnableNewPrimaryKeysByDefault** — If you specifically create a new primary key constraint but do not enable or disable it, the system relies on the value of the parameter

EnableNewPrimaryKeysByDefault. If the parameter is set to 1 (enabled), the constraint you created is automatically enforced even though you did not specifically enable it when you created it.

- **EnableNewUniqueKeysByDefault** — If you specifically create a new unique key constraint but do not enable or disable it, the system relies on the value of the parameter `EnableNewUniqueKeysByDefault`.
- **EnableNewCheckConstraintsByDefault** — If you specifically create a new check constraint but do not enable or disable it, the system relies on the value of the parameter `EnableNewCheckConstraintsByDefault`. This parameter is the only one of the three that is set to 1 (enabled) by default.

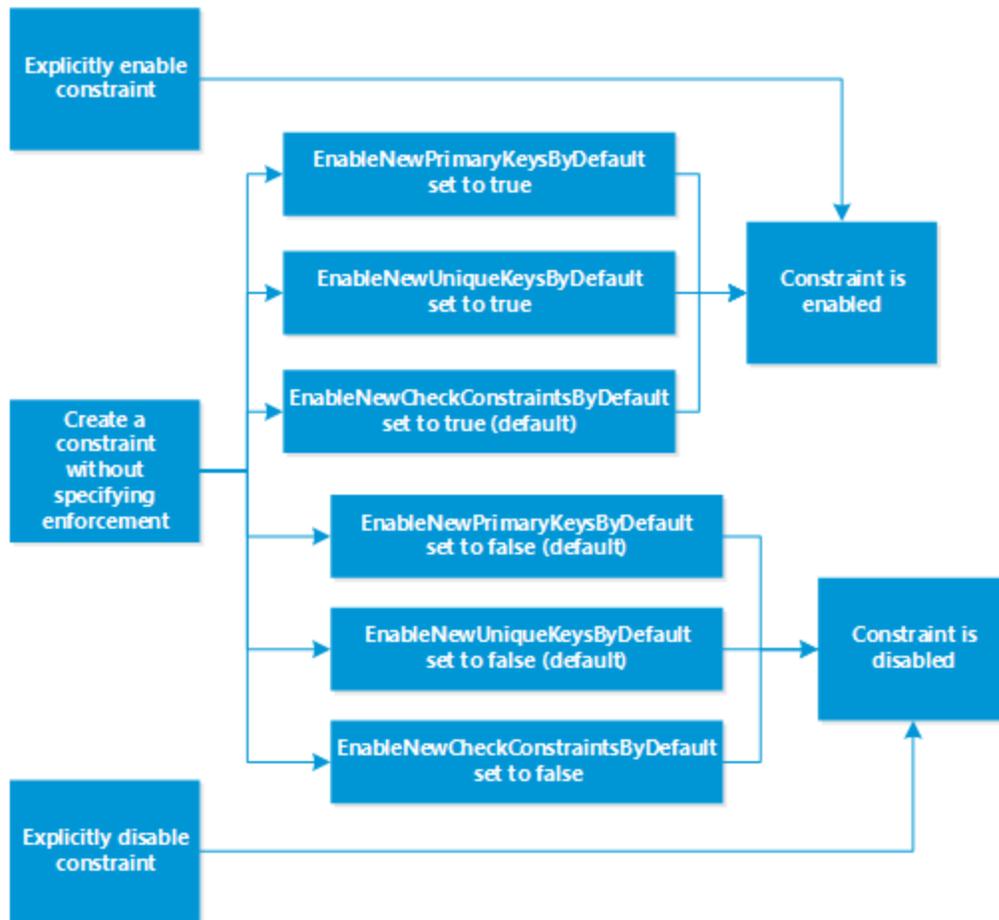

In regards to constraint enablement, you can:

- **Enable or Disable a Constraint When Creating** — You can specifically enable or disable when you create the constraint using `CREATE TABLE` or `ALTER TABLE`. If you do so, the constraint remains enabled or disabled regardless of the setting of the parameters `EnableNewPrimaryKeysByDefault`, `EnableNewUniqueKeysByDefault`, or `EnableNewCheckConstraintsByDefault`.
- **Create a Constraint Without Enabling or Disabling** — You can also create a constraint using `CREATE TABLE` or add a constraint using `ALTER TABLE` without specifically enabling or disabling it using the `ENABLED` or `DISABLED` keyword. If you do so, Vertica looks at the setting of the parameters at the moment you create or alter the constraint to determine whether that constraint is enabled or disabled. Note that, if you alter an existing constraint using `ALTER TABLE ALTER CONSTRAINT`, you must specifically enable or disable it using either the `ENABLED` or `DISABLED` keyword.

Important: When creating a constraint without enabling it, Vertica uses the settings of `EnableNewPrimaryKeysByDefault`, `EnableNewUniqueKeysByDefault`, and `EnableNewCheckConstraintsByDefault` that are in effect at the time of creation.

The following figure summarizes constraint enablement.

Enforcement of Primary, Unique Key, and Check Constraints

Enabling or Disabling Automatic Enforcement of Individual Constraints

To enable or disable individual constraints, use the [CREATE TABLE](#) or [ALTER TABLE](#) statement with the `ENABLED` or `DISABLED` options, as shown in the following examples.

The following sample uses `ALTER TABLE` to create and enable a primary key constraint on a sample table called `mytable`.

```
ALTER TABLE mytable ADD CONSTRAINT primarysample PRIMARY KEY(id) ENABLED;
```

The following sample specifically disables the constraint.

```
ALTER TABLE mytable ALTER CONSTRAINT primarysample DISABLED;
```

The following sample uses CREATE TABLE to create a primary key constraint without explicitly enabling it. In this case, the constraint is enabled only if EnableNewPrimaryKeysByDefault is also enabled. If EnableNewPrimaryKeysByDefault is set to 1 (enabled), then this constraint is enforced. If EnableNewPrimaryKeysByDefault is at its default setting (disabled), then this constraint is not enforced.

```
CREATE TABLE mytable (id INT PRIMARY KEY);
```

The following sample uses CREATE TABLE to create a primary key constraint and enable it. This statement enables the constraint regardless of how you set the parameter EnableNewPrimaryKeysByDefault.

```
CREATE TABLE mytable (id INT PRIMARY KEY ENABLED);
```

The following example uses CREATE TABLE to create and specifically disable the check constraint, chyear. This statement disables the constraint regardless of the setting of how you set the parameter EnableNewCheckConstraintsByDefault.

```
CREATE TABLE emphire (hire_date INT, termination_date INT CONSTRAINT chyear  
CHECK (termination_date >= hire_date) DISABLED, firstnameof VARCHAR, lastnameof VARCHAR);
```

Checking Whether Constraints Are Enabled

Use the SELECT statement to list constraints and confirm whether they are enabled or disabled.

This example shows a query that lists all tables along with their associated primary key, unique, and check constraint types. The query also indicates whether the constraints are enabled or disabled.

```
select table_name, constraint_name, constraint_type, is_enabled  
from v_catalog.constraint_columns where constraint_type in ('p',  
'u', 'c') order by table_name;
```

The following output shows the results of this query. The constraint_type column indicates whether the constraint is a primary key, unique key, or check constraint (p, u, or c, respectively). The is_enabled column indicates whether the constraint is enabled or disabled (t or f respectively).

```
table_name | constraint_name | constraint_type | is_enabled  
-----+-----+-----+-----  
table01   | pksample       | p               | t
```

```
table02    | uniquesample | u          | f  
table03    | checksample  | c          | t  
  
(3 rows)
```

The following example is similar but shows how you can create a query that lists associated columns instead of tables. You could add both tables and columns to the same query, if you want.

```
select column_name, constraint_name, constraint_type, is_enabled  
from v_catalog.constraint_columns where constraint_type in ('p',  
'u', 'c') order by column_name;
```

Sample output follows.

```
column_name | constraint_name | constraint_type | is_enabled  
-----+-----+-----+-----  
col1_key    | pksample       | p              | t  
vendor_key  | uniquesample   | u              | f  
zip_key     | checksample    | c              | t  
  
(2 rows)
```

The following example statement shows how to create a sample table with a multi-column constraint.

```
CREATE TABLE table09 (column1 int, column2 int, CONSTRAINT  
multicsample PRIMARY KEY (column1, column2) ENABLED);
```

Here's the output listing associated columns.

```
column_name | constraint_name | constraint_type | is_enabled  
-----+-----+-----+-----  
column1     | multicsample    | p              | t  
column2     | multicsample    | p              | t  
  
(2 rows)
```

Choosing Default Enforcement for Newly Declared or Modified Constraints

The `EnableNewPrimaryKeysByDefault` and `EnableNewUniqueKeysByDefault` parameter settings govern automatic enforcement of primary key and unique key constraints. The parameter

`EnableNewCheckConstraintsByDefault` governs automatic enforcement of check constraints, and is the only one of the three parameters that is enabled by default.

Important: If you disable enforcement with a parameter, the constraints you create or modify are not enforced unless you specifically enable them using `CREATE TABLE` or `ALTER TABLE`.

You do not need to restart your database once you have set these parameters.

- To enable or disable enforcement of newly created primary keys, set the parameter `EnableNewPrimaryKeysByDefault`. To disable, keep the default setting of 0. To enforce the constraints, set `EnableNewPrimaryKeysByDefault` to 1 to enable.

```
ALTER DATABASE VMart SET EnableNewPrimaryKeysByDefault = 1;
```

- To enable or disable enforcement of newly created constraints for unique keys, set the parameter `EnableNewUniqueKeysByDefault`. To disable, keep the default setting of 0. Set `EnableNewUniqueKeysByDefault` to 1 to enable.

```
ALTER DATABASE VMart SET EnableNewUniqueKeysByDefault = 1;
```

- To enable or disable enforcement of newly created check constraints, set the parameter `EnableNewCheckConstraintsByDefault`. To enable, keep the default setting of 1. Set `EnableNewCheckConstraintsByDefault` to 0 to disable.

```
ALTER DATABASE VMart SET EnableNewCheckConstraintsByDefault = 0;
```

You can check individual parameter values using `SHOW CURRENT`:

```
=> show current EnableNewCheckConstraintsByDefault;
 level | name | setting
-----+-----+-----
DATABASE | EnableNewCheckConstraintsByDefault | 0
```

When you upgrade to Vertica 7.0.x, the primary and unique key constraints in any tables you carry over are disabled. Existing constraints are not automatically enforced. To enable existing constraints and make them automatically enforceable, manually enable each constraint using the `ALTER TABLE ALTER CONSTRAINT` statement. This statement triggers constraint enforcement for the existing table contents. Statements roll back if one or more violations occur.

How Enabled Primary and Unique Key Constraints Affect Locks

If you enable automatic constraint enforcement, Vertica uses an Insert-Validate (IV) lock. The IV lock is needed for operations where the system performs constraint validation for enabled PRIMARY or UNIQUE key constraints. Such operations can include INSERT, COPY, MERGE, UPDATE, MOVE_PARTITIONS_TO_TABLE.

How DML Operates with Constraints

With enforced primary or unique key constraints, DML operates in two-stages.

- **First Stage.** The first stage is the same as it would be for an unenforced constraint, taking, for example, an I lock. (This could be done by several sessions concurrently loading the same table.)
- **Second Stage.** The second stage includes the IV lock. Vertica takes an IV lock to make sure that the data does not violate your constraint. After performing this check, Vertica can commit the data.

Delays in Bulk Loading Caused by Constraint Validation

In bulk load situations, some transactions could be temporarily blocked while primary or unique key constraints are validated. For example:

You could have three sessions (for example, sessions 1, 2 and 3). Each session concurrently has an I lock for a bulk load. Session 1 takes an IV lock to validate constraints. Only one session can hold an IV lock on a given table; other sessions can continue loading the table while holding I locks.

Sessions 2 and 3 wait for session 1 to validate constraints, and then commit, releasing the IV lock. (If session 1 fails, the statement rolls back, and the next session can obtain the IV lock. While sessions can load the table in parallel, an IV lock requires that sessions takes turns obtaining the IV lock for the final stage of constraint validation.)

For information on lock modes and compatibility and conversion matrices, see [Lock Modes](#) in Vertica Concepts. See also the [LOCKS](#) and [LOCK_USAGE](#) sections in the SQL Reference Manual.

Projections for Enabled Primary and Unique Key Constraints

To enforce primary and unique key constraints, Vertica creates special key projections as needed in response to DML or DDL, which are checked for constraint violations. If a constraint violation occurs, Vertica rolls back the statement and any special key projection it created. The system returns an error specifying the unique or primary key constraint that was violated.

If you have added a constraint on a table that is empty, Vertica does not immediately create a special key projection for that constraint. Vertica defers creation of a special key projection until the first row of data is added to the table using a DML or COPY statement. If you add a constraint to a populated table, Vertica chooses an existing projection for enforcement of the constraint, if possible. If none of the existing projections are sufficient to validate the constraint, Vertica creates a new projection for the enabled constraint.

You can check primary and unique key constraint projections by querying the [PROJECTIONS](#) systems table under the [V_CATALOG Schema](#). Each entry applying to a key constraint projection include the column name `IS_KEY_CONSTRAINT_PROJECTION`.

If you drop an enabled primary or unique key constraint, the system may drop an associated projection if one was automatically created. You can drop a specific projection even if a key constraint is enabled:

- If you drop a specific projection without including the `CASCADE` option in your `DROP` statement, Vertica issues a warning about dropping a projection for an enabled constraint.
- If you drop a specific projection and include the `CASCADE` option in your `DROP` statement, Vertica drops the projection without issuing the warning.

In either case, the next time Vertica needs to enforce the constraint for DML, the system creates a new special key projection, unless an existing projection can enforce the same enabled constraint. The time it takes to regenerate a key projection depends upon the volume of the table.

Note: If you subsequently use `ANALYZE_CONSTRAINTS` on a table that has enabled primary or unique key constraints (and thus their associated projections), `ANALYZE_CONSTRAINTS` can leverage the projections previously created for enforcement, resulting in a performance improvement for [ANALYZE_CONSTRAINTS](#).

Deciding Whether to Enable Primary Key, Unique Key, and Check Constraints

You have the option to choose automatic enforcement of primary key, unique key, and check constraints. Depending upon your specific scenario, you can either enable this feature, or use `ANALYZE_CONSTRAINTS` to validate constraints. Consider these factors:

- [Benefits of Enabling Primary Key, Unique Key, and Check Constraints](#)
- [Considerations Before Enabling Constraints](#)
- [Where Constraints Are Enforced](#)
- [Impact of Floating Point Values in Primary Keys When Using Automatic Enforcement](#)
- [Constraint Enforcement Limitations](#)

For more information on using `ANALYZE_CONSTRAINTS` and how automatic enforcement differs, see the Administrator's Guide section, [Detecting Constraint Violations with `ANALYZE_CONSTRAINTS`](#).

Benefits of Enabling Primary Key, Unique Key, and Check Constraints

When you enable primary key, unique key, or check constraints, Vertica validates data before it is inserted. Because you do not need to validate data using `ANALYZE_CONSTRAINTS` after insertion, query speed improves.

Having enabled key constraints, particularly on primary keys, can help the optimizer produce faster query plans, particularly for joins. When a table has an enabled primary key constraint, the optimizer can assume that it has no rows with duplicate values across the key set.

Vertica automatically creates special purpose projections, if necessary, to enforce enabled key constraints. In some cases Vertica can use an existing projection instead.

Considerations Before Enabling Constraints

Multiple factors affect performance. The enforcement process can slow DML and bulk loading.

If you are doing bulk loads, consider the size of your tables and the number of columns in your keys. You could decide to disable automatic enforcement for fact tables, which tend to be larger, but enable enforcement for dimension tables. For fact tables, you could choose manual constraint validation using [ANALYZE_CONSTRAINTS](#), and avoid the load-time overhead of automatic validation.

When you enable automatic enforcement of primary key, unique key, or check constraints, statement rollbacks occur if validation fails during DML. Vertica completely rolls back the statement causing the failure. When deciding to enable automatic enforcement of constraints, consider the impact of statements rolling back on violations. For example, you issue ten insert statements, none of which have committed. If the sixth statement introduces a duplicate, that statement is rolled back. The other statements that do not introduce duplicates can commit.

Note: Vertica performs primary key, unique key, and check constraint enforcement at the SQL statement level rather than the transaction level. You cannot defer enforcement until transaction commit.

Where Constraints Are Enforced

Automatic enforcement of constraints occurs in:

- INSERT statements — Both in single row insertions, and in an INSERT statement that includes the SELECT parameter.
- Bulk loads — On bulk loads that use the COPY statement.
- UPDATE or MERGE statements — All UPDATE and MERGE statements.
- Meta functions — On COPY_PARTITIONS_TO_TABLE, MOVE_PARTITIONS_TO_TABLE and SWAP_PARTITIONS_BETWEEN_TABLES.
- ALTER TABLE statements — On statements that include either the ADD CONSTRAINT or ALTER CONSTRAINT parameters where you are enabling a constraint and the table has existing data.

Impact of Floating Point Values in Primary Keys When Using Automatic Enforcement

Vertica allows NaN, +Inf, and -Inf values in a FLOAT type column, even if the column is part of a primary key. Because FLOAT types provide imprecise arithmetic, Vertica recommends that you not use columns with floating point values within primary keys.

If you do decide to use a FLOAT type within a primary key, note the following in regards to primary key enforcement. (This behavior is the same regardless of whether you enable an automatic constraint or check constraints manually with `ANALYZE_CONSTRAINTS`.)

- For the purpose of enforcing key constraints, Vertica considers two NaNs, (or two +Inf, or two -Inf) values to be equal.
- If a table has an enabled single column primary key constraint of type FLOAT, only one tuple can have a NaN value for the column. Otherwise, the constraint is violated. This is also true for +Inf and -Inf values. Note that this differs from the IEEE 754 standard, which specifies that multiple NaN values are different from each other.
- A join on a single column that contains FLOAT values fails if the table that includes a primary key contains multiple tuples with two NaNs (or +Inf, or -Inf) values.

For information on floating point type, see [DOUBLE PRECISION \(FLOAT\)](#).

Constraint Enforcement Limitations

You can only enable or disable automatic enforcement for primary key, unique key, and check constraints. Vertica does not support automatic enforcement of foreign keys and referential integrity. You can manually validate foreign key constraints using the meta-function [ANALYZE_CONSTRAINTS](#).

Vertica does not support automatic enforcement of constraints on external tables.

Limitations on Using Automatic Enforcement for Local and Global Temporary Tables

This section includes limitations and related notes on using automatic enforcement of primary and unique key constraints with local and global temporary tables. For general information on temporary tables, see [Creating Temporary Tables](#).

Limitations for Local and Global Temporary Tables

Vertica displays an error message if you add an enabled constraint to a local or global temporary table that contains data. Vertica displays the error because it cannot create

projections for enabled constraints on a temporary table if that table is already populated with data.

Limitations Specific to Global Temporary Tables

You cannot use ALTER TABLE to add a new or enable an existing primary or unique key constraint on a global temporary table. Use CREATE TABLE to enable a constraint on a global temporary table.

You can use ALTER TABLE to add a new or enable an existing primary or unique key constraint on a local temporary table if the local temporary table is empty.

Note: You can use ALTER TABLE to disable an already enabled primary or unique key constraint on a global temporary table.

Reporting Constraint Violations

For enabled constraints, Vertica reports multiple constraint violations before roll back. It reports multiple violations for primary key and unique constraints in all circumstances (for example, when you are loading or moving data). However, Vertica behaves differently for check constraints.

Reporting Primary Key and Unique Constraint Violations

The following example shows multiple duplicates in a file named `sampledatafile.tbl`. The sample table named `pktest` includes an enabled primary key comprised of the column `cost`. Vertica reports the duplicates when you attempt to load the table.

```
VMart=> CREATE TABLE pktest(cost int constraint costcons primary key enabled,destination int,timemorn
int,finish int);
CREATE TABLE

VMart=> copy pktest from '/home/dbadmin/test/sampledatafile.tbl' delimiter ',';

ERROR 6745: Duplicate key values: 'cost=106'
-- violates constraint 'public.pktest.costcons'

DETAIL: Additional violations:
Constraint 'public.pktest.costcons':
duplicate key values: 'cost=110'; 'cost=114'; 'cost=115'; 'cost=116'; 'cost=117';
'cost=118'; 'cost=119'; 'cost=120'; 'cost=121'; 'cost=122'; 'cost=123'; 'cost=124';
'cost=125'; 'cost=135'; 'cost=136'; 'cost=137'; 'cost=138'; 'cost=139'; 'cost=150';
'cost=151'; 'cost=20'; 'cost=200'; 'cost=251'; 'cost=252'; 'cost=255'; 'cost=257';
'cost=258'; 'cost=261'; 'cost=263';
```

```
Note: there were additional errors
```

As shown in the example, Vertica provides more complete information on the first violation, including the name of the constraint that was violated:

```
ERROR 6745: Duplicate key values: 'cost=106'  
-- violates constraint 'public.pktest.costcons'
```

For subsequent violations, it reports abbreviated detail, up to a maximum of 30 violations. If there are more than 30 violations, Vertica adds the note "there were additional errors" at the end of the list of violations:

```
DETAIL: Additional violations:  
Constraint 'public.pktest.costcons':  
duplicate key values: 'cost=110'; 'cost=114'; 'cost=115'; 'cost=116'; 'cost=117';  
'cost=118'; 'cost=119'; 'cost=120'; 'cost=121'; 'cost=122'; 'cost=123'; 'cost=124';  
'cost=125'; 'cost=135'; 'cost=136'; 'cost=137'; 'cost=138'; 'cost=139'; 'cost=150';  
'cost=151'; 'cost=20'; 'cost=200'; 'cost=251'; 'cost=252'; 'cost=255'; 'cost=257';  
'cost=258'; 'cost=261'; 'cost=263';
```

```
Note: there were additional errors
```

Refer to the section [Primary Key Constraints](#) for general information on where Vertica applies enforcement for enabled primary key and unique constraints.

Reporting Multiple Check Constraints

For enabled check constraints, Vertica reports only one constraint violation before roll back with three exceptions:

- You add or change an enabled check constraint on a table that already contains data.
- You move or copy partitions to a table, or when you swap partitions between tables.
- You copy a table using the Vertica function `COPY_TABLE`.

Refer to the section [Check Constraints](#) for general information on where Vertica applies enforcement for enabled check constraints.

This example shows multiple check constraint violations using the Vertica function `COPY_TABLE`.

```
VMart=> create table a(a int);  
CREATE TABLE  
VMart=> create table b(a int check(a>5));  
CREATE TABLE
```

```
VMart=> copy b from stdin;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 6
>> 7
>> 8
>> \.
VMart=> copy a from stdin;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1
>> 2
>> 3
>> 4
>> 1
>> 2
>> 3
>> 4
>> \.
VMart=> select copy_table('a','b');
NOTICE 7636: Validating enabled constraints on table 'public.b'...
ERROR 7231: Check constraint 'public.b.C_CHECK' (b.a > 5) violation in table 'public.b': 'a=1'
DETAIL: Additional violations:
Check constraint 'public.b.C_CHECK':
violations: 'a=2'; 'a=3'; 'a=4'
```

Naming Constraints

You can create and name constraints in different ways, as the following examples show. Micro Focus recommends that you name your constraints. If you do not name your constraints, Vertica assigns a name. The examples show various statement syntaxes for creating and altering named and unnamed constraints.

Naming a Primary Key Constraint

Create a table with a named primary key, where the named constraint is `myconstraint`.

```
=> CREATE TABLE addapk (col1 INT CONSTRAINT myconstraint PRIMARY KEY ENABLED, col2 INT);
CREATE TABLE
```

Query the `PRIMARY_KEYS` table to view the constraint.

```
=> SELECT constraint_name, column_name, constraint_type, is_enabled FROM PRIMARY_KEYS WHERE table_
name IN ('addapk');
```

```
constraint_name | column_name | constraint_type | is_enabled
-----+-----+-----+-----
```

```
myconstraint | col1 | p | t  
(1 row)
```

Creating a Primary Key Constraint Without Naming

Create a table with a primary key constraint, where you do not name the constraint. In this case, Vertica assigns a name to the constraint.

```
=> CREATE TABLE addapk (col1 INT PRIMARY KEY ENABLED, col2 INT);
```

Query the PRIMARY_KEYS table to view the constraint. Vertica has named the constraint C_PRIMARY.

```
=> SELECT constraint_name, column_name, constraint_type, is_enabled FROM PRIMARY_KEYS WHERE table_name IN ('addapk');
```

```
constraint_name | column_name | constraint_type | is_enabled  
-----+-----+-----+-----  
C_PRIMARY      | col1       | p              | t  
(1 row)
```

Altering Named and Unnamed Constraints

Alter a table that includes a constraint that you named.

```
=> ALTER TABLE addapk ALTER CONSTRAINT myconstraint DISABLED;
```

Alter a table with a constraint to which Vertica has assigned a name.

```
=> ALTER TABLE addapk ALTER CONSTRAINT C_PRIMARY DISABLED;
```

Alter a table by adding a newly named constraint.

```
=> CREATE TABLE addapk (col1 INT, col2 INT);  
CREATE TABLE  
  
=> ALTER TABLE addapk ADD CONSTRAINT myconstraint PRIMARY KEY (COL1) ENABLED;  
WARNING 2623: Column "col1" definition changed to NOT NULL  
ALTER TABLE
```

Alter a table, and let Vertica name the constraint.

```
=> CREATE TABLE addapk (col1 INT, col2 INT);  
CREATE TABLE  
  
=> ALTER TABLE addapk ADD PRIMARY KEY (COL1) ENABLED;  
WARNING 2623: Column "col1" definition changed to NOT NULL
```

```
ALTER TABLE
```

Creating a Multi-Column Constraint

Create a table with a primary key that comprises three columns.

```
=> CREATE TABLE addapk (col1 INT, col2 INT, col3 INT, col4 INT, col5 INT, PRIMARY KEY  
(col1,col2,col3) ENABLED);
```

Query the PRIMARY_KEYS table to view the multi-column primary key constraint.

```
=> SELECT constraint_name, column_name, constraint_type, is_enabled FROM PRIMARY_KEYS WHERE table_  
name IN ('addapk');
```

constraint_name	column_name	constraint_type	is_enabled
C_PRIMARY	col1	p	t
C_PRIMARY	col2	p	t
C_PRIMARY	col3	p	t

(3 rows)

Create a table with a primary key that comprises three columns, and name the constraint.

```
=> CREATE TABLE addapk (col1 INT, col2 INT, col3 INT, col4 INT, col5 INT, CONSTRAINT myconstraint  
PRIMARY KEY (col1,col2,col3) ENABLED);  
CREATE TABLE
```

Add a three-column primary key after you create the table.

```
=> CREATE TABLE addapk (col1 INT, col2 INT, col3 INT, col4 INT, col5 INT);  
CREATE TABLE  
  
=> ALTER TABLE addapk ADD CONSTRAINT myconstraint PRIMARY KEY (col1,col2,col3) ENABLED;  
WARNING 2623: Column "col1" definition changed to NOT NULL  
WARNING 2623: Column "col2" definition changed to NOT NULL  
WARNING 2623: Column "col3" definition changed to NOT NULL  
ALTER TABLE
```

Creating Multiple Constraint Types

The following example adds three constraints, including primary key, unique, and check constraints.

```
=> CREATE TABLE addapk (col1 INT CONSTRAINT myPKconstraint PRIMARY KEY ENABLED, col2 INT CONSTRAINT  
myUconstraint UNIQUE ENABLED, col3 INT CONSTRAINT myChconstraint CHECK(col1<col2));  
CREATE TABLE
```

Query the CONSTRAINT_COLUMNS table to view the constraints.

```
=> SELECT column_name, constraint_name, constraint_type, is_enabled FROM constraint_columns WHERE  
constraint_type IN ('c','p','u') AND table_name IN ('addapk');
```

column_name	constraint_name	constraint_type	is_enabled
col1	myCHconstraint	c	t
col1	myPKconstraint	p	t
col2	myUconstraint	u	t
col2	myCHconstraint	c	t

(4 rows)

Detecting Constraint Violations with `ANALYZE_CONSTRAINTS`

Use the [ANALYZE_CONSTRAINTS](#) function to manually validate table constraints.

Ways to Use `ANALYZE_CONSTRAINTS`

You can use `ANALYZE_CONSTRAINTS` instead of (or as a supplement to) automatic enforcement of primary key, unique key, and check constraints. For information on automatic enforcement, see [Enforcing Primary Key, Unique Key, and Check Constraints Automatically](#).

If you do enable primary key, unique key, and check constraints, note that `ANALYZE_CONSTRAINTS` does not check whether the constraints are disabled or enabled. You can use `ANALYZE_CONSTRAINTS` where:

- Primary key, unique key, and check constraints are disabled.
- Enabled and disabled constraints are mixed.

You can use `ANALYZE_CONSTRAINTS` to validate referential integrity of foreign keys. Vertica does not support automatic enforcement of foreign keys.

How to Use `ANALYZE_CONSTRAINTS` to Detect Violations

The `ANALYZE_CONSTRAINTS` function analyzes and reports on constraint violations within the current schema search path. To check for constraint violations:

- Pass an empty argument to check for violations on all tables within the current schema.
- Pass a single table argument to check for violations on the specified table.
- Pass two arguments, a table name and a column or list of columns, to check for violations in those columns.

See the examples in [ANALYZE_CONSTRAINTS](#) for more information.

How ANALYZE_CONSTRAINTS Differs from Automatic Constraint Enforcement

Use ANALYZE_CONSTRAINTS as a reporting mechanism to find constraint violations. ANALYZE_CONSTRAINTS differs from automatic enforcement in that it does not enforce constraints.

Automatic enforcement of primary key, unique key, and check constraints does enforce constraints.

If you have set your constraints for automatic enforcement, during a bulk load Vertica reports on one row and rolls back the statement that introduced the constraint violation. If you want to see a report for all constraint violations:

- Disable the automatic enforcement of your constraints.
- After the bulk load, run ANALYZE_CONSTRAINTS. ANALYZE_CONSTRAINTS analyzes and reports all rows that violate a constraint, without removing the offending rows.

Impact of Floating Point Values In Primary Keys When Using ANALYZE_CONSTRAINTS

Vertica allows NaN, +Inf, and -Inf values in a FLOAT type column, even if the column is part of a primary key. Because FLOAT types provide imprecise arithmetic, Vertica recommends that you not use columns with floating point values within primary keys.

If you do decide to use a FLOAT type within a primary key, note the following in regards to primary key enforcement. (This behavior is the same regardless of whether you enable an automatic constraint or check constraints manually with ANALYZE_CONSTRAINTS.)

- For the purpose of enforcing key constraints, Vertica considers two NaNs, (or two +Inf, or two -Inf) values to be equal.
- If a table has an enabled single column primary key constraint of type FLOAT, only one tuple can have a NaN value for the column. Otherwise, the constraint is violated. This is also true for +Inf and -Inf values. Note that this differs from the IEEE 754 standard, which specifies that multiple NaN values are different from each other.
- A join on a single column that contains FLOAT values fails if the table that includes a primary key contains multiple tuples with two NaNs (or +Inf, or -Inf) values.

For information on floating point type, see [DOUBLE PRECISION \(FLOAT\)](#).

Examples

If you provide the following inputs, Vertica returns one row, indicating one violation, because the same primary key value (10) was inserted into table t1 twice.

```
=> CREATE TABLE t1(c1 INT);
=> ALTER TABLE t1 ADD CONSTRAINT pk_t1 PRIMARY KEY (c1);
=> CREATE PROJECTION t1_p (c1) AS SELECT *
    FROM t1 UNSEGMENTED ALL NODES;
=> INSERT INTO t1 values (10);
=> INSERT INTO t1 values (10); --Duplicate primary key value

=> \x
Expanded display is on.

=> SELECT ANALYZE_CONSTRAINTS('t1');

-[ RECORD 1 ]-----
Schema Name | public
Table Name  | t1
Column Names | c1
Constraint Name | pk_t1
Constraint Type | PRIMARY
Column Values | ('10')
```

In the preceding query, if you give the second INSERT statement any different value, the result is 0 rows (no violations).

In the following example, create a table that contains three integer columns, one a unique key and one a primary key.

```
=> CREATE TABLE table_1(
  a INTEGER,
  b_UK INTEGER UNIQUE,
  c_PK INTEGER PRIMARY KEY
);
```

Insert some values into table table_1 and commit the changes:

```
=> INSERT INTO table_1 values (1, 1, 1);
=> COMMIT;
```

Run ANALYZE_CONSTRAINTS on table table_1. No constraint violations are reported:

```
=> SELECT ANALYZE_CONSTRAINTS('table_1');
(No rows)
```

Insert duplicate unique and primary key values and run ANALYZE_CONSTRAINTS on table table_1 again. Vertica returns two violations: one against the primary key and one against the unique key:

```
=> INSERT INTO table_1 VALUES (1, 1, 1);
=> COMMIT;
=> SELECT ANALYZE_CONSTRAINTS('table_1');

-[ RECORD 1 ]-----
Schema Name      | public
Table Name       | table_1
Column Names     | b_UK
Constraint Name  | C_UNIQUE
Constraint Type  | UNIQUE
Column Values    | ('1')
-[ RECORD 2 ]-----
Schema Name      | public
Table Name       | table_1
Column Names     | c_PK
Constraint Name  | C_PRIMARY
Constraint Type  | PRIMARY
Column Values    | ('1')
```

The following example shows how you can look for constraint violations on only the unique key in the table `table_1`, qualified with its schema name.

```
=> SELECT ANALYZE_CONSTRAINTS('public.table_1', 'b_UK');

-[ RECORD 1 ]-----
Schema Name      | public
Table Name       | table_1
Column Names     | b_UK
Constraint Name  | C_UNIQUE
Constraint Type  | UNIQUE
Column Values    | ('1')

(1 row)
```

The following example shows that you can specify the same column more than once; `ANALYZE_CONSTRAINTS`, however, returns the violation only once.

```
=> SELECT ANALYZE_CONSTRAINTS('table_1', 'c_PK, C_PK');

-[ RECORD 1 ]-----
Schema Name      | public
Table Name       | table_1
Column Names     | c_PK
Constraint Name  | C_PRIMARY
Constraint Type  | PRIMARY
Column Values    | ('1')
```

The following example creates a new table, `table_2`, and inserts a foreign key and different (character) data types.

```
=> CREATE TABLE table_2 (
  x VARCHAR(3),
  y_PK VARCHAR(4),
  z_FK INTEGER REFERENCES table_1(c_PK));
```

Alter the table to create a multicolumn unique key and multicolumn foreign key and create superprojections:

```
=> ALTER TABLE table_2
  ADD CONSTRAINT table_2_multiuk PRIMARY KEY (x, y_PK);
WARNING 2623: Column "x" definition changed to NOT NULL
WARNING 2623: Column "y_PK" definition changed to NOT NULL
```

The following statement inserts a missing foreign key (0) into table `table_2` and commits the changes.

```
=> INSERT INTO table_2 VALUES ('r1', 'Xpk1', 0);
=> COMMIT;
```

Checking for constraints on the table `table_2` in the public schema detects a foreign key violation:

```
=> SELECT ANALYZE_CONSTRAINTS('public.table_2');

-[ RECORD 1 ]-----
Schema Name   | public
Table Name    | table_2
Column Names  | z_FK
Constraint Name | C_FOREIGN
Constraint Type | FOREIGN
Column Values  | ('0')
```

Now add a duplicate value into the unique key and commit the changes:

```
=> INSERT INTO table_2 VALUES ('r2', 'Xpk1', 1);
=> INSERT INTO table_2 VALUES ('r1', 'Xpk1', 1);
=> COMMIT;
```

Checking for constraint violations on table `table_2` detects the duplicate unique key error:

```
=> SELECT ANALYZE_CONSTRAINTS('table_2');

-[ RECORD 1 ]-----
Schema Name   | public
Table Name    | table_2
Column Names  | z_FK
Constraint Name | C_FOREIGN
Constraint Type | FOREIGN
Column Values  | ('0')
-[ RECORD 2 ]-----
Schema Name   | public
Table Name    | table_2
Column Names  | x, y_PK
Constraint Name | table_2_multiuk
Constraint Type | PRIMARY
Column Values  | ('r1', 'Xpk1')
```

Create a table with multicolumn foreign key and then create the superprojections:

```
=> CREATE TABLE table_3(  
    z_fk1 VARCHAR(3),  
    z_fk2 VARCHAR(4));  
=> ALTER TABLE table_3  
    ADD CONSTRAINT table_3_multifk FOREIGN KEY (z_fk1, z_fk2)  
    REFERENCES table_2(x, y_PK);
```

Insert a foreign key that matches a foreign key in table `table_2` and commit the changes:

```
=> INSERT INTO table_3 VALUES ('r1', 'Xpk1');  
=> COMMIT;
```

Check for constraints on table `table_3`. The query detects no violations:

```
=> SELECT ANALYZE_CONSTRAINTS('table_3');  
(No rows)
```

Add a value that does not match and commit the change:

```
=> INSERT INTO table_3 VALUES ('r1', 'NONE');  
=> COMMIT;
```

Check for constraints on table `table_3`. The query detects a foreign key violation:

```
=> SELECT ANALYZE_CONSTRAINTS('table_3');
```

```
-[ RECORD 1 ]---+-----  
Schema Name   | public  
Table Name    | table_3  
Column Names  | z_fk1, z_fk2  
Constraint Name | table_3_multifk  
Constraint Type | FOREIGN  
Column Values  | ('r1', 'NONE')
```

To analyze all constraints on all tables, issue the following statement.

```
SELECT ANALYZE_CONSTRAINTS('');
```

Clean up your database:

```
=> DROP TABLE table_1 CASCADE;  
=> DROP TABLE table_2 CASCADE;  
=> DROP TABLE table_3 CASCADE;
```

To learn how to remove violating rows, see the [DISABLE_DUPLICATE_KEY_ERROR](#) function.

Fixing Constraint Violations

When Vertica finds duplicate primary key or unique values at run time, use the [DISABLE_DUPLICATE_KEY_ERROR](#) function to suppress error messaging. Queries execute as though no constraints are defined on the schema and the effects are session scoped.

The `DISABLE_DUPLICATE_KEY_ERROR` function is for use only for key constraints that are not automatically enabled.

Caution: When called, `DISABLE_DUPLICATE_KEY_ERROR` suppresses data integrity checking and can lead to incorrect query results. Use this function only after you insert duplicate primary keys into a dimension table in the presence of a pre-join projection. Correct the violations and reenables integrity checking with [REENABLE_DUPLICATE_KEY_ERROR](#).

Reenabling Error Reporting

If you ran [DISABLE_DUPLICATE_KEY_ERROR](#) to suppress error reporting while fixing duplicate key violations, you can get incorrect query results going forward. As soon as you fix the violations, run the [REENABLE_DUPLICATE_KEY_ERROR](#) function to restore the default behavior of error reporting.

The effects of this function are session scoped.

Managing Queries

This section covers the following topics:

- [Query Plans](#): Describes how Vertica creates and uses query plans, which optimize access to information in the Vertica database.
- [Directed Queries](#): Shows how to save query plan information.

Query Plans

A query plan is a sequence of step-like paths that the Vertica cost-based query optimizer uses to execute queries. Vertica can produce different query plans for a given query. For each query plan, the query optimizer evaluates the data to be queried: number of rows, column statistics such as number of distinct values (cardinality), distribution of data across nodes. It also evaluates available resources such as CPUs and network topology, and other environment factors. The query optimizer uses this information to develop several potential plans. It then compares plans and chooses one, generally the plan with the [lowest cost](#).

Viewing Query Plans

You can obtain query plans in two ways:

- The [EXPLAIN](#) statement outputs query plans in various [text formats](#).
- Management Console provides a graphical interface for viewing query plans. For detailed information, see [Managing Queries in MC](#) in Using Management Console.

You can also observe the real-time flow of data through a query plan by querying the system table [QUERY_PLAN_PROFILES](#). For more information, see [Profiling Query Plans](#).

EXPLAIN-Generated Query Plans

EXPLAIN returns the optimizer's query plan for executing a specified query. For example:

```
QUERY PLAN DESCRIPTION:
-----

EXPLAIN SELECT customer_name, customer_state FROM customer_dimension WHERE customer_state IN
('MA','NH') AND customer_gender='Male' ORDER BY customer_name LIMIT 10;

Access Path:
+-SELECT LIMIT 10 [Cost: 365, Rows: 10] (PATH ID: 0)
| Output Only: 10 tuples
| Execute on: Query Initiator
| +---> SORT [TOPK] [Cost: 365, Rows: 544] (PATH ID: 1)
| | Order: customer_dimension.customer_name ASC
| | Output Only: 10 tuples
| | Execute on: Query Initiator
| | +---> STORAGE ACCESS for customer_dimension [Cost: 326, Rows: 544] (PATH ID: 2)
| | | Projection: public.customer_dimension_DBD_1_rep_VMartDesign_node0001
| | | Materialize: customer_dimension.customer_state, customer_dimension.customer_name
| | | Filter: (customer_dimension.customer_gender = 'Male')
| | | Filter: (customer_dimension.customer_state = ANY (ARRAY['MA', 'NH']))
| | | Execute on: Query Initiator
```

You can use **EXPLAIN** to evaluate choices that the optimizer makes with respect to a given query. If you think query performance is less than optimal, run it through the Database Designer. For more information, see [Incremental Design](#) and [Reducing Run-time of Queries](#).

Query Plan Cost Estimation

The query optimizer chooses a query plan based on cost estimates. The query optimizer uses information from a number of sources to develop potential plans and determine their relative costs. These include:

- Number of table rows
- Column statistics, including: number of distinct values (cardinality), minimum/maximum values, distribution of values, and disk space usage
- Access path that is likely to require fewest I/O operations, and lowest CPU, memory, and network usage
- Available eligible projections

- Join options: join types (merge versus hash joins), join order
- Query predicates
- Data segmentation across cluster nodes

Many important optimizer decisions rely on statistics, which the query optimizer uses to determine the final plan to execute a query. Therefore, it is important that statistics be up to date. Without reasonably accurate statistics, the optimizer could choose a suboptimal plan, which might affect query performance.

Vertica provides hints about statistics in the query plan. See [Query Plan Statistics](#).

Cost versus Execution Runtime

Although costs correlate to query runtime, they do not provide an estimate of actual runtime. For example, if the optimizer determines that Plan A costs twice as much as Plan B, it is likely that Plan A will require more time to run. However, this cost estimate does not necessarily indicate that Plan A will run twice as long as Plan B.

Also, plan costs for different queries are not directly comparable. For example, if the estimated cost of Plan X for query1 is greater than the cost of Plan Y for query2, it is not necessarily true that Plan X's runtime is greater than Plan Y's runtime.

EXPLAIN Output Options

By default, EXPLAIN output represents the query plan as a hierarchy, where each level (path) represents a single database operation that the optimizer uses to execute a query. EXPLAIN output also appends DOT language source so you can display this output graphically with open source [Graphviz](#) tools.

You can qualify EXPLAIN with three output options:

- **JSON** produces the query plan in JSON format.
- **VERBOSE** increases the amount of detail in the rendered query plan. This option is valid for default and JSON output.
- **LOCAL** (on a multi-node database) shows the local query plans assigned to each node, which together comprise the total (global) query plan. If you omit this option, Vertica shows only the global query plan. Local query plan are shown only in DOT language source, which can be rendered in [Graphviz](#).

You can also [write EXPLAIN output to a file](#).

JSON Output

The following EXPLAIN statement specifies the same query shown earlier, but this time specifies to produce output in JSON format:

```
=> EXPLAIN JSON SELECT customer_name, customer_state FROM customer_dimension WHERE customer_state IN ('MA','NH') AND customer_gender='Male' ORDER BY customer_name LIMIT 10;
```

```
QUERY PLAN DESCRIPTION:

| | | Projection: public.customer_dimension_DBD_1_rep_VMartDesign_node0001
| | | Materialize: customer_dimension.customer_state, customer_dimension.customer_name
| | | Filter: (customer_dimension.customer_gender = 'Male')/* sel=0.351351 ndv= 2 */
| | | Filter: (customer_dimension.customer_state = ANY (ARRAY['MA', 'NH']))/* sel=0.030928 ndv=
4 */
| | | Execute on: Query Initiator
| | | Sort Key: (customer_dimension.customer_type, customer_dimension.store_membership_card,
customer_dimension.title, customer_dimension.customer_region, customer_dimension.number_of_children,
customer_dimension.customer_key)

```

Local Output

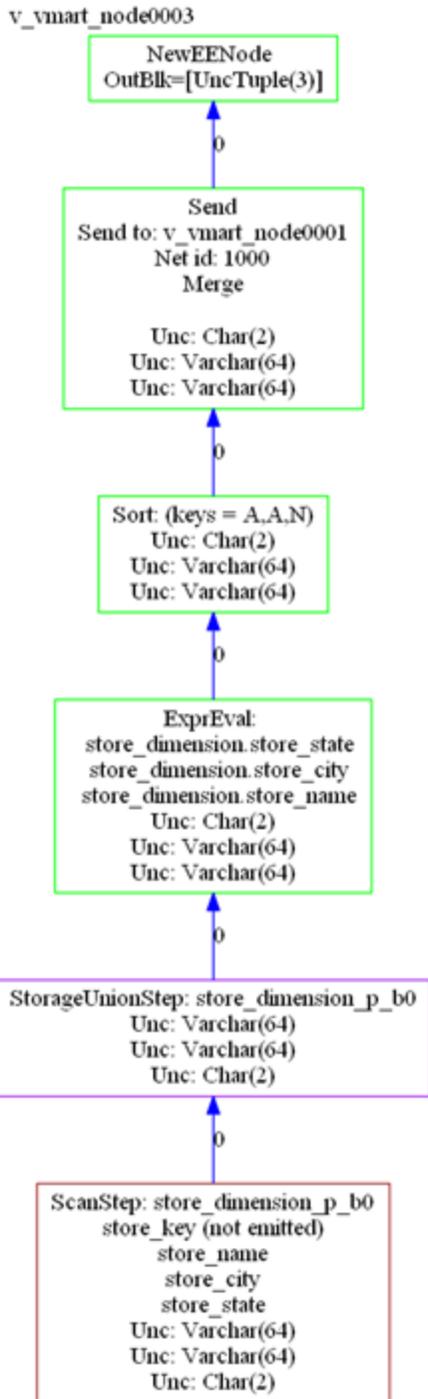

The following statement includes the LOCAL option:

```
=> EXPLAIN LOCAL SELECT store_name, store_city, store_state  
FROM store.store_dimension ORDER BY store_state ASC, store_city ASC;
```

The output includes GraphViz source, which describes the local query plans assigned to each node. For example, output for this statement on a three-node database includes a GraphViz description of the following query plan for one node (v_vmart_node0003):

```
-----  
PLAN: v_vmart_node0003 (GraphViz Format)  
-----  
digraph G {  
graph [rankdir=BT, label = "v_vmart_node0003\n", labelloc=t, labeljust=l ordering=out]  
0[label = "NewEENode \nOutBlk=[UncTuple(3)]", color = "green", shape = "box"];  
1[label = "Send\nSend to: v_vmart_node0001\nNet id: 1000\nMerge\n\nUnc: Char(2)\nUnc: Varchar  
(64)\nUnc: Varchar(64)", color = "green", shape = "box";  
2[label = "Sort: (keys = A,A,N)\nUnc: Char(2)\nUnc: Varchar(64)\nUnc: Varchar(64)", color = "green",  
shape = "box"];  
3[label = "ExprEval: \n store_dimension.store_state\n store_dimension.store_city\n store_  
dimension.store_name\nUnc: Char(2)\nUnc: Varchar(64)\nUnc: Varchar(64)  
", color = "green", shape = "box";  
4[label = "StorageUnionStep: store_dimension_p_b0\nUnc: Varchar(64)\nUnc: Varchar(64)\nUnc: Char  
(2)", color = "purple", shape = "box";  
5[label = "ScanStep: store_dimension_p_b0\nstore_key (not emitted)\nstore_name\nstore_city\nstore_  
state\nUnc: Varchar(64)\nUnc: Varchar(64)\nUnc: Char(2)", color  
= "brown", shape = "box"];  
1->0 [label = "\u0000",color = "blue"];  
2->1 [label = "\u0000",color = "blue"];  
3->2 [label = "\u0000",color = "blue"];  
4->3 [label = "\u0000",color = "blue"];  
5->4 [label = "\u0000",color = "blue"];  
}
```

GraphViz renders this output as follows:

Writing EXPLAIN Output to a File

To save EXPLAIN output to a file, use the vsql \o command:

1. Turn on saving output to a file using the `\o` command. For example:

```
vmartdb=> \o /home/dbadmin/my-plan-output
```

2. Use `EXPLAIN` to obtain the desired query plan:

```
vmartdb=> EXPLAIN SELECT * FROM customer_dimension;
```

3. Turn off saving output to a file using the `\o` command.

```
vmartdb=> \o
```

Note: The `\o` command continues to write command-line output to the file until you reissue the `\o` command.

Query Plan Information and Structure

Depending on the query and database schema, `EXPLAIN` output includes the following information:

- Tables referenced by the statement
- Estimated costs
- Estimated row cardinality
- Path ID, an integer that links to error messages and profiling counters so you troubleshoot performance issues more easily. For more information, see [Profiling Query Plans](#).
- Data operations such as `SORT`, `FILTER`, `LIMIT`, and `GROUP BY`
- Projections used
- Information about statistics—for example, whether they are current or out of range
- Algorithms chosen for operations into the query, such as `HASH/MERGE` or `GROUPBY HASH/GROUPBY PIPELINED`
- Data redistribution (broadcast, segmentation) across cluster nodes

Example

In the EXPLAIN output that follows, the optimizer processes a query in three steps, where each step identified by a unique path ID:

- 0: Limit
- 1: Sort
- 2: Storage access and filter

QUERY PLAN DESCRIPTION:

```
EXPLAIN SELECT customer_name, customer_state FROM customer_dimension  
WHERE customer_state IN ('MA','NH') AND customer_gender = 'Male'  
ORDER BY customer_name LIMIT 10;
```

Access Path:

```
+--SELECT LIMIT 10 [Cost: 365, Rows: 10] (PATH ID: 0) ← Limit  
| Output Only: 10 tuples  
| Execute on: Query Initiator  
| +----> SORT [TOPK] [Cost: 365, Rows: 544] (PATH ID: 1) ← Sort  
| | Order: customer_dimension.customer_name ASC  
| | Output Only: 10 tuples  
| | Execute on: Query Initiator  
| | +----> STORAGE ACCESS for customer_dimension [Cost: 326, Rows: 544] (PATH ID: 2)  
| | | Projection: public.customer_dimension_DBD_1_rep_VMartDesign_node0001  
| | | Materialize: customer_dimension.customer_state, customer_dimension.customer_name  
| | | Filter: (customer_dimension.customer_gender = 'Male')  
| | | Filter: (customer_dimension.customer_state = ANY (ARRAY['MA', 'NH']))  
| | | Execute on: Query Initiator
```

Storage access and filter

Note: A storage access operation can scan more than the columns in the SELECT list— for example, columns referenced in WHERE clause.

Query Plan Statistics

If you query a table whose statistics are unavailable or out-of-date, the optimizer might choose a sub-optimal query plan.

You can resolve many issues related to table statistics by calling [ANALYZE_STATISTICS](#). This function let you update statistics at various scopes: one or more table columns, a single table, or all database tables.

If you update statistics and find that the query still performs sub-optimally, run your query through Database Designer and choose incremental design as the design type.

For detailed information about updating database statistics, see [Collecting Database Statistics](#).

Statistics Hints in Query Plans

Query plans can contain information about table statistics through two hints: `NO STATISTICS` and `STALE STATISTICS`. For example, the following query plan fragment includes `NO STATISTICS` to indicate that histograms are unavailable:

```
| | +-- Outer -> STORAGE ACCESS for fact [Cost: 604, Rows: 10K (NO STATISTICS)]
```

The following query plan fragment includes `STALE STATISTICS` to indicate that the predicate has fallen outside the histogram range:

```
| | +-- Outer -> STORAGE ACCESS for fact [Cost: 35, Rows: 1 (STALE STATISTICS)]
```

Cost and Rows Path

The following EXPLAIN output shows the Cost operator:

```
Access Path: +-SELECT LIMIT 10 [Cost: 370, Rows: 10] (PATH ID: 0)
| Output Only: 10 tuples
| Execute on: Query Initiator
| +---> SORT [Cost: 370, Rows: 544] (PATH ID: 1)
| | Order: customer_dimension.customer_name ASC
| | Output Only: 10 tuples
| | Execute on: Query Initiator
| | +---> STORAGE ACCESS for customer_dimension [Cost: 331, Rows: 544] (PATH ID: 2)
| | | Projection: public.customer_dimension_DBD_1_rep_vmartdb_design_vmartdb_design_node0001
| | | Materialize: customer_dimension.customer_state, customer_dimension.customer_name
| | | Filter: (customer_dimension.customer_gender = 'Male')
| | | Filter: (customer_dimension.customer_state = ANY (ARRAY['MA', 'NH']))
| | | Execute on: Query Initiator
```

The Row operator is the number of rows the optimizer estimates the query will return. Letters after numbers refer to the units of measure (K=thousand, M=million, B=billion, T=trillion), so the output for the following query indicates that the number of rows to return is 50 *thousand*.

```
=> EXPLAIN SELECT customer_gender FROM customer_dimension;
Access Path:
+-STORAGE ACCESS for customer_dimension [Cost: 17, Rows: 50K (3 RLE)] (PATH ID: 1)
| Projection: public.customer_dimension_DBD_1_rep_vmartdb_design_vmartdb_design_node0001
| Materialize: customer_dimension.customer_gender
| Execute on: Query Initiator
```

The reference to (3 RLE) in the STORAGE ACCESS path means that the optimizer estimates that the storage access operator returns 50K rows. Because the column is run-length encoded (RLE), the real number of RLE rows returned is only three rows:

- 1 row for female
- 1 row for male
- 1 row that represents unknown (NULL) gender

Note: See [Query Plans](#) for more information about how the optimizer estimates cost.

Projection Path

You can see which projections the optimizer chose for the query plan by looking at the Projection path in the textual output:

```
EXPLAIN SELECT
  customer_name,
  customer_state
FROM customer_dimension
WHERE customer_state in ('MA','NH')
AND customer_gender = 'Male'
ORDER BY customer_name
LIMIT 10;
Access Path:
+-SELECT LIMIT 10 [Cost: 370, Rows: 10] (PATH ID: 0)
| Output Only: 10 tuples
| Execute on: Query Initiator
| +---> SORT [Cost: 370, Rows: 544] (PATH ID: 1)
| | Order: customer_dimension.customer_name ASC
| | Output Only: 10 tuples
| | Execute on: Query Initiator
| | +---> STORAGE ACCESS for customer_dimension [Cost: 331, Rows: 544] (PATH ID: 2)
| | | Projection: public.customer_dimension_DBD_1_rep_vmart_vmart_node0001
| | | Materialize: customer_dimension.customer_state, customer_dimension.customer_name
| | | Filter: (customer_dimension.customer_gender = 'Male')
| | | Filter: (customer_dimension.customer_state = ANY (ARRAY['MA', 'NH']))
| | | Execute on: Query Initiator
```

The query optimizer automatically picks the best projections, but without reasonably accurate statistics, the optimizer could choose a suboptimal projection or join order for a query. For details, see [Collecting Statistics](#).

Vertica considers which projection to choose for a plan by considering the following aspects:

- How columns are joined in the query
- How the projections are grouped or sorted
- Whether SQL analytic operations applied
- Any column information from a projection's storage on disk

As Vertica scans the possibilities for each plan, projections with the higher initial costs could end up in the final plan because they make joins cheaper. For example, a query can be answered with many possible plans, which the optimizer considers before choosing one of them. For efficiency, the optimizer uses sophisticated algorithms to prune intermediate partial plan fragments with higher cost. The optimizer knows that intermediate plan fragments might initially look bad (due to high storage access cost) but which produce excellent final plans due to other optimizations that it allows.

If your statistics are up to date but the query still performs poorly, run the query through the Database Designer. For details, see [Incremental Design](#)

Tips

- To test different segmented projections, refer to the projection by name in the query.
- For optimal performance, write queries so the columns are sorted the same way that the projection columns are sorted.

See Also

- [Reducing Query Run Time](#)
- [Creating Custom Designs](#)
- [Physical Schema](#)

Join Path

Just like a join query, which references two or more tables, the Join step in a query plan has two input branches:

- The left input, which is the outer table of the join
- The right input, which is the inner table of the join

In the following query, the T1 table is the left input because it is on the left side of the JOIN keyword, and the T2 table is the right input, because it is on the right side of the JOIN keyword:

```
SELECT * FROM T1 JOIN T2 ON T1.x = T2.x;
```

Outer versus Inner Join

Query performance is better if the small table is used as the inner input to the join. The query optimizer automatically reorders the inputs to joins to ensure that this is the case unless the join in question is an outer join.

Note: If the configuration parameter `EnableForceOuter` is set to 1, you can control join inputs for specific tables through `ALTER TABLE . . FORCE OUTER`. For details, see [Controlling Join Inputs](#) in *Analyzing Data*.

The following example shows a query and its plan for a left outer join:

```
=> EXPLAIN SELECT CD.annual_income,OSI.sale_date_key
-> FROM online_sales.online_sales_fact OSI
-> LEFT OUTER JOIN customer_dimension CD ON CD.customer_key = OSI.customer_key;
Access Path:
+-JOIN HASH [LeftOuter] [Cost: 4K, Rows: 5M] (PATH ID: 1)
|   Join Cond: (CD.customer_key = OSI.customer_key)
|   Materialize at Output: OSI.sale_date_key
|   Execute on: All Nodes
|   +-- Outer -> STORAGE ACCESS for OSI [Cost: 3K, Rows: 5M] (PATH ID: 2)
|   |   Projection: online_sales.online_sales_fact_DBD_12_seg_vmartdb_design_vmartdb_design
|   |   Materialize: OSI.customer_key
|   |   Execute on: All Nodes
|   +-- Inner -> STORAGE ACCESS for CD [Cost: 264, Rows: 50K] (PATH ID: 3)
|   |   Projection: public.customer_dimension_DBD_1_rep_vmartdb_design_vmartdb_design_node0001
|   |   Materialize: CD.annual_income, CD.customer_key
|   |   Execute on: All Nodes
```

The following example shows a query and its plan for a full outer join:

```
=> EXPLAIN SELECT CD.annual_income,OSI.sale_date_key
-> FROM online_sales.online_sales_fact OSI
-> FULL OUTER JOIN customer_dimension CD ON CD.customer_key = OSI.customer_key;
Access Path:
+-JOIN HASH [FullOuter] [Cost: 18K, Rows: 5M] (PATH ID: 1) Outer (RESEGMENT) Inner (FILTER)
|   Join Cond: (CD.customer_key = OSI.customer_key)
|   Execute on: All Nodes
|   +-- Outer -> STORAGE ACCESS for OSI [Cost: 3K, Rows: 5M] (PATH ID: 2)
|   |   Projection: online_sales.online_sales_fact_DBD_12_seg_vmartdb_design_vmartdb_design
|   |   Materialize: OSI.sale_date_key, OSI.customer_key
|   |   Execute on: All Nodes
|   +-- Inner -> STORAGE ACCESS for CD [Cost: 264, Rows: 50K] (PATH ID: 3)
|   |   Projection: public.customer_dimension_DBD_1_rep_vmartdb_design_vmartdb_design_node0001
|   |   Materialize: CD.annual_income, CD.customer_key
|   |   Execute on: All Nodes
```

Hash and Merge Joins

Vertica has two join algorithms to choose from: merge join and hash join. The optimizer automatically chooses the most appropriate algorithm, given the query and projections in a

system.

For the following query, the optimizer chooses a hash join.

```
=> EXPLAIN SELECT CD.annual_income,OSI.sale_date_key
-> FROM online_sales.online_sales_fact OSI
-> INNER JOIN customer_dimension CD ON CD.customer_key = OSI.customer_key;
Access Path:
+-JOIN HASH [Cost: 4K, Rows: 5M] (PATH ID: 1)
|   Join Cond: (CD.customer_key = OSI.customer_key)
|   Materialize at Output: OSI.sale_date_key
|   Execute on: All Nodes
| +- Outer -> STORAGE ACCESS for OSI [Cost: 3K, Rows: 5M] (PATH ID: 2)
| |   Projection: online_sales.online_sales_fact_DBD_12_seg_vmartdb_design_vmartdb_design
| |   Materialize: OSI.customer_key
| |   Execute on: All Nodes
| +- Inner -> STORAGE ACCESS for CD [Cost: 264, Rows: 50K] (PATH ID: 3)
| |   Projection: public.customer_dimension_DBD_1_rep_vmartdb_design_vmartdb_design_node0001
| |   Materialize: CD.annual_income, CD.customer_key
| |   Execute on: All Nodes
```

Tip: If you get a hash join when you are expecting a merge join, it means that at least one of the projections is not sorted on the join column (for example, `customer_key` in the preceding query). To facilitate a merge join, you might need to create different projections that are sorted on the join columns.

In the next example, the optimizer chooses a merge join. The optimizer's first pass performs a merge join because the inputs are presorted, and then it performs a hash join.

```
=> EXPLAIN SELECT count(*) FROM online_sales.online_sales_fact OSI
-> INNER JOIN customer_dimension CD ON CD.customer_key = OSI.customer_key
-> INNER JOIN product_dimension PD ON PD.product_key = OSI.product_key;
Access Path:
+-GROUPBY NOTHING [Cost: 8K, Rows: 1] (PATH ID: 1)
|   Aggregates: count(*)
|   Execute on: All Nodes
| +--> JOIN HASH [Cost: 7K, Rows: 5M] (PATH ID: 2)
| |   Join Cond: (PD.product_key = OSI.product_key)
| |   Materialize at Input: OSI.product_key
| |   Execute on: All Nodes
| | +- Outer -> JOIN MERGEJOIN(inputs presorted) [Cost: 4K, Rows: 5M] (PATH ID: 3)
| | |   Join Cond: (CD.customer_key = OSI.customer_key)
| | |   Execute on: All Nodes
| | | +- Outer -> STORAGE ACCESS for OSI [Cost: 3K, Rows: 5M] (PATH ID: 4)
| | | |   Projection: online_sales.online_sales_fact_DBD_12_seg_vmartdb_design_vmartdb_design
| | | |   Materialize: OSI.customer_key
| | | |   Execute on: All Nodes
| | | +- Inner -> STORAGE ACCESS for CD [Cost: 132, Rows: 50K] (PATH ID: 5)
| | | |   Projection: public.customer_dimension_DBD_1_rep_vmartdb_design_vmartdb_design_node0001
| | | |   Materialize: CD.customer_key
| | | |   Execute on: All Nodes
| | +- Inner -> STORAGE ACCESS for PD [Cost: 152, Rows: 60K] (PATH ID: 6)
| | |   Projection: public.product_dimension_DBD_2_rep_vmartdb_design_vmartdb_design_node0001
| | |   Materialize: PD.product_key
| | |   Execute on: All Nodes
```

Inequality Joins

Vertica processes joins with equality predicates very efficiently. The query plan shows equality join predicates as join condition (Join Cond).

```
=> EXPLAIN SELECT CD.annual_income, OSI.sale_date_key
-> FROM online_sales.online_sales_fact OSI
-> INNER JOIN customer_dimension CD
-> ON CD.customer_key = OSI.customer_key;
Access Path:
+-JOIN HASH [Cost: 4K, Rows: 5M] (PATH ID: 1)
| Join Cond: (CD.customer_key = OSI.customer_key)
| Materialize at Output: OSI.sale_date_key
| Execute on: All Nodes
| +-- Outer -> STORAGE ACCESS for OSI [Cost: 3K, Rows: 5M] (PATH ID: 2)
| | Projection: online_sales.online_sales_fact_DBD_12_seg_vmartdb_design_vmartdb_design
| | Materialize: OSI.customer_key
| | Execute on: All Nodes
| +-- Inner -> STORAGE ACCESS for CD [Cost: 264, Rows: 50K] (PATH ID: 3)
| | Projection: public.customer_dimension_DBD_1_rep_vmartdb_design_vmartdb_design_node0001
| | Materialize: CD.annual_income, CD.customer_key
| | Execute on: All Nodes
```

However, inequality joins are treated like cross joins and can run less efficiently, which you can see by the change in cost between the two queries:

```
=> EXPLAIN SELECT CD.annual_income, OSI.sale_date_key
-> FROM online_sales.online_sales_fact OSI
-> INNER JOIN customer_dimension CD
-> ON CD.customer_key < OSI.customer_key;
Access Path:
+-JOIN HASH [Cost: 98M, Rows: 5M] (PATH ID: 1)
| Join Filter: (CD.customer_key < OSI.customer_key)
| Materialize at Output: CD.annual_income
| Execute on: All Nodes
| +-- Outer -> STORAGE ACCESS for CD [Cost: 132, Rows: 50K] (PATH ID: 2)
| | Projection: public.customer_dimension_DBD_1_rep_vmartdb_design_vmartdb_design_node0001
| | Materialize: CD.customer_key
| | Execute on: All Nodes
| +-- Inner -> STORAGE ACCESS for OSI [Cost: 3K, Rows: 5M] (PATH ID: 3)
| | Projection: online_sales.online_sales_fact_DBD_12_seg_vmartdb_design_vmartdb_design
| | Materialize: OSI.sale_date_key, OSI.customer_key
| | Execute on: All Nodes
```

Event Series Joins

Event series joins are denoted by the INTERPOLATED path.

```
=> EXPLAIN SELECT * FROM hTicks h FULL OUTER JOIN aTicks a -> ON (h.time INTERPOLATE PREVIOUS
Access Path:
+-JOIN (INTERPOLATED) [FullOuter] [Cost: 31, Rows: 4 (NO STATISTICS)] (PATH ID: 1)
Outer (SORT ON JOIN KEY) Inner (SORT ON JOIN KEY)
```

```
| Join Cond: (h."time" = a."time")
| Execute on: Query Initiator
| +-- Outer -> STORAGE ACCESS for h [Cost: 15, Rows: 4 (NO STATISTICS)] (PATH ID: 2)
| | Projection: public.hTicks_node0004
| | Materialize: h.stock, h."time", h.price
| | Execute on: Query Initiator
| +-- Inner -> STORAGE ACCESS for a [Cost: 15, Rows: 4 (NO STATISTICS)] (PATH ID: 3)
| | Projection: public.aTicks_node0004
| | Materialize: a.stock, a."time", a.price
| | Execute on: Query Initiator
```

Path ID

The `PATH ID` is a unique identifier that Vertica assigns to each operation (path) within a query plan. The same identifier is shared by:

- [Query plans](#)
- Join error messages
- System tables [EXECUTION_ENGINE_PROFILES](#) and [QUERY_PLAN_PROFILES](#)

Path IDs can help you trace issues to their root cause. For example, if a query returns a join error, preface the query with `EXPLAIN` and look for `PATH ID n` in the query plan to see which join in the query had the problem.

For example, the following `EXPLAIN` output shows the path ID for each path in the optimizer's query plan:

```
=> EXPLAIN SELECT * FROM fact JOIN dim ON x=y JOIN ext on y=z;
Access Path:
+-JOIN MERGEJOIN(inputs presorted) [Cost: 815, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
| Join Cond: (dim.y = ext.z)
| Materialize at Output: fact.x
| Execute on: All Nodes
| +-- Outer -> JOIN MERGEJOIN(inputs presorted) [Cost: 408, Rows: 10K (NO STATISTICS)] (PATH ID: 2)
| | Join Cond: (fact.x = dim.y)
| | Execute on: All Nodes
| | +-- Outer -> STORAGE ACCESS for fact [Cost: 202, Rows: 10K (NO STATISTICS)] (PATH ID: 3)
| | | Projection: public.fact_super
| | | Materialize: fact.x
| | | Execute on: All Nodes
| | +-- Inner -> STORAGE ACCESS for dim [Cost: 202, Rows: 10K (NO STATISTICS)] (PATH ID: 4)
| | | Projection: public.dim_super
| | | Materialize: dim.y
| | | Execute on: All Nodes
| +-- Inner -> STORAGE ACCESS for ext [Cost: 202, Rows: 10K (NO STATISTICS)] (PATH ID: 5)
| | Projection: public.ext_super
| | Materialize: ext.z
| | Execute on: All Nodes
```

Filter Path

The **Filter** step evaluates predicates on a single table. It accepts a set of rows, eliminates some of them (based on the criteria you provide in your query), and returns the rest. For example, the optimizer can filter local data of a join input that will be joined with another re-segmented join input.

The following statement queries the `customer_dimension` table and uses the `WHERE` clause to filter the results only for male customers in Massachusetts and New Hampshire.

```
EXPLAIN SELECT
  CD.customer_name,
  CD.customer_state,
  AVG(CD.customer_age) AS avg_age,
  COUNT(*) AS count
FROM customer_dimension CD
WHERE CD.customer_state in ('MA','NH') AND CD.customer_gender = 'Male'
GROUP BY CD.customer_state, CD.customer_name;
```

The query plan output is as follows:

```
Access Path:
+-GROUPBY HASH [Cost: 378, Rows: 544] (PATH ID: 1)
|  Aggregates: sum_float(CD.customer_age), count(CD.customer_age), count(*)
|  Group By: CD.customer_state, CD.customer_name
|  Execute on: Query Initiator
| +---> STORAGE ACCESS for CD [Cost: 372, Rows: 544] (PATH ID: 2)
| |   Projection: public.customer_dimension_DBD_1_rep_vmartdb_design_vmartdb_design_node0001
| |   Materialize: CD.customer_state, CD.customer_name, CD.customer_age
| |   Filter: (CD.customer_gender = 'Male')
| |   Filter: (CD.customer_state = ANY (ARRAY['MA', 'NH']))
| |   Execute on: Query Initiator
```

GROUP BY Paths

A **GROUP BY** operation has two algorithms:

- **GROUPBY PIPELINED** requires that inputs be presorted on the columns specified in the group, which means that Vertica need only retain data in the current group in memory. **GROUPBY PIPELINED** operations are preferred because they are generally faster and require less memory than **GROUPBY HASH**. **GROUPBY PIPELINED** is especially useful for queries that process large numbers of high-cardinality group by columns or **DISTINCT** aggregates.
- **GROUPBY HASH** input is not sorted by the group columns, so Vertica builds a hash table on those group columns in order to process the aggregates and group by expressions.

```
=> EXPLAIN SELECT COUNT(DISTINCT annual_income) FROM customer_dimension
WHERE customer_gender = 'Female';

Access Path: +-GROUPBY NOTHING [Cost: 161, Rows: 1] (PATH ID: 1)
| Aggregates: count(DISTINCT customer_dimension.annual_income)
| +---> GROUPBY PIPELINED [Cost: 158, Rows: 10K] (PATH ID: 2)
| | Group By: customer_dimension.annual_income
| | +---> STORAGE ACCESS for customer_dimension [Cost: 144, Rows: 47K] (PATH ID: 3)
| | | Projection: public.customer_dimension_DBD_1_rep_vmartdb_design_vmartdb_design_node0001
| | | Materialize: customer_dimension.annual_income
| | | Filter: (customer_dimension.customer_gender = 'Female')
```

Tip: If EXPLAIN reports GROUPBY HASH, modify the projection design to force it to use GROUPBY PIPELINED.

Sort Path

The SORT operator sorts the data according to a specified list of columns. The EXPLAIN output indicates the sort expressions and if the sort order is ascending (ASC) or descending (DESC).

For example, the following query plan shows the column list nature of the SORT operator:

```
EXPLAIN SELECT
  CD.customer_name,
  CD.customer_state,
  AVG(CD.customer_age) AS avg_age,
  COUNT(*) AS count
FROM customer_dimension CD
WHERE CD.customer_state in ('MA','NH')
  AND CD.customer_gender = 'Male'
GROUP BY CD.customer_state, CD.customer_name
ORDER BY avg_age, customer_name;

Access Path:
+-SORT [Cost: 422, Rows: 544] (PATH ID: 1)
| Order: (<SVAR> / float8(<SVAR>)) ASC, CD.customer_name ASC
| Execute on: Query Initiator
| +---> GROUPBY HASH [Cost: 378, Rows: 544] (PATH ID: 2)
| | Aggregates: sum_float(CD.customer_age), count(CD.customer_age), count(*)
| | Group By: CD.customer_state, CD.customer_name
| | Execute on: Query Initiator
| | +---> STORAGE ACCESS for CD [Cost: 372, Rows: 544] (PATH ID: 3)
| | | Projection: public.customer_dimension_DBD_1_rep_vmart_vmart_node0001
| | | Materialize: CD.customer_state, CD.customer_name, CD.customer_age
| | | Filter: (CD.customer_gender = 'Male')
| | | Filter: (CD.customer_state = ANY (ARRAY['MA', 'NH']))
| | | Execute on: Query Initiator
```

If you change the sort order to descending, the change appears in the query plan:

```
EXPLAIN SELECT
  CD.customer_name,
  CD.customer_state,
```

```
AVG(CD.customer_age) AS avg_age,  
COUNT(*) AS count  
FROM customer_dimension CD  
WHERE CD.customer_state in ('MA','NH')  
AND CD.customer_gender = 'Male'  
GROUP BY CD.customer_state, CD.customer_name  
ORDER BY avg_age DESC, customer_name;  
Access Path:  
+-SORT [Cost: 422, Rows: 544] (PATH ID: 1)  
| Order: (<SVAR> / float8(<SVAR>)) DESC, CD.customer_name ASC  
| Execute on: Query Initiator  
| +---> GROUPBY HASH [Cost: 378, Rows: 544] (PATH ID: 2)  
| | Aggregates: sum_float(CD.customer_age), count(CD.customer_age), count(*)  
| | Group By: CD.customer_state, CD.customer_name  
| | Execute on: Query Initiator  
| | +----> STORAGE ACCESS for CD [Cost: 372, Rows: 544] (PATH ID: 3)  
| | | Projection: public.customer_dimension_DBD_1_rep_vmart_vmart_node0001  
| | | Materialize: CD.customer_state, CD.customer_name, CD.customer_age  
| | | Filter: (CD.customer_gender = 'Male')  
| | | Filter: (CD.customer_state = ANY (ARRAY['MA', 'NH']))  
| | | Execute on: Query Initiator
```

Limit Path

The LIMIT path restricts the number of result rows based on the LIMIT clause in the query. Using the LIMIT clause in queries with thousands of rows might increase query performance.

The optimizer pushes the LIMIT operation as far down as possible in queries. A single LIMIT clause in the query can generate multiple Output Only plan annotations.

```
=> EXPLAIN SELECT COUNT(DISTINCT annual_income) FROM customer_dimension LIMIT 10;  
Access Path:  
+-SELECT LIMIT 10 [Cost: 161, Rows: 10] (PATH ID: 0)  
| Output Only: 10 tuples  
| +---> GROUPBY NOTHING [Cost: 161, Rows: 1] (PATH ID: 1)  
| | Aggregates: count(DISTINCT customer_dimension.annual_income)  
| | Output Only: 10 tuples  
| | +----> GROUPBY HASH (SORT OUTPUT) [Cost: 158, Rows: 10K] (PATH ID: 2)  
| | | Group By: customer_dimension.annual_income  
| | | +----> STORAGE ACCESS for customer_dimension [Cost: 132, Rows: 50K] (PATH ID: 3)  
| | | | Projection: public.customer_dimension_DBD_1_rep_vmartdb_design_vmartdb_design_node0001  
| | | | Materialize: customer_dimension.annual_income
```

Data Redistribution Path

The optimizer can redistribute join data in two ways:

- Broadcasting
- Resegmentation

Broadcasting

Broadcasting sends a complete copy of an intermediate result to all nodes in the cluster. Broadcast is used for joins in the following cases:

- One table is very small (usually the inner table) compared to the other.
- Vertica can avoid other large upstream resegmentation operations.
- Outer join or subquery semantics require one side of the join to be replicated.

For example:

```
=> EXPLAIN SELECT * FROM T1 LEFT JOIN T2 ON T1.a > T2.y;
Access Path:
+-JOIN HASH [LeftOuter] [Cost: 40K, Rows: 10K (NO STATISTICS)] (PATH ID: 1) Inner (BROADCAST)
|   Join Filter: (T1.a > T2.y)
|   Materialize at Output: T1.b
|   Execute on: All Nodes
|   +-- Outer -> STORAGE ACCESS for T1 [Cost: 151, Rows: 10K (NO STATISTICS)] (PATH ID: 2)
|   |       Projection: public.T1_b0
|   |       Materialize: T1.a
|   |       Execute on: All Nodes
|   +-- Inner -> STORAGE ACCESS for T2 [Cost: 302, Rows: 10K (NO STATISTICS)] (PATH ID: 3)
|   |       Projection: public.T2_b0
|   |       Materialize: T2.x, T2.y
|   |       Execute on: All Nodes
```

Resegmentation

Resegmentation takes an existing projection or intermediate relation and resegments the data evenly across all cluster nodes. At the end of the resegmentation operation, every row from the input relation is on exactly one node. Resegmentation is the operation used most often for distributed joins in Vertica if the data is not already segmented for local joins. For more detail, see [Identical Segmentation](#) in Analyzing Data.

For example:

```
=> CREATE TABLE T1 (a INT, b INT) SEGMENTED BY HASH(a) ALL NODES;
=> CREATE TABLE T2 (x INT, y INT) SEGMENTED BY HASH(x) ALL NODES;
=> EXPLAIN SELECT * FROM T1 JOIN T2 ON T1.a = T2.y;

----- QUERY PLAN DESCRIPTION: -----
Access Path:
+-JOIN HASH [Cost: 639, Rows: 10K (NO STATISTICS)] (PATH ID: 1) Inner (RESEGMENT)
|   Join Cond: (T1.a = T2.y)
|   Materialize at Output: T1.b
|   Execute on: All Nodes
|   +-- Outer -> STORAGE ACCESS for T1 [Cost: 151, Rows: 10K (NO STATISTICS)] (PATH ID: 2)
```

```
| |      Projection: public.T1_b0
| |      Materialize: T1.a
| |      Execute on: All Nodes
| +-- Inner -> STORAGE ACCESS for T2 [Cost: 302, Rows: 10K (NO STATISTICS)] (PATH ID: 3)
| |      Projection: public.T2_b0
| |      Materialize: T2.x, T2.y
| |      Execute on: All Nodes
```

Analytic Function Path

Vertica attempts to optimize multiple SQL-99 [Analytic Functions](#) from the same query by grouping them together in Analytic Group areas.

For each analytical group, Vertica performs a distributed sort and resegment of the data, if necessary.

You can tell how many sorts and resegments are required based on the query plan.

For example, the following query plan shows that the [FIRST_VALUE](#) and [LAST_VALUE](#) functions are in the same analytic group because their `OVER` clause is the same. In contrast, `ROW_NUMBER()` has a different `ORDER BY` clause, so it is in a different analytic group. Because both groups share the same `PARTITION BY deal_stage` clause, the data does not need to be resegmented between groups :

```
EXPLAIN SELECT
  first_value(deal_size) OVER (PARTITION BY deal_stage
  ORDER BY deal_size),
  last_value(deal_size) OVER (PARTITION BY deal_stage
  ORDER BY deal_size),
  row_number() OVER (PARTITION BY deal_stage
  ORDER BY largest_bill_amount)
FROM customer_dimension;

Access Path:
+-ANALYTICAL [Cost: 1K, Rows: 50K] (PATH ID: 1)
| Analytic Group
|   Functions: row_number()
|   Group Sort: customer_dimension.deal_stage ASC, customer_dimension.largest_bill_amount ASC NULLS
LAST
| Analytic Group
|   Functions: first_value(), last_value()
|   Group Filter: customer_dimension.deal_stage
|   Group Sort: customer_dimension.deal_stage ASC, customer_dimension.deal_size ASC NULL LAST
|   Execute on: All Nodes
| +--> STORAGE ACCESS for customer_dimension [Cost: 263, Rows: 50K]
|   (PATH ID: 2)
| |      Projection: public.customer_dimension_DBD_1_rep_vmart_vmart_node0001
| |      Materialize: customer_dimension.largest_bill_amount,
| |      customer_dimension.deal_stage, customer_dimension.deal_size
| |      Execute on: All Nodes
```

[Invoking Analytic Functions](#)

Node Down Information

Vertica provides performance optimization when cluster nodes fail by distributing the work of the down nodes uniformly among available nodes throughout the cluster.

When a node in your cluster is down, the query plan identifies which node the query will execute on. To help you quickly identify down nodes on large clusters, EXPLAIN output lists up to six nodes, if the number of running nodes is less than or equal to six, and lists only down nodes if the number of running nodes is more than six.

Note: The node that executes down node queries is not always the same one.

The following table provides more detail:

Node state	EXPLAIN output
If all nodes are up, EXPLAIN output indicates All Nodes.	Execute on: All Nodes
If fewer than 6 nodes are up, EXPLAIN lists up to six running nodes.	Execute on: [node_list].
If more than 6 nodes are up, EXPLAIN lists only non-running nodes.	Execute on: All Nodes Except [node_list]
If the node list contains non-ephemeral nodes, the EXPLAIN output indicates All Permanent Nodes.	Execute on: All Permanent Nodes
If the path is being run on the query initiator, the EXPLAIN output indicates Query Initiator.	Execute on: Query Initiator

Examples

In the following example, the down node is v_vmart_node0005, and the node v_vmart_node0006 will execute this run of the query.

```
=> EXPLAIN SELECT * FROM test;  
QUERY PLAN
```

```
-----  
QUERY PLAN DESCRIPTION:  
-----  
EXPLAIN SELECT * FROM my1table;  
Access Path:  
+-STORAGE ACCESS for my1table [Cost: 10, Rows: 2] (PATH ID: 1)  
| Projection: public.my1table_b0  
| Materialize: my1table.c1, my1table.c2  
| Execute on: All Except v_vmart_node0005  
+-STORAGE ACCESS for my1table (REPLACEMENT FOR DOWN NODE) [Cost: 66, Rows: 2]  
| Projection: public.my1table_b1  
| Materialize: my1table.c1, my1table.c2  
| Execute on: v_vmart_node0006
```

The `All Permanent Nodes` output in the following example fragment denotes that the node list is for permanent (non-ephemeral) nodes only:

```
=> EXPLAIN SELECT * FROM my2table;  
Access Path:  
+-STORAGE ACCESS for my2table [Cost: 18, Rows:6 (NO STATISTICS)] (PATH ID: 1)  
| Projection: public.my2table_b0  
| Materialize: my2table.x, my2table.y, my2table.z  
| Execute on: All Permanent Nodes
```

MERGE Path

Vertica prepares an optimized query plan for a [MERGE](#) statement if the statement and its tables meet the criteria described in [MERGE Optimization](#).

Use the [EXPLAIN](#) keyword to determine whether Vertica can produce an optimized query plan for a given [MERGE](#) statement. If optimization is possible, the [EXPLAIN](#)-generated output contains a `[Semi]` path, as shown in the following sample fragment:

```
...  
Access Path:  
+-DML DELETE [Cost: 0, Rows: 0]  
| Target Projection: public.A_b1 (DELETE ON CONTAINER)  
| Target Prep:  
| Execute on: All Nodes  
| +--> JOIN MERGEJOIN(inputs presorted) [Semi] [Cost: 6, Rows: 1 (NO STATISTICS)] (PATH ID: 1)  
| | Inner (RESEGMENT)  
| | | Join Cond: (A.a1 = VAL(2))  
| | | Execute on: All Nodes  
| | +-- Outer -> STORAGE ACCESS for A [Cost: 2, Rows: 2 (NO STATISTICS)] (PATH ID: 2)  
...
```

Conversely, if Vertica cannot create an optimized plan, [EXPLAIN](#)-generated output contains `RightOuter` path:

```
...  
Access Path: +-DML MERGE
```

```
| Target Projection: public.locations_b1
| Target Projection: public.locations_b0
| Target Prep:
| Execute on: All Nodes
| +---> JOIN MERGEJOIN(inputs presorted) [RightOuter] [Cost: 28, Rows: 3 (NO STATISTICS)] (PATH ID:
1) Outer (RESEGMENT) Inner (RESEGMENT)
| |      Join Cond: (locations.user_id = VAL(2)) AND (locations.location_x = VAL(2)) AND
(locations.location_y = VAL(2))
| |      Execute on: All Nodes
| | +-- Outer -> STORAGE ACCESS for <No Alias> [Cost: 15, Rows: 2 (NO STATISTICS)] (PATH ID: 2)
...

```

Directed Queries

Directed queries encapsulate information that the optimizer can use to create a query plan. Directed queries can serve the following goals:

- Preserve current query plans before a scheduled upgrade. In most instances, queries perform more efficiently after a Vertica upgrade. In the few cases where this is not so, you can use directed queries that you created before upgrading, to recreate query plans from the earlier version.
- Enable you to create query plans that improve optimizer performance. Occasionally, you might want to influence the optimizer to make better choices in executing a given query. For example, you can choose a different projection, or force a different join order. In this case, you can use a directed query to create a query plan that preempts any plan that the optimizer might otherwise create.
- Redirect an input query to a query that uses different semantics—for example, map a join query to a SELECT statement that queries a flattened table.

Directed Query Components

A directed query pairs two components:

- **Input query:** A query that triggers use of this directed query when it is active.
- **Annotated query:** A SQL statement with embedded optimizer hints, which instruct the optimizer how to create a query plan for the specified input query. These hints specify important query plan elements, such as join order and projection choices.

You can also use most optimizer hints directly in vsql. For information about these and other hints, see [Hints](#) in the SQL Reference Manual.

Vertica provides two methods for creating directed queries:

- The optimizer can generate an annotated query from a given input query and pair the two as a directed query.
- You can write your own annotated query and pair it with an input query.

For a description of both methods, see [Creating Directed Queries](#).

Creating Directed Queries

`CREATE DIRECTED QUERY` associates an input query with a query annotated with optimizer hints. It stores the association under a unique identifier. `CREATE DIRECTED QUERY` has two variants:

- `CREATE DIRECTED QUERY OPTIMIZER` directs the query optimizer to generate annotated SQL from the specified input query. The annotated query contains hints that the optimizer can use to recreate its current query plan for that input query.
- `CREATE DIRECTED QUERY CUSTOM` specifies an annotated query supplied by the user. Vertica associates the annotated query with the input query specified by the last `SAVE QUERY` statement.

In both cases, Vertica associates the annotated query and input query, and registers their association in the system table `V_CATALOG.DIRECTED_QUERIES` under `query_name`.

[The two approaches can be used together](#): you can use the annotated SQL that the optimizer creates as the basis for creating your own (custom) directed queries.

Optimizer-Generated Directed Queries

`CREATE DIRECTED QUERY OPTIMIZER` passes an input query to the optimizer, which generates an annotated query from its own query plan. It then pairs the input and annotated queries and saves them as a directed query.

Note: The input query that you supply for optimizer-generated directed queries supports only one optimizer hint, `IGNORECONST`.

You can use optimized-generated directed queries to capture query plans before you upgrade. Doing so can be especially useful if you detect diminished performance of a given query after

the upgrade. In this case, you can use the corresponding directed query to recreate an earlier query plan, and compare its performance to the plan generated by the current optimizer.

For example, the following SQL statements create and activate the directed query `findBostonCashiers_OPT`:

```
=> CREATE DIRECTED QUERY OPTIMIZER 'findBostonCashiers_OPT'
    SELECT employee_first_name, employee_last_name FROM public.employee_dimension
        WHERE employee_city='Boston' and job_title='Cashier';
CREATE DIRECTED QUERY

=> ACTIVATE DIRECTED QUERY findBostonCashiers_OPT;
ACTIVATE DIRECTED QUERY
```

After this directed query plan is activated, the optimizer uses it to generate a query plan for all subsequent invocations of its input query. You can view the optimizer-generated annotated query by either calling [GET DIRECTED QUERY](#) or querying the system table [V_CATALOG.DIRECTED_QUERIES](#):

```
=> SELECT query_name, annotated_query FROM V_CATALOG.DIRECTED_QUERIES WHERE query_name =
'findBostonCashiers_OPT';
-[ RECORD 1 ]-----+-----
query_name      | findBostonCashiers_OPT
annotated_query | SELECT /*+ verbatim */ employee_dimension.employee_first_name AS employee_first_
name, employee_dimension.employee_last_name AS employee_last_name
FROM public.employee_dimension AS employee_dimension/*+projs('public.employee_dimension')*/
WHERE (employee_dimension.employee_city = 'Boston'::varchar(6)) AND (employee_dimension.job_title =
'Cashier'::varchar(7))
```

The annotated SQL includes two hints:

- `/*+verbatim*/` specifies to execute the annotated query exactly as written and produce a query plan accordingly.
- `/*+projs('public.Emp_Dimension')*/` directs the optimizer to create a query plan that uses the projection `public.Emp_Dimension`.

The following EXPLAIN statement verifies the optimizer's use of this directed query and the specified projection:

```
QUERY PLAN DESCRIPTION:
-----
EXPLAIN SELECT employee_first_name, employee_last_name FROM employee_dimension WHERE employee_
city='Boston' AND job_title='Cashier';

The following active directed query(query name: findBostonCashiers_OPT) is being executed:
SELECT /*+verbatim*/ employee_dimension.employee_first_name, employee_dimension.employee_last_name
FROM public.employee_dimension employee_dimension/*+projs('public.employee_dimension')*/ WHERE
((employee_dimension.employee_city = 'Boston'::varchar(6)) AND (employee_dimension.job_title =
'Cashier'::varchar(7)))

Access Path:
```

```
+--STORAGE ACCESS for employee_dimension [Cost: 60, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
| Projection: public.employee_dimension_b0
| Materialize: employee_dimension.employee_first_name, employee_dimension.employee_last_name
| Filter: (employee_dimension.employee_city = 'Boston')
| Filter: (employee_dimension.job_title = 'Cashier')
| Execute on: All Nodes
```

Custom Directed Queries

`CREATE DIRECTED QUERY CUSTOM` specifies an annotated query and pairs it to an input query previously saved by `SAVE QUERY`. The `SAVE QUERY` statement must precede `CREATE DIRECTED QUERY CUSTOM`. `SAVE QUERY` temporarily saves an input query for use in creating a directed query. You must issue both statements in the same user session.

Note: The input query that you supply to `SAVE QUERY` supports only one optimizer hint, `IGNORECONST`.

In the following example, `SAVE QUERY` saves a query. The `CREATE DIRECTED QUERY CUSTOM` statement that follows it provides an annotated query that includes a `/*+projs*/` hint. This hint instructs the optimizer to use the projection `public.Emp_Dimension_Unseg`:

```
=> SAVE QUERY SELECT employee_first_name, employee_last_name FROM employee_dimension
    WHERE employee_city='Boston' AND job_title='Cashier';
SAVE QUERY

=> CREATE DIRECTED QUERY CUSTOM 'findBostonCashiers_CUSTOM'
    SELECT employee_first_name, employee_last_name
    FROM employee_dimension /*+Projs('public.emp_dimension_unseg')*/
    WHERE employee_city='Boston' AND job_title='Cashier';
CREATE DIRECTED QUERY
```

Caution: Vertica associates a saved query and annotated query without checking whether the input and annotated queries are compatible. Be careful to sequence `SAVE QUERY` and `CREATE DIRECTED QUERY CUSTOM` so the saved and directed queries are correctly matched.

After this directed query plan is activated, the optimizer uses it to generate a query plan for all subsequent invocations of its input query. The following `EXPLAIN` output verifies the optimizer's use of this directed query and the projection it specifies:

```
=> DEACTIVATE DIRECTED QUERY findBostonCashiers_OPT;
DEACTIVATE DIRECTED QUERY
=> ACTIVATE DIRECTED QUERY findBostonCashiers_CUSTOM;
ACTIVATE DIRECTED QUERY
```

```
=> EXPLAIN SELECT employee_first_name, employee_last_name FROM employee_dimension
    WHERE employee_city='Boston' AND job_title='Cashier';

QUERY PLAN
-----
QUERY PLAN DESCRIPTION:
-----
EXPLAIN SELECT employee_first_name, employee_last_name FROM employee_dimension where employee_
city='Boston' AND job_title='Cashier';

The following active directed query(query name: findBostonCashiers_CUSTOM) is being executed:
SELECT employee_dimension.employee_first_name, employee_dimension.employee_last_name FROM
public.employee_dimension/*+Projs('public.Emp_Dimension_Unseg')*/ WHERE ((employee_
dimension.employee_city = 'Boston'::varchar(6)) AND (employee_dimension.job_title =
'Cashier'::varchar(7)))

Access Path:
+-STORAGE ACCESS for employee_dimension [Cost: 158, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
| Projection: public.emp_dimension_unseg
| Materialize: employee_dimension.employee_first_name, employee_dimension.employee_last_name
| Filter: (employee_dimension.employee_city = 'Boston')
| Filter: (employee_dimension.job_title = 'Cashier')
| Execute on: Query Initiator
```

Using Optimizer-Generated and Custom Directed Queries Together

You can use the annotated SQL that the optimizer creates as the basis for creating your own (custom) directed queries. This approach can be especially useful in evaluating the plan that the optimizer creates to handle a given query, and testing plan modifications.

For example, you might want to modify how the optimizer implements the following query:

```
=> SELECT customers.name FROM
(purchase JOIN customers ON customers.customer_id = purchase.customer_id)
JOIN item ON purchase.item_id = item.item_id
WHERE item.type = 'household' AND customers.age < 30 AND MONTH(purchase.date) = 'March';
```

When you run EXPLAIN on this query, you discover that the optimizer uses projection `customers_proj_age` for the `customers` table. This projection is sorted on the column `customers.age`. Consequently, the optimizer hash-joins the tables `customers` and `purchase` on `customer_id`.

After analyzing the `customers` table data, you make two observations:

- Most customers are under 30, so it makes more sense to use a different projection, `customers_proj_id`, which is sorted on customer IDs.
- Because the inner join projections are both sorted on customer IDs, the query plan should also specify a merge join.

You can create a directed query that encapsulates these changes as follows:

1. Create an optimizer-generated directed query from the input query, by using **CREATE DIRECTED QUERY OPTIMIZER**:

```
=> CREATE DIRECTED QUERY OPTIMIZER totalStoreSales SELECT customers.name FROM
  (purchase JOIN customers ON customers.customer_id = purchase.customer_id)
  JOIN item ON purchase.item_id = item.item_id)
  WHERE item.type = 'household' AND customers.age < 30 AND month(purchase.date) = 'March';
CREATE DIRECTED QUERY
```

Note: **CREATE DIRECTED QUERY OPTIMIZER** provides a convenient short cut for creating syntactically correct annotated queries that you can edit. For full information about supported optimizer hints, see [Hints](#) in the SQL Reference Manual.

2. Get the annotated query generated for this directed query: call **GET DIRECTED QUERY** or query the system table **V_CATALOG.DIRECTED_QUERIES**. The following example queries the system table:

```
=> SELECT annotated_query FROM V_CATALOG.DIRECTED_QUERIES WHERE query_name='totalStoreSales';
-[ RECORD 1 ]---+-----
annotated_query | SELECT /*+ SYNTACTIC_JOIN,VERBATIM */ customers.name
FROM ((purchase /*+PROJS('purchase_cid')*/
JOIN /*+ JTYPE(H) */ customers /*+PROJS('customers_proj_age')*/
ON customers.customer_id = purchase.customer_id)
JOIN /*+ JTYPE(H) */ item /*+PROJS('item_proj_type')*/
ON purchase.item_id = item.item_id)
WHERE item.type = 'household' AND customers.age < 30 AND month(purchase.date) = 'March'
```

3. Modify the annotated query:

```
SELECT /*+ SYNTACTIC_JOIN,VERBATIM */ customers.name
FROM ((purchase /*+PROJS('purchase_cid')*/
JOIN /*+ JTYPE(M) */ customers /*+PROJS('customers_proj_id')*/
ON customers.customer_id = purchase.customer_id)
JOIN /*+ JTYPE(H) */ item /*+PROJS('item_proj_type')*/
ON purchase.item_id = item.item_id)
WHERE item.type = 'household' AND customers.age < 30 AND month(purchase.date) = 'March'
```

4. Use the modified annotated query to create the desired directed query:
 - Save the desired input query with **SAVE QUERY**:

```
=> SAVE QUERY customers.name FROM
  (purchase JOIN customers ON customers.customer_id = purchase.customer_id)
  JOIN item ON purchase.item_id = item.item_id)
  WHERE item.type = 'household' AND customers.age < 30 AND month(purchase.date) = 'March';
SAVE QUERY
```

- Create a custom directed query that associates the saved input query with the modified annotated query:

```
=> CREATE DIRECTED QUERY CUSTOM 'getCustomersUnder30'  
SELECT /*+ SYNTACTIC_JOIN,VERBATIM */ customers.name FROM  
((purchase /*+PROJS('purchase_cid')*/  
  JOIN /*+ JTYPE(M) */ customers /*+PROJS('customers_proj_id')*/  
  ON customers.customer_id = purchase.customer_id)  
 JOIN /*+ JTYPE(H) */ item /*+PROJS('item_proj_type')*/ ON purchase.item_id = item.item_id)  
WHERE item.type = 'household' AND customers.age < 30 AND month(purchase.date) = 'March'  
CREATE DIRECTED QUERY
```

5. Activate this directed query:

```
ACTIVATE DIRECTED QUERY getCustomersUnder30;  
ACTIVATE DIRECTED QUERY
```

When the optimizer processes a query that matches this directed query's input query, it uses the directed query's annotated query to generate a query plan.

Setting Hints in Annotated Queries

The hints in a directed query's annotated query provide the Vertica optimizer instructions how to execute an input query. Annotated queries support the following hints:

- **Join hints** specify join order, join type, and join data distribution: [SYNTACTIC_JOIN](#), [DISTRIB](#), [JTYPE](#), [UTYPE](#).
- **Table hints** specify which projections to include and exclude in the query plan: [PROJS](#), [SKIP_PROJS](#).
- [IGNORECONST](#) is supported for a directed query's input and annotated queries. For more information, see [Ignoring Constants in Directed Queries](#)
- [VERBATIM](#) enforces execution of an annotated query exactly as written.

Other hints in annotated queries such as [DIRECT](#) or [LABEL](#) are ignored.

You can use hints in a vsql query the same as in an annotated query, with two exceptions: [IGNORECONST](#) and [VERBATIM](#) are invalid for use in vsql. For general information about using hints, see [Hints](#) in the SQL Reference Manual.

Ignoring Constants in Directed Queries

The `IGNORECONST` hint lets you create directed queries that support input queries with various conditions. For example, you might want to use the same directed query for the following input queries:

```
=> SELECT Employee_first_name, Employee_last_name FROM EMP_Dimension WHERE  
Employee_city='Boston' and Employee_position='Cashier';  
  
=> SELECT Employee_first_name, Employee_last_name FROM EMP_Dimension WHERE  
Employee_city='Chicago' and Employee_position='Greeter';
```

In this case, you can create a directed query where input and annotated queries qualify the settings for `Employee_city` and `Employee_position` with `IGNORECONST` hints:

```
=> SAVE QUERY SELECT Employee_first_name, Employee_last_name FROM EMP_Dimension  
WHERE Employee_city='somewhere' /*+IGNORECONST(1)*/  
AND Employee_position='somejob' /*+IGNORECONST(2)*/;  
SAVE QUERY  
  
=> CREATE DIRECTED QUERY CUSTOM 'findEmployees'  
SELECT Employee_first_name, Employee_last_name  
FROM EMP_Dimension /*+projs('public.Emp_Dimension_Unseg')*/  
WHERE Employee_city='somewhere' /*+IGNORECONST(1)*/  
AND Employee_position='somejob' /*+IGNORECONST(2)*/  
CREATE DIRECTED QUERY  
  
=> ACTIVATE DIRECTED QUERY findEmployees;  
ACTIVATE DIRECTED QUERY
```

`IGNORECONST` requires an integer argument. This argument matches constants in input and annotated queries that you want the optimizer to ignore. In the previous example, the input and annotated queries of the directed query, `findEmployees`, use `IGNORECONST` to pair two sets of constants:

- `IGNORECONST(1)` pairs input and annotated query settings for `Employee_city`.
- `IGNORECONST(2)` pairs input and annotated query settings for `Employee_position`.

When the optimizer maps input queries to the directed query `findEmployees`, the `IGNORECONST` arguments for `Employee_city` and `Employee_position` tell it to ignore the saved values for these two columns. Thus, users can supply any values for these columns.

For example, the following query plan shows how the optimizer maps one user query to the directed query `findEmployees`:

```
QUERY PLAN DESCRIPTION:
-----

EXPLAIN SELECT Employee_first_name, Employee_last_name FROM EMP_Dimension WHERE Employee_
city='Boston' AND Employee_position='Cashier';

The following active directed query is being executed:
SELECT EMP_Dimension.Employee_first_name, EMP_Dimension.Employee_last_name FROM public.Emp_Dimension
EMP_Dimension/*+projs('public.Emp_Dimension_Unseg')*/ WHERE (EMP_Dimension.Employee_city =
'Boston'::varchar(6)) AND (Emp_Dimension.Employee_position = 'Cashier'::varchar(7))

Access Path:
+-STORAGE ACCESS for EMP_Dimension [Cost: 154, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
| Projection: public.Emp_Dimension_Unseg
| Materialize: EMP_Dimension.Employee_first_name, EMP_Dimension.Employee_last_name
| Filter: (EMP_Dimension.Employee_city = 'Boston')
| Filter: (Emp_Dimension.Employee_position = 'Cashier')
| Execute on: Query Initiator
```

Embedding IGNORECONST Hints in Optimizer-Generated Directed Queries

You can embed `IGNORECONST` hints in the input query argument of `CREATE DIRECTED QUERY OPTIMIZER`. The optimizer creates an annotated query that includes `IGNORECONST` hints for the corresponding columns. For example, given this `CREATE DIRECTED QUERY OPTIMIZER` statement:

```
=> CREATE DIRECTED QUERY OPTIMIZER findGreetersAnyCity
SELECT Employee_first_name, Employee_last_name
FROM EMP_Dimension /*+projs('public.Emp_Dimension_Unseg')*/
WHERE Employee_city='anywhere'/*+IGNORECONST(9)*/ AND Employee_position='Greeter';
CREATE DIRECTED QUERY
```

the optimizer creates the following annotated query:

```
SELECT /*+ verbatim */ EMP_Dimension.Employee_first_name AS Employee_first_name, EMP_
Dimension.Employee_last_name AS Employee_last_name
FROM public.Emp_Dimension AS EMP_Dimension/*+projs('public.Emp_Dimension_Unseg')*/
WHERE (EMP_Dimension.Employee_city = 'anywhere'::varchar(8) /*+IgnoreConst(9)*/) AND (EMP_
Dimension.Employee_position = 'Greeter'::varchar(7))
```

Mapping One-to-Many IGNORECONST Hints

The examples shown so far demonstrate one-to-one pairings of IGNORECONST hints. You can also use IGNORECONST to map one input constant to multiple constants in an annotated query. This approach can be especially useful when you want to provide the optimizer with explicit instructions how to execute a query that joins tables.

For example, this simple query joins two tables:

```
SELECT * FROM S JOIN T ON S.a = T.b WHERE S.a = 8;
```

In this case, the optimizer can infer that `S.a` and `T.b` have the same value and implements the join accordingly. In other cases, you might want to provide the optimizer explicit guidance on implementing a join condition. Given the previous input query, you can create a directed query that uses the IGNORECONST hint to map query input for `S.a` to `S.a` and `T.b`:

```
=> SAVE QUERY SELECT * FROM S JOIN T ON S.a = T.b WHERE S.a = 999/*+IGNORECONST(1)*/;  
SAVE QUERY  
  
=> CREATE DIRECTED QUERY CUSTOM joinST SELECT * FROM S JOIN T ON S.a = T.b  
WHERE S.a = 999/*+IGNORECONST(1)*/ AND T.b = 999/*+IGNORECONST(1)*/;  
CREATE DIRECTED QUERY  
  
=> ACTIVATE DIRECTED QUERY joinST;  
ACTIVATE DIRECTED QUERY
```

Now, given the following input query:

```
SELECT * FROM S JOIN T ON S.a = T.b WHERE S.a = 3;
```

the optimizer uses the directed query `joinST` and its IGNORECONST hints to rewrite the query as follows:

```
QUERY PLAN DESCRIPTION:  
-----  
  
EXPLAIN SELECT * FROM S JOIN T ON S.a = T.b WHERE S.a = 3;  
  
The following active directed query(query name: joinST) is being executed:  
SELECT S.a, T.b FROM (public.S JOIN public.T ON ((S.a = T.b))) WHERE ((S.a = 3) AND (T.b = 3))  
  
Access Path:  
+-JOIN MERGEJOIN(inputs presorted) [Cost: 11, Rows: 9 (NO STATISTICS)] (PATH ID: 1)  
|   Join Cond: (S.a = T.b)  
|   Execute on: v_vmart_node0002  
| +- Outer -> STORAGE ACCESS for S [Cost: 5, Rows: 9 (NO STATISTICS)] (PATH ID: 2)  
| |   Projection: public.S_b0  
| |   Materialize: S.a  
| |   Filter: (S.a = 3)
```

```
| |      Execute on: v_vmart_node0002
| |      Runtime Filter: (SIP1(MergeJoin): S.a)
| +-- Inner -> STORAGE ACCESS for T [Cost: 5, Rows: 9 (NO STATISTICS)] (PATH ID: 3)
| |      Projection: public.T_b0
| |      Materialize: T.b
| |      Filter: (T.b = 3)
| |      Execute on: v_vmart_node0002
```

Rewriting Queries

You can use directed queries to change the semantics of a given query—that is, substitute one query for another. This can be especially important when you have little or no control over the content and format of input queries that your Vertica database processes. You can map these queries to directed queries that rewrite the original input for optimal execution.

The following sections describe two use cases:

- [Rewriting Join Queries](#)
- [Using Query Templates](#)

Rewriting Join Queries

Many of your input queries join multiple tables. With the recent introduction of [flattened tables](#), you've determined that in many cases, it would be more efficient to denormalize much of your data in several wide tables and query those tables directly. You cannot revise the input queries themselves. However, you can use directed queries to map these queries to queries on the flattened table data.

For example, the following query aggregates regional sales of white wine products, by joining three tables in the VMart database:

```
=> SELECT SD.store_region AS 'Sales Region',
       SD.store_city AS 'City',
       SUM(SF.gross_profit_dollar_amount) Total
FROM store.store_sales_fact SF
JOIN store.store_dimension SD ON SF.store_key=SD.store_key
JOIN product_dimension P ON SF.product_key||SF.product_version=P.product_key||P.product_version
WHERE P.product_description ILIKE '%wine%' AND P.product_description ILIKE '%white%'
GROUP BY ROLLUP (SD.store_region, SD.store_city)
ORDER BY 1,3 DESC;
```

You can consolidate the joined table data in a single flattened table, and query this table instead. By doing so, you can access the same data faster. You can create this table with the following SQL:

```
CREATE TABLE store.store_sales_wide AS SELECT * from store.store_sales_fact;
ALTER TABLE store.store_sales_wide ADD COLUMN store_name VARCHAR(64)
  SET USING (SELECT store_name FROM store.store_dimension
  WHERE store.store_sales_wide.store_key=store.store_dimension.store_key);
ALTER TABLE store.store_sales_wide ADD COLUMN store_city varchar(64)
  SET USING (SELECT store_city FROM store.store_dimension
  WHERE store.store_sales_wide.store_key=store.store_dimension.store_key);
ALTER TABLE store.store_sales_wide ADD COLUMN store_state char(2)
  SET USING (SELECT store_state char FROM store.store_dimension
  WHERE store.store_sales_wide.store_key=store.store_dimension.store_key);
ALTER TABLE store.store_sales_wide ADD COLUMN store_region varchar(64)
  SET USING (SELECT store_region FROM store.store_dimension
  WHERE store.store_sales_wide.store_key=store.store_dimension.store_key);
ALTER TABLE store.store_sales_wide add column product_description VARCHAR(128)
  SET USING (SELECT product_description FROM public.product_dimension
  WHERE store_sales_wide.product_key||store_sales_wide.product_version = product_dimension.product_
  key||product_dimension.product_version);
ALTER TABLE store.store_sales_wide ADD COLUMN sku_number char(32)
  SET USING (SELECT sku_number char FROM product_dimension
  WHERE store_sales_wide.product_key||store_sales_wide.product_version = product_dimension.product_
  key||product_dimension.product_version);

SELECT REFRESH_COLUMNS ('store.store_sales_wide','', 'rebuild');
```

After creating this table and refreshing its SET USING columns, you can rewrite the earlier query as follows:

```
=> SELECT store_region AS 'Sales Region',
  store_city AS 'City',
  SUM(gross_profit_dollar_amount) AS Total
  FROM store.store_sales_wide
  WHERE product_description ILIKE '%wine%' AND product_description ILIKE '%white%'
  GROUP BY ROLLUP (store_region, store_city)
  ORDER BY 1,3 DESC;
```

Sales Region	City	Total
East		762632
East	Sterling Heights	67391
East	Allentown	64528
East	Elizabeth	58784
East	New Haven	57730
East	Boston	57315
East	Lowell	42734
East	Charlotte	40757
East	Erie	39070
East	Washington	38792
East	Waterbury	35369
East	Hartford	27684
East	Clarksville	25953
East	Stamford	25657
East	Memphis	25629
East	Baltimore	23999

East	Columbia	22573
East	Manchester	22496
East	Nashville	22353
East	Cambridge	14385
East	Philadelphia	13017
East	Alexandria	12273
East	New York	12261
East	Portsmouth	11882
MidWest		494182
MidWest	Lansing	69157
MidWest	Livonia	62269
...		

Querying the flattened table is more efficient; however, you still must account for input queries that continue to use the earlier join syntax. You can do so by creating a [custom directed query](#), which redirects these input queries to the desired syntax:

1. [Save the input query](#):

```
=> SAVE QUERY SELECT SD.store_region AS 'Sales Region',
    SD.store_city AS 'City',
    SUM(SF.gross_profit_dollar_amount) Total
FROM store.store_sales_fact SF
JOIN store.store_dimension SD ON SF.store_key=SD.store_key
JOIN product_dimension P ON SF.product_key||SF.product_version=P.product_key||P.product_
version
WHERE P.product_description ILIKE '%wine%' AND P.product_description ILIKE '%white%'
GROUP BY ROLLUP (SD.store_region, SD.store_city)
ORDER BY 1,3 DESC;
SAVE QUERY
```

2. [Map the saved query to a directed query with the desired syntax, and activate the directed query](#):

```
=> CREATE DIRECTED QUERY CUSTOM 'RegionalSalesWhiteWine'
    SELECT store_region AS 'Sales Region',
    store_city AS 'City',
    SUM(gross_profit_dollar_amount) AS Total
FROM store.store_sales_wide
WHERE product_description ILIKE '%wine%' AND product_description ILIKE '%white%'
GROUP BY ROLLUP (store_region, store_city)
ORDER BY 1,3 DESC;
CREATE DIRECTED QUERY

=> ACTIVATE DIRECTED QUERY RegionalSalesWhiteWine;
ACTIVATE DIRECTED QUERY
```

When directed query `RegionalSalesWhiteWine` is active, the query optimizer maps all queries that match the original input format to the directed query, as shown in the following query plan:

```
=> EXPLAIN SELECT SD.store_region AS 'Sales Region',
      SD.store_city AS 'City',
      SUM(SF.gross_profit_dollar_amount) Total
FROM store.store_sales_fact SF
JOIN store.store_dimension SD ON SF.store_key=SD.store_key
JOIN product_dimension P ON SF.product_key||SF.product_version=P.product_key||P.product_version
WHERE P.product_description ILIKE '%wine%' AND P.product_description ILIKE '%white%'
GROUP BY ROLLUP (SD.store_region, SD.store_city)
ORDER BY 1,3 DESC;
```

The following active directed query(query name: RegionalSalesWhiteWine) is being executed:

```
SELECT store_sales_wide.store_region AS "Sales Region",
      store_sales_wide.store_city AS City,
      sum(store_sales_wide.gross_profit_dollar_amount) AS Total FROM store.store_sales_wide
WHERE ((store_sales_wide.product_description ~* '%wine%'::varchar(6))
AND (store_sales_wide.product_description ~* '%white%'::varchar(7)))
GROUP BY GROUPING SETS((store_sales_wide.store_region, store_sales_wide.store_city), (store_sales_
wide.store_region), ())
ORDER BY store_sales_wide.store_region, sum(store_sales_wide.gross_profit_dollar_amount) DESC
```

Access Path:

```
+--SORT [Cost: 76K, Rows: 100] (PATH ID: 1)
| Order: store_sales_wide.store_region ASC, sum(store_sales_wide.gross_profit_dollar_amount) DESC
| Execute on: All Nodes
| +---> GROUPBY HASH (GLOBAL RESEGMENT GROUPS) (LOCAL RESEGMENT GROUPS) [Cost: 76K, Rows: 100] (PATH
ID: 2)
| | Aggregates: sum(store_sales_wide.gross_profit_dollar_amount)
| | Group By: store_sales_wide.store_region, store_sales_wide.store_city
| | Grouping Sets: (store_sales_wide.store_region, store_sales_wide.store_city, <SVAR>),
(store_sales_wide.store_region, <SVAR>), (<SVAR>)
| | Execute on: All Nodes
| | +---> STORAGE ACCESS for store_sales_wide [Cost: 23K, Rows: 2M] (PATH ID: 3)
| | | Projection: store.store_sales_wide_super
| | | Materialize: store_sales_wide.gross_profit_dollar_amount, store_sales_wide.store_city,
store_sales_wide.store_region
| | | Filter: ((store_sales_wide.product_description ~* '%wine%') AND (store_sales_
wide.product_description ~* '%white%'))
| | | Execute on: All Nodes
```

To compare the costs of executing the directed query and executing the original input query, deactivate the directed query and use EXPLAIN on the original input query. The optimizer reverts to creating a plan for the input query that incurs significantly greater cost, as shown in the following query plan:

```
=> DEACTIVATE DIRECTED QUERY RegionalSalesWhiteWine;
DEACTIVATE DIRECTED QUERY

=> EXPLAIN SELECT SD.store_region AS 'Sales Region',
      SD.store_city AS 'City',
      SUM(SF.gross_profit_dollar_amount) Total
FROM store.store_sales_fact SF
JOIN store.store_dimension SD ON SF.store_key=SD.store_key
JOIN product_dimension P ON SF.product_key||SF.product_version=P.product_key||P.product_version
WHERE P.product_description ILIKE '%wine%' AND P.product_description ILIKE '%white%'
GROUP BY ROLLUP (SD.store_region, SD.store_city)
ORDER BY 1,3 DESC;
```

```

Access Path:
+-SORT [Cost: 192K, Rows: 100] (PATH ID: 1)
| Order: SD.store_region ASC, sum(SF.gross_profit_dollar_amount) DESC
| Execute on: All Nodes
| +---> GROUPBY HASH (GLOBAL RESEGMENT GROUPS) (LOCAL RESEGMENT GROUPS) [Cost: 192K, Rows: 100]
(PATH ID: 2)
| | Aggregates: sum(SF.gross_profit_dollar_amount)
| | Group By: SD.store_region, SD.store_city
| | Grouping Sets: (SD.store_region, SD.store_city, <SVAR>), (SD.store_region, <SVAR>),
(<SVAR>)
| | Execute on: All Nodes

```

Using Query Templates

You can use directed queries to implement multiple queries that are identical except for the predicate strings on which query results are filtered. For example, directed query `RegionalSalesWhiteWine` only handles input queries that filter on `product_description` values containing the strings `wine` and `white`. You can create a modified version of this directed query that matches the syntax of multiple input queries, which differ only in their pairs of input values—for example, `wine` and `red`.

You create this query template in the following steps:

1. Use the input query on the flattened table to create an [optimized-generated directed query](#):

```
=> CREATE DIRECTED QUERY optimizer RegionalSalesTemp
  SELECT store_region AS 'Sales Region',
         store_city AS 'City',
         SUM(gross_profit_dollar_amount) AS Total
  FROM store.store_sales_wide
  WHERE product_description ILIKE '%wine%'
         AND product_description ILIKE '%white%'
  GROUP BY ROLLUP (store_region, store_city)
  ORDER BY 1,3 DESC;
CREATE DIRECTED QUERY
```

2. Modify the original join input query with [IGNORECONST](#) hints and [save it](#):

```
=> SAVE QUERY SELECT SD.store_region AS 'Sales Region',
  SD.store_city AS 'City',
  SUM(SF.gross_profit_dollar_amount) Total
  FROM store.store_sales_fact SF
  JOIN store.store_dimension SD ON SF.store_key=SD.store_key
  JOIN product_dimension P ON SF.product_key||SF.product_version=P.product_key||P.product_
  version
  WHERE P.product_description ILIKE 'desc-string1' /*+IGNORECONST(1)*/
         AND P.product_description ILIKE 'desc-string2' /*+IGNORECONST(2)*/
  GROUP BY ROLLUP (SD.store_region, SD.store_city)
  ORDER BY 1,3 DESC;
SAVE QUERY
```

3. [Get the optimizer-generated query](#) from system table [DIRECTED_QUERIES](#):

```
=> \x
=> SELECT annotated_query FROM DIRECTED_QUERIES WHERE query_name='RegionalSalesTemp';
-[ RECORD 1 ]-----+-----
annotated_query | SELECT /*+verbatim*/ store_sales_wide.store_region AS "Sales Region",
  store_sales_wide.store_city AS City,
  sum(store_sales_wide.gross_profit_dollar_amount) AS Total
  FROM store.store_sales_wide AS store_sales_wide/*+projs('store.store_sales_wide')*/
  WHERE ((store_sales_wide.product_description ~* '%wine% '::varchar(6))
         AND (store_sales_wide.product_description ~* '%white% '::varchar(7)))
  GROUP BY /*+GByType(Hash)*/ GROUPING SETS((1, 2), (1), ())
  ORDER BY 1 ASC, 3 DESC
(1 row)
```

4. Create a modified version of the annotated query that qualifies the input values with [IGNORECONST](#) hints. Use this version to create a custom directed query, and then activate it:

```
=> CREATE DIRECTED QUERY CUSTOM RegionalSales
  SELECT /*+verbatim*/ store_sales_wide.store_region AS "Sales Region",
         store_sales_wide.store_city AS City,
         sum(store_sales_wide.gross_profit_dollar_amount) AS Total
  FROM store.store_sales_wide AS store_sales_wide/*+projs('store.store_sales_wide')*/
  WHERE ((store_sales_wide.product_description ~* 'desc-str'/*+IGNORECONST(1)*/)
         AND (store_sales_wide.product_description ~* 'desc-str'/*+IGNORECONST(2)*/))
```

```
GROUP BY /*+GByType(Hash)*/ GROUPING SETS((1, 2), (1), ())
ORDER BY 1 ASC, 3 DESC;
CREATE DIRECTED QUERY

=> ACTIVATE DIRECTED QUERY RegionalSales;
```

After activating this directed query, Vertica can use it for input queries that match the template. These queries can use any pair of strings to filter the result set. For example, the following input query filters on the strings `chicken` and `frozen`:

```
EXPLAIN SELECT SD.store_region AS 'Sales Region',
  SD.store_city AS 'City',
  SUM(SF.gross_profit_dollar_amount) Total
FROM store.store_sales_fact SF
JOIN store.store_dimension SD ON SF.store_key=SD.store_key
JOIN product_dimension P ON SF.product_key||SF.product_version=P.product_key||P.product_version
WHERE P.product_description ILIKE '%chicken%' AND P.product_description ILIKE '%frozen%'
GROUP BY ROLLUP (SD.store_region, SD.store_city)
ORDER BY 1,3 DESC;
```

The following active directed query(query name: `RegionalSales`) is being executed:

```
SELECT /*+verbatim*/ store_sales_wide.store_region AS "Sales Region",
  store_sales_wide.store_city AS City,
  sum(store_sales_wide.gross_profit_dollar_amount) AS Total
FROM store.store_sales_wide store_sales_wide/*+projs('store.store_sales_wide')*/
WHERE ((store_sales_wide.product_description ~* '%chicken%'::varchar(9))
  AND (store_sales_wide.product_description ~* '%frozen%'::varchar(8)))
GROUP BY /*+GByType(Hash)*/ GROUPING SETS((store_sales_wide.store_region, store_sales_wide.store_
city), (store_sales_wide.store_region), ())
ORDER BY store_sales_wide.store_region, sum(store_sales_wide.gross_profit_dollar_amount) DESC
```

Access Path:

```
+--SORT [Cost: 214K, Rows: 100] (PATH ID: 1)
| Order: store_sales_wide.store_region ASC, sum(store_sales_wide.gross_profit_dollar_amount) DESC
| Execute on: All Nodes
| +---> GROUPBY HASH (GLOBAL RESEGMENT GROUPS) (LOCAL RESEGMENT GROUPS) [Cost: 214K, Rows: 100]
(PATH ID: 2)
| | Aggregates: sum(store_sales_wide.gross_profit_dollar_amount)
| | Group By: store_sales_wide.store_region, store_sales_wide.store_city
| | Grouping Sets: (store_sales_wide.store_region, store_sales_wide.store_city, <SVAR>),
(store_sales_wide.store_region, <SVAR>), (<SVAR>)
| | Execute on: All Nodes
| | +---> STORAGE ACCESS for store_sales_wide [Cost: 39K, Rows: 5M] (PATH ID: 3)
| | | Projection: store.store_sales_wide_super
| | | Materialize: store_sales_wide.gross_profit_dollar_amount, store_sales_wide.store_city,
store_sales_wide.store_region
| | | Filter: ((store_sales_wide.product_description ~* '%chicken%') AND (store_sales_
wide.product_description ~* '%frozen%'))
| | | Execute on: All Nodes
```

When you execute this query, it returns with the following results:

Sales Region	City	Total
East		1421528

East	Sterling Heights	122205
East	Elizabeth	121061
East	Boston	113776

Managing Directed Queries

Vertica provides a number of ways to manage directed queries:

- [Getting Directed Queries](#)
- [Identifying Active Directed Queries](#)
- [Activating and Deactivating Directed Queries](#)
- [Exporting Directed Queries from the Catalog](#)
- [Dropping Directed Queries](#)

Getting Directed Queries

You can obtain catalog information about directed queries in two ways:

- [Run the statement](#) `GET DIRECTED QUERY.`
- [Query the system table](#) `V_CATALOG.DIRECTED_QUERIES.`

Run GET DIRECTED QUERY

`GET DIRECTED QUERY` queries the system table `V_CATALOG.DIRECTED_QUERIES` on the specified input query. It returns a list of directed queries that map to the input query.

The following `GET DIRECTED QUERY` statement returns two directed queries that map to the same input query, `findBostonCashiers_OPT` and `findBostonCashiers_CUSTOM`:

```
=> GET DIRECTED QUERY SELECT employee_first_name, employee_last_name
    FROM employee_dimension WHERE employee_city='Boston' AND job_title='Cashier';
-[ RECORD 1 ]---+
query_name      | findBostonCashiers_OPT
is_active       | f
vertica_version | Vertica Analytic Database v7.2.3
comment         | Optimizer-generated directed query
creation_date   | 2016-04-25 08:17:26.913339
annotated_query | SELECT /*+ verbatim */ employee_dimension.employee_first_name AS employee_first_
name, employee_dimension.employee_last_name AS employee_last_name
FROM public.employee_dimension AS employee_dimension/*+projs('public.employee_dimension')*/
WHERE (employee_dimension.employee_city = 'Boston'::varchar(6)) AND (employee_dimension.job_title =
'Cashier'::varchar(7))
-[ RECORD 2 ]---+
query_name      | findBostonCashiers_CUSTOM
is_active       | t
vertica_version | Vertica Analytic Database v7.2.3
comment         | Custom directed query
creation_date   | 2016-04-25 09:15:11.464417
annotated_query | SELECT employee_dimension.employee_first_name, employee_dimension.employee_last_
name FROM public.employee_dimension/*+Projs('public.Emp_Dimension_Unseg')*/ WHERE ((employee_
dimension.employee_city = 'Boston'::varchar(6)) AND (employee_dimension.job_title =
'Cashier'::varchar(7)))
```

Query V_CATALOG.DIRECTED_QUERIES

You can query the system table `V_CATALOG.DIRECTED_QUERIES` directly. For example:

```
=> SELECT query_name, is_active FROM V_CATALOG.DIRECTED_QUERIES WHERE query_name ILIKE
'%findBostonCashiers%';
      query_name      | is_active
-----+-----
 findBostonCashiers_CUSTOM | t
 findBostonCashiers_OPT   | f
(2 rows)

(2 rows)
```

Caution: Query results for the fields `input_query` and `annotated_query` are truncated after 8192 characters. You can get the full content of both fields in two ways:

- Use the statement [GET DIRECTED QUERY](#).
- Use [EXPORT_CATALOG](#) to export directed queries.

Identifying Active Directed Queries

Multiple directed queries can map to the same input query. The `is_active` column returned by [GET DIRECTED QUERY](#) clarifies which directed queries are active. If multiple directed queries are active for the same input query, the optimizer uses the first one to be created. In that case, you can use [EXPLAIN](#) to identify which directed query is active.

Note: It is good practice to activate only one directed query at a time for a given input query.

In the following example, `GET DIRECTED QUERY` returns with two directed queries that map to the same input query: `findBostonCashiers_OPT`, and `findBostonCashiers_CUSTOM`. Only `findBostonCashiers_CUSTOM` is flagged as active:

```
=> GET DIRECTED QUERY SELECT Employee_first_name, Employee_last_name FROM Emp_Dimension
    WHERE Employee_city='Boston' and Employee_position='Cashier';
-[ RECORD 1 ]----+
query_name      | findBostonCashiers_OPT
is_active       | f
vertica_version | Vertica Analytic Database v7.2.0
comment         | Optimizer-generated directed query
creation_date   | 2015-09-02 09:36:29.395702
annotated_query | SELECT /*+ verbatim */ Emp_Dimension.Employee_first_name AS Employee_first_name,
Emp_Dimension.Employee_last_name AS Employee_last_name
FROM public.Emp_Dimension AS Emp_Dimension/*+projs('public.Emp_Dimension')*/
WHERE (Emp_Dimension.Employee_city = 'Boston'::varchar(6)) AND (Emp_Dimension.Employee_position =
'Cashier'::varchar(7))
-[ RECORD 2 ]----+
query_name      | findBostonCashiers_CUSTOM
is_active       | t
vertica_version | Vertica Analytic Database v7.2.0-20150902
comment         | Custom directed query
creation_date   | 2015-09-02 13:27:38.225568
annotated_query | SELECT Emp_Dimension.Employee_first_name, Emp_Dimension.Employee_last_name FROM
public.Emp_Dimension/*+Projs('public.Emp_Dimension_Unseg')*/ WHERE ((Emp_Dimension.Employee_city =
'Boston'::varchar(6)) AND (Emp_Dimension.Employee_position = 'Cashier'::varchar(7)))
```

If you run `EXPLAIN` on the same input query, it returns with a query plan that confirms use of `findBostonCashiers_CUSTOM` as the active directed query:

```
=> EXPLAIN SELECT Employee_first_name, Employee_last_name FROM Emp_Dimension WHERE Employee_
city='Boston' AND Employee_position='Cashier';
```

QUERY PLAN

QUERY PLAN DESCRIPTION:

```
EXPLAIN SELECT Employee_first_name, Employee_last_name FROM Emp_Dimension WHERE Employee_
city='Boston' AND Employee_position='Cashier';
```

The following active directed query(query name: findBostonCashiers_CUSTOM) is being executed:

```
SELECT Emp_Dimension.Employee_first_name, Emp_Dimension.Employee_last_name FROM public.Emp_
Dimension/*+Projs('public.Emp_Dimension_Unseg')*/ WHERE ((Emp_Dimension.Employee_city =
'Boston'::varchar(6)) AND (Emp_Dimension.Employee_position = 'Cashier'::varchar(7)))
```

Access Path:

```
+--STORAGE ACCESS for Emp_Dimension [Cost: 154, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
| Projection: public.Emp_Dimension_Unseg
| Materialize: Emp_Dimension.Employee_first_name, Emp_Dimension.Employee_last_name
| Filter: (Emp_Dimension.Employee_city = 'Boston')
| Filter: (Emp_Dimension.Employee_position = 'Cashier')
| Execute on: Query Initiator
```

Activating and Deactivating Directed Queries

The optimizer uses only directed queries that are active. If multiple directed queries share the same input query, the optimizer uses the first one to be created.

You activate and deactivate directed queries with [ACTIVATE DIRECTED QUERY](#) and [DEACTIVATE DIRECTED QUERY](#), respectively. For example, the following [ACTIVATE DIRECTED QUERY](#) statement deactivates `findBostonCashiers_OPT` and activates `findBostonCashiers_CUSTOM`:

```
=> DEACTIVATE DIRECTED QUERY findBostonCashiers_OPT;
DEACTIVATE DIRECTED QUERY;
=> ACTIVATE DIRECTED QUERY findBostonCashiers_CUSTOM;
ACTIVATE DIRECTED QUERY;
```

Vertica uses the active directed query for a given query across all sessions until it is explicitly deactivated by `DEACTIVATE DIRECTED QUERY` or removed from storage by [DROP DIRECTED QUERY](#). If a directed query is active at the time of database shutdown, Vertica automatically reactivates it when you restart the database.

After a direct query is deactivated, the query optimizer handles subsequent invocations of the input query by using another directed query, if one is available. Otherwise, it generates its own query plan.

Exporting Directed Queries from the Catalog

Tip: You can also export query plans as directed queries to an external SQL file. See [Batch Query Plan Export](#).

Before upgrading to a new version of Vertica, you can export directed queries for those queries whose optimal performance is critical to your system:

1. Use `EXPORT_CATALOG` with the argument `DIRECTED_QUERIES` to export from the database catalog all current directed queries and their current activation status:

```
=> SELECT EXPORT_CATALOG('../..../export_directedqueries', 'DIRECTED_QUERIES');
EXPORT_CATALOG
-----
Catalog data exported successfully
```

2. `EXPORT_CATALOG` creates a script to recreate the directed queries, as in the following example:

```
SAVE QUERY SELECT employee_dimension.employee_first_name, employee_dimension.employee_last_name
FROM public.employee_dimension WHERE ((employee_dimension.employee_city = 'Boston'::varchar(6))
AND (employee_dimension.job_title = 'Cashier'::varchar(7)));
CREATE DIRECTED QUERY CUSTOM findBostonCashiers_OPT COMMENT 'Optimizer-generated directed query'
OPTVER 'Vertica Analytic Database v7.2.3-20160425' PSDATE '2016-04-25 08:17:26.913339' SELECT
/*+ verbatim */ employee_dimension.employee_first_name AS employee_first_name, employee_
dimension.employee_last_name AS employee_last_name
FROM public.employee_dimension AS employee_dimension/*+projs('public.employee_dimension')*/
WHERE (employee_dimension.employee_city = 'Boston'::varchar(6)) AND (employee_dimension.job_
title = 'Cashier'::varchar(7));
DEACTIVATE DIRECTED QUERY findBostonCashiers_OPT;

SAVE QUERY SELECT employee_dimension.employee_first_name, employee_dimension.employee_last_name
FROM public.employee_dimension WHERE ((employee_dimension.employee_city = 'Boston'::varchar(6))
AND (employee_dimension.job_title = 'Cashier'::varchar(7)));
CREATE DIRECTED QUERY CUSTOM findBostonCashiers_CUSTOM COMMENT 'Custom directed query' OPTVER
'Vertica Analytic Database v7.2.3-20160425' PSDATE '2016-04-25 09:15:11.464417' SELECT employee_
dimension.employee_first_name, employee_dimension.employee_last_name FROM public.employee_
dimension/*+Projs('public.Emp_Dimension_Unseg')*/ WHERE ((employee_dimension.employee_city =
'Boston'::varchar(6)) AND (employee_dimension.job_title = 'Cashier'::varchar(7)));
ACTIVATE DIRECTED QUERY findBostonCashiers_CUSTOM;
```

Note: The script that `EXPORT_CATALOG` creates specifies to recreate all directed queries with `CREATE DIRECTED QUERY CUSTOM`, regardless of how they were created originally.

3. After the upgrade is complete, remove each directed query from the database catalog with **DROP DIRECTED QUERY**. Alternatively, edit the export script and insert a **DROP DIRECTED QUERY** statement before each **CREATE DIRECTED QUERY** statement. For example, you might modify the script generated earlier with the changes shown in bold:

```
SAVE QUERY SELECT employee_dimension.employee_first_name, ...
DROP DIRECTED QUERY findBostonCashiers_OPT
CREATE DIRECTED QUERY CUSTOM findBostonCashiers_OPT COMMENT 'Optimizer-generated ...
DEACTIVATE DIRECTED QUERY findBostonCashiers_OPT;

SAVE QUERY SELECT employee_dimension.employee_first_name, ...
DROP DIRECTED QUERY findBostonCashiers_CUSTOM
CREATE DIRECTED QUERY CUSTOM findBostonCashiers_CUSTOM COMMENT 'Custom directed query'...
ACTIVATE DIRECTED QUERY findBostonCashiers_CUSTOM;
```

4. When you run this script, Vertica recreates the directed queries and restores their activation status:

```
=> \i /home/dbadmin/export_directedqueries
SAVE QUERY
DROP DIRECTED QUERY
CREATE DIRECTED QUERY
DEACTIVATE DIRECTED QUERY
SAVE QUERY
DROP DIRECTED QUERY
CREATE DIRECTED QUERY
DEACTIVATE DIRECTED QUERY
```

Dropping Directed Queries

DROP DIRECTED QUERY removes the specified directed query from the database catalog. If the directed query is active, Vertica deactivates it before removal.

For example:

```
=> DROP DIRECTED QUERY findBostonCashiers_CUSTOM;
DROP DIRECTED QUERY
```

Batch Query Plan Export

Before upgrading to a new Vertica version, you might wish to use directed queries to save query plans for possible reuse in the new database. You cannot predict which query plans are likely candidates for reuse, so you probably want to save query plans for many, or all, database queries. However, you run hundreds of queries each day. Saving query plans for each one to

the database catalog through repetitive calls to [CREATE DIRECTED QUERY](#) is impractical. Moreover, doing so can significantly increase catalog size and possibly impact performance.

In this case, you can bypass the database catalog and batch export query plans as directed queries to an external SQL file. By offloading query plan storage, you can save any number of query plans from the current database without impacting catalog size and performance. After the upgrade, you can decide which query plans you wish to retain in the new database, and selectively import the corresponding directed queries.

Vertica provides a set of meta-functions that support this approach:

- [EXPORT_DIRECTED_QUERIES](#) generates query plans from a set of input queries, and writes SQL for creating directed queries that encapsulate those plans.
- [IMPORT_DIRECTED_QUERIES](#) imports to the database catalog directed queries from a SQL file that was generated by [EXPORT_DIRECTED_QUERIES](#).

Exporting Directed Queries

You can batch export any number of query plans as directed queries to an external SQL file, as follows:

1. Create a SQL file that contains the input queries whose query plans you wish to save. See [Output File](#) below.
2. Call the meta-function [EXPORT_DIRECTED_QUERIES](#) on that SQL file. The meta-function takes two arguments:
 - The input queries file.
 - The name of an external file. [EXPORT_DIRECTED_QUERIES](#) writes SQL for creating directed queries to this file. If you supply an empty string, Vertica writes the SQL to standard output. For details, see [Output File](#) below.

For example, the following [EXPORT_DIRECTED_QUERIES](#) statement specifies input file `inputQueries` and output file `outputQueries`:

```
=> SELECT EXPORT_DIRECTED_QUERIES('/home/dbadmin/inputQueries', '/home/dbadmin/outputQueries');
          EXPORT_DIRECTED_QUERIES
-----
 1 queries successfully exported.
Queries exported to /home/dbadmin/outputQueries.

(1 row)
```

Input File

The input file that you supply to `EXPORT_DIRECTED_QUERIES` contains one or more input queries. For each input query, you can optionally specify two fields that are used in the generated directed query:

- `DirQueryName` provides the directed query's unique identifier, a string that conforms to conventions described in [Identifiers](#).
- `DirQueryComment` specifies a quote-delimited string, up to 128 characters.

You format each input query as follows:

```
--DirQueryName=query-name  
--DirQueryComment='comment'  
input-query
```

For example, a file can specify one input query as follows:

```
--DirQueryName=FindEmployeesBoston  
--DirQueryComment='This query finds all Boston employees, ordered by position'  
SELECT employee_dimension.employee_first_name, employee_dimension.employee_last_name, employee_  
dimension.job_title FROM public.employee_dimension WHERE (employee_dimension.employee_city =  
'Boston'::varchar(6)) ORDER BY employee_dimension.job_title;
```

Output File

`EXPORT_DIRECTED_QUERIES` generates SQL for creating directed queries, and writes the SQL to the specified file or to standard output. In both cases, output conforms to the following format:

```
/* Query: directed-query-name */  
/* Comment: directed-query-comment */  
SAVE QUERY input-query;  
CREATE DIRECTED QUERY CUSTOM 'directed-query-name'  
COMMENT 'directed-query-comment'  
OPTVER 'vertica-release-num'  
PSDATE 'timestamp'  
annotated-query
```

For example, given the previous input, Vertica writes the following output to `/home/dbadmin/outputQueries`:

```
/* Query: FindEmployeesBoston */  
/* Comment: This query finds all Boston employees, ordered by position */  
SAVE QUERY SELECT employee_dimension.employee_first_name, employee_dimension.employee_last_name,  
employee_dimension.job_title FROM public.employee_dimension WHERE (employee_dimension.employee_city =
```

```
'Boston'::varchar(6)) ORDER BY employee_dimension.job_title;
CREATE DIRECTED QUERY CUSTOM 'FindEmployeesBoston'
COMMENT 'This query finds all Boston employees, ordered by position'
OPTVER 'Vertica Analytic Database v8.0.1-20161013'
PSDATE '2016-10-13 08:59:58.054505'
SELECT /*+verbatim*/employee_dimension.employee_first_name AS employee_first_name, employee_
dimension.employee_last_name AS employee_last_name, employee_dimension.job_title AS job_title
FROM public.employee_dimension AS employee_dimension/*+projs('public.employee_dimension')*/
WHERE (employee_dimension.employee_city = 'Boston'::varchar(6))
ORDER BY 3 ASC;
```

If a given input query omits `DirQueryName` and `DirQueryComment` fields, `EXPORT_DIRECTED_QUERIES` automatically generates the following output:

- `/* Query: Autaname:timestamp.n */`, where `n` is a zero-based integer index that ensures uniqueness among auto-generated names with the same timestamp.
- `/* Comment: Optimizer-generated directed query */`

For example, the following input file contains one `SELECT` statement, and omits the `DirQueryName` and `DirQueryComment` fields:

```
SELECT employee_dimension.employee_first_name, employee_dimension.employee_last_name
FROM public.employee_dimension WHERE (employee_dimension.employee_city = 'Boston'::varchar(6))
ORDER BY employee_dimension.job_title
```

Given this file, `EXPORT_DIRECTED_QUERIES` generates the following output :

```
/* Query: Autaname:2016-10-13 09:44:33.527548.0 */
/* Comment: Optimizer-generated directed query */
SAVE QUERY SELECT employee_dimension.employee_first_name, employee_dimension.employee_last_name,
employee_dimension.job_title FROM public.employee_dimension WHERE (employee_dimension.employee_city =
'Boston'::varchar(6)) ORDER BY employee_dimension.job_title;
CREATE DIRECTED QUERY CUSTOM 'Autaname:2016-10-13 09:44:33.527548.0'
COMMENT 'Optimizer-generated directed query'
...
```

Error File

If any errors or warnings occur during `EXPORT_DIRECTED_QUERIES` execution, it returns with a message like this one:

```
1 queries successfully exported.
1 warning message was generated.
Queries exported to /home/dbadmin/outputQueries.
See error report, /home/dbadmin/outputQueries.err for details.
```

`EXPORT_DIRECTED_QUERIES` writes all errors and warnings to a file that it creates on the same path as the output file, and uses the output file's base name.

In the previous example, the output filename is `/home/dbadmin/outputQueries`, so `EXPORT_DIRECTED_QUERIES` writes errors to `/home/dbadmin/outputQueries.err`.

The error file can capture a number of errors, such as all instances where `EXPORT_DIRECTED_QUERIES` was unable to create a directed query. In the following example, the error file contains a warning that no name field was supplied for the specified input query, and records the name that was auto-generated for it:

```
-----  
WARNING: Name field not supplied. Using auto-generated name: 'Autoname:2016-10-13 09:44:33.527548.0'  
Input Query: SELECT employee_dimension.employee_first_name, employee_dimension.employee_last_name,  
employee_dimension.job_title FROM public.employee_dimension WHERE (employee_dimension.employee_city =  
'Boston'::varchar(6)) ORDER BY employee_dimension.job_title;  
END WARNING
```

Importing Directed Queries

After you determine which exported query plans you wish to use in the current database, you import them with [IMPORT_DIRECTED_QUERIES](#). You supply this function with the name of the export file that you created with `EXPORT_DIRECTED_QUERIES`, and the names of directed queries you wish to import. For example:

```
=> SELECT IMPORT_DIRECTED_QUERIES('/home/dbadmin/outputQueries', 'FindEmployeesBoston');  
IMPORT_DIRECTED_QUERIES  
-----  
1 directed queries successfully imported.  
To activate a query named 'my_query1':  
=>ACTIVATE DIRECTED QUERY 'my_query1';  
  
(1 row)
```

After importing the desired directed queries, you must activate them with [ACTIVATE DIRECTED QUERY](#) before you can use them to create query plans.

Half Join and Cross Join Semantics

The Vertica optimizer uses several keywords in directed queries to recreate cross join and half join subqueries. It also supports an additional set of keywords to express complex cross joins and half joins. You can also use these keywords in queries that you execute directly in `vsq`.

Caution: These keywords do not conform with standard SQL; they are intended for use only by the Vertica optimizer.

For details, see the following topics:

- [Half-Join Subquery Semantics](#)
- [Complex Join Semantics](#)

Half-Join Subquery Semantics

The Vertica optimizer uses several keywords in directed queries to recreate half-join subqueries with certain search operators, such as [ANY](#) or [NOT IN](#):

- [SEMI JOIN](#)
- [NULLAWARE ANTI JOIN](#)
- [SEMIALL JOIN](#)
- [ANTI JOIN](#)

SEMI JOIN

Recreates a query that contains a subquery preceded by an [IN](#), [EXIST](#), or [ANY](#) operator and executes a semi-join.

Input query

```
SELECT product_description FROM product_dimension
WHERE product_dimension.product_key IN (SELECT qty_in_stock from inventory_fact);
```

Query plan

```
QUERY PLAN DESCRIPTION:
-----

explain SELECT product_description FROM product_dimension WHERE product_dimension.product_key IN
(SELECT qty_in_stock from inventory_fact);

Access Path:
+-JOIN HASH [Semi] [Cost: 1K, Rows: 30K] (PATH ID: 1) Outer (FILTER) Inner (RESEGMENT)
|   Join Cond: (product_dimension.product_key = VAL(2))
|   Materialize at Output: product_dimension.product_description
|   Execute on: All Nodes
|   +-- Outer -> STORAGE ACCESS for product_dimension [Cost: 152, Rows: 60K] (PATH ID: 2)
|   |   Projection: public.product_dimension
|   |   Materialize: product_dimension.product_key
|   |   Execute on: All Nodes
|   |   Runtime Filter: (SIP1(HashJoin): product_dimension.product_key)
|   +-- Inner -> SELECT [Cost: 248, Rows: 300K] (PATH ID: 3)
|   |   Execute on: All Nodes
|   +----> STORAGE ACCESS for inventory_fact [Cost: 248, Rows: 300K] (PATH ID: 4)
```

```
| | | Projection: public.inventory_fact_b0  
| | | Materialize: inventory_fact.qty_in_stock  
| | | Execute on: All Nodes
```

Optimizer-generated annotated query

```
SELECT /*+ syntactic_join */ product_dimension.product_description AS product_description  
FROM (public.product_dimension AS product_dimension/*+projs('public.product_dimension')*/  
SEMI JOIN /*+Distrib(F,R),JType(H)*/ (SELECT inventory_fact.qty_in_stock AS qty_in_stock  
FROM public.inventory_fact AS inventory_fact/*+projs('public.inventory_fact')*/) AS subQ_1  
ON (product_dimension.product_key = subQ_1.qty_in_stock))
```

NULLAWARE ANTI JOIN

Recreates a query that contains a subquery preceded by a **NOT IN** or **!=ALL** operator, and executes a null-aware anti-join.

Input query

```
SELECT product_description FROM product_dimension  
WHERE product_dimension.product_key NOT IN (SELECT qty_in_stock from inventory_fact);
```

Query plan

```
QUERY PLAN DESCRIPTION:  
-----  
  
EXPLAIN SELECT product_description FROM product_dimension WHERE product_dimension.product_key not IN  
(SELECT qty_in_stock from inventory_fact);  
  
Access Path:  
+-JOIN HASH [Anti][NotInAnti] [Cost: 7K, Rows: 30K] (PATH ID: 1) Inner (BROADCAST)  
| Join Cond: (product_dimension.product_key = VAL(2))  
| Materialize at Output: product_dimension.product_description  
| Execute on: Query Initiator  
| +-- Outer -> STORAGE ACCESS for product_dimension [Cost: 152, Rows: 60K] (PATH ID: 2)  
| | Projection: public.product_dimension_DBD_2_rep_VMartDesign  
| | Materialize: product_dimension.product_key  
| | Execute on: Query Initiator  
| +-- Inner -> SELECT [Cost: 248, Rows: 300K] (PATH ID: 3)  
| | Execute on: All Nodes  
| | +---> STORAGE ACCESS for inventory_fact [Cost: 248, Rows: 300K] (PATH ID: 4)  
| | | Projection: public.inventory_fact_DBD_9_seg_VMartDesign_b0  
| | | Materialize: inventory_fact.qty_in_stock  
| | | Execute on: All Nodes
```

Optimizer-generated annotated query

```
SELECT /*+ syntactic_join */ product_dimension.product_description AS product_description
FROM (public.product_dimension AS product_dimension/*+projs('public.product_dimension')*/
NULLAWARE ANTI JOIN /*+Distrib(L,B),JType(H)*/ (SELECT inventory_fact.qty_in_stock AS qty_in_stock
FROM public.inventory_fact AS inventory_fact/*+projs('public.inventory_fact')*/) AS subQ_1
ON (product_dimension.product_key = subQ_1.qty_in_stock))
```

SEMIALL JOIN

Recreates a query that contains a subquery preceded by an [ALL](#) operator, and executes a semi-all join.

Input query

```
SELECT product_key, product_description FROM product_dimension
WHERE product_dimension.product_key > ALL (SELECT product_key from inventory_fact);
```

Query plan

```
QUERY PLAN DESCRIPTION:
-----

explain SELECT product_key, product_description FROM product_dimension WHERE product_
dimension.product_key > ALL (SELECT product_key from inventory_fact);

Access Path:
+-JOIN HASH [Semi][All] [Cost: 7M, Rows: 30K] (PATH ID: 1) Outer (FILTER) Inner (BROADCAST)
|  Join Filter: (product_dimension.product_key > VAL(2))
|  Materialize at Output: product_dimension.product_description
|  Execute on: All Nodes
|  +- Outer -> STORAGE ACCESS for product_dimension [Cost: 152, Rows: 60K] (PATH ID: 2)
|  |  Projection: public.product_dimension
|  |  Materialize: product_dimension.product_key

|  +- Inner -> SELECT [Cost: 248, Rows: 300K] (PATH ID: 3)
|  |  Execute on: All Nodes
|  |  +---> STORAGE ACCESS for inventory_fact [Cost: 248, Rows: 300K] (PATH ID: 4)
|  |  |  Projection: public.inventory_fact_b0
|  |  |  Materialize: inventory_fact.product_key
|  |  |  Execute on: All Nodes
```

Optimizer-generated annotated query

```
SELECT /*+ syntactic_join */ product_dimension.product_key AS product_key, product_dimension.product_
description AS product_description
FROM (public.product_dimension AS product_dimension/*+projs('public.product_dimension')*/
SEMIALL JOIN /*+Distrib(F,B),JType(H)*/ (SELECT inventory_fact.product_key AS product_key FROM
public.inventory_fact AS inventory_fact/*+projs('public.inventory_fact')*/) AS subQ_1
ON (product_dimension.product_key > subQ_1.product_key))
```

ANTI JOIN

Recreates a query that contains a subquery preceded by a **NOT EXISTS** operator, and executes an anti-join.

Input query

```
SELECT product_key, product_description FROM product_dimension
WHERE NOT EXISTS (SELECT inventory_fact.product_key FROM inventory_fact
WHERE inventory_fact.product_key=product_dimension.product_key);
```

Query plan

QUERY PLAN DESCRIPTION:

```
-----

explain SELECT product_key, product_description FROM product_dimension WHERE NOT EXISTS (SELECT
inventory_fact.product_
key FROM inventory_fact WHERE inventory_fact.product_key=product_dimension.product_key);
```

Access Path:

```
+--JOIN HASH [Anti] [Cost: 703, Rows: 30K] (PATH ID: 1) Outer (FILTER)
|   Join Cond: (VAL(1) = product_dimension.product_key)
|   Materialize at Output: product_dimension.product_description
|   Execute on: All Nodes
| +-- Outer -> STORAGE ACCESS for product_dimension [Cost: 152, Rows: 60K] (PATH ID: 2)
| |   Projection: public.product_dimension_DBD_2_rep_VMartDesign
| |   Materialize: product_dimension.product_key
| |   Execute on: All Nodes
| +-- Inner -> SELECT [Cost: 248, Rows: 300K] (PATH ID: 3)
| |   Execute on: All Nodes
| | +----> STORAGE ACCESS for inventory_fact [Cost: 248, Rows: 300K] (PATH ID: 4)
| | |   Projection: public.inventory_fact_DBD_9_seg_VMartDesign_b0
| | |   Materialize: inventory_fact.product_key
| | |   Execute on: All Nodes
```

Optimizer-generated annotated query

```
SELECT /*+ syntactic_join */ product_dimension.product_key AS product_key, product_dimension.product_
description AS product_description
FROM (public.product_dimension AS product_dimension/*+projs('public.product_dimension')*/
ANTI JOIN /*+Distrib(F,L),JType(H)*/ (SELECT inventory_fact.product_key AS "inventory_fact.product_
key"
FROM public.inventory_fact AS inventory_fact/*+projs('public.inventory_fact')*/) AS subQ_1
ON (subQ_1."inventory_fact.product_key" = product_dimension.product_key))
```

Complex Join Semantics

The Vertica optimizer uses a set of keywords to express **complex cross joins** and **half joins**. All complex joins are indicated by the keyword **COMPLEX**, which is inserted before the keyword

JOIN—for example, `CROSS COMPLEX JOIN`. Semantics for complex half joins have an additional requirement, which is detailed [below](#).

Complex Cross Join

Vertica uses the keyword phrase `CROSS COMPLEX JOIN` to describe all complex cross joins. For example:

Input query

```
SELECT
  (SELECT max(sales_quantity) FROM store.store_sales_fact) *
  (SELECT max(sales_quantity) FROM online_sales.online_sales_fact);
```

Query plan

```
QUERY PLAN DESCRIPTION:
-----

EXPLAIN SELECT
  (SELECT max(sales_quantity) FROM store.store_sales_fact) *
  (SELECT max(sales_quantity) FROM online_sales.online_sales_fact);

Access Path:
+-JOIN (CROSS JOIN) [Cost: 4K, Rows: 1 (NO STATISTICS)] (PATH ID: 1)
|   Execute on: Query Initiator
| +- Outer -> JOIN (CROSS JOIN) [Cost: 2K, Rows: 1 (NO STATISTICS)] (PATH ID: 2)
| |   Execute on: Query Initiator
| | +- Outer -> STORAGE ACCESS for dual [Cost: 10, Rows: 1] (PATH ID: 3)
| | |   Projection: v_catalog.dual_p
| | |   Materialize: dual.dummy
| | |   Execute on: Query Initiator
| | +- Inner -> SELECT [Cost: 2K, Rows: 1 (NO STATISTICS)] (PATH ID: 4)
| | |   Execute on: Query Initiator
| | | +-> GROUPBY NOTHING [Cost: 2K, Rows: 1 (NO STATISTICS)] (PATH ID: 5)
| | | |   Aggregates: max(store_sales_fact.sales_quantity)
| | | |   Execute on: All Nodes
| | | +-> STORAGE ACCESS for store_sales_fact [Cost: 1K, Rows: 5M (NO STATISTICS)] (PATH ID: 6)
| | | |   Projection: store.store_sales_fact_super
| | | |   Materialize: store_sales_fact.sales_quantity
| | | |   Execute on: All Nodes
| +- Inner -> SELECT [Cost: 2K, Rows: 1 (NO STATISTICS)] (PATH ID: 7)
| |   Execute on: Query Initiator
| | +-> GROUPBY NOTHING [Cost: 2K, Rows: 1 (NO STATISTICS)] (PATH ID: 8)
| | |   Aggregates: max(online_sales_fact.sales_quantity)
| | |   Execute on: All Nodes
| | +-> STORAGE ACCESS for online_sales_fact [Cost: 1K, Rows: 5M (NO STATISTICS)] (PATH ID: 9)
| | |   Projection: online_sales.online_sales_fact_super
| | |   Materialize: online_sales_fact.sales_quantity
| | |   Execute on: All Nodes
```

Optimizer-generated annotated query

The following annotated query returns the same results as the input query shown earlier. As with all optimizer-generated annotated queries, you can execute this query directly in vsql, either as written or with modifications:

```
SELECT /*+syntactic_join,verbatim*/ (subQ_1.max * subQ_2.max) AS "?column?"
FROM ((v_catalog.dual AS dual CROSS COMPLEX JOIN /*+Distrib(L,L),JType(H)*/
(SELECT max(store_sales_fact.sales_quantity) AS max
FROM store_sales_fact AS store_sales_fact/*+projs('store_sales_fact')*/) AS subQ_1 )
CROSS COMPLEX JOIN /*+Distrib(L,L),JType(H)*/ (SELECT max(online_sales_fact.sales_quantity) AS max
FROM online_sales_fact AS online_sales_fact/*+projs('online_sales_fact')*/)
AS subQ_2 )
```

Complex Half Join

Complex half joins are expressed by one of the following keywords:

- SEMI COMPLEX JOIN
- NULLAWARE ANTI COMPLEX JOIN
- SEMIALL COMPLEX JOIN
- ANTI COMPLEX JOIN

An additional requirement applies to all complex half joins: each subquery's SELECT list ends with a dummy column (labeled as false) that invokes the Vertica meta-function `complex_join_marker()`. As the subquery processes each row, `complex_join_marker()` returns true or false to indicate the row's inclusion or exclusion from the result set. The result set returns with this flag to the outer query, which can use the flag from this and other subqueries to filter its own result set.

For example, the query optimizer rewrites the following input query as a NULLAWARE ANTI COMPLEX JOIN. The join returns all rows from the subquery with their `complex_join_marker()` flag set to the appropriate Boolean value.

Input query

```
SELECT product_dimension.product_description FROM public.product_dimension
WHERE (NOT (product_dimension.product_key NOT IN (SELECT inventory_fact.qty_in_stock FROM
public.inventory_fact)));
```

Query plan

QUERY PLAN DESCRIPTION:

```
EXPLAIN SELECT product_dimension.product_description FROM public.product_dimension
WHERE (NOT (product_dimension.product_key NOT IN (SELECT inventory_fact.qty_in_stock FROM
```

```
public.inventory_fact));  
  
Access Path:  
+-JOIN HASH [Anti][NotInAnti] [Cost: 3K, Rows: 30K] (PATH ID: 1) Inner (BROADCAST)  
| Join Cond: (product_dimension.product_key = VAL(2))  
| Materialize at Output: product_dimension.product_description  
| Filter: (NOT VAL(2))  
| Execute on: All Nodes  
| +- Outer -> STORAGE ACCESS for product_dimension [Cost: 56, Rows: 60K] (PATH ID: 2)  
| | Projection: public.product_dimension_super  
| | Materialize: product_dimension.product_key  
| | Execute on: All Nodes  
| +- Inner -> SELECT [Cost: 248, Rows: 300K] (PATH ID: 3)  
| | Execute on: All Nodes  
| | +---> STORAGE ACCESS for inventory_fact [Cost: 248, Rows: 300K] (PATH ID: 4)  
| | | Projection: public.inventory_fact_super  
| | | Materialize: inventory_fact.qty_in_stock  
| | | Execute on: All Nodes
```

Optimizer-generated annotated query

The following annotated query returns the same results as the input query shown earlier. As with all optimizer-generated annotated queries, you can execute this query directly in vsql, either as written or with modifications. For example, you can control the outer query's output by modifying how its predicate evaluates the flag `subQ_1."false"`.

```
SELECT /*+syntactic_join,verbatim*/ product_dimension.product_description AS product_description  
FROM (public.product_dimension AS product_dimension/*+projs('public.product_dimension')*/  
NULLAWARE ANTI COMPLEX JOIN /*+Distrib(L,B),JType(H)*/  
  (SELECT inventory_fact.qty_in_stock AS qty_in_stock, complex_join_marker() AS "false"  
   FROM public.inventory_fact AS inventory_fact/*+projs('public.inventory_fact')*/) AS subQ_1  
ON (product_dimension.product_key = subQ_1.qty_in_stock)) WHERE (NOT subQ_1."false")
```

Restrictions

Directed queries support a wide range of queries; however, a number of exceptions apply. Vertica handles all exceptions through optimizer-generated warnings. The sections below divide these restrictions into several categories.

Tables and Projections

The following restrictions apply:

- Optimizer-generated directed queries do not support queries that reference system tables or Data Collector tables. One exception applies: explicit and implicit references to [V_CATALOG.DUAL](#).

- Optimizer-generated directed queries do not support queries that include tables with access policies.
- Directed queries do not support tables without projections.

Functions

Queries are not supported that include the following functions:

- [Vertica meta-functions](#)
- [Pattern-matching functions](#)
- `GROUPING_ID` with no arguments

Operators and Clauses

Queries are not supported that include the following:

- WITH clauses [when materialization is enabled](#).
- Queries that include date/time literals that reference the current time, such as NOW or YESTERDAY

Data Types

Queries are not supported that include [GEOMETRY data types](#).

Using Text Search

Text Search allows you to quickly search the contents of a single CHAR, VARCHAR, LONG VARCHAR, VARBINARY, or LONG VARBINARY field within a table to locate a specific keyword.

You can use this feature on columns that are queried repeatedly regarding their contents. After you create the text index, DML operations become slightly slower on the source table. This performance change results from syncing the text index and source table. Any time an operation is performed on the source table, the text index updates in the background. Regular queries on the source table are not affected.

The text index contains all of the words from the source table's text field, as well as any other additional columns you included during index creation. Additional columns are not indexed, their values are just passed through to the text index. The text index is like any other table in the Vertica Analytics Platform, except it is linked to the source table internally.

You first create a text index on the table you plan to search. Then, after you have indexed your table, you can run a query against the text index for a specific keyword. This query returns a doc_id for each instance of the keyword. After querying the text index, joining the text index back to the source table should give a significant performance improvement over directly querying the source table about the contents of its text field.

Important: Do not alter the contents or definitions of the text index. If the contents or definitions of the text index are altered, then the results do not appropriately match the source table.

Creating a Text Index

In the following example, you perform a text search using a source table called t_log. This source table has two columns:

- One column containing the table's primary key
- Another column containing log file information

You must associate a projection with the source table. Use a projection that is sorted by the primary key and either segmented by hash(id) or unsegmented. You can define this projection on the source table, along with any other existing projections.

Create a text index on the table for which you want to perform a text search.

```
=> CREATE TEXT INDEX text_index ON t_log (id, text);
```

The text index contains two columns:

- `doc_id` uses the unique identifier from the source table.
- `token` is populated with text strings from the designated column from the source table. The word column results from tokenizing and stemming the words found in the text column.

If your table is partitioned then your text index also contains a third column named *partition*.

```
=> SELECT * FROM text_index;
      token      | doc_id | partition
-----+-----+-----
<info>          |      6 |      2014
<warning>      |      2 |      2014
<warning>      |      3 |      2014
<warning>      |      4 |      2014
<warning>      |      5 |      2014
database        |      6 |      2014
execute:        |      6 |      2014
object          |      4 |      2014
object          |      5 |      2014
[catalog]       |      4 |      2014
[catalog]       |      5 |      2014
```

You create a text index on a source table only once. In the future, you do not have to re-create the text index each time the source table is updated or changed.

Your text index stays synchronized to the contents of the source table through any operation that is run on the source table. These operations include, but are not limited to:

- COPY
- INSERT
- UPDATE
- DELETE
- DROP PARTITION
- MOVE_PARTITION_TO_TABLE
When you move or swap partitions in a source table that is indexed, verify that the destination table already exists and is indexed in the same way.

Creating a Text Index on a Flex Table

In the following example, you create a text index on a flex table. The example assumes that you have created a flex table called `mountains`. See [Getting Started](#) in Using Flex Tables to create the flex table used in this example.

Before you can create a text index on your flex table, add a primary key constraint to the flex table.

```
=> ALTER TABLE mountains ADD PRIMARY KEY (__identity__);
```

Create a text index on the table for which you want to perform a text search. Tokenize the `__raw__` column with the `FlexTokenizer` and specify the data type as `LONG VARBINARY`. It is important to use the `FlexTokenizer` when creating text indices on flex tables because the data type of the `__raw__` column differs from the default `StringTokenizer`.

```
=> CREATE TEXT INDEX flex_text_index ON mountains(__identity__, __raw__) TOKENIZER  
public.FlexTokenizer(long varbinary);
```

The text index contains two columns:

- `doc_id` uses the unique identifier from the source table.
- `token` is populated with text strings from the designated column from the source table. The word column results from tokenizing and stemming the words found in the text column.

If your table is partitioned then your text index also contains a third column named *partition*.

```
=> SELECT * FROM flex_text_index;  
  token | doc_id  
-----+-----  
  50.6  |      5  
  Mt    |      5  
  Washington |      5  
  mountain |      5  
  12.2  |      3  
  15.4  |      2  
  17000 |      3  
  29029 |      2  
  Denali |      3  
  Helen |      2  
  Mt    |      2  
  St    |      2  
  mountain |      3  
  volcano |      2  
  29029 |      1  
  34.1  |      1  
  Everest |      1
```

```
mountain | 1
14000   | 4
Kilimanjaro | 4
mountain | 4
(21 rows)
```

You create a text index on a source table only once. In the future, you do not have to re-create the text index each time the source table is updated or changed.

Your text index stays synchronized to the contents of the source table through any operation that is run on the source table. These operations include, but are not limited to:

- COPY
- INSERT
- UPDATE
- DELETE
- DROP PARTITION

- MOVE_PARTITION_TO_TABLE

When you move or swap partitions in a source table that is indexed, verify that the destination table already exists and is indexed in the same way.

Searching a Text Index

After you create a text index, write a query to run against the index to search for a specific keyword.

In the following example, you use a WHERE clause to search for the keyword <WARNING> in the text index. The WHERE clause should use the stemmer you used to create the text index. When you use the STEMMER keyword, it stems the keyword to match the keywords in your text index. If you did not use the STEMMER keyword, then the default stemmer is `v_txtindex.StemmerCaseInsensitive`. If you used STEMMER NONE, then you can omit STEMMER keyword from the WHERE clause.

```
=> SELECT * FROM text_index WHERE token = v_txtindex.StemmerCaseInsensitive('<WARNING>');
 token | doc_id
-----+-----
<warning> | 2
<warning> | 3
<warning> | 4
<warning> | 5
```

(4 rows)

Next, write a query to display the full contents of the source table that match the keyword you searched for in the text index.

```
=> SELECT * FROM t_log WHERE id IN (SELECT doc_id FROM text_index WHERE token = v_
txtindex.StemmerCaseInsensitive('<WARNING>'));
id | date | text
-----+-----+-----
-----
4 | 2014-06-04 | 11:00:49.568 unknown:0x7f9207607700 [Catalog] <WARNING> validateDependencies:
Object 45035968
5 | 2014-06-04 | 11:00:49.568 unknown:0x7f9207607700 [Catalog] <WARNING> validateDependencies:
Object 45030
2 | 2013-06-04 | 11:00:49.568 unknown:0x7f9207607700 [Catalog] <WARNING> validateDependencies:
Object 4503
3 | 2013-06-04 | 11:00:49.568 unknown:0x7f9207607700 [Catalog] <WARNING> validateDependencies:
Object 45066
(4 rows)
```

Use the `doc_id` to find the exact location of the keyword in the source table. The `doc_id` matches the unique identifier from the source table. This matching allows you to quickly find the instance of the keyword in your table.

Performing a Case-Sensitive and Case-Insensitive Text Search Query

Your text index is optimized to match all instances of words depending upon your stemmer. By default, the case insensitive stemmer is applied to all text indices that do not specify a stemmer. Therefore, if the queries you plan to write against your text index are case sensitive, then Micro Focus recommends you use a case sensitive stemmer to build your text index.

The following examples show queries that match case-sensitive and case-insensitive words that you can use when performing a text search.

This query finds case-insensitive records in a case insensitive text index:

```
=> SELECT * FROM t_log WHERE id IN (SELECT doc_id FROM text_index WHERE token = v_
txtindex.StemmerCaseInsensitive('warning'));
```

This query finds case-sensitive records in a case sensitive text index:

```
=> SELECT * FROM t_log_case_sensitive WHERE id IN (SELECT doc_id FROM text_index WHERE token = v_
txtindex.StemmerCaseSensitive('Warning'));
```

Including and Excluding Keywords in a Text Search Query

Your text index also allows you to perform more detailed queries to find multiple keywords or omit results with other keywords. The following example shows a more detailed query that you can use when performing a text search.

In this example, `t_log` is the source table, and `text_index` is the text index. The query finds records that either contain:

- Both the words '<WARNING>' and 'validate'
- Only the word '[Log]' and does not contain 'validateDependencies'

```
SELECT * FROM t_log where (  
  id IN (SELECT doc_id FROM text_index WHERE token = v_txtindex.StemmerCaseSensitive('<WARNING>'))  
  AND ( id IN (SELECT doc_id FROM text_index WHERE token = v_txtindex.StemmerCaseSensitive  
( 'validate'  
  OR id IN (SELECT doc_id FROM text_index WHERE token = v_txtindex.StemmerCaseSensitive(''  
[Log]'))  
  AND NOT (id IN (SELECT doc_id FROM text_index WHERE token = v_txtindex.StemmerCaseSensitive  
( 'validateDependencies'))));
```

This query returns the following results:

```
id | date | | text  
-----+-----+-----+-----  
-----

Dropping a Text Index

Dropping a text index removes the specified text index from the database.

You can drop a text index when:

- It is no longer queried frequently.
- An administrative task needs to be performed on the source table and requires the text index to be dropped.

Dropping the text index does not drop the source table associated with the text index. However, if you drop the source table associated with a text index, then that text index is also dropped. Vertica considers the text index a dependent object.

The following example illustrates how to drop a text index named `text_index`:

```
=> DROP TEXT INDEX text_index;  
DROP INDEX
```

Stemmers and Tokenizers

Vertica provides default stemmers and tokenizers. You can also create your own custom stemmers and tokenizers. The following topics explain the default stemmers and tokenizers, and the requirements for creating custom stemmers and tokenizers in Vertica.

- [Vertica Stemmers](#)
- [Vertica Tokenizers](#)
- [Configuring a Tokenizer](#)
- [Requirements for Custom Stemmers and Tokenizers](#)

Vertica Stemmers

Vertica *stemmers* use the Porter stemming algorithm to find words derived from the same base/root word. For example, if you perform a search on a text index for the keyword *database*, you might also want to get results containing the word *databases*.

To achieve this type of matching, Vertica stores words in their stemmed form when using any of the `v_txtindex` stemmers.

The Vertica Analytics Platform provides the following stemmers:

Name	Description
<code>v_txtindex.Stemmer(long varchar)</code>	Not sensitive to case; outputs lowercase words.

Name	Description
	Stems strings from a Vertica table. Alias of StemmerCaseInsensitive.
v_txtindex.StemmerCaseSensitive(long varchar)	Sensitive to case. Stems strings from a Vertica table.
v_txtindex.StemmerCaseInsensitive (long varchar)	Default stemmer used if no stemmer is specified when creating a text index. Not sensitive to case; outputs lowercase words. Stems strings from a Vertica table.
v_txtindex.caseInsensitiveNoStemming (long varchar)	Not sensitive to case; outputs lowercase words. Does not use the Porter Stemming algorithm.

Examples

The following examples show how to use a stemmer when creating a text index.

Create a text index using the StemmerCaseInsensitive stemmer:

```
=> CREATE TEXT INDEX idx_100 ON top_100 (id, feedback) STEMMER v_txtindex.StemmerCaseInsensitive(long varchar)
                                     TOKENIZER v_txtindex.StringTokenizer
(long varchar);
```

Create a text index using the StemmerCaseSensitive stemmer:

```
=> CREATE TEXT INDEX idx_unstruc ON unstruc_data (__identity__, __raw__) STEMMER v_
txtindex.StemmerCaseSensitive(long varchar)
                                     TOKENIZER
public.FlexTokenizer(long varbinary);
```

Create a text index without using a stemmer:

```
=> CREATE TEXT INDEX idx_logs FROM sys_logs ON (id, message) STEMMER NONE TOKENIZER v_
txtindex.StringTokenizer(long varchar);
```

Vertica Tokenizers

The Vertica Analytics Platform provides the following pre-configured tokenizers:

Name	Description
public.FlexTokenizer(long varbinary)	Splits the values in your Flex Table by white space.
v_txtindex.StringTokenizer(long varchar)	Splits the string into words by splitting on white space.
v_txtindex.AdvancedLogTokenizer	Uses the default parameters for all tokenizer parameters. For more information, see Advanced Log Tokenizer .
v_txtindex.BasicLogTokenizer	Uses the default values for all tokenizer parameters except minorseparator, which is set to an empty list. For more information, see Basic Log Tokenizer .
v_txtindex.WhitespaceLogTokenizer	Uses default values for tokenizer parameters, except for majorseparators, which uses E' \t\n\f\r'; and minorseparator, which uses an empty list. For more information, see Whitespace Log Tokenizer .

Vertica also provides the following tokenizer, which is not pre-configured:

Name	Description
v_txtindex.ICUTokenizer	Supports multiple languages. Tokenizes based on the conventions of the language you set in the locale parameter. For more information, see ICU Tokenizer.

Examples

The following examples show how you can use a pre-configured tokenizer when creating a text index.

Use the StringTokenizer to create an index from the top_100:

```
=> CREATE TEXT INDEX idx_100 FROM top_100 on (id, feedback)
      TOKENIZER v_txtindex.StringTokenizer(long varchar)
      STEMMER v_txtindex.StemmerCaseInsensitive(long varchar);
```

Use the FlexTokenizer to create an index from unstructured data:

```
=> CREATE TEXT INDEX idx_unstruc FROM unstruc_data on (__identity__, __raw__)
      TOKENIZER public.FlexTokenizer(long varbinary)
      STEMMER v_txtindex.StemmerCaseSensitive(long varchar);
```

Advanced Log Tokenizer

Returns tokens that can include minor separators. You can use this tokenizer in situations when your tokens are separated by whitespace or various punctuation. The advanced log tokenizer offers more granularity than the basic log tokenizer in defining separators through the addition of minor separators. This approach is frequently appropriate for analyzing log files.

Important: If you create a database with no tables and the k-safety has increased, you must rebalance your data using [REBALANCE_CLUSTER](#) before using a Vertica tokenizer.

Parameters

Parameter Name	Parameter Value
stopwordscaseinsensitive	' '
minorseparators	E' / :=@. - \$#% \ _ '
majorseparators	E' [] < > () { } ! ; , ' ' " * & ? + \ r \ n \ t '
minLength	'2'
maxLength	'128'
used	'True'

Examples

The following example shows how you can create a text index, from the table foo, using the Advanced Log Tokenizer without a stemmer.

```
=> CREATE TABLE foo (id INT PRIMARY KEY NOT NULL, text VARCHAR(250));
=> COPY foo FROM STDIN;
End with a backslash and a period on a line by itself.
>> 1|2014-05-10 00:00:05.700433 %ASA-6-302013: Built outbound TCP connection 9986454 for
outside:101.123.123.111/443 (101.123.123.111/443)
>> \.
=> CREATE PROJECTION foo_projection AS SELECT * FROM foo ORDER BY id
                               SEGMENTED BY HASH(id) ALL NODES KSAFE;
=> CREATE TEXT INDEX indexfoo_AdvancedLogTokenizer ON foo (id, text)
                               TOKENIZER v_txtindex.AdvancedLogTokenizer(LONG VARCHAR) STEMMER NONE;
=> SELECT * FROM indexfoo_AdvancedLogTokenizer;
      token                | doc_id
-----+-----
%ASA-6-302013:           |      1

```

Basic Log Tokenizer

Returns tokens that exclude specified minor separators. You can use this tokenizer in situations when your tokens are separated by whitespace or various punctuation. This approach is frequently appropriate for analyzing log files.

Important: If you create a database with no tables and the k-safety has increased, you must rebalance your data using [REBALANCE_CLUSTER](#) before using a Vertica tokenizer.

Parameters

Parameter Name	Parameter Value
stopwordscaseinsensitive	' '
minorseparators	' '
majorseparators	E' []<>(){} !;, '"*&?+\r\n\t'
minLength	'2'
maxLength	'128'
used	'True'

Examples

The following example shows how you can create a text index, from the table foo, using the Basic Log Tokenizer without a stemmer.

```
=> CREATE TABLE foo (id INT PRIMARY KEY NOT NULL,text VARCHAR(250));
=> COPY foo FROM STDIN;
End with a backslash and a period on a line by itself.
>> 1|2014-05-10 00:00:05.700433 %ASA-6-302013: Built outbound TCP connection 9986454 for
outside:101.123.123.111/443 (101.123.123.111/443)
>> \.
=> CREATE PROJECTION foo_projection AS SELECT * FROM foo ORDER BY id
          SEGMENTED BY HASH(id) ALL NODES KSAFE;
=> CREATE TEXT INDEX indexfoo_BasicLogTokenizer ON foo (id, text)
          TOKENIZER v_txtindex.BasicLogTokenizer(LONG VARCHAR) STEMMER NONE;
=> SELECT * FROM indexfoo_BasicLogTokenizer;
      token          | doc_id
-----+-----
%ASA-6-302013:      |      1

outside:101.123.123.111/443 |      1
(11 rows)
```

Whitespace Log Tokenizer

Returns only tokens surrounded by whitespace. You can use this tokenizer in situations where you want the tokens in your source document to be separated by whitespace characters only. This approach lets you retain the ability to set stop words and token length limits.

Important: If you create a database with no tables and the k-safety has increased, you must rebalance your data using [REBALANCE_CLUSTER](#) before using a Vertica tokenizer.

Parameters

Parameter Name	Parameter Value
stopwordscaseinsensitive	' '
minorseparators	' '

Parameter Name	Parameter Value
majorseparators	E' \t\n\f\r'
minLength	'2'
maxLength	'128'
used	'True'

Examples

The following example shows how you can create a text index, from the table foo, using the Whitespace Log Tokenizer without a stemmer.

```
=> CREATE TABLE foo (id INT PRIMARY KEY NOT NULL,text VARCHAR(250));
=> COPY foo FROM STDIN;
End with a backslash and a period on a line by itself.
>> 1|2014-05-10 00:00:05.700433 %ASA-6-302013: Built outbound TCP connection 998 6454 for
outside:101.123.123.111/443 (101.123.123.111/443)
>> \.
=> CREATE PROJECTION foo_projection AS SELECT * FROM foo ORDER BY id
                               SEGMENTED BY HASH(id) ALL NODES KSAFE;
=> CREATE TEXT INDEX indexfoo_WhitespaceLogTokenizer ON foo (id, text)
                               TOKENIZER v_txtindex.WhitespaceLogTokenizer(LONG VARCHAR) STEMMER NONE;
=> SELECT * FROM indexfoo_WhitespaceLogTokenizer;
      token          | doc_id

(12 rows)
```

ICU Tokenizer

Supports multiple languages. You can use this tokenizer to identify word boundaries in languages other than English, including Asian languages that are not separated by whitespace.

The ICU Tokenizer is not pre-configured. You configure the tokenizer by first creating a User-Defined Transform Function (UDTF). Then set the parameter, locale, to identify the language to tokenizer.

Important: If you create a database with no tables and the k-safety has increased, you must rebalance your data using [REBALANCE_CLUSTER](#) before using a Vertica tokenizer.

Parameters

Parameter Name	Parameter Value
locale	Uses the POSIX naming convention: language[_COUNTRY] Identify the language using its ISO-639 code, and the country using its ISO-3166 code. For example, the parameter value for simplified Chinese is zh_CN, and the value for Spanish is es_ES. The default value is English if you do not specify a locale.

Example

The following example steps show how you can configure the ICU Tokenizer for simplified Chinese, then create a text index from the table foo, which contains Chinese characters.

For more on how to configure tokenizers, see [Configuring a Tokenizer](#).

1. Create the tokenizer using a UDTF. The example tokenizer is named ICUChineseTokenizer.

```
VMart=> CREATE OR REPLACE TRANSFORM FUNCTION v_txtindex.ICUChineseTokenizer AS LANGUAGE 'C++'  
NAME 'ICUTokenizerFactory' LIBRARY v_txtindex.logSearchLib NOT FENCED;  
CREATE TRANSFORM FUNCTION
```

2. Get the procedure ID of the tokenizer.

```
VMart=> SELECT proc_oid from vs_procedures where procedure_name = 'ICUChineseTokenizer';  
  
   proc_oid  
-----  
  45035996280452894  
(1 row)
```

3. Set the parameter, locale, to simplified Chinese. Identify the tokenizer using its procedure ID.

```
VMart=> SELECT v_txtindex.SET_TOKENIZER_PARAMETER('locale','zh_CN' using parameters proc_  
oid='45035996280452894');  
   SET_TOKENIZER_PARAMETER  
-----  
   t
```

```
(1 row)
```

4. Lock the tokenizer.

```
VMart=> SELECT v_txtindex.SET_TOKENIZER_PARAMETER('used','true' using parameters proc_
oid='45035996273762696');
SET_TOKENIZER_PARAMETER
-----
t
(1 row)
```

5. Create an example table, foo, containing simplified Chinese text to index.

```
VMart=> CREATE TABLE foo(doc_id integer primary key not null,text varchar(250));
CREATE TABLE

VMart=> INSERT INTO foo values(1, u&'\4E2D\534E\4EBA\6C11\5171\548C\56FD');
OUTPUT
-----
1
```

6. Create an index, index_example, on the table foo. The example creates the index without a stemmer; Vertica stemmers work only on English text. Using a stemmer for English on non-English text can cause incorrect tokenization.

```
VMart=> CREATE TEXT INDEX index_example ON foo (doc_id, text) TOKENIZER v_
txtindex.ICUChineseTokenizer(long varchar) stemmer none;
CREATE INDEX
```

7. View the new index.

```
VMart=> SELECT * FROM index_example ORDER BY token,doc_id;
token | doc_id
-----+-----
中华  |      1
人民  |      1
共和国 |      1
(3 rows)
```

Configuring a Tokenizer

You configure a tokenizer by creating a User-Defined Transform Function (UDTF) using one of the two base UDTFs in the `v_txtindex.AdvTxtSearchLib` library. The library contains two base tokenizers: one for Log Words and one for Ngrams. You can configure each base function with or without positional relevance.

You can choose among several different tokenizer base configurations:

Type	Position	Without Position
Ngram	logNgramTokenizerPositionFactory	logNgramTokenizerFactory
Words	logWordITokenizerPositionFactory	logWordITokenizerFactory

Create a logWord tokenizer without positional relevance:

```
=> CREATE TRANSFORM FUNCTION v_txtindex.fooTokenizer AS LANGUAGE 'C++' NAME  
'logWordITokenizerFactory' LIBRARY v_txtindex.logSearchLib NOT FENCED;
```

Retrieve a Tokenizer's proc_oid

After you create the tokenizer, Vertica writes the name and proc_oid to the system table vs_procedures. You must retrieve the tokenizer's proc_oid to perform additional configuration.

Enter the following query, substituting your own tokenizer name:

```
=> SELECT proc_oid FROM vs_procedures WHERE procedure_name = 'fooTokenizer';
```

Set Tokenizer Parameters

Use the tokenizer's proc_oid to configure the tokenizer. See [Configuring a Tokenizer](#) for more information about getting the proc_oid of your tokenizer. The following examples show how you can configure each of the tokenizer parameters:

Configure stop words:

```
=> SELECT v_txtindex.SET_TOKENIZER_PARAMETER('stopwordscaseinsensitive', 'for,the' USING PARAMETERS  
proc_oid='45035996274128376');
```

Configure major separators:

```
=> SELECT v_txtindex.SET_TOKENIZER_PARAMETER('majorseparators', E'{}()&[]' USING PARAMETERS proc_  
oid='45035996274128376');
```

Configure minor separators:

```
=> SELECT v_txtindex.SET_TOKENIZER_PARAMETER('minorseparators', '-,$' USING PARAMETERS proc_  
oid='45035996274128376');
```

Configure minimum length:

```
=> SELECT v_txtindex.SET_TOKENIZER_PARAMETER('minlength', '1' USING PARAMETERS proc_  
oid='45035996274128376');
```

Configure maximum length:

```
=> SELECT v_txtindex.SET_TOKENIZER_PARAMETER('maxlength', '140' USING PARAMETERS proc_
oid='45035996274128376');
```

Configure ngramssize:

```
=> SELECT v_txtindex.SET_TOKENIZER_PARAMETER('ngramssize', '2' USING PARAMETERS proc_
oid='45035996274128376');
```

Lock Tokenizer Parameters

When you finish configuring the tokenizer, set the parameter, `used`, to `True`. After changing this setting, you are no longer able to alter the parameters of the tokenizer. At this point, the tokenizer is ready for you to use to create a text index.

Configure the `used` parameter:

```
=> SELECT v_txtindex.SET_TOKENIZER_PARAMETER('used', 'True' USING PARAMETERS proc_
oid='45035996274128376');
```

See Also

[SET_TOKENIZER_PARAMETER](#)

View Tokenizer Parameters

After creating a custom tokenizer, you can view the tokenizer's parameter settings in either of two ways:

- Use the `GET_TOKENIZER_PARAMETER` — [View individual tokenizer parameter settings](#).
- Use the `READ_CONFIG_FILE` — [View all tokenizer parameter settings](#).

View Individual Tokenizer Parameter Settings

If you need to see an individual parameter setting for a tokenizer, you can use `GET_TOKENIZER_PARAMETER` to see specific tokenizer parameter settings:

```
=> SELECT v_txtindex.GET_TOKENIZER_PARAMETER('majorseparators' USING PARAMETERS proc_
oid='45035996274126984');
getTokenizerParameter
-----
{ } ( ) & [ ]
```

(1 row)

For more information, see [GET_TOKENIZER_PARAMETER](#).

View All Tokenizer Parameter Settings

If you need to see all of the parameters for a tokenizer, you can use `READ_CONFIG_FILE` to see all of the parameter settings for your tokenizer:

```
=> SELECT v_txtindex.READ_CONFIG_FILE( USING PARAMETERS proc_oid='45035996274126984') OVER();
      config_key | config_value
-----+-----
majorseparators | {}()&[]
maxlength       | 140
minlength       | 1
minorseparators | -, $
stopwordscaseinsensitive | for, the
                | type | 1
                | used | true
(7 rows)
```

If the parameter, `used`, is set to `False`, then you can only view the parameters that have been applied to the tokenizer.

Note: Vertica automatically supplies the value for `Type`, unless you are using an ngram tokenizer, which allows you to set it.

For more information, see [READ_CONFIG_FILE](#).

Delete Tokenizer Config File

Use the `DELETE_TOKENIZER_CONFIG_FILE` function to delete a tokenizer configuration file. This function does not delete the User- Defined Transform Function (UDTF). It only deletes the configuration file associated with the UDTF.

Delete the tokenizer configuration file when the parameter, `used`, is set to `False`:

```
=> SELECT v_txtindex.DELETE_TOKENIZER_CONFIG_FILE(USING PARAMETERS proc_oid='45035996274127086');
```

Delete the tokenizer configuration file with the parameter, `confirm`, set to `True`. This setting forces the configuration file deletion, even if the parameter, `used`, is also set to `True`:

```
=> SELECT v_txtindex.DELETE_TOKENIZER_CONFIG_FILE(USING PARAMETERS proc_oid='45035996274126984',
confirm='true');
```

For more information, see [DELETE_TOKENIZER_CONFIG_FILE](#).

Requirements for Custom Stemmers and Tokenizers

Sometimes, you may want specific tokenization or stemming behavior that differs from what Vertica provides. In such cases, you can implement your own custom User Defined Extensions (UDx) to replace the stemmer or tokenizer. For more information about building custom UDxs see [Developing User-Defined Extensions \(UDxs\)](#).

Before implementing a custom stemmer or tokenizer in Vertica verify that the UDx extension meets these requirements.

Note: Custom tokenizers can return multi-column text indices.

Vertica Stemmer Requirements

Comply with these requirements when you create custom stemmers:

- Must be a User Defined Scalar Function (UDSF) or a SQL Function
- Can be written in C++, Java, or R
- Volatility set to stable or immutable

Supported Data Input Types:

- Varchar
- Long varchar

Supported Data Output Types:

- Varchar
- Long varchar

Vertica Tokenizer Requirements

To create custom tokenizers, follow these requirements:

- Must be a User Defined Transform Function (UDTF)
- Can be written in C++, Java, or R

- Input type must match the type of the input text

Supported Data Input Types:

- Char
- Varchar
- Long varchar
- Varbinary
- Long varbinary

Supported Data Output Types:

- Varchar
- Long varchar

Bulk-Loading Data

This section describes different methods to bulk-load data into a Vertica database using the `COPY` statement. In its simplest form, `COPY` copies data from a source to a file, as follows:

```
COPY target-table FROM data-source
```

Source data can be a data stream, or a file stored on the host or client. `COPY` supports numerous options, including:

- Incoming data format
- Metadata about the data load
- The best parser to use for different types of data
- Parallel load streams to load data
- Data transforms as `COPY` loads data
- Saving rejected data from parse errors to files or a table

Checking Data Format Before or After Loading

Vertica supports loading data files in the Unicode UTF-8 format. You can load ASCII data, which is UTF-8 compatible. Character sets like ISO 8859-1 (Latin1) are incompatible with UTF-8 and are not supported.

Before loading data from text files, you can use several Linux tools to ensure that your data is in UTF-8 format. The `file` command reports the encoding of any text files. For example:

```
$ file Date_Dimension.tbl
Date_Dimension.tbl: ASCII text
```

The `file` command could indicate ASCII TEXT even though the file contains multibyte characters.

To check for multibyte characters in an ASCII file, use the `wc` command. For example:

```
$ wc Date_Dimension.tbl
1828  5484 221822 Date_Dimension.tbl
```

If the `wc` command returns an error such as `Invalid or incomplete multibyte or wide character`, the data file is using an incompatible character set.

This example describes files that are not UTF-8 data files. Two text files have filenames starting with the string `data`. To check their format, use the `file` command as follows:

```
$ file data*
data1.txt: Little-endian UTF-16 Unicode text
data2.txt: ISO-8859 text
```

The results indicate that neither of the files is in UTF-8 format.

Converting Files Before Loading Data

To convert files before loading them into Vertica, use the `iconv` UNIX command. For example, to convert the `data2.txt` file from the previous example, use the `iconv` command as follows:

```
iconv -f ISO88599 -t utf-8 data2.txt > data2-utf8.txt
```

See the man pages for `file` and `iconv` for more information.

Checking UTF-8 Compliance After Loading Data

After loading data, use the `ISUTF8` function to verify that all of the string-based data in the table is in UTF-8 format. For example, if you loaded data into a table named `nametable` that has a `VARCHAR` column named `name`, you can use this statement to verify that all of the strings are UTF-8 encoded:

```
=> SELECT name FROM nametable WHERE ISUTF8(name) = FALSE;
```

If all of the strings are in UTF-8 format, the query should not return any rows.

Performing the Initial Database Load

To perform the initial database load, use `COPY` with its `DIRECT` parameter from `vsq`.

Tip: Vertica supports multiple schema types. If you have a star schema, load the smaller tables before you load the largest tables.

Only a superuser can use the `COPY` statement to bulk load data. Two exceptions to the superuser requirement are to:

1. Run COPY to load from a stream on the host (such as STDIN) rather than a file (see [Streaming Data Via JDBC](#)).
2. Use the COPY statement with the FROM LOCAL option.

A non-superuser can also perform a [batch load with a JDBC prepared statement](#), which invokes COPY to load data as a background task.

Extracting Data From an Existing Database

If possible, export the data in text form to a local file or attached disk. When working with large amounts of load data (> 500GB), Vertica recommends that you test the load process using smaller load files as described in [Configuration Procedure](#) to avoid compatibility or file formatting issues.

ETL products typically use ODBC or JDBC to extract data, which gives them program-level access to modify load file column values, as needed.

Database systems typically provide a variety of export methods.

Tip: To export data from an Oracle database, run a SELECT query in Oracle's SQL*Plus command line query tool using a specified column delimiter, suppressed headers, and so forth. Redirect the output to a local file.

Smaller tables generally fit into a single load file. Split any large tables into 250-500GB load files. For example, a 10 TB fact table will require 20-40 load files to maintain performance.

Checking for Delimiter Characters in Load Data

The default delimiter for the COPY statement is a vertical bar (|). Before loading your data, make sure that no CHAR(N) or VARCHAR(N) data values include the delimiter character.

To test for the existence of a specific character in a column, use a query such as this:

```
SELECT COUNT(*) FROM T WHERE X LIKE '%|%'
```

If only a few rows contain |, you can eliminate them from the load file using a WHERE clause and load them separately using a different delimiter.

Tip: For loading data from an Oracle database, use a WHERE clause to avoid problem rows in the main load file, and the negated WHERE clause with REGEX_REPLACE for problem rows.

Moving Data From an Existing Database to Vertica Nodes

To move data from an existing database to Vertica, consider using:

- USB 2.0 (or possibly SATA) disks
- A fast local network connection

Deliver chunks of data to the different Vertica nodes by connecting the transport disk or by writing files from network copy.

Loading From a Local Hard Disk

USB 2.0 disks can deliver data at about 30 MB per second, or 108 GB per hour. USB 2.0 disks are easy to use for transporting data from Linux to Linux. Set up an ext4 filesystem on the disk and write large files there. Linux 2.6 has USB plug-and-play support, so a USB 2.0 disk is instantly usable on various Linux systems.

For other UNIX variants, if there is no common filesystem format available, use the disk without a filesystem to copy a single large file. For example:

```
$ cp bigfile /dev/sdc1
```

Even without a filesystem on the disk, plug-and-play support still works on Linux to provide a device node for the disk. To find out the assigned device, plug in the disk and enter:

```
$ dmesg | tail -40
```

SATA disks are usually internal, but can be external, or unmounted safely if they are internal.

Loading Over the Network

A 1Gbps (gigabits per second) network can deliver about 50 MB/s, or 180GB/hr. Vertica can load about 30-50GB/hour/node for a 1-Ksafe projection design. Therefore, you should use a dedicated 1Gbps LAN. Using a LAN with a performance that is < 1Gbps will be proportionally slower. Vertica recommends not loading data across an external network, because the delays over distance slow down the TCP protocol to a small fraction of its available bandwidth, even without competing traffic.

Note: The actual load rates you obtain can be higher or lower depending on the properties of the data, number of columns, number of projections, and hardware and network speeds. Load speeds can be further improved by using multiple parallel streams.

Loading From Windows

Use NTFS for loading files directly from Windows to Linux. Although Red Hat Linux as originally installed can read Windows FAT32 file systems, this is not recommended.

Using Load Scripts

You can write and run a load script for the `COPY` statement using a simple text-delimited file format. For information about other load formats see [Specifying a COPY Parser](#). Vertica recommends that you load the smaller tables before the largest tables. To check data formats before loading, see [Checking Data Format Before or After Loading](#).

Using Absolute Paths in a Load Script

Unless you are using the `COPY FROM LOCAL` statement, using `COPY` on a remote client requires an absolute path for a data file. You cannot use relative paths on a remote client. For a load script, you can use vsql variables to specify the locations of data files relative to your Linux working directory.

To use vsql variables to specify data file locations:

1. Create a vsql variable containing your Linux current directory.

```
\set t_pwd `pwd`
```

2. Create another vsql variable that uses a path relative to the Linux current directory variable for a specific data file.

```
\set input_file `\:t_pwd'/Date_Dimension.tbl`
```

3. Use the second variable in the `COPY` statement:

```
=> COPY Date_Dimension FROM :input_file DELIMITER '|';
```

4. Repeat steps 2 and 3 to load all data files.

Note: COPY FROM LOCAL does not require an absolute path for data files. You can use paths that are relative to the client's directory system.

Running a Load Script

You can run a load script on any host, as long as the data files are on that host.

1. Change your Linux working directory to the location of the data files.

```
$ cd /opt/vertica/doc/retail_example_database
```

2. Run the Administration Tools.

```
$ /opt/vertica/bin/admintools
```

3. Connect to the database.
4. Run the load script.

Loading Data Interactively

Micro Focus recommends using the COPY statement in script files, as described in [Using Load Scripts](#). You can also load data interactively by piping a text file to vsq1 and executing a COPY (or COPY FROM LOCAL) statement with the standard input stream as the input file.

For example:

```
$ cat fact_table.tbl | vsq1 -c "COPY FACT_TABLE FROM STDIN DELIMITER '|' DIRECT";  
$ cat fact_table.tbl | vsq1 -c "COPY FACT_TABLE FROM LOCAL STDIN DELIMITER '|' DIRECT";
```

Using COPY and COPY LOCAL

The COPY statement bulk loads data into a Vertica database. You can initiate loading one or more files or pipes on a cluster host. You can also load directly from a client system, using the COPY statement with its FROM LOCAL option.

COPY lets you load *parsed* or *computed* data. Parsed data is from a table or schema using one or more columns, and computed data is calculated with a column expression on one or more column values.

COPY invokes different parsers depending on the data format you specify:

- Delimited text (the default parser format, but never specified)
- Native binary (NATIVE) (not supported with COPY LOCAL)
- Native varchar (NATIVE VARCHAR) (not supported with COPY LOCAL)
- Fixed-width data (FIXEDWIDTH)
- ORC (Optimized Row Columnar) and Parquet Hadoop files (not supported with COPY LOCAL)

To use one of the several flex table parsers, use the parser parameter, followed by the parser of choice.

COPY has many options, which you can combine to make importing data flexible. For detailed syntax of the various options see the SQL Reference Manual. For example:

For this option...	See this section...
Read uncompressed data, or data in GZIP, BZIP, or LZO compressed forms.	Specifying COPY FROM Options
Insert data into the WOS (memory) or directly into the ROS (disk).	Choosing a Load Method
Set parameters such as data delimiters and quote characters for the entire load operation or, for specific columns.	Loading UTF-8 Format Data
Transform data before inserting it into the database.	Transforming Data During Loads

Copying Data from a Vertica Client

Use `COPY LOCAL` to load files on a client system to the Vertica database. For example, to copy a GZIP file from your local client, use a command such as this:

```
=> COPY store.store_dimension FROM LOCAL '/usr/files/my_data/input_file' GZIP;
```

You can use a comma-separated list to load multiple files of the same compression type. `COPY LOCAL` then concatenates the files into a single file, so you cannot combine files with different compression types in the list. When listing multiple files, be sure to specify the type of every input file, such as BZIP, as shown:

```
=> COPY simple_table FROM LOCAL 'input_file.bz' BZIP, 'input_file.bz' BZIP;
```

You can load data from a local client from STDIN, as follows:

```
=> COPY simple_table FROM LOCAL STDIN;
```

Loading Data from an IDOL CFS Client

The IDOL Connector Framework Server (CFS) VerticalIndexer feature lets CFS clients connect to your Vertica database using ODBC. After it is connected, CFS uses `COPY . . . FROM LOCAL` statements to load IDOL document metadata into an existing flex table. For more information, see the [Using Flex Tables for IDOL Data](#) section in Using Flex Tables.

Transforming Data During Loads

To promote a consistent database and reduce the need for scripts to transform data at the source, you can transform data with an expression as part of loading. Transforming data while loading is useful for computing values to insert into a target database column from other columns in the source database.

To transform data during load, use the following syntax to specify the target column for which you want to compute values, as an expression:

```
COPY [ [database-name.]schema-name.]table ([[Column as Expression] / column[FORMAT 'format']  
[ ,...]])  
FROM ...
```

Understanding Transformation Requirements

When transforming data during loads, the [COPY](#) statement must contain at least one parsed column. The parsed column can [be a FILLER column](#).

Specify only RAW data in the parsed column source data. If you specify nulls in that RAW data, the columns are evaluated with the same rules as for SQL statement expressions.

You can intersperse parsed and computed columns in a [COPY](#) statement.

Loading FLOAT Values

Vertica parses [floating-point values](#) internally. [COPY](#) does not require you to cast floats explicitly, unless you need to transform the values for another reason.

Using Expressions in COPY Statements

The expression in a [COPY](#) statement can be as simple as a single column, or more complex, such as a case statement for multiple columns. An expression can specify multiple columns, and multiple expressions can refer to the same parsed column. You can use expressions for columns of all supported data types.

[COPY](#) expressions can use many Vertica-supported SQL functions, operators, constants, NULLs, and comments, including these functions:

- [Date/time](#)
-
- [String](#)
- [Null-handling](#)
- [System information](#)

Requirements and restrictions

- [COPY](#) expressions cannot use SQL meta functions ([Vertica-specific](#)), [analytic](#) functions, [aggregate](#) functions, or computed columns.

- For computed columns, you must list all parsed columns in the COPY statement expression. Do not specify FORMAT or RAW in the source data for a computed column.
- Expressions used in a COPY statement can contain only constants. The return data type of the expression must be coercible to that of the target column. Parsed column parameters are also coerced to match the expression.

Handling Expression Errors

Errors in expressions within your COPY statement are SQL errors. As such, they are handled differently from parse errors. When a parse error occurs, COPY rejects the row and adds it to the rejected data file or table. COPY also adds the reason for a rejected row to the exceptions file, or the rejected data table. For example, COPY parsing does not implicitly cast data types. If a type mismatch occurs between the data being loaded and a column type (such as attempting to load a text value into a FLOAT column), COPY rejects the row, and continues processing.

If an error occurs in an expression in your COPY statement, the entire load fails. For example, if your COPY statement has a transform function expression, and a syntax error exists in that expression, the entire load is rolled back. All SQL errors (including COPY rollback from an expression, are stored in the Vertica-specific log file. However, unlike parse rejections and exception messages, SQL expression errors are brief, and may require further research.

Transformation Example

Following is a small transformation example.

1. Create a table t.

```
=> CREATE TABLE t (  
    year VARCHAR(10),  
    month VARCHAR(10),  
    day VARCHAR(10),  
    k timestamp  
);
```

2. Use COPY to copy the table, computing values for the year, month, and day columns in the target database, based on the timestamp columns in the source table.
3. Load the parsed column, timestamp, from the source data to the target database.

```
=> COPY t(year AS TO_CHAR(k, 'YYYY'),
          month AS TO_CHAR(k, 'Month'),
          day AS TO_CHAR(k, 'DD'),
          k FORMAT 'YYYY-MM-DD') FROM STDIN NO COMMIT;
2009-06-17
1979-06-30
2007-11-26
\.
```

4. Select the table contents to see the results:

```
SELECT * FROM t;
 year | month | day | k
-----+-----+-----+-----
 2009 | June  | 17  | 2009-06-17 00:00:00
 1979 | June  | 30  | 1979-06-30 00:00:00
 2007 | November | 26  | 2007-11-26 00:00:00
(3 rows)
```

Deriving Table Columns From Data File Columns

You can use [COPY](#) to derive a table column from the data file to load. For more information, see [Manipulating Source Data Columns](#).

Specifying COPY FROM Options

Each COPY statement requires a FROM option to indicate the location of the file or files being loaded. This syntax excerpt shows the available FROM keywords, and their associated file format options:

```
FROM { STDIN ..... [ BZIP | GZIP | LZO | UNCOMPRESSED ]
... | 'pathToData' [ ON nodename | ON nodeset | ON ANY NODE ]
..... [ BZIP | GZIP | LZO | UNCOMPRESSED ] [, ...]
... | LOCAL STDIN | 'pathToData'
..... [ BZIP | GZIP | LZO | UNCOMPRESSED ] [, ...]
}
```

Each of the FROM keywords lets you optionally specify the format of the load file as UNCOMPRESSED, BZIP, GZIP, or LZO.

Note: When using COPY in conjunction with a CREATE EXTERNAL TABLE statement, you cannot use the COPY FROM STDIN or LOCAL options.

Loading from STDIN

Using STDIN for the FROM option lets you load uncompressed data, BZIP, or GZIP files.

Loading from a Specific Path

You must use the *pathToData* argument to indicate the location of the file to load. You can optionally indicate which node or nodes should parse the input by using any of the following:

- A node name
- A set of nodes
- ON ANY NODE

You can load one or more files, using a path on the local file system or in HDFS.

Using the ON ANY NODE clause indicates that the source file to load is available on all of the nodes. If you specify this clause, COPY opens the file and parses it from any node in the cluster. ON ANY NODE is the default for HDFS paths.

Using the ON *nodeset* clause indicates that the source file is on all named nodes. If you specify this clause, COPY opens the file and parses it from any node in the set. Be sure that the source file you specify is available and accessible on each applicable cluster node.

If *pathToData* resolves to a storage location on a local file system (not HDFS), and the user invoking COPY is not a superuser, these permissions are required:

- The storage location must have been created with the USER option (see [CREATE LOCATION](#))
- The user must already have been granted READ access to the storage location where the file or files exist, as described in [GRANT \(Storage Location\)](#)

If a user with privileges, who is not a superuser, invokes COPY from that storage location, Vertica prevents symbolic links from allowing unauthorized access.

Loading BZIP and GZIP Files

You can load files compressed with BZIP or GZIP. To do so, you must indicate the compression format for each file when loading multiple files. For example, this statement copies a BZIP file into the flex table `twitter`, using the `fjsonparser`:

```
=> COPY twitter FROM '/server1/TWITTER/tweets1.json.bz2' BZIP parser fjsonparser() direct;
Rows Loaded
-----
      172094
(1 row)
```

Loading LZO Files

You can load LZO files using the same COPY statements as you use for BZIP and GZIP files. The following statement loads an LZO file delimited with '|' characters into the flex table twitter:

```
=> COPY twitter FROM '/server1/TWITTER/tweets2.lzo' LZO DELIMITER '|';
Rows Loaded
-----
      19421
(3 rows)
```

Vertica supports the following options to the `lzop` command used to compress the file:

- compression level: -1 through -9, --fast, --best
- -F, --no-checksum, --crc32, --adler32

For more information about these options, see lzop.org.

Loading with Wildcards (glob)

You can invoke COPY for a large number of files in a shared directory with a single statement such as:

```
=> COPY myTable FROM '/data/manyfiles/*.dat' ON ANY NODE;
```

The glob (*) must indicate a set of files, not directories. The following statement fails if `/data/manyfiles` contains any subdirectories:

```
=> COPY myTable FROM '/data/manyfiles/*' ON ANY NODE;
```

Using a wildcard with the `ON ANY NODE` clause expands the file list on the initiator node. This command then distributes the individual files among all nodes, so that the COPY workload is evenly distributed across the entire cluster.

`ON ANY NODE` is the default for HDFS paths, as in the following example:

```
=> COPY myTable FROM 'hdfs:///data/manyfiles/*';
```

You can also distribute a file set across a subset of nodes, which you might do to balance concurrent loads. For example, this command distributes the loading of individual files among the three named nodes:

```
=> COPY myTable FROM '/mydirectory/ofmanyfiles/*.dat'  
    ON (v_vmart_node0001, v_vmart_node0002, v_vmart_node0003);
```

Distributing file loads across nodes depends on two configuration parameters, `EnableApportionLoad` and `EnableApportionFileLoad`. Both are enabled by default. See [General Parameters](#) for more information about these parameters.

Loading from a Local Client

To bulk load data from a client, and without requiring database superuser privileges, use the `COPY FROM LOCAL` option. You can load from either `STDIN`, or a specific path, but not from a specific node (or `ON ANY NODE`), since you are loading from the client. All local files are loaded and parsed serially with each `COPY` statement, so you cannot perform parallel loads with the `LOCAL` option. See [Using Parallel Load Streams](#).

You can load one or more files in the supported formats: `UNCOMPRESSED`, `BZIP`, `GZIP`, or `LZO`.

For specific information about saving rejected data and exceptions files when using `COPY` from `LOCAL`, see [Capturing Load Rejections and Exceptions](#).

Choosing a Load Method

You can specify how Vertica loads table data at two levels:

- Table metadata, through [CREATE TABLE](#) and [ALTER TABLE](#)
- DML statements: [COPY/COPY FROM VERTICA](#), [INSERT](#), [MERGE](#), and [UPDATE](#)

If a table specifies a load option, Vertica uses it for all DML operations unless the DML statement specifies otherwise.

Load Options and Hints

[CREATE TABLE](#) and [ALTER TABLE](#), and copy operations [COPY/COPY FROM VERTICA](#) support the following load options:

- **AUTO** (default): Initially loads data into WOS, suitable for smaller bulk loads.
- **DIRECT**: Loads data directly into ROS containers, suitable for large (>100 MB) bulk loads.
- **TRICKLE**: Loads data only into WOS, suitable for frequent incremental loads.

Vertica also supports three load hints: `/*+AUTO*/*`, `/*+DIRECT*/*`, and `/*+TRICKLE*/*`. These hints let you control how individual **INSERT**, **MERGE**, and **UPDATE** operations load table data, overriding the target table's load setting, if any.

AUTO: Loading Into WOS

If no load option is specified for an operation, Vertica uses the **AUTO** method to load data into WOS. After WOS reaches full capacity, Vertica continues to load data to ROS containers.

DIRECT: Loading Directly to ROS

The **DIRECT** option specifies to load data directly into ROS containers, bypassing WOS. **DIRECT** is best suited for large data loads (100 MB or more).

Note: A large initial bulk load can temporarily affect query performance while Vertica organizes the data.

For example:

```
COPY a FROM stdin DIRECT;  
COPY b FROM LOCAL STDIN DIRECT;
```

Tip: Avoid using **DIRECT** to load many smaller data sets. This approach results in many ROS containers that must be combined later.

TRICKLE Loading

Use the **TRICKLE** load option to load data incrementally after the initial bulk load is complete. Trickle loading loads data into the WOS. If the WOS becomes full, an error occurs and the entire data load is rolled back. Use this option only when the following conditions are true:

- You have a finely tuned load and moveout process at your site.
- You are confident that the WOS can hold the data you are loading.

This option is more efficient than AUTO when you want to load data into partitioned tables.

Overriding COPY Auto Commit

By default, COPY automatically commits itself and other current transactions except when loading temporary tables. You can override this behavior by qualifying the COPY statement with the NO COMMIT option. When you specify NO COMMIT, Vertica does not commit the transaction until you explicitly issue a COMMIT statement.

You can use COPY . . . NO COMMIT in two ways:

- Execute multiple COPY commands as a single transaction.
- Check data for constraint violations before committing the load.

Combine Multiple COPY Statements in Same Transaction

When you combine multiple COPY . . . NO COMMIT statements in the same transaction, Vertica can consolidate the data for all operations into fewer ROS containers, and thereby perform more efficiently.

For example, the following set of COPY . . . NO COMMIT statements performs several copy statements sequentially, and then commits them all. In this way, all of the copied data is either committed or rolled back as a single transaction.

```
COPY... NO COMMIT;  
COPY... NO COMMIT;  
COPY... NO COMMIT;  
COPY X FROM LOCAL NO COMMIT;  
COMMIT;
```

Tip: Vertica recommends that you [COMMIT](#) or [ROLLBACK](#) the current transaction before you use COPY . . . NO COMMIT. Otherwise, if a previous operation such as INSERT is in progress, COPY . . . NO COMMIT adds that operation to its own transaction. In this case, the previous operation and copy operation are combined as a single transaction, which requires an explicit COMMIT statement.

Check Constraint Violations

Unless you have enabled enforcement of primary key, unique, or check constraints, Vertica does not check for constraint violations when loading data. You can use `COPY . . . NO COMMIT` to troubleshoot loaded data for constraint violations. Before committing the load, test the data with [ANALYZE_CONSTRAINTS](#). If you find any constraint violations, you can roll back the load.

For details on `ANALYZE_CONSTRAINTS`, see [Detecting Constraint Violations with ANALYZE_CONSTRAINTS](#).

For details on automatic enforcement of primary key, unique, and check constraints, see [Enforcing Primary Key, Unique Key, and Check Constraints Automatically](#).

Specifying a COPY Parser

By default, `COPY` uses the `DELIMITER` parser to load raw data into the database. Raw input data must be in UTF-8, delimited text format. Data is compressed and encoded for efficient storage.

Note: `COPY` cannot explicitly specify the `DELIMITER` parser.

If the raw data to load does not consist primarily of delimited text, specify the parser that is most appropriate, one of the following:

- `NATIVE` (binary)
- `NATIVE VARCHAR`
- `FIXEDWIDTH`
- ORC and PARQUET (see [Reading Hadoop Columnar File Formats](#))

Using a different parser for your data can improve load performance. If delimited input data includes binary data types, `COPY` translates the data on input. See [Using Load Scripts](#) and [Loading Binary \(Native\) Data](#) for examples. You can also load binary data, but only if it adheres to the `COPY` format requirements, described in [Creating Native Binary Format Files](#).

The same bulk load `COPY` statement cannot mix raw data types that require different parsers, such as `NATIVE` and `FIXEDWIDTH`. For information about verifying input data formats, see [Checking Data Format Before or After Loading](#).

Flex Table Parsers

You can use flex parsers to load data into standard, columnar tables. Use the flex parser that best matches your needs, as described in the [Using Flex Table Parsers](#) section of Using Flex Tables:

- FAVROPARSER
- FCEFPARSER
- FCSVPARSER
- FDELIMITEDPARSER
- FDELIMITEDPAIRPARSER
- FJSONPARSER
- FREGEXPARSER

Loading data with the flex parsers makes loading data flexible. For example, you can load JSON data into a columnar table in one load with the FJSONPARSER, and delimited data into the same table in another with the default COPY parser. Using Flex Tables describes this use case and presents an example.

Specifying Load Metadata

In addition to choosing a parser option, COPY supports other options to determine how to handle raw data. These options are considered load metadata, and you can specify metadata options in different parts of the COPY statement as follows:

	Qualifies:		
Metadata option	Column expression	COLUMN OPTION	FROM options
DELIMITER	Y	Y	Y
ENCLOSED BY	Y	Y	Y
ESCAPE AS	Y	Y	Y

	Qualifies:		
Metadata option	Column expression	COLUMN OPTION	FROM options
NULL	Y	Y	Y
TRIM	Y		Y
RECORD TERMINATOR			Y
SKIP			Y
SKIP BYTES			Y (fixed-width only)
TRAILING NULLCOLS			Y

The following precedence rules apply to all data loads:

- All column-level parameters override statement-level parameters.
- COPY uses the statement-level parameter if you do not specify a column-level parameter.
- COPY uses the default metadata values for the DELIMITER, ENCLOSED BY, ESCAPE AS, and NULL options if you do not specify them at either the statement or column level.

When you specify any metadata options, COPY uses the parser to produce the best results and stores the raw data and its corresponding metadata in the following formats:

Raw data format	Metadata format	Parser
UTF-8	UTF-8	DELIMITER
Binary	Binary	NATIVE
UTF-8	Binary	NATIVE VARCHAR
UTF-8	UTF-8	FIXEDWIDTH

Interpreting Last Column End of Row Values

When bulk-loading delimited text data using the default parser (DELIMITED), the last column end of row value can be any of the following:

- Record terminator
- EOF designator
- Delimiter and a record terminator

Note: The FIXEDWIDTH parser always requires exactly a record terminator. No other permutations work.

For example, given a three-column table, the following input rows for a COPY statement using a comma (,) delimiter are each valid:

```
1,1,11
1,1,
1,1,
```

The following examples illustrate how COPY can interpret different last column end of data row values.

Using a Single End of Row Definition

To see how COPY interprets a single end of row definition:

1. Create a two-column table `two_col`, specifying column `b` with a default value of 5:

```
=> CREATE TABLE two_col (a int, b int DEFAULT 5);
CREATE TABLE
```

2. COPY the `two_col` table using a comma (,) delimiter, and enter values for only one column (as a single, multi-line entry):

```
=> COPY two_col from stdin delimiter ',';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1,
>> 1,
>> \.
```

The COPY statement complete successfully.

3. Query table `two_col`, to display the two NULL values for column `b` as blank:

```
=> SELECT * FROM two_col;
a | b
```

```
----+----  
1 |  
1 |  
(2 rows)
```

Here, COPY expects two values for each column, but gets only one. Each input value is followed by a delimiter (,), and an implicit record terminator (a newline character, \n). You supply a record terminator with the ENTER or RETURN key. This character is not represented on the screen.

In this case, the delimiter (,) and record terminator (\n) are handled independently. COPY interprets the delimiter (,) to indicate the end of one value, and the record terminator (\n) to specify the end of the column row. Since no value follows the delimiter, COPY supplies an empty string before the record terminator. By default, the empty string signifies a NULL, which is a valid column value.

Using a Delimiter and Record Terminator End of Row Definition

To use a delimiter and record terminator together as an end of row definition:

1. Copy column a (a) of the two_col table, using a comma delimiter again, and enter two values:

```
=> COPY two_col (a) FROM STDIN delimiter ',';  
Enter data to be copied followed by a newline.  
End with a backslash and a period on a line by itself.  
>> 2,  
>> 2,  
>> \.
```

The COPY statement again completes successfully.

2. Query table two_col to see that column b now includes two rows with its default value (5):

```
=> SELECT * FROM two_col;  
a | b  
----+----  
1 |  
1 |  
2 | 5  
2 | 5  
(4 rows)
```

In this example, COPY expects values for only one column, because of the column (a) directive. As such, COPY interprets the delimiter and record terminator together as a single,

valid, last column end of row definition. Before parsing incoming data, COPY populates column b with its default value, because the table definition has two columns and the COPY statement supplies only one. This example populates the second column with its default column list value, while the previous example used the supplied input data.

Loading UTF-8 Format Data

You can specify these parameters at either a statement or column basis:

- ENCLOSED BY
- ESCAPE AS
- NULL
- DELIMITER

Loading Special Characters As Literals

The default COPY statement escape key is a backslash (\). By preceding any *special character* with an escape character, COPY interprets the character that follows literally, and copies it into the database. These are the special characters that you escape to load them as literals:

Special Character	COPY Statement Usage
Vertical bar ()	Default COPY ... DELIMITER character
Empty string (' ')	Default COPY ... NULL string.
Backslash (\)	Default COPY ... ESC character.
Newline and other control characters	Various

To use a special character as a literal, prefix it with an escape character. For example, to include a literal backslash (\) in the loaded data (such as when including a file path), use two backslashes (\\). COPY removes the escape character from the input when it loads escaped characters.

Using a Custom Column Separator (DELIMITER)

The default COPY delimiter is a vertical bar (|). The DELIMITER is a single ASCII character used to separate columns within each record of a file. Between two delimiters, COPY interprets all

string data in load files as characters. Do not enclose character strings in quotes, since quote characters are also treated as literals between delimiters.

You can define a different delimiter using any ASCII value in the range E'\000' to E'\177' inclusive. For instance, if you are loading CSV data files, and the files use a comma (,) character as a delimiter, you can change the default delimiter to a comma. You cannot use the same character for both the DELIMITER and NULL options.

If the delimiter character is among a string of data values, use the ESCAPE AS character (\ by default) to indicate that the delimiter should be treated as a literal.

The COPY statement accepts empty values (two consecutive delimiters) as valid input data for CHAR and VARCHAR data types. COPY stores empty columns as an empty string (' '). An empty string is not equivalent to a NULL string.

To indicate a non-printing delimiter character (such as a tab), specify the character in extended string syntax (E'...'). If your database has StandardConformingStrings enabled, use a Unicode string literal (U&'...'). For example, use either E'\t' or U&'\0009' to specify tab as the delimiter.

Using a Custom Column Option DELIMITER

This example, redefines the default delimiter through the COLUMN OPTION parameter.

1. Create a simple table.

```
=> CREATE TABLE t(      pk INT,
      co11 VARCHAR(10),
      co12 VARCHAR(10),
      co13 VARCHAR(10),
      co14 TIMESTAMP);
```

2. Use the COLUMN OPTION parameter to change the co11 default delimiter to a tilde (~).

```
=> COPY t COLUMN OPTION(co11 DELIMITER '~') FROM STDIN NO COMMIT;
>> 1|ee~gg|yy|1999-12-12
>> \.
=> SELECT * FROM t;
 pk | co11 | co12 | co13 |          co14
-----+-----+-----+-----+-----
  1 | ee   | gg   | yy   | 1999-12-12 00:00:00
(1 row)
```

Defining a Null Value (NULL)

The default NULL value for COPY is an empty string (' '). You can specify a NULL as any ASCII value in the range E '\001' to E '\177' inclusive (any ASCII character except NUL: E '\000'). You cannot use the same character for both the DELIMITER and NULL options.

When NULL is an empty string (' '), use quotes to insert an empty string instead of a NULL. For example, using NULL " ENCLOSED BY ' " ' :

- 1 | | 3 — Inserts a NULL in the second column.
- 1 | " " | 3 — Inserts an empty string instead of a NULL in the second columns.

To input an empty or literal string, use quotes (ENCLOSED BY); for example:

```
NULL 'NULL 'literal'
```

A NULL is case-insensitive and must be the only value between the data field delimiters. For example, if the null string is NULL and the delimiter is the default vertical bar (|):

| NULL | indicates a null value.

| NULL | does not indicate a null value.

When you use the COPY command in a script, you must substitute a double-backslash for each null string that includes a backslash. For example, the scripts used to load the example database contain:

```
COPY ... NULL E'\\n' ...
```

Loading NULL Values

You can specify NULL by entering fields without content into a data file, using a field delimiter.

For example, given the default delimiter (|) and default NULL (empty string) definition, COPY inserts the following input data:

```
| | 1| 2 | 3  
4 | | 5  
6 | |
```

into the table as follows:

```
(null, null, 1)(null, 2, 3)  
(4, null, 5)
```

```
(6, null, null)
```

If NULL is set as a literal (' null '), COPY inserts the following inputs:

```
null | null | 1null | 2 | 3
4 | null | 5
6 | null | null
```

as follows:

```
(null, null, 1)(null, 2, 3)
(4, null, 5)
(6, null, null)
```

Filling Columns with Trailing Nulls (TRAILING NULLCOLS)

Loading data using the TRAILING NULLCOLS option inserts NULL values into any columns without data. Before inserting TRAILING NULLCOLS, Vertica verifies that the column does not have a NOT NULL constraint.

To use the TRAILING NULLCOLS parameter to handle inserts with fewer values than data columns:

1. Create a table:

```
=> CREATE TABLE z (a INT,
  b INT,
  c INT );
```

2. Insert some values into the table:

```
=> INSERT INTO z VALUES (1, 2, 3);
```

3. Query table z to see the inputs:

```
=> SELECT * FROM z;
 a | b | c
---+---+---
 1 | 2 | 3
(1 row)
```

4. Insert two rows of data from STDIN, using TRAILING NULLCOLS:

```
=> COPY z FROM STDIN TRAILING NULLCOLS;  
>> 4 | 5 | 6  
>> 7 | 8  
>> \.
```

5. Query table z again to see the results. Using TRAILING NULLCOLS, the COPY statement correctly handled the third row of column c, which had no value:

```
=> SELECT * FROM z;  
 a | b | c  
---+---+---  
 1 | 2 | 3  
 4 | 5 | 6  
 7 | 8 |  
(3 rows)
```

Attempting to Fill a NOT NULL Column with TRAILING NULLCOLS

You cannot use TRAILING NULLCOLS on a column that has a NOT NULL constraint. For instance:

1. Create a table n, declaring column b with a NOT NULL constraint:

```
=> CREATE TABLE n ( a INT,  
                    b INT NOT NULL,  
                    c INT );
```

2. Insert some table values:

```
=> INSERT INTO n VALUES (1, 2, 3);  
=> SELECT * FROM n;  
 a | b | c  
---+---+---  
 1 | 2 | 3  
(1 row)
```

3. Use COPY with TRAILING NULLCOLS on table n to see the COPY error due to the column constraint:

```
=> COPY n FROM STDIN trailing nullcols abort on error;  
Enter data to be copied followed by a newline.  
End with a backslash and a period on a line by itself.  
>> 4 | 5 | 6  
>> 7 | 8
```

```
>> 9
>> \.
ERROR: COPY: Input record 3 has been rejected (Cannot set trailing column to NULL as column 2
(b) is NOT NULL)
```

4. Query the table to see that the COPY statement values were rejected:

```
=> SELECT * FROM n;
 a | b | c
-----+-----
 1 | 2 | 3
(1 row)
```

Changing the Default Escape Character (ESCAPE AS)

The default escape character is a backslash (\). To change the default to a different character, use the `ESCAPE AS` option. To use an alternative escape character:

```
=> COPY mytable FROM '/data/input.txt' ESCAPE AS E('\001');
```

You can set the escape character to be any ASCII value value in the range `E '\001'` to `E '\177'` inclusive.

Eliminating Escape Character Handling

If you do not want any escape character and want to prevent any characters from being interpreted as escape sequences, use the `NO ESCAPE` option as part of the `COPY` statement.

Delimiting Characters (ENCLOSED BY)

The `COPY ENCLOSED BY` parameter lets you set an ASCII character to delimit characters to embed in string values. You can use any ASCII value in the range `E '\001'` to `E '\177'` inclusive (any ASCII character except `NULL: E '\000'`) for the `ENCLOSED BY` value. Using double quotation marks (") is the most commonly used quotation character. For instance, the following parameter specifies that input data to the `COPY` statement is enclosed within double quotes:

```
ENCLOSED BY '"'
```

With the following input (using the default `DELIMITER (|)` character), specifying:

```
"vertica | value"
```

Results in:

- Column 1 containing "vertica
- Column 2 containing value"

Notice the double quotes (") before `vertica` and after `value`.

Using the following sample input data as follows, columns are distributed as shown:

```
"1", "vertica,value", ",", ""
```

```
col1 | col2          | col3 | col4-----+-----+-----+-----  
1    | vertica,value | ,    | '  '  
(1 row)
```

Alternatively, write the above example using any ASCII character of your choosing:

```
~1~, ~vertica,value~, ~,~, ~'~
```

If you use a single quote ('), rather than double quotes (") as the ENCLOSED BY character, you must escape it using extended string syntax, a Unicode literal string (if `StandardConformingStrings` is enabled), or by using four single quotes:

```
ENCLOSED BY E'\''ENCLOSED BY U&'\0027'  
ENCLOSED BY ''''
```

Using any of the definitions means the following input is properly parsed:

```
'1', 'vertica,value', ',', '\'
```

See [String Literals \(Character\)](#) for an explanation of the string literal formats you can use to specify the ENCLOSED BY parameter.

Use the ESCAPE AS character to embed the ENCLOSED BY delimiter within character string values. For example, using the default ESCAPE AS character (\) and double quote as the ENCLOSED BY character, the following input returns "vertica":

```
"\"vertica\""
```

Using ENCLOSED BY for a Single Column

The following example uses double quotes to enclose a single column (rather than the entire row). The COPY statement also specifies a comma (,) as the delimiter.

```
=> COPY Retail.Dim (Dno, Dname ENCLOSED BY '"', Dstore) FROM '/home/dbadmin/dim3.txt'  
DELIMITER ','  
EXCEPTIONS '/home/dbadmin/exp.txt';
```

This example correctly loads data such as:

```
123,"Smith, John",9832
```

Specifying a Custom End of Record String (RECORD TERMINATOR)

To specify the literal character string that indicates the end of a data file record, use the `RECORD TERMINATOR` parameter, followed by the string to use. If you do not specify a value, then Vertica attempts to determine the correct line ending, accepting either just a linefeed (`E'\n'`) common on UNIX systems, or a carriage return and linefeed (`E'\r\n'`) common on Windows platforms.

For example, if your file contains comma-separated values terminated by line feeds that you want to maintain, use the `RECORD TERMINATOR` option to specify an alternative value:

```
=> COPY mytable FROM STDIN DELIMITER ',' RECORD TERMINATOR E'\n';
```

To specify the `RECORD TERMINATOR` as non-printing characters, use either the extended string syntax or Unicode string literals. The following table lists some common record terminator characters. See [String Literals](#) for an explanation of the literal string formats.

Extended String Syntax	Unicode Literal String	Description	ASCII Decimal
<code>E'\b'</code>	<code>U&'\0008'</code>	Backspace	8
<code>E'\t'</code>	<code>U&'\0009'</code>	Horizontal tab	9
<code>E'\n'</code>	<code>U&'\000a'</code>	Linefeed	10
<code>E'\f'</code>	<code>U&'\000c'</code>	Formfeed	12
<code>E'\r'</code>	<code>U&'\000d'</code>	Carriage return	13
<code>E'\''</code>	<code>U&'\005c'</code>	Backslash	92

If you use the `RECORD TERMINATOR` option to specify a custom value, be sure the input file matches the value. Otherwise, you may get inconsistent data loads.

Note: The record terminator cannot be the same as `DELIMITER`, `NULL`, `ESCAPE`, or `ENCLOSED BY`.

If using JDBC, Micro Focus recommends that you use the following value for the RECORD TERMINATOR:

```
System.getProperty("line.separator")
```

Examples

The following examples use a comma (,) as the DELIMITER for readability.

```
,1,2,3,,1,2,3  
1,2,3,
```

Leading (, 1) and trailing (3,) delimiters are ignored. Thus, the rows all have three columns.

123, '\\n', \\n, 456	Using a non-default null string, the row is interpreted as: 123 newLine \\n 456
----------------------	---

123, this\\, that\\, or the other, something else, 456	The row would be interpreted as: 123 this, that, or the other something else 456
--	--

Loading Binary (Native) Data

You can load binary data using the NATIVE parser option, except with COPY LOCAL, which does not support this option. Since binary-format data does not require the use and processing of delimiters, it precludes the need to convert integers, dates, and timestamps from text to their native storage format, and improves load performance over delimited data. All binary-format files must adhere to the formatting specifications described in [Appendix: Binary File Formats](#).

Native binary format data files are typically larger than their delimited text format counterparts, so compress the data before loading it. The NATIVE parser does not support concatenated compressed binary files. You can load native (binary) format files when developing plug-ins to ETL applications.

There is no copy format to load binary data byte-for-byte because the column and record separators in the data would have to be escaped. Binary data type values are padded and translated on input, and also in the functions, operators, and casts supported.

Loading Hexadecimal, Octal, and Bitstring Data

You can use the formats hexadecimal, octal, and bitstring only to load binary columns. To specify these column formats, use the [COPY](#) statement's `FORMAT` options:

- Hexadecimal
- Octal
- Bitstring

The following examples illustrate how to use the `FORMAT` option.

1. Create a table:

```
=> CREATE TABLE t(oct VARBINARY(5),  
  hex VARBINARY(5),  
  bitstring VARBINARY(5) );
```

2. Create the projection:

```
=> CREATE PROJECTION t_p(oct, hex, bitstring) AS SELECT * FROM t;
```

3. Use a `COPY` statement with the `STDIN` clause, specifying each of the formats:

```
=> COPY t (oct FORMAT 'octal', hex FORMAT 'hex',  
  bitstring FORMAT 'bitstring')  
  FROM STDIN DELIMITER ',';
```

4. Enter the data to load, ending the statement with a backslash (\) and a period (.) on a separate line:

```
Enter data to be copied followed by a newline.  
End with a backslash and a period on a line by itself.  
>> 141142143144145,0x6162636465,0110000101100010011000110110010001100101  
>> \.
```

5. Use a select query on table `t` to view the input values results:

```
=> SELECT * FROM t;  
  oct | hex | bitstring  
-----+-----+-----  
abcde | abcde | abcde  
(1 row)
```

COPY uses the same default format to load binary data, as used to input binary data. Since the backslash character ('\ ') is the default escape character, you must escape octal input values. For example, enter the byte '\141' as '\\141'.

Note: If you enter an escape character followed by an invalid octal digit or an escape character being escaped, COPY returns an error.

On input, COPY translates string data as follows:

- Uses the [HEX_TO_BINARY](#) function to translate from hexadecimal representation to binary.
- Uses the [BITSTRING_TO_BINARY](#) function to translate from bitstring representation to binary.

Both functions take a VARCHAR argument and return a VARBINARY value.

You can also use the escape character to represent the (decimal) byte 92 by escaping it twice; for example, '\\\\'. Note that vsql inputs the escaped backslash as four backslashes. Equivalent inputs are hex value '\0x5c' and octal value '\134' ($134 = 1 \times 8^2 + 3 \times 8^1 + 4 \times 8^0 = 92$).

You can load a delimiter value if you escape it with a backslash. For example, given delimiter '|', '\\\001\\|\002' is loaded as {1,124,2}, which can also be represented in octal format as '\\\001\\174\\002'.

If you insert a value with more bytes than fit into the target column, COPY returns an error. For example, if column c1 is VARBINARY(1):

```
=> INSERT INTO t (c1) values ('ab'); ERROR: 2-byte value too long for type Varbinary(1)
```

If you implicitly or explicitly cast a value with more bytes than fit the target data type, COPY silently truncates the data. For example:

```
=> SELECT 'abcd'::binary(2);
binary
-----
ab
(1 row)
```

Hexadecimal Data

The optional '\0x' prefix indicates that a value is hexadecimal, not decimal, although not all hexadecimal values use A-F; for example, 5396. COPY ignores the \0x prefix when loading the input data.

If there are an odd number of characters in the hexadecimal value, the first character is treated as the low nibble of the first (furthest to the left) byte.

Octal Data

Loading octal format data requires that each byte be represented by a three-digit octal code. The first digit must be in the range [0,3] and the second and third digits must both be in the range [0,7].

If the length of an octal value is not a multiple of three, or if one of the three digits is not in the proper range, the value is invalid and COPY rejects the row in which the value appears. If you supply an invalid octal value, COPY returns an error. For example:

```
SELECT '\\000\\387'::binary(8);  
ERROR: invalid input syntax for type binary
```

Rows that contain binary values with invalid octal representations are also rejected. For example, COPY rejects '\\008' because '\\ 008' is not a valid octal number.

BitString Data

Loading bitstring data requires that each character must be zero (0) or one (1), in multiples of eight characters. If the bitstring value is not a multiple of eight characters, COPY treats the first n characters as the low bits of the first byte (furthest to the left), where n is the remainder of the value's length, divided by eight.

Examples

The following example shows VARBINARY HEX_TO_BINARY(VARCHAR) and VARCHAR TO_HEX(VARBINARY) usage.

1. Create table `t` and its projection with binary columns:

```
=> CREATE TABLE t (c BINARY(1));  
=> CREATE PROJECTION t_p (c) AS SELECT c FROM t;
```

2. Insert minimum and maximum byte values, including an IP address represented as a character string:

```
=> INSERT INTO t values(HEX_TO_BINARY('0x00'));  
=> INSERT INTO t values(HEX_TO_BINARY('0xFF'));
```

```
=> INSERT INTO t values (V6_ATON('2001:DB8::8:800:200C:417A'));
```

Use the `TO_HEX` function to format binary values in hexadecimal on output:

```
=> SELECT TO_HEX(c) FROM t;
to_hex
-----
00
ff
20
(3 rows)
```

Loading Native Varchar Data

Use the `NATIVE VARCHAR` parser option when the raw data consists primarily of `CHAR` or `VARCHAR` data. `COPY` performs the conversion to the actual table data types on the database server. This parser option is not supported with `COPY LOCAL`.

Using `NATIVE VARCHAR` does not provide the same efficiency as `NATIVE`. However, `NATIVE VARCHAR` precludes the need to use delimiters or to escape special characters, such as quotes, which can make working with client applications easier.

Note: `NATIVE VARCHAR` does not support concatenated compressed files.

Batch data inserts performed through the Vertica ODBC and JDBC drivers automatically use the `NATIVE VARCHAR` format.

Loading Fixed-Width Format Data

Use the `FIXEDWIDTH` parser option to bulk load fixed-width data. You must specify the `COLSIZES` option values to specify the number of bytes for each column. The definition of the

table you are loading (`COPY table f (x, y, z)`) determines the number of `COLSIZES` values to declare.

To load fixed-width data, use the `COLSIZES` option to specify the number of bytes for each input column. If any records do not have values, `COPY` inserts one or more null characters to equal the specified number of bytes. The last record in a fixed-width data file must include a record terminator to determine the end of the load data.

Supported Options for Fixed-Width Data Loads

Loading fixed-width data supports the options listed in the [COPY Option Parser Dependencies](#).

These options are not supported:

- `DELIMITER`
- `ENCLOSED BY`
- `ESCAPE AS`
- `TRAILING NULLCOLS`

Using Nulls in Fixed-Width Data

The default `NULL` string for a fixed-width load cannot be an empty string, and instead, consists of all spaces. The number of spaces depends on the column width declared with the `COLSIZES (integer, [, ...])` option.

For fixed-width loads, the `NULL` definition depends on whether you specify `NULL` at the column or statement level:

- *Statement level:* `NULL` must be defined as a single-character. The default (or custom) `NULL` character is repeated for the entire width of the column.
- *Column level:* `NULL` must be defined as a string whose length matches the column width.

For fixed-width loads, if the input data column has fewer values than the specified column size, `COPY` inserts `NULL` characters. The number of `NULL`s must match the declared column width. If you specify a `NULL` string at the column level, `COPY` matches the string with the column width.

Note: To turn off `NULL`s, use the `NULL AS` option and specify `NULL AS ''`.

Defining a Null Character (Statement Level)

1. Create a two-column table (fw):

```
=> CREATE TABLE fw(co int, ci int);  
CREATE TABLE
```

2. Copy the table, specifying null as 'N', and enter some data:

```
=> COPY fw FROM STDIN FIXEDWIDTH colsizes(2,2) null AS 'N' NO COMMIT;  
Enter data to be copied followed by a newline.  
End with a backslash and a period on a line by itself.  
>> NN12  
>> 23NN  
>> NNNN  
>> nnnn  
>> \.
```

3. Select all (*) from the table:

```
=> SELECT * FROM fw;  
co | ci  
----+----  
23 |  
   |  
   | 12  
(4 rows)
```

Defining a Custom Record Terminator

To define a record terminator other than the COPY default when loading fixed-width data, take these steps:

1. Create table fw with two columns, co and ci:

```
=> CREATE TABLE fw(co int, ci int);  
CREATE TABLE
```

2. Copy table fw, specifying two 2-byte column sizes, and specifying a comma (,) as the record terminator:

```
=> COPY fw FROM STDIN FIXEDWIDTH colsizes(2,2) RECORD TERMINATOR ',';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1234,1444,6666
>> \.
```

3. Query all data in table fw:

```
=> SELECT * FROM fw;
 co | ci
-----+-----
 12 | 34
 14 | 44
(2 rows)
```

The SELECT output indicates only two values. COPY rejected the third value (6666) because it was not followed by a comma (,) record terminator. Fixed-width data requires a trailing record terminator only if you explicitly specify a record terminator explicitly.

Copying Fixed-Width Data

Use COPY FIXEDWIDTH COLSIZES (n [, ...]) to load files into a Vertica database. By default, all spaces are NULLs. For example:

```
=> CREATE TABLE mytest(co int, ci int);
=> CREATE PROJECTION mytest_p1 AS SELECT * FROM mytest SEGMENTED BY HASH(co) ALL NODES;
=> COPY mytest(co,ci) FROM STDIN FIXEDWIDTH colsizes(6,4) NO COMMIT;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> \.
=> SELECT * FROM mytest ORDER BY co;
 co | ci
-----+-----
(0 rows)
```

Skipping Content in Fixed-Width Data

The COPY statement has two options to skip input data. The SKIP BYTES option is only for fixed-width data loads:

SKIP BYTES <i>num-bytes</i>	Skips the specified number of bytes from the input data.
SKIP <i>num-records</i>	Skips the specified number of records.

The following example uses SKIP BYTES to skip 11 bytes when loading a fixed-width table with two columns (4 and 6 bytes):

1. Copy a table using SKIP BYTES:

```
=> COPY fw FROM STDIN FIXEDWIDTH colsizes (4,6) SKIP BYTES 11;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 2222666666
>> 1111999999
>> 1632641282
>> \.
```

2. Query all data in table fw:

```
=> SELECT * FROM fw ORDER BY co;
  co |  ci
-----+-----
 1111 | 999999
 1632 | 641282
(2 rows)
```

The output confirms that COPY skipped the first 11 bytes of loaded data.

The following example uses SKIP when loading a fixed-width (4,6) table:

1. Copy a table, using SKIP to skip two records of input data:

```
=> COPY fw FROM STDIN FIXEDWIDTH colsizes (4,6) SKIP 2;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 2222666666
>> 1111999999
>> 1632641282
>> 3333888888
>> \.
```

2. Query all data in table fw:

```
=> SELECT * FROM fw ORDER BY co;
  co |  ci
-----+-----
 1632 | 641282
 3333 | 888888
(2 rows)
```

The output confirms that COPY skipped the first two records of load data.

Trimming Characters in Fixed-Width Data Loads

Use the TRIM option to trim a character. TRIM accepts a single-byte character, which is trimmed at the beginning and end of the data. For fixed-width data loads, when you specify a TRIM character, COPY first checks to see if the row is NULL. If the row is not null, COPY trims the character(s). The next example instructs COPY to trim the character A, and shows the results:

1. Copy table fw, specifying TRIM character A:

```
=> COPY fw FROM STDIN FIXEDWIDTH colsizes(4,6) TRIM 'A';  
Enter data to be copied followed by a newline.  
End with a backslash and a period on a line by itself.  
>> A22A444444  
>> A22AA44444A  
>> \.
```

2. Query all data in table fw:

```
=> SELECT * FROM fw ORDER BY co;  
co | ci  
----+-----  
22 | 4444  
22 | 444444  
(2 rows)
```

Using Padding in Fixed-Width Data Loads

By default, the padding character is ' ' (a single space). The padding behavior for fixed-width data loads is similar to how a space is treated in other formats, differing by data type as follows:

Data type	Padding
Integer	Leading and trailing spaces
Bool	Leading and trailing spaces
Float	Leading and trailing spaces
[var]Binary	None, all characters are significant.
[Var]Char	Trailing spaces if string is too large

Data type	Padding
DateInterval Time Timestamp TimestampTZ TimeTZ	None, all characters are significant. COPY uses an internal algorithm to parse these data types.
Date (formatted)	Use the COPY FORMAT option string to match the expected column length.
Numerics	Leading and trailing spaces

Bulk Loading and Exporting Data From Amazon S3

The Vertica library for Amazon Web Services (AWS) is a set of functions and configurable session parameters. These parameters allow you to directly exchange data between Vertica and Amazon S3 storage without any third-party scripts or programs.

To use the AWS library, you must have access to an Amazon S3 storage account.

Related Topics

- [Configure the AWS Library](#)
- [Loading Data From Amazon S3](#)
- [Exporting Data to Amazon S3 From Vertica](#)

Configuring the Vertica Library for Amazon Web Services

Configure the Vertica library for Amazon Web Services (AWS) by setting session parameters with your AWS access key credentials and region. You can set your session parameters directly, or you can store your credentials in a table and set them with the `AWS_SET_CONFIG` function.

Because the AWS library is configured with session parameters, you must reconfigure the library with each new session.

Important: Your AWS access key ID and secret access key are different from your account access credentials. For more information about AWS access keys, visit the [AWS documentation](#).

Use either of the following methods to securely set and store your AWS account credentials:

- [Configuring Session Parameters Directly](#)
- [Configuring Session Parameters Using Keychains](#)

Note: To increase security, configure session parameters directly to avoid storing credentials within Vertica.

AWS Access Key Requirements

In order to communicate with AWS, your access key must have the following permissions:

- s3:GetObject
- s3:PutObject
- s3:ListBucket

For security purposes, Micro Focus International plc recommends that you create a separate access key with limited permissions specifically for use with the Vertica Library for AWS.

Configuring Session Parameters Directly

Set the following session parameters for AWS using your own credentials:

- `aws_id` — This value is your AWS access key ID.

```
=> ALTER SESSION SET UDPARAMETER FOR awslib aws_id='AKABCOEXAMPLEPKPXYZQ';
```

- `aws_secret` — This value is your AWS secret access key.

```
=> ALTER SESSION SET UDPARAMETER FOR awslib aws_secret='CEXAMPLE3tEXAMPLE1wEXAMPLEFrFEXAMPLE6+Yz';
```

- `aws_region` - This value is the AWS region associated with the S3 bucket you intend to access. Left unconfigured, `aws_region` will default to `us-east-1`. It identifies the default

server used by Amazon S3.

```
=> ALTER SESSION SET UDPARAMETER FOR awslib aws_region='us-east-1';
```

Important: Parameter values are case sensitive.

Configuring Session Parameters Using Credentials Stored in a Table

You can place your credentials in a table and secure them with a [row-level access policy](#). You can then call your credentials with the `AWS_SET_CONFIG` scalar meta-function. This approach allows you to store your credentials on your cluster for future session parameter configuration. You must have `dbadmin` access to create access policies.

1. Create a table with rows or columns corresponding with your credentials:

```
=> CREATE TABLE keychain(accesskey varchar, secretaccesskey varchar);
```

2. Store your credentials in the corresponding columns:

```
=> COPY keychain FROM STDIN;  
Enter data to be copied followed by a newline.  
End with a backslash and a period on a line by itself.  
>> AEXAMPLEI5EXAMPLEYXQ|CCEXAMPLEtFjTEXAMPLEiEXAMPLE6+Yz  
>> \.
```

3. Set a [row-level access policy](#) appropriate to your security situation.
4. With each new session, configure your session parameters by calling the `AWS_SET_CONFIG` parameter in a `SELECT` statement:

```
=> SELECT AWS_SET_CONFIG('aws_id', accesskey), AWS_SET_CONFIG('aws_secret', secretaccesskey)  
FROM keychain;  
aws_set_config | aws_set_config  
-----+-----  
aws_id        | aws_secret  
(1 row)
```

Important: Micro Focus International plc recommends that you *not* use the `AWS_SET_CONFIG` function to configure your library directly. When you do so, your credentials are recorded in the server log.

5. After you have configured your session parameters, verify them:

```
=> SHOW SESSION UDPARAMETER ALL;
```

Loading Data From Amazon S3

After you configure the Vertica library for Amazon Web Services (AWS), you can copy data from S3. To do so, use COPY with the S3 UDSOURCE containing the location of your S3 bucket and object. You can use either a standard HTTPS URL, or the S3 URL scheme, as the following examples show.

Use COPY with a standard HTTPS URL:

```
=> COPY exampleTable SOURCE S3(url='https://s3.amazonaws.com/exampleBucket/object');
```

Use COPY with the S3 URL scheme:

```
=> COPY exampleTable SOURCE S3(url='s3://exampleBucket/object');
```

You can use the S3 UDSOURCE with any [UDParser](#) or [UDFilter](#) to import any data format supported by Vertica. If Vertica encounters an error with AWS during an S3 import operation which it cannot resolve, it will abort the import and pass the AWS error information on in the Vertica error report.

Importing Multiple Specific Files

Import multiple specific files by separating the URLs with a bar:

```
=> COPY exampleTable SOURCE s3(url='s3://exampleBucket/object1|S3://exampleBucket/object2');
```

Specify your own delimiter:

```
=> COPY exampleTable SOURCE S3(url='s3://exampleBucket/object1,s3://exampleBucket/object2',  
delimiter=',');
```

Importing Multiple Files Using Glob Expansion

In addition to importing single and multiple files by specifying exact URL addresses and the URL parameter, you can use glob expansion to import multiple files in a bucket or subdirectory by specifying the location with the bucket parameter.

Import from all files in a bucket using glob expansion:

```
=> COPY exampleTable SOURCE S3(bucket='s3://exampleBucket/*');
```

Import from all files in a subdirectory using glob expansion:

```
=> COPY exampleTable SOURCE S3(bucket='s3://exampleBucket/subdirectory/*');
```

Import all files with a 'db_' prefix:

```
=> COPY exampleTable SOURCE S3(bucket='s3://exampleBucket/db_*');
```

Import all files with a .csv suffix:

```
=> COPY exampleTable SOURCE S3(bucket='s3://exampleBucket/*.csv');
```

Exporting Data to Amazon S3 From Vertica

After you configure the library for Amazon Web Services (AWS), you can export Vertica data to Amazon S3 by calling the S3EXPORT() transform function. S3EXPORT() writes data to files, based on the URL you provide. Vertica performs all communication over HTTPS, regardless of the URL type you use. Vertica does not support virtual host style URLs. If you use HTTPS URL constructions, you must use path style URLs.

Note: If your S3 bucket contains a period in its path, then you should set the `prepend_hash` parameter to `True`.

You can control the output of `S3EXPORT()` in the following ways:

- [Adjust the base query provided to S3EXPORT](#)
- [Adjust the parameters of S3EXPORT](#)
- [Adjust the partition of your result set with the OVER\(\) clause](#)

Adjust the Query Provided to S3EXPORT

By adjusting the query given to `S3EXPORT()`, you can export anything from tables to reporting queries.

This example exports a whole table:

```
=> SELECT S3EXPORT( * USING PARAMETERS url='s3://exampleBucket/object') OVER(PARTITION BEST) FROM
exampleTable;
 rows | url
-----+-----
   606 | s3://exampleBucket/object
(1 row)
```

This example exports the results of a query:

```
=> SELECT S3EXPORT(customer_name, annual_income USING PARAMETERS url='s3://exampleBucket/object')
OVER()
  FROM public.customer_dimension
  WHERE (customer_gender, annual_income) IN
  (SELECT customer_gender, MAX(annual_income)
   FROM public.customer_dimension
   GROUP BY customer_gender);

 rows | url
-----+-----
   606 | s3://exampleBucket/object
(1 row)
```

Adjust the Parameters of S3EXPORT

Vertica exports partition data in chunks set by the `chunksizes` parameter. In its default setting, this multipart parameter instructs AWS to recombine the chunks into a single S3 object. However, if your export exceeds the S3 object size limit, or you want to fix the size of output objects, you can disable multipart uploads. Disabling allows you to set chunking to any size you

prefer under the AWS PUT limit. This approach causes each partition to write your export into multiple incrementing S3 objects.

This example shows how you can export a 27 MB file with multipart disabled and chunk size left to the 10 MB default:

```
=> SELECT S3EXPORT(* USING PARAMETERS url='s3://examplebucket/object',
                        multipart=false) OVER()
        FROM exampleTable;
rows  | url
-----+-----
1048576 | s3://exampleBucket/object
(1 row)
```

Results:

```
10244k  object.699b7f63.1
10244k  object.699b7f63.2
6152k   object.699b7f63.3
```

The base name of the resulting objects matches the provided URL. However, the partition is now split into three parts with a maximum chunk size of 10 MB.

Adjust the Partition of Your Result Set with the OVER Clause

Use the OVER clause to control your export partitions. Using the OVER() clause without qualification results in a single partition processed by the initiator for all of the query data. This example shows how to call the function with an unqualified OVER() clause:

```
=> SELECT S3EXPORT(name, company USING PARAMETERS url='s3://exampleBucket/object',
                        delimiter=',') OVER()
        FROM exampleTable WHERE company='Vertica';
rows  | url
-----+-----
606   | s3://exampleBucket/object
(1 row)
```

You can also use window clauses, such as [window partition clauses](#) and [window order clauses](#), to manage exported objects.

This example shows how you can use a window partition clause to partition S3 objects based on company values:

```
=> SELECT S3EXPORT(name, company
                USING PARAMETERS url='s3://exampleBucket/object',
                delimiter=',') OVER(PARTITION BY company) AS MEDIAN
        FROM exampleTable;
```

Manipulating Source Data Columns

When loading data, your source data might contain one or more columns that do not exist in the target table. Or, the source and target tables have matched columns, but you want to omit one or more source columns from the target table.

The [COPY](#) command's `FILLER` parameter helps you accomplish these tasks:

- Ignore input columns from the source data.
- Transform source data before loading it into the target table.

The `FILLER` parameter identifies a column of source data that the `COPY` command can ignore, or use to compute new values that are loaded into the target table. Define the `FILLER` parameter data type so it is compatible with the source data. For example, be sure to define a `VARCHAR` so its length can contain all source data; otherwise, data could be truncated. You can specify multiple filler columns, where each filler column is specified by its own `FILLER` parameter.

Use FILLER to Ignore Some Values and Compute New Values for the Target Table

Using SQL operators or functions, you can combine two or more source columns into one column; you can also split one column into multiple columns—for example, split date strings into day, month, and year components and load these into target table columns.

The following `COPY` statement reads all of the source data, but only loads the source columns `first_name` and `last_name`. It constructs the data for `full_name` by concatenating each of the source data columns. To do this, use the `FILLER` parameter to ignore the `middle_name`

column on load, but use the column when concatenating data to populate the `full_name` column.

```
=> CREATE TABLE names(first_name VARCHAR(20), last_name VARCHAR(20), full_name VARCHAR(60));
CREATE TABLE
=> COPY names(first_name,
              middle_name FILLER VARCHAR(20),
              last_name,
              full_name AS first_name||' '||middle_name||' '||last_name)
FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> Marc|Gregory|Smith
>> Sue|Lucia|Temp
>> Jon|Pete|Hamilton
>> \.
=> SELECT * FROM names;
 first_name | last_name |      full_name
-----+-----+-----
 Jon       | Hamilton | Jon Pete Hamilton
 Marc      | Smith    | Marc Gregory Smith
 Sue       | Temp     | Sue Lucia Temp
(3 rows)
```

If the source field's data type is `VARCHAR`, be sure to set the `VARCHAR` length to ensure that the combined length of all `FILLER` source fields does not exceed the target column's defined length; otherwise, the `COPY` command could return with an error.

Using Parallel Load Streams

Vertica can divide the work of loading data, taking advantage of parallelism to speed up the operation. Vertica supports several types of parallelism:

- **Distributed load:** Files in a multi-file load are loaded on several nodes in parallel, instead of all being loaded on a single node.
- **Apportioned load:** A single large file or other single source is divided into segments (portions), which are assigned to several nodes to be loaded in parallel.

Caution: If the file is different on two nodes, an incorrect or incomplete result is returned, with no error or warning.

Apportioned load is enabled by default. If you want to disable it, set the `EnableApportionLoad` configuration parameter to 0.

- **Cooperative parse:** A source being loaded on a single node uses multi-threading to parallelize the parse. Cooperative parse is enabled by default. If you want to disable it, set

the EnableCooperativeParse configuration parameter to 0.

See [General Parameters](#) for information about the configuration parameters.

Specifying Distributed File Loads

The COPY FROM statement provides several ways to distribute a file load.

You can direct individual files in a multi-file load to specific nodes, as in the following example of distributed load.

```
=> COPY t FROM '/data/file1.dat' ON v_vmart_node0001, '/data/file2.dat' ON v_vmart_node0002;
```

You can use globbing (wildcard expansion) to specify a group of files with the ON ANY NODE directive, as in the following example.

- If apportioned load is enabled (the default), Vertica assigns different files to different nodes. Both the EnableApportionedLoad and EnableApportionedFileLoad must be set to 1.
- If apportioned load is disabled, a single node loads all the data.

```
=> COPY t FROM '/data/*.dat' ON ANY NODE;
```

If you have a single file instead of a group of files, you can still, potentially, benefit from apportioned load. The file must be large enough to divide into portions at least equal to ApportionedFileMinimumPortionSizeKB in size. You must also use a parser that supports apportioned load. The delimited parser built into Vertica supports apportioned load, but other parsers might not.

The following example shows how you can load a single large file using multiple nodes.

```
=> COPY t FROM '/data/bigfile.dat' ON ANY NODE;
```

You can limit the nodes that participate in an apportioned load. Doing so is useful if you need to balance several concurrent loads. Vertica apportions each load individually; it does not account for other loads that might be in progress on those nodes. You can, therefore, potentially speed up your loads by managing apportioning yourself.

The following example shows how you can apportion loads on specific nodes.

```
=> COPY t FROM '/data/big1.dat' ON (v_vmart_node0001, v_vmart_node0002, v_vmart_node0003),  
      '/data/big2.dat' ON (v_vmart_node0004, v_vmart_node0005);
```

Loaded files can be of different formats, such as BZIP, GZIP, and others. However, because file compression is a filter, you cannot use apportioned load for a compressed file.

Specifying Distributed Loads with Sources

You can also apportion loads using COPY WITH SOURCE. You can create sources and parsers with the User-Defined Load (UDL) API. If both the source and parser support apportioned load, and EnableApportionLoad is set, then Vertica attempts to divide the load among nodes.

The following example shows a load that you could apportion.

```
=> COPY t WITH SOURCE MySource() PARSER MyParser();
```

The built-in delimited parser supports apportioning, so you can use it with a user-defined source, as in the following example.

```
=> COPY t WITH SOURCE MySource();
```

Number of Load Streams

Although the number of files you can load is not restricted, the optimal number of load streams depends on several factors, including:

- Number of nodes
- Physical and logical schemas
- Host processors
- Memory
- Disk space

Using too many load streams can deplete or reduce system memory required for optimal query processing. See [Best Practices for Managing Workload Resources](#) for advice on configuring load streams.

Monitoring COPY Loads and Metrics

You can check COPY loads using:

- Vertica functions
- LOAD_STREAMS system table
- LOAD_SOURCES system table

Using Vertica Functions

Two meta-functions return COPY metrics for the number of accepted or rejected rows from a COPY statement:

1. To get the number of accepted rows, use the [GET_NUM_ACCEPTED_ROWS](#) function:

```
=> select get_num_accepted_rows();
get_num_accepted_rows
-----
                        11
(1 row)
```

2. To check the number of rejected rows, use the [GET_NUM_REJECTED_ROWS](#) function:

```
=> select get_num_rejected_rows();
get_num_rejected_rows
-----
                        0
(1 row)
```

Note: GET_NUM_ACCEPTED_ROWS and GET_NUM_REJECTED_ROWS support loads from STDIN, COPY LOCAL from a Vertica client, or a single file on the initiator. You cannot use these functions for multi-node loads.

Using the CURRENT_LOAD_SOURCE Function

You can include the CURRENT_LOAD_SOURCE function as a part of the COPY statement. Doing so allows you to insert into a column the input file name or value computed by this function.

To insert the file names into a column from multiple source files:

```
=> COPY t (c1, c2, c3 as CURRENT_LOAD_SOURCE()) FROM '/home/load_file_1' ON exampledb_node02,
'/home/load_file_2' ON exampledb_node03 DELIMITER ',';
```

Using the LOAD_STREAMS System Table

Vertica includes a set of system tables that include monitoring information, as described in [Using System Tables](#). The `LOAD_STREAMS` system table includes information about load stream metrics from `COPY` and `COPY FROM VERTICA` statements. Thus, you can query table values to get `COPY` metrics.

To see all table columns:

```
=> SELECT * FROM load_streams;
```

Using the STREAM NAME Parameter

Using the `STREAM NAME` parameter as part of the `COPY` statement labels `COPY` streams explicitly so they are easier to identify in the `LOAD_STREAMS` system table.

To use the `STREAM NAME` parameter:

```
=> COPY mytable FROM myfile DELIMITER '|' DIRECT STREAM NAME 'My stream name';
```

The `LOAD_STREAMS` system table includes stream names for every `COPY` statement that takes more than 1-second to run. The 1-second duration includes the time to plan and execute the statement.

Vertica maintains system table metrics until they reach a designated size quota (in kilobytes). This quota is set through internal processes, which you cannot set or view directly.

Other LOAD_STREAMS Columns for COPY Metrics

These `LOAD_STREAMS` system table column values depend on the load status:

- `ACCEPTED_ROW_COUNT`
- `REJECTED_ROW_COUNT`
- `PARSE_COMPLETE_PERCENT`
- `SORT_COMPLETE_PERCENT`

When a COPY statement using the DIRECT option is in progress, the ACCEPTED_ROW_COUNT value can increase during parsing. This value can reach the maximum number of rows in the input file.

If COPY reads input data from multiple named pipes, the PARSE_COMPLETE_PERCENT value remains at zero (0) until *all* named pipes return an EOF. While COPY awaits an EOF from multiple pipes, it can appear to be hung. However, before canceling the COPY statement, check your [system CPU and disk accesses](#) to determine if any activity is in progress.

In a typical load, the PARSE_COMPLETE_PERCENT value can either increase slowly or jump quickly to 100%, if you are loading from named pipes or STDIN. However, SORT_COMPLETE_PERCENT remains at 0 when loading from named pipes or STDIN. After PARSE_COMPLETE_PERCENT reaches 100%, SORT_COMPLETE_PERCENT increases to 100%. Depending on the data sizes, a significant lag can occur between the time PARSE_COMPLETE_PERCENT reaches 100% and the time SORT_COMPLETE_PERCENT begins to increase.

This example shows how you can set the VSQL expanded display and then select various columns of data from the LOAD_STREAMS system table:

```
=> \pset expanded
Expanded display is on.
=> SELECT stream_name, table_name, load_start, accepted_row_count,
        rejected_row_count, read_bytes, unsorted_row_count, sorted_row_count,
        sort_complete_percent FROM load_streams;
-[ RECORD 1 ]-----+-----
stream_name      | fact-13
table_name       | fact
load_start       | 2010-12-28 15:07:41.132053
accepted_row_count | 900
rejected_row_count | 100
read_bytes       | 11975
input_file_size_bytes | 0
parse_complete_percent | 0
unsorted_row_count | 3600
sorted_row_count  | 3600
sort_complete_percent | 100
```

See the [SQL Reference Manual](#) for other meta-function details.

Using the LOAD_SOURCES System Table

The LOAD_STREAMS table shows the total number of rows that were loaded or rejected. Grouping this information by source can help you determine from where data is coming. The [LOAD_SOURCES](#) system table includes some of the same data as LOAD_STREAMS does but adds this source-specific information. If apportioning is enabled, [LOAD_SOURCES](#) also provides information about how loads are apportioned among nodes.

You can use this table to identify causes of differing query results. For example, you can use the following statement to create an external table based on globs:

```
=> CREATE EXTERNAL TABLE tt AS COPY WITH SOURCE AWS(dir = 'foo', file = '*');
```

If you select from this table, Vertica loads data from every file in the `foo` directory and creates one row in the `LOAD_SOURCES` table for each file. Suppose you later repeat the query and see different results. You could look at the `LOAD_SOURCES` table and discover that—between the two queries—somebody added another file to the `foo` directory. Because each file is recorded in `LOAD_SOURCES`, you can see the new file that explains the changed query results.

If you are using many data sources, you might prefer to disable this reporting. To disable reporting, set the `LoadSourceStatisticsLimit` configuration parameter to 0. This parameter sets the upper bound on the number of sources profiled by `LOAD_SOURCES` per load. The default value is 256.

Capturing Load Rejections and Exceptions

Loading data with `COPY` has two main phases, *parsing* and *loading*. Rejected data is created whenever `COPY` cannot parse a row of data. Following are some parser errors that can cause a rejected row:

- Unsupported parser options
- Incorrect data types for the table into which data is being loaded
- Malformed context for the parser in use
- Missing delimiters

Other problems can occur during the load phase, but such problems are not rejected data from parser errors.

Several optional parameters let you determine how strictly `COPY` handles rejections when parsing data. For example, you can have `COPY` fail when it rejects a single row, or allow a specific number of parsing rejections before the load fails. This section presents the parameters to determine how `COPY` handles rejected data.

Save Rejected Rows (REJECTED DATA and EXCEPTIONS)

The `COPY` statement automatically saves a copy of each rejected row in a *rejected-data* file. `COPY` also saves a corresponding explanation of what caused the rejection in an *exceptions* file. By default, Vertica saves both files in a database catalog subdirectory, called `CopyErrorLogs`, as listed in this example:

```
v_mart_node003_catalog\COPYErrorLogs\trans-STDIN-copy-from-rejected-data.1  
v_mart_node003_catalog\COPYErrorLogs\trans-STDIN-copy-from-exceptions.1
```

You can optionally save COPY rejections and exceptions in two other ways:

- Use the REJECTED DATA *reject_file* and EXCEPTIONS *except_file* parameters to save both files to a location of your choice. The *reject_file* includes rejected rows, while the exceptions file contains a description of why each row was rejected.
- Use the REJECTED DATA AS TABLE *reject_table* clause. Saving rejected rows to a *reject_table* also retains the exception descriptions.

Note: Vertica recommends saving rejected data to a table. However, saving to a table excludes saving to a default or specific rejected data file.

If you save COPY rejected data to a table, the table files are stored in the data subdirectory. For example, in a VMart database installation, rejected data table records are stored in the RejectionTableData directory as follows:

```
=> cd v_mart_node003_data\RejectionTableData\  
=> ls  
TABLE_REJECTED_RECORDS_"bg"_mytest01.example.-25441:0x6361_45035996273805099_1.1  
TABLE_REJECTED_RECORDS_"bg"_mytest01.example.-25441:0x6361_45035996273805113_2.2  
.  
.  
.  
TABLE_REJECTED_RECORDS_"delimr"_mytest01.example.-5958:0x3d47_45035996273815749_1.1  
TABLE_REJECTED_RECORDS_"delimr"_mytest01.example.-5958:0x3d47_45035996273815749_1.2
```

COPY LOCAL Rejected Data

For COPY LOCAL operations, you must use the REJECTED DATA *reject_file* and EXCEPTIONS *except_file* parameters explicitly. The *reject_file* and *except_file* paths must reside on the client. If *path* resolves to a storage location and the user invoking COPY is not a superuser, the following permissions are required:

- The storage location must have been created with the USER usage type (see [CREATE LOCATION](#)).
- The user must already have been granted access to the storage location where the files exist, as described in [GRANT \(Storage Location\)](#)

Enforce Truncating or Rejecting Rows (ENFORCELENGTH)

When parsing data of type CHAR, VARCHAR, BINARY, or VARBINARY, rows may exceed the target table length. By default, COPY truncates such rows without rejecting them.

Use the ENFORCELENGTH parameter to reject rows that exceed the target table.

For example, loading 'abc' into a table column specified as VARCHAR(2) results in COPY truncating the value to 'ab' and loading it. Loading the same row with the ENFORCELENGTH parameter causes COPY to reject the row.

Note: Vertica supports NATIVE and NATIVE VARCHAR values up to 65K. If any value exceeds this limit, COPY rejects the row, even when ENFORCELENGTH is not in use.

Specify a Maximum Number of Rejections (REJECTMAX)

The REJECTMAX parameter specifies the maximum number of logical records that can be rejected before a load fails. A rejected row consists of the data that could not be parsed into the corresponding data type during a bulk load. Rejected data does not indicate referential constraints. For information about using constraints, and the option of enforcing constraints during bulk loading, see [About Constraints](#).

When the number of rejected records becomes equal to the REJECTMAX value, the load fails. If you do not specify a value for REJECTMAX, or if the value is 0, COPY allows an unlimited number of exceptions to occur.

Abort Data Loads for Any Error (ABORT ON ERROR)

Using the ABORT ON ERROR argument is the most restrictive way to load data, because no exceptions or rejections are allowed. A COPY operation stops if any row is rejected. No data is loaded and Vertica rolls back the command.

If you use the ABORT ON ERROR as part of a CREATE EXTERNAL TABLE AS COPY FROM statement, the option is used whenever a query references the external table. The offending error is saved in the COPY exceptions or rejected data file.

Understanding Row Rejections and Roll Back Errors

Depending on the type of error that COPY encounters, Vertica does one of the following:

- Rejects the offending row and loads other rows into a table
- Rolls back the entire COPY statement without loading any data

Note: If you specify `ABORT ON ERROR` with the COPY statement, the load automatically rolls back if COPY cannot parse *any* row.

The following table summarizes the difference between a rejected row or rollback.

Rejected Rows	Load Roll back
<p>COPY cannot parse rows that contain any of the following:</p> <ul style="list-style-type: none">• Incompatible data types• Missing fields• Missing delimiters	<p>COPY rolls back a statement if it encounters any of these conditions:</p> <ul style="list-style-type: none">• Server-side errors, such as lack of memory• Primary key or foreign key constraint violations• Loading NULL data into a NOT NULL column

This example illustrates what happens when Vertica cannot coerce a row to the requested data type. For example, in the following COPY statement, `"a::INT + b::INT"` is a SQL expression in which a and b are derived values:

```
=> CREATE TABLE t (i INT);
=> COPY t (a FILLER VARCHAR, b FILLER VARCHAR, i AS a::INT + b::INT)
    FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> cat|dog
>> \.
```

Vertica cannot parse the row to the requested data type and rejects the row:

```
ERROR 2827: Could not convert "cat" from column "*FILLER*".a to an int8
```

If a resolved to 'cat' and b to 'dog', the next expression `'cat'::INT + 'dog'::INT` would return an expression evaluator error:

```
=> SELECT 'cat'::INT + 'dog'::INT;
ERROR 3681: Invalid input syntax for integer: "cat"
```

The following COPY statement would also roll back because Vertica cannot parse the row to the requested data type:

```
=> COPY t (a FILLER VARCHAR, i AS a::INT) FROM STDIN;
```

In the following COPY statement, Vertica rejects only the offending row without rolling back the statement. Instead of evaluating the 'cat' row as a VARCHAR type, COPY parses 'cat' directly as an INTEGER.

```
=> COPY t (a FILLER INT, i AS a) FROM STDIN;
```

See Also

- [Cast Failures](#)

Saving Load Rejections (REJECTED DATA)

COPY load rejections are data rows that did not load due to a parser exception. By default, if you do not specify a rejected data file, COPY saves rejected data files to this location:

catalog_dir/CopyErrorLogs/target_table-source-copy-from-rejected-data.n

<i>catalog_dir/</i>	The database catalog files directory, for example: <code>/home/dbadmin/VMart/v_vmart_node0001_catalog</code>
<i>target_table</i>	The table into which data was loaded (<i>target_table</i>).
<i>source</i>	The source of the load data, which can be STDIN, or a file name, such as <code>baseball.csv</code> .
<i>copy-from-rejected-data.n</i>	The default name for a rejected data file, followed by <i>n</i> suffix, indicating the number of files, such as <code>.1</code> , <code>.2</code> , <code>.3</code> . For example, this default file name indicates file 3 after loading from STDIN: <code>fw-STDIN-copy-from-rejected-data.3</code> .

Saving rejected data to the default location, or to a location of your choice, lets you review the file contents, resolve problems, and reload the data from the rejected data files. Saving rejected data to a table, lets you query the table to see rejected data rows and the reasons (exceptions) why the rows could not be parsed. Vertica recommends saving rejected data to a table.

Multiple Rejected Data Files

Unless a load is very small (< 10MB), COPY creates more than one file to hold rejected rows. Several factors determine how many files COPY creates for rejected data. Here are some of the factors:

- Number of sources being loaded
- Total number of rejected rows
- Size of the source file (or files)
- Cooperative parsing and number of threads being used
- UDLs that support apportioned loads
- For your own COPY parser, the number of objects returned from `prepareUDSources()`

Naming Conventions for Rejected Files

You can specify one or more rejected data files with the files you are loading. Use the REJECTED DATA parameter to specify a file location and name, and separate consecutive rejected data file names with a comma (,). Do not use the ON ANY NODE option because it is applicable only to load files.

If you specify one or more files, and COPY requires multiple files for rejected data, COPY uses the rejected data file names you supply as a prefix, and appends a numeric suffix to each rejected data file. For example, if you specify the name `my_rejects` for the REJECTED_DATA parameter, and the file you are loading is large enough (> 10MB), several files such as the following will exist:

- `my_rejects-1`
- `my_rejects-2`
- `my_rejects-3`

COPY uses cooperative parsing by default, having the nodes parse a specific part of the file contents. Depending on the file or portion size, each thread generates at least one rejected data file per source file or portion, and returns load results to the initiator node. The file suffix is a thread index when COPY uses multiple threads (.1, .2, .3, and so on).

The maximum number of rejected data files cannot be greater than the number of sources being loaded, per thread to parse any portion. The resource pool determines the maximum number of threads. For cooperative parse, use all available threads.

If you use COPY with a UDL that supports apportioned load, the file suffix is an offset value. UDL's that support apportioned loading render cooperative parsing unnecessary. For apportioned loads, COPY creates at least one rejected file per data portion, and more files depending on the size of the load and number of rejected rows.

For all data loads except COPY LOCAL, COPY behaves as follows:

No rejected data file specified...	Rejected data file specified...
For a single data file (<i>pathToData</i> or STDIN), COPY stores one or more rejected data files in the default location.	For one data file, COPY interprets the rejected data path as a file, and stores all rejected data at the location. If more than one files is required from parallel processing, COPY appends a numeric suffix. If the path is not a file, COPY returns an error.
For multiple source files, COPY stores all rejected data in separate files in the default directory, using the source file as a file name prefix, as noted.	For multiple source files, COPY interprets the rejected path as a directory. COPY stores all information in separate files, one for each source. If path is not a directory, COPY returns an error. COPY accepts only one path per node. For example, if you specify the rejected data path as <code>my_rejected_data</code> , COPY creates a directory of that name on each node. If you provide more than one rejected data path, COPY returns an error.
Rejected data files are returned to the initiator node.	Rejected data files are not shipped to the initiator node.

Maximum Length File Names

Loading multiple input files in one statement, requires specifying full path names for each file. Keep in mind that long input file names, combined with rejected data file names, can exceed the operating system's maximum length (typically 255 characters). To work around file names that exceed the maximum length, use a path for the rejected data file that differs from the default path—for example, `\tmp\.`

Saving Rejected Data To a Table

Use the `REJECTED DATA` parameter with the `AS TABLE` clause to specify a table in which to save rejected data. Saving rejected data to a file is mutually exclusive with using the `AS TABLE` clause.

When you use the `AS TABLE` clause, Vertica creates a new table if one does not exist, or appends to an existing table. If no parsing rejections occur during a load, the table exists but is empty. The next time you load data, Vertica inserts any rejected rows to the existing table.

The load rejection tables are a special type of table with the following capabilities and limitations:

- Support `SELECT` statements
- Can use `DROP TABLE`
- Cannot be created outside of a `COPY` statement
- Do not support DML and DDL activities
- Are not K-safe

To make the data in a rejected table K-safe, you can do one of the following:

- Write a `CREATE TABLE . . AS` statement, such as this example:

```
=> CREATE TABLE new_table AS SELECT * FROM rejected_table;
```

- Create a table to store rejected records, and run `INSERT . . SELECT` operations into the new table

Using `COPY NO COMMIT`

If the `COPY` statement includes options `NO COMMIT` and `REJECTED DATA AS TABLE`, and the *reject-table* does not already exist, Vertica Analytics Platform saves the rejected data table as a `LOCAL TEMP` table and returns a message that a `LOCAL TEMP` table is being created.

Rejected-data tables are useful for Extract-Load-Transform workflows, where you will likely use temporary tables more frequently. The rejected-data tables let you quickly load data and identify which records failed to load. If you load data into a temporary table that you created using the `ON COMMIT DELETE` clause, the `COPY` operation will not commit.

Location of Rejected Data Table Records

When you save rejected records to a table, using the `REJECTED DATA AS TABLE table_name` option, the data for the table is saved in a database data subdirectory, `RejectionTableData`. For example, for a VMart database, table data files reside here:

```
/home/dbadmin/VMart/v_vmart_node0001_data/RejectionTableData
```

Rejected data tables include both rejected data and the reason for the rejection (exceptions), along with other data columns, described next. Vertica suggests that you periodically drop any rejected data tables that you no longer require.

Querying a Rejected Data Table

When you specify a rejected data table when loading data with `COPY`, you can query that table for information about rejected data after the load operation is complete. For example:

1. Create the loader table:

```
=> CREATE TABLE loader(a INT)
CREATE TABLE
```

2. Use `COPY` to load values, saving rejected data to a table, `loader_rejects`:

```
=> COPY loader FROM STDIN REJECTED DATA AS TABLE loader_rejects;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1
>> 2
>> 3
>> a
>> \.
```

3. Query the loader table after loading data:

```
=> SELECT * FROM loader;
 x
 ---
 1
 2
 3
(3 rows)
```

4. Query the `loader_rejects` table to see its column rows:

```
=> SELECT * FROM loader_rejects;
-[ RECORD 1 ]-----+-----
node_name           | v_vmart_node0001
file_name           | STDIN
session_id          | v_vmart_node0001.example.-24016:0x3439
transaction_id      | 45035996274080923
statement_id        | 1
batch_number        | 0
row_number          | 4
rejected_data       | a
rejected_data_orig_length | 1
rejected_reason     | Invalid integer format 'a' for column 1 (x)
```

The rejected data table has the following columns:

Column	Data Type	Description
node_name	VARCHAR	The name of the Vertica node on which the input load file was located.
file_name	VARCHAR	The name of the file being loaded, which applies if you loaded a file (as opposed to using STDIN).
session_id	VARCHAR	The session ID number in which the COPY statement occurred.
transaction_id	INTEGER	Identifier for the transaction within the session, if any; otherwise NULL.
statement_id	INTEGER	The unique identification number of the statement within the transaction that included the rejected data. <div style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p>Tip: You can use the <code>session_id</code>, <code>transaction_id</code>, and <code>statement_id</code> columns to create joins with many system tables. For example, if you join against the <code>QUERY_REQUESTS</code> table using those three columns, the <code>QUERY_REQUESTS.REQUEST</code> column contains the actual COPY statement (as a string) used to load this data.</p> </div>
batch_number	INTEGER	INTERNAL USE. Represents which batch (chunk) the data comes from.

row_number	INTEGER	The rejected row number from the input file.
rejected_data	LONG VARCHAR	The data that was not loaded.
rejected_data_orig_length	INTEGER	The length of the rejected data.
rejected_reason	VARCHAR	The error that caused the rejected row. This column returns the same message that exists in a load exceptions file when you do not save to a table.

Exporting the Rejected Records Table

You can export the contents of the column `rejected_data` to a file to capture only the data rejected during the first `COPY` statement. Then, correct the data in the file, save it, and load the updated file.

To export rejected records:

1. Create a sample table:

```
=> CREATE TABLE t (i int);  
CREATE TABLE
```

2. Copy data directly into the table, using a table to store rejected data:

```
=> COPY t FROM STDIN REJECTED DATA AS TABLE t_rejects;  
Enter data to be copied followed by a newline.  
End with a backslash and a period on a line by itself.  
>> 1  
>> 2  
>> 3  
>> 4  
>> a  
>> b  
>> c  
>> \.
```

3. Show only tuples and set the output format:

```
=> \t  
Showing only tuples.  
=> \a  
Output format is unaligned.
```

4. Output to a file:

```
=> \o rejected.txt  
=> select rejected_data from t_rejects;  
=> \o
```

5. Use the catcommand on the saved file:

```
=> \! cat rejected.txt  
a  
b  
c
```

After a file exists, you can fix load errors and use the corrected file as load input to the COPY statement.

Saving Load Exceptions (EXCEPTIONS)

COPY exceptions consist of informational messages describing why a row of data could not be parsed. The optional EXCEPTIONS parameter lets you specify a file to which COPY writes exceptions. If you do not use this parameter, COPY saves exception files to the following default location:

catalog_dir/CopyErrorLogs/tablename-filename-of-source-copy-from-exceptions

<i>catalog_dir</i>	The database catalog files directory
<i>tablename-filename- of-source</i>	The names of the table and data file
<i>-copy-from-exceptions</i>	The file suffix appended to the table and source file name

Note: Using REJECTED DATA AS TABLE *r_table* is mutually exclusive with using the EXCEPTIONS *filename* parameter. The rejected data table includes a column with the exceptions messages. COPY does not permit both parameters. Trying to do so results in this error:

```
ERROR 0: Cannot specify both an exceptions file and a rejected table in the same statement
```

The optional EXCEPTIONS parameter lets you specify a file of your choice to which COPY writes load exceptions. The EXCEPTIONS file indicates the input line number and the reason for each data record exception in this format:

```
COPY: Input record number in <pathofinputfile> has been rejected (reason). Please see pathrejectfile, record recordnum for the rejected record.
```

If copying from STDIN, the *filename-of-source* is STDIN.

Note: You can use specific rejected data and exceptions files with one or more of the files you are loading. Separate consecutive rejected data and exception file names with a comma (,) in the COPY statement.

You must specify a filename in the path to load multiple input files. Keep in mind that long table names combined with long data file names can exceed the operating system's maximum length (typically 255 characters). To work around file names exceeding the maximum length, use a path for the exceptions file that differs from the default path; for example, `\tmp\<shorter-file-name>`.

For all data loads (except for COPY LOCAL), COPY behaves as follows:

No Exceptions file specified...	Exceptions file specified...
For one data source file (<i>pathToData</i> or STDIN), all information stored as one file in the default directory.	For one data file, the path is treated as a file, and COPY stores all information in this file. If the path is not a file, COPY returns an error.
For multiple data files, all information stored as separate files, one for each data file in default directory.	For multiple data files, the path is treated as a directory and COPY stores all information in separate files, one for each data file. If path is not a directory, COPY returns an error.
	Exceptions files are not stored on the initiator node.
	You can specify only one path per node. If you specify more than one path per node, COPY returns an error.

COPY Rejected Data and Exception Files

When executing a COPY statement, and parallel processing is ON (the default setting), COPY creates separate threads to process load files. Typically, the number of threads depends on the number of node cores in the system. Each node processes part of the load data. If the load succeeds overall, any parser rejections that occur during load processing are written to that node's specific rejected data and exceptions files. If the load fails, the rejected data file contents can be incomplete, or empty. If you do not specify a file name explicitly, COPY uses a default name and location for rejected data files. See the next topic for specifying your own rejected data and exception files.

Both rejected data and exceptions files are saved and stored on a per-node basis. This example uses multiple files as COPY inputs. Since the statement does not include either the REJECTED

DATA or EXCEPTIONS parameters, rejected data and exceptions files are written to the default location, the database catalog subdirectory, CopyErrorLogs, on each node:

```
\set dir `pwd`/data/ \set remote_dir /vertica/test_dev/tmp_ms/  
\set file1 ''':dir'C1_large_tbl.dat'''  
\set file2 ''':dir'C2_large_tbl.dat'''  
\set file3 ''':remote_dir'C3_large_tbl.dat'''  
\set file4 ''':remote_dir'C4_large_tbl.dat'''  
  
=>COPY large_tbl FROM :file1 ON site01,:file2 ON site01,  
                    :file3 ON site02,  
                    :file4 ON site02  
                    DELIMITER '|';
```

Note: The RETURNREJECTED parameter is supported only for internal use by the JDBC and ODBC drivers. Be aware that the Vertica internal-use options can change without notice.

Specifying Rejected Data and Exceptions Files

The optional COPY REJECTED DATA and EXCEPTIONS parameters 'path' element lets you specify a non-default path in which to store the files.

If *path* resolves to a storage location, and the user invoking COPY is not a superuser, these are the required permissions:

- The storage location must have been created (or altered) with the USER option (see [CREATE LOCATION](#) and [ALTER_LOCATION_USE](#))
- The user must already have been granted READ access to the storage location where the file (s) exist, as described in [GRANT \(Storage Location\)](#)

Both parameters also have an optional ON *nodename* clause that uses the specified path:

```
...[ EXCEPTIONS 'path' [ ON nodename ] [, ... ] ]...[ REJECTED DATA 'path' [ ON nodename ] [, ... ] ]
```

While '*path*' specifies the location of the rejected data and exceptions files (with their corresponding parameters), the optional ON *nodename* clause moves any existing rejected data and exception files on the node to the specified path on the same node.

Saving Rejected Data and Exceptions Files to a Single Server

The COPY statement does not have a facility to merge exception and rejected data files after COPY processing is complete. To see the contents of exception and rejected data files requires accessing each node's specific files.

Note: To save all exceptions and rejected data files on a network host, be sure to give each node's files unique names, so that different cluster nodes do not overwrite other nodes' files. For instance, if you set up a server with two directories (`/vertica/exceptions` and `/vertica/rejections`), specify file names for each Vertica cluster node to identify each node, such as `node01_exceptions.txt` and `node02_exceptions.txt`. This way, each cluster node's files are easily distinguishable in the exceptions and rejections directories.

Using VSQL Variables for Rejected Data and Exceptions Files

This example uses `vsql` variables to specify the path and file names to use with the exceptions and rejected data parameters (`except_s1` and `reject_s1`). The `COPY` statement specifies a single input file (`large_tbl`) on the initiator node:

```
\set dir `pwd`/data/ \set file1 ''':dir'C1_large_tbl.dat''
\set except_s1 ''':dir'exceptions''
\set reject_s1 ''':dir'rejections''

COPY large_tbl FROM :file1 ON site01 DELIMITER '|'
REJECTED DATA :reject_s1 ON site01
EXCEPTIONS :except_s1 ON site01;
```

This example uses variables to specify exception and rejected data files (`except_s2` and `reject_s2`) on a remote node. The `COPY` statement consists of a single input file on a remote node (`site02`):

```
\set remote_dir /vertica/test_dev/tmp_ms/ \set except_s2 ''':remote_dir'exceptions''
\set reject_s2 ''':remote_dir'rejections''

COPY large_tbl FROM :file1 ON site02 DELIMITER '|'
REJECTED DATA :reject_s2 ON site02
EXCEPTIONS :except_s2 ON site02;
```

This example uses variables to specify that the exception and rejected data files are on a remote node (indicated by `:remote_dir`). The inputs to the `COPY` statement consist of multiple data files on two nodes (`site01` and `site02`). The exceptions and rejected data options use the `ON nodename` clause with the variables to indicate where the files reside (`site01` and `site02`):

```
\set dir `pwd`/data/ \set remote_dir /vertica/test_dev/tmp_ms/
\set except_s1 ''':dir''''
\set reject_s1 ''':dir''''
\set except_s2 ''':remote_dir''''
\set reject_s2 ''':remote_dir''''

COPY large_tbl FROM :file1 ON site01,
                  :file2 ON site01,
```

```
:file3 ON site02,  
:file4 ON site02  
DELIMITER '|'   
REJECTED DATA :reject_s1 ON site01, :reject_s2 ON site02  
EXCEPTIONS :except_s1 ON site01, :except_s2 ON site02;
```

COPY LOCAL Rejection and Exception Files

Invoking COPY LOCAL (or COPY LOCAL FROM STDIN) does not automatically create rejected data and exceptions files. This behavior differs from using COPY, which saves both files automatically, regardless of whether you use the optional REJECTED DATA and EXCEPTIONS parameters to specify either file explicitly.

Use the REJECTED DATA and EXCEPTIONS parameters with COPY LOCAL and COPY LOCAL FROM STDIN to save the corresponding output files on the client. If you do *not* use these options, rejected data parsing events (and the exceptions that describe them) are not retained, even if they occur.

You can load multiple input files using COPY LOCAL (or COPY LOCAL FROM STDIN). If you also use the REJECTED DATA and EXCEPTIONS options, the statement writes rejected rows and exceptions and to separate files. The respective files contain all rejected rows and corresponding exceptions, respectively, regardless of how many input files were loaded.

Note: Because COPY LOCAL (and COPY LOCAL FROM STDIN) must write any rejected rows and exceptions to the client, you cannot use the [ON nodename] clause with either the rejected data or exceptions options.

Specifying Rejected Data and Exceptions Files

To save any rejected data and their exceptions to files:

1. In the COPY LOCAL (and COPY LOCAL FROM STDIN) statement, use the REJECTED DATA 'path' and the EXCEPTIONS 'path' parameters, respectively.
2. Specify two different file names for the two options. You cannot use one file for both the REJECTED DATA and the EXCEPTIONS.
3. When you invoke COPY LOCAL or COPY LOCAL FROM STDIN, the files you specify need not pre-exist. If they do, COPY LOCAL must be able to overwrite them.

You can specify the path and file names with vsql variables:

```
\set rejected ../except_reject/copyLocal.rejected  
\set exceptions ../except_reject/copyLocal.exceptions
```

Note: Using COPY LOCAL does not support storing rejected data in a table, as you can when using the COPY statement.

When you use the COPY LOCAL or COPY LOCAL FROM STDIN statement, specify the variable names for the files with their corresponding parameters:

```
=> COPY large_tbl FROM LOCAL rejected data :rejected exceptions :exceptions;  
=> COPY large_tbl FROM LOCAL STDIN rejected data :rejected exceptions :exceptions;
```

Referential Integrity Load Violation

Vertica checks for constraint violations during query execution. It checks for violations during load operations only if you enable primary or unique key enforcement. In this case, Vertica checks for referential integrity constraint violations when loading data.

If Vertica detects a referential integrity constraint violation, the load rolls back and Vertica returns an error.

See Also

- [Detecting Constraint Violations with ANALYZE_CONSTRAINTS](#)
- [COPY](#)
- [ANALYZE_CONSTRAINTS](#)

Trickle Loading Data

After an initial bulk data load is complete, use `COPY . . . TRICKLE` to load data incrementally with new and changed data.

By default, your database uses transaction isolation level `READ COMMITTED`. Using this isolation level has these benefits:

- Users can see the most recently committed data without holding any locks.
- New data can be loaded while concurrent queries are running.

See [Change Transaction Isolation Levels](#).

Using INSERT, UPDATE, and DELETE

DML statements `INSERT`, `UPDATE`, and `DELETE` perform the same functions that they do in any ACID compliant database. `INSERT` is typically used to load individual rows into physical memory or load a table using an `INSERT AS SELECT` clause. `UPDATE` and `DELETE` are used to modify the data.

You can intermix `INSERT`, `UPDATE`, and `DELETE`. Vertica follows the SQL-92 transaction model. In other words, you do not have to explicitly start a transaction but you must use a `COMMIT` or `ROLLBACK` command (or `COPY`) to end a transaction. If you cancel a DML statement, Vertica rolls back the statement.

Vertica differs from traditional databases in two ways:

- `DELETE` does not actually delete data from disk storage; it marks rows as deleted so they are available for historical queries.
- `UPDATE` writes two rows: one with new data and one marked for deletion.

Unless you specify otherwise, `INSERT`, `UPDATE` and `DELETE` statements write data to the WOS. On overflow, the statements write data to the ROS.

Tip: For large `INSERT` or `UPDATE` operations, use the `DIRECT` hint. This hint forces Vertica to load all data directly to ROS. Loading large number of rows as single row inserts is not recommended for performance reasons. Instead, use `COPY`.

Use of WOS for Trickle Loads

During trickle loading, the WOS (node memory) permits the Vertica to efficiently batch small data loads into larger ones for I/O purposes. Loading to WOS is significantly faster than loading to disk, but it has size constraints. To help balance speed, memory size, and data flow, trickle loading defers the work of sorting, encoding, and writing to disk. The Tuple Mover's moveout process performs those tasks in the background when a table or DML operation uses trickle loading as its [load method](#).

WOS capacity is significantly less than ROS. When incoming data exceeds WOS capacity, Vertica spills small loads directly to disk. While no data is lost when the WOS gets full and spills to ROS, it can result in wasted I/O bandwidth. For optimal performance, follow the guidelines described in [Managing the Tuple Mover](#) to avoid WOS overflow.

If the WOS becomes full, before the tuple mover can move data to ROS, the entire load fails and is rolled back.

Importing and Exporting Data Across Databases

Vertica can easily import data from and export data to other Vertica databases. Importing and exporting data is useful for common tasks such as moving data back and forth between a development or test database and a production database, or between databases that have different purposes but need to share data on a regular basis.

Moving Data Directly Between Databases

Use the following statements move data to and from another Vertica database:

- [COPY FROM VERTICA](#)
- [EXPORT TO VERTICA](#)

To execute either of these statements requires first creating a connection to the other Vertica database.

Creating SQL Scripts to Export Data

Three functions return a SQL script you can use to export database objects to recreate elsewhere:

- [EXPORT_CATALOG](#)
- [EXPORT_OBJECTS](#)
- [EXPORT_TABLES](#)

While copying and exporting data is similar to [Backing Up and Restoring the Database](#), you should use them for different purposes, outlined below:

Task	Backup and Restore	COPY and EXPORT Statements
Back up or restore an entire database, or	YES	NO

Task	Backup and Restore	COPY and EXPORT Statements
incremental changes		
Manage database objects (a single table or selected table rows)	YES	YES
Use external locations to back up and restore your database	YES	NO
Use direct connections between two databases	NO	YES
Use external shell scripts to back up and restore your database	YES	NO
Use SQL commands to incorporate copy and export tasks into DB operations	NO	YES

The following sections explain how you import and export data between Vertica databases.

When importing from or exporting to a Vertica database, you can connect only to a database that uses trusted- (username-only) or password-based authentication, as described in [Security and Authentication](#). SSL authentication is not supported.

Other Exports

This section is about exporting data to another Vertica database. For information about exporting data to Parquet files in HDFS, see [Exporting Data](#) in [Integrating with Apache Hadoop](#).

Exporting Data to Another Vertica Database

You can export a table, specific columns in a table, or the results of a [SELECT](#) statement to another Vertica database. The table in the target database receiving the exported data must already exist, and have columns that match (or can be coerced to) the data types of the columns you are exporting.

You can import data from an earlier Vertica release, if the earlier release is a version of the last major release before the target database release.

Exported data is always written in AUTO mode. For details, see [Choosing a Load Method](#).

Export Process

Exporting is a three-step process:

1. **CONNECT** connects to the target database.

Caution: The export operation fails if either side of the connection is a single-node cluster installed to `localhost`, or you do not specify a host name or IP address.

2. **EXPORT TO VERTICA** exports the data. You can export only one table at a time. Use multiple **EXPORT** statements to export multiple tables or the results of multiple **SELECT** statements. All statements use the same connection to the target database.
3. **DISCONNECT** disconnects from the target database when the export operation is complete.

Exporting Identity Columns

You can export tables (or columns) that contain identity and auto-increment values, but the sequence values are not incremented automatically at the target table. You must use **ALTER SEQUENCE** to make updates.

Export identity (and auto-increment) columns as follows:

- If both source and destination tables have an identity column and configuration parameter `CopyFromVerticaWithIdentity` is set to `true` (1), you do not need to list them.
- If source table has an identity column, but target table does not, you must explicitly list the source and target columns.

Caution: Failure to list which identity columns to export can cause an error, because the identity column will be interpreted as missing in the destination table.

By default, **EXPORT TO VERTICA** exports all identity columns. To disable this behavior globally, set the `CopyFromVerticaWithIdentity` configuration parameter.

Exporting GEOMETRY and GEOGRAPHY Data Types

You can export columns containing Vertica [geospatial data types](#). Vertica supports the following export methods for these data types:

Export/Copy Support	Target version: 8.0 SP1 and later	Target version: Previous
Source version: 8.0 SP1 and later	Export/Copy	Export
Source version: Previous	Copy	Not supported

Examples of Exporting Data

The following example demonstrates using the three-step process listed above to export data.

First, open the connection to the other database, then perform a simple export of an entire table to an identical table in the target database.

```
=> CONNECT TO VERTICA testdb USER dbadmin PASSWORD '' ON 'VertTest01',5433;
CONNECT
=> EXPORT TO VERTICA testdb.customer_dimension FROM customer_dimension;
Rows Exported
-----
                23416
(1 row)
```

The following statement demonstrates exporting a portion of a table using a simple [SELECT](#) statement.

```
=> EXPORT TO VERTICA testdb.ma_customers AS SELECT customer_key, customer_name, annual_income
FROM customer_dimension WHERE customer_state = 'MA';
Rows Exported
-----
                3429
(1 row)
```

This statement exports several columns from one table to several different columns in the target database table using column lists. Remember that when supplying both a source and destination column list, the number of columns must match.

```
=> EXPORT TO VERTICA testdb.people (name, gender, age) FROM customer_dimension
(customer_name, customer_gender, customer_age);
```

```
Rows Exported
-----
          23416
(1 row)
```

You can also use `EXPORT TO VERTICA` with a `SELECT AT EPOCH LATEST` expression to include data from the latest committed DML transaction.

Disconnect from the database when the export is complete:

```
=> DISCONNECT testdb;
DISCONNECT
```

Note: Closing your session also closes the database connection. However, it is a good practice to explicitly close the connection to the other database, both to free up resources and to prevent issues with other SQL scripts you may run in your session. Always closing the connection prevents potential errors if you run a script in the same session that attempts to open a connection to the same database, since each session can only have one connection to a particular database at a time.

Copying Data from Another Vertica Database

You can import a table or specific columns in a table from another Vertica database. The table receiving the copied data must already exist, and have columns that match (or can be coerced into) the data types of the columns you are copying from the other database. You can import data from an earlier Vertica release, if the earlier release is a version of the last major release before the target database release.

Import Process

Importing is a three-step process:

1. `CONNECT` connects to the database that contains the data to import.

Note: The import operation fails if either side of the connection is a single-node cluster installed to `localhost`, or you do not specify a host name or IP address.

2. [COPY FROM VERTICA](#) imports table data to the target database. To import data from multiple tables, issue multiple `COPY FROM VERTICA` statements using the same connection to the source database.
3. [DISCONNECT](#) disconnects from the source database when the copy operation is complete.

Importing Identity Columns

You can import identity (and auto-increment) columns as follows:

- If both source and destination tables have an identity column and configuration parameter `CopyFromVerticaWithIdentity` is set to true (1), you do not need to list them.
- If source table has an identity column, but target table does not, you must explicitly list the source and target columns.

Caution: Failure to list which identity columns to export can cause an error, because the identity column will be interpreted as missing in the destination table.

After importing the columns, the identity column values do not increment automatically. Use [ALTER SEQUENCE](#) to make updates.

The default behavior for this statement is to import Identity (and Auto-increment) columns by specifying them directly in the source table. To disable this behavior globally, set the `CopyFromVerticaWithIdentity` configuration parameter, described in [Configuration Parameters](#).

Examples

This example demonstrates connecting to another database, copying the contents of an entire table from the source database to an identically-defined table in the current database directly into ROS, and then closing the connection:

```
=> CONNECT TO VERTICA vmart USER dbadmin PASSWORD '' ON 'VertTest01',5433;
CONNECT
=> COPY customer_dimension FROM VERTICA vmart.customer_dimension DIRECT;
  Rows Loaded
-----
          500000
(1 row)
=> DISCONNECT vmart;
DISCONNECT
```

This example demonstrates copying several columns from a table in the source database into a table in the local database:

```
=> CONNECT TO VERTICA vmart USER dbadmin PASSWORD '' ON 'VertTest01',5433;
CONNECT
=> COPY people (name, gender, age) FROM VERTICA
-> vmart.customer_dimension (customer_name, customer_gender,
-> customer_age);
Rows Loaded
-----
      500000
(1 row)
=> DISCONNECT vmart;
DISCONNECT
```

Changing Node Export Addresses

You can change the export address for your Vertica cluster. You might need to do so to export data between clusters in different network subnets.

1. Create a subnet for importing and exporting data between Vertica clusters. The CREATE SUBNET statement identifies the public network IP addresses residing on the same subnet.

```
=> CREATE SUBNET kv_subnet with '10.10.10.0';
```

2. Alter the database to specify the subnet name of a public network for import/export.

```
=> ALTER DATABASE VMartDB EXPORT ON kv_subnet;
```

3. Create network interfaces for importing and exporting data from individual nodes to other Vertica clusters. The CREATE NETWORK INTERFACE statement identifies the public network IP addresses residing on multiple subnets.

```
=> CREATE NETWORK INTERFACE kv_node1 on v_VMartDB_node0001 with '10.10.10.1';
=> CREATE NETWORK INTERFACE kv_node2 on v_VMartDB_node0002 with '10.10.10.2';
=> CREATE NETWORK INTERFACE kv_node3 on v_VMartDB_node0003 with '10.10.10.3';
=> CREATE NETWORK INTERFACE kv_node4 on v_VMartDB_node0004 with '10.10.10.4';
```

For users on Amazon Web Services (AWS) or using Network Address Translation (NAT), refer to [Vertica on Amazon Web Services](#).

4. Alter the node settings to change the export address. When used with the EXPORT ON clause, the ALTER NODE specifies the network interface of the public network on individual

nodes for importing and exporting data.

```
=> ALTER NODE v_VMartDB_node0001 export on kv_node1;  
=> ALTER NODE v_VMartDB_node0002 export on kv_node2;  
=> ALTER NODE v_VMartDB_node0003 export on kv_node3;  
=> ALTER NODE v_VMartDB_node0004 export on kv_node4;
```

5. Verify if the node address and the export address are different on different network subnets of the Vertica cluster.

```
=> SELECT node_name, node_address, export_address FROM nodes;  
   node_name      | node_address      | export_address  
-----+-----+-----  
v_VMartDB_node0001 | 192.168.100.101 | 10.10.10.1  
v_VMartDB_node0002 | 192.168.100.102 | 10.10.10.2  
v_VMartDB_node0003 | 192.168.100.103 | 10.10.10.3  
v_VMartDB_node0004 | 192.168.100.104 | 10.10.10.4
```

Creating a network interface and altering the node settings to change the export address takes precedence over creating a subnet and altering the database for import/export.

Using Public and Private IP Networks

In many configurations, Vertica cluster hosts use two network IP addresses as follows:

- A private address for communication between the cluster hosts.
- A public IP address for communication with client connections.

By default, importing from and exporting to another Vertica database uses the private network.

Note: Ensure port 5433 or the port the Vertica database is using is not blocked.

To use the public network address for copy and export activities, as well as moving large amounts of data, configure the system to use the public network to support exporting to or importing from another Vertica cluster:

- [Identify the Public Network to Vertica](#)
- [Identify the Database or Nodes Used for Import/Export](#)

In certain instances, both public and private addresses exceed the demand capacity of a single Local Area Network (LAN). If you encounter this type of scenario, then configure your Vertica cluster to use two LANs: one for public network traffic and one for private network traffic.

Identify the Public Network to Vertica

To be able to import to or export from a public network, Vertica needs to be aware of the IP addresses of the nodes or clusters on the public network that will be used for import/export activities. Your public network might be configured in either of these ways:

- Public network IP addresses reside on the same subnet (create a subnet)
- Public network IP addresses are on multiple subnets (create a network interface)

To identify public network IP addresses residing on the same subnet:

- Use the [CREATE SUBNET](#) statement provide your subnet with a name and to identify the subnet routing prefix.

To identify public network IP addresses residing on multiple subnets:

- Use the [CREATE NETWORK INTERFACE](#) statement to configure import/export from specific nodes in the Vertica cluster.

After you've identified the subnet or network interface to be used for import/export, you must [Identify the Database Or Nodes Used For Import/Export](#).

See Also

- [CREATE SUBNET](#)
- [ALTER SUBNET](#)
- [DROP SUBNET](#)
- [CREATE NETWORK INTERFACE](#)
- [ALTER NETWORK INTERFACE](#)
- [DROP NETWORK INTERFACE](#)

Identify the Database or Nodes Used for Import/Export

After you identify the public network to Vertica, you can configure a database and its nodes to use it for import and export operations:

- Use [ALTER DATABASE](#) to specify a subnet on the public network for the database. After doing so,, all nodes in the database automatically use the network interface on the subnet for import/export operations.
- On each database node, use [ALTER NODE](#) to specify a network interface of the public network.

See Also

- [CREATE PROCEDURE](#)
- [CREATE NETWORK INTERFACE](#)
- [V_MONITOR.NETWORKINTERFACES](#)

Handling Node Failure During Copy/Export

When an export (`EXPORT TO VERTICA`) or import from Vertica (`COPY FROM VERTICA`) task is in progress, and a non-initiator node fails, Vertica does not complete the task automatically. A non-initiator node is any node that is not the source or target node in your export or import statement. To complete the task, you must run the statement again.

You address the problem of a non-initiator node failing during an import or export as follows:

Note: Both Vertica databases must be running in a safe state.

1. You export or import from one cluster to another using the `EXPORT TO VERTICA` or `COPY FROM VERTICA` statement.

During the export or import, a non-initiating node on the target or source cluster fails. Vertica issues an error message that indicates possible node failure, one of the following:

- `ERROR 4534: Receive on v_tpchdb1_node0002: Message receipt from v_tpchdb2_node0005 failed`
 - `WARNING 4539: Received no response from v_tpchdb1_node0004 in abandon plan`
 - `ERROR 3322: [tpchdb2] Execution canceled by operator`
2. Complete your import or export by running the statement again. The failed node does not need to be up for Vertica to successfully complete the export or import.

Using EXPORT Functions

Vertica provides several `EXPORT_` functions that let you recreate a database, or specific schemas and tables, in a target database. For example, you can use the `EXPORT_` functions to transfer some or all of the designs and objects you create in a development or test environment to a production database.

The `EXPORT_` functions create SQL scripts that you can run to generate the exported database designs or objects. These functions serve different purposes to the export statements, [COPY FROM VERTICA](#) (pull data) and [EXPORT TO VERTICA](#) (push data). These statements transfer data directly from source to target database across a network connection between both. They are dynamic actions and do not generate SQL scripts.

The `EXPORT_` functions appear in the following table. Depending on what you need to export, you can use one or more of the functions. `EXPORT_CATALOG` creates the most comprehensive SQL script, while `EXPORT_TABLES` and `EXPORT_OBJECTS` are subsets of that function to narrow the export scope.

Use this function...	To recreate...
EXPORT_CATALOG	These catalog items: <ul style="list-style-type: none">• An existing schema design, tables, projections, constraints, and views• The Database Designer-created schema design, tables, projections, constraints, and views• A design on a different cluster.
EXPORT_TABLES	Non-virtual objects up to, and including, the schema of one or more tables.
EXPORT_OBJECTS	Catalog objects in order dependency for replication.

The designs and object definitions that the script creates depend on the `EXPORT_` function scope you specify. The following sections give examples of the commands and output for each function and the scopes it supports.

Saving Scripts for Export Functions

All of the examples in this section were generated using the standard Vertica VMART database, with some additional test objects and tables. One output directory was created for all SQL scripts that the functions created:

```
/home/dbadmin/xtest
```

If you specify the destination argument as an empty string (' '), the function writes the export results to STDOUT.

Note: A superuser can export all available database output to a file with the EXPORT_ functions. For a non-superuser, the EXPORT_ functions generate a script containing only the objects to which the user has access.

Exporting the Catalog

The function [EXPORT_CATALOG](#) generates a SQL script for copying a database design to another cluster. This script replicates the physical schema design of the source database. You call this function as follows:

```
EXPORT_CATALOG ( [ 'destination' ] , [ 'scope' ] )
```

Note: This function and [EXPORT_OBJECTS](#) return equivalent output.

Setting Scope of Export

You can set the scope of the export operation to various levels:

To export...	Use this scope...
Schemas, tables, constraints, views, and projections	DESIGN (default)
All design objects and system objects created in Database Designer, such as design contexts and their tables	DESIGN ALL
Only tables, constraints, and projection	TABLES

Exporting All Catalog Objects

Use the DESIGN scope to export all design elements of a source database in order dependency. This scope exports all catalog objects in their OID (unique object ID) order, including schemas, tables, constraints, views, and all types of projections. This is the most comprehensive export scope, without the Database Designer elements, if they exist.

```
=> SELECT EXPORT_CATALOG(  
      '/home/dbadmin/xtest/sql_cat_design.sql',  
      'DESIGN' );  
      EXPORT_CATALOG  
-----  
Catalog data exported successfully  
(1 row)
```

The SQL script includes the following types of statements, each needed to recreate a new database:

- CREATE SCHEMA
- CREATE TABLE
- CREATE VIEW
- CREATE SEQUENCE
- CREATE PROJECTION (with ORDER BY and SEGMENTED BY)
- ALTER TABLE (to add constraints)
- PARTITION BY

Projection Considerations

If a projection to export was created with no ORDER BY clause, the SQL script reflects the default behavior for projections. Vertica implicitly creates projections using a sort order based on the SELECT columns in the projection definition. The EXPORT_CATALOG script reflects this behavior.

The EXPORT_CATALOG script is portable if all projections were generated using UNSEGMENTED ALL NODES or SEGMENTED ALL NODES.

Exporting Database Designer Schema and Designs

Use the DESIGN ALL scope to generate a script to recreate all design elements of a source database and the design and system objects that were created by the Database Designer:

```
=> SELECT EXPORT_CATALOG (  
    '/home/dbadmin/xtest/sql_cat_design_all.sql',  
    'DESIGN_ALL');  
    EXPORT_CATALOG  
-----  
Catalog data exported successfully  
(1 row)
```

Exporting Table Objects

Use the TABLES scope to generate a script to recreate all schemas tables, constraints, and sequences:

```
=> SELECT EXPORT_CATALOG (  
    '/home/dbadmin/xtest/sql_cat_tables.sql',  
    'TABLES');  
    EXPORT_CATALOG  
-----  
Catalog data exported successfully  
(1 row)
```

The SQL script includes the following types of statements:

- CREATE SCHEMA
- CREATE TABLE
- ALTER TABLE (to add constraints)
- CREATE SEQUENCE

See Also

- [EXPORT_CATALOG](#)
- [EXPORT_OBJECTS](#)
- [EXPORT_TABLES](#)

- [Exporting Tables](#)
- [Exporting Objects](#)

Exporting Tables

Use the Vertica function [EXPORT_TABLES](#) to recreate one or more tables, and related non-virtual objects, on a different cluster. `EXPORT_TABLES` has the following syntax:

```
EXPORT_TABLES( [ 'destination' ] [, 'scope' ] )
```

Setting Scope of Export

You can set the scope of the export operation to various levels:

To export...	Use this scope...
All objects to which the user has access, including constraints.	An empty string (' ')
One or more named objects, such as tables or sequences in one or more schemas. You can optionally qualify the schema with a database prefix, <code>myvertica.myschema.newtable</code> .	A comma-delimited list of table objects. For example: <code>'myschema.newtable, yourschema.oldtable'</code>
A named table object in the current search path. You can specify a schema, table, or sequence. If you specify a schema, <code>EXPORT_TABLES</code> exports all table objects in that schema to which the user has access.	The table object's name and, optionally, its path: <code>'VMart.myschema'</code>

The SQL script includes only the non-virtual objects to which the current user has access.

Note: `EXPORT_TABLES` does not export views. If you specify a view name, Vertica silently ignores it and the view is omitted from the generated script. To export views, use [EXPORT_OBJECTS](#).

Exporting All Table Objects

If you set the scope parameter to an empty string (' '), Vertica exports all tables and their related objects:

```
=> SELECT EXPORT_TABLES(  
    '/home/dbadmin/xtest/sql_tables_empty.sql',  
    '');  
    EXPORT_TABLES  
-----  
Catalog data exported successfully  
(1 row)
```

The SQL script includes the following types of statements, depending on what is required to recreate the tables and any related objects (such as sequences):

- CREATE SCHEMA
- CREATE TABLE
- ALTER TABLE (to add constraints)
- CREATE SEQUENCE
- PARTITION BY

Exporting a List of Tables

Use EXPORT_TABLE with a comma-separated list of objects, including tables, views, or schemas:

```
=> SELECT EXPORT_TABLES(  
    '/home/dbadmin/xtest/sql_tables_del.sql'  
    'public.student, public.test7');  
    EXPORT_TABLES  
-----  
Catalog data exported successfully  
(1 row)
```

The SQL script can include the following types of statements, depending on what is required to recreate the exported objects:

- CREATE SCHEMA
- CREATE TABLE
- ALTER TABLE (to add constraints)
- CREATE SEQUENCE

Exporting a Single Table Object

Use `EXPORT_TABLES` to export one or more database table objects.

This example exports a named sequence, `my_seq`, qualifying the sequence with the schema name (`public`):

```
=> SELECT EXPORT_TABLES(  
      '/home/dbadmin/xtest/export_one_sequence.sql',  
      'public.my_seq');  
      EXPORT_TABLES  
-----  
Catalog data exported successfully  
(1 row)
```

Following are the contents of the `export_one_sequence.sql` output file using a more command:

```
$ more export_one_sequence.sql  
CREATE SEQUENCE public.my_seq ;
```

See Also

[Exporting Objects](#)

Exporting Objects

The Vertica function `EXPORT_OBJECTS` generates a SQL script that you can use to recreate non-virtual catalog objects on a different cluster, as follows:

```
EXPORT_OBJECTS( [ 'destination' ] [, 'scope' ] [, 'ksafe' ] )
```

Note: This function and `EXPORT_CATALOG` return equivalent output.

Setting Scope of Export

You can set the scope of the export operation to various levels:

To export...	Use this scope...
All non-virtual objects to which the user has access, including constraints.	An empty string (' ')

To export...	Use this scope...
One or more named objects, such as tables or views in one or more schemas. You can optionally qualify the schema with a database prefix, <code>myvertica.myschema.newtable</code> .	A comma-delimited list of items. For example: <code>'myschema.newtable, yourschema.oldtable'</code>
A named database object in the current search path. You can specify a schema, table, or view. If the object is a schema, the script includes objects to which the user has access.	The table object's name and, optionally, its path: <code>'VMart.myschema'</code>

The SQL script includes only the non-virtual objects to which the current user has access.

`EXPORT_OBJECTS` always tries to recreate projection statements with their `KSAFE` clauses, if any; otherwise, with their `OFFSET` clauses.

Function Syntax

```
EXPORT_OBJECTS( [ 'destination' ] , [ 'scope' ] , [ 'ksafe' ] )
```

Exporting All Objects

If you set the `scope` parameter to an empty string (`' '`), Vertica exports all non-virtual objects from the source database in order dependency. Running the generated SQL script on another cluster creates all referenced objects and their dependent objects.

By default, the function's `KSAFE` argument is set to `true`. In this case, the generated script calls `MARK_DESIGN_KSAFE`, which propagates the K-safety setting of the original database.

```
=> SELECT EXPORT_OBJECTS(
      '/home/dbadmin/xtest/sql_objects_all.sql',
      '',
      'true');
      EXPORT_OBJECTS
-----
Catalog data exported successfully
(1 row)
```

The SQL script includes the following types of statements:

- CREATE SCHEMA
- CREATE TABLE

- CREATE VIEW
- CREATE SEQUENCE
- CREATE PROJECTION (with ORDER BY and SEGMENTED BY)
- ALTER TABLE (to add constraints)
- PARTITION BY

Here is a snippet that includes the start and end of the output SQL file, including the MARK_DESIGN_KSAFE statement:

```
CREATE SCHEMA store;
CREATE SCHEMA online_sales;
CREATE SEQUENCE public.my_seq ;
CREATE TABLE public.customer_dimension
(
    customer_key int NOT NULL,
    customer_type varchar(16),
    customer_name varchar(256),
    customer_gender varchar(8),
    title varchar(8),
    household_id int,
    ...
);
.
.
.
SELECT MARK_DESIGN_KSAFE(1);
```

Exporting a List of Objects

Use a comma-separated list of objects as the function scope. The list can include one or more tables, sequences, and views in the same, or different schemas, depending on how you qualify the object name. For instance, specify a table from one schema, and a view from another (schema2.view1).

The SQL script includes the following types of statements, depending on what objects you include in the list:

- CREATE SCHEMA
- CREATE TABLE
- ALTER TABLE (to add constraints)

- CREATE VIEW
- CREATE SEQUENCE

If you specify a view without its dependencies, the function displays a WARNING. The SQL script includes a CREATE statement for the dependent object, but will be unable to create it without the necessary relations:

```
=> SELECT EXPORT_OBJECTS(  
      'nameObjectsList',  
      'test2, tt, my_seq, v2' );  
WARNING 0: View public.v2 depends on other relations  
      EXPORT_OBJECTS  
-----  
      Catalog data exported successfully  
(1 row)
```

This example explicitly sets the *ksafe* argument explicitly to true.

```
=> SELECT EXPORT_OBJECTS(  
      '/home/dbadmin/xtest/sql_objects_table_view_KSAFE.sql',  
      'v1, test7',  
      'true');  
      EXPORT_OBJECTS  
-----  
      Catalog data exported successfully  
(1 row)
```

Here are the contents of the output file of the example, showing the sample table test7 and the v1 view:

```
CREATE TABLE public.test7  
(  
  a int,  
  c int NOT NULL DEFAULT 4,  
  bb int  
);  
CREATE VIEW public.v1 AS  
  SELECT tt.a  
  FROM public.tt;  
  
SELECT MARK_DESIGN_KSAFE(1);
```

Exporting a Single Object

Specify a single database object as the function scope. The object can be a schema, table, sequence, or view. The function exports all non-virtual objects associated with the one you specify.

```
=> SELECT EXPORT_OBJECTS(  
      '/home/dbadmin/xtest/sql_objects_viewobject_KSAFE.sql',  
      'v1',  
      'true');  
      EXPORT_OBJECTS  
-----  
Catalog data exported successfully  
(1 row)
```

The output file contains the v1 view:

```
CREATE VIEW public.v1 AS  
  SELECT tt.a  
  FROM public.tt;  
  
SELECT MARK_DESIGN_KSAFE(1);
```

[Exporting Tables](#)

Managing Storage Locations

Vertica *storage locations* are the paths to file destinations you designate to store data and temporary files. Every node in the cluster requires at least one area in which to store data and another separate area in which to store database catalog files. You set up these locations as part of installation and setup. (See [Prepare Disk Storage Locations](#) in Installing Vertica for disk space requirements.)

Important: While no technical issue prevents you from using `CREATE LOCATION` to add one or more Network File System (NFS) storage locations, Vertica does not support NFS data or catalog storage except for MapR mount points. You will be unable to run queries against any other NFS data. When creating locations on MapR file systems, you must specify `ALL NODES SHARED`.

How Vertica Uses Storage Locations

Every time you add data to the database or perform a DML operation, the new data is held in memory (WOS) and moved to storage locations on disk (ROS) at regular intervals. Depending on the configuration of your database, many ROS containers are likely to exist.

You can label the storage locations you create to reference them in object storage policies. If an object to store has no associated storage policy, Vertica uses the available storage location and default storage algorithms to store data. If the object has a storage policy, Vertica stores the data at the object's designated storage location. See [Creating Storage Policies](#). If you no longer need a storage location, you can retire or drop it, as described in [Retiring Storage Locations](#) and [Dropping Storage Locations](#).

Comparing Local and Shared Storage Locations

You can define two types of storage locations:

- **Local**—Stores data in a unique location for each node. Local is the default for a storage location. You do not have to specify it explicitly. This location is in a directory in a file system that the node can access, and is often in the node's own file system. You can create a local

storage location for a single node or for all nodes in the cluster. Cluster-wide storage locations are the most common type of storage. Vertica defaults to using a local cluster-wide storage location for storing all data. If you want it to store data differently, you must create additional storage locations.

- **Shared**—Stores data on a single file system to which all nodes in the cluster have access. This shared file system is often hosted outside of the cluster, such as on a distributed file system like HDFS. When you create a shared storage location, each node in the Vertica cluster creates its own subdirectory in the location. The separate directories prevent nodes from overwriting each other's data. Currently, Vertica supports only HDFS shared storage locations. You cannot use NFS as a Vertica shared storage location except when using MapR mount points. See [Vertica Storage Location for HDFS](#) in Integrating with Apache Hadoop for more information.

Viewing Storage Locations and Policies

You can monitor information about available storage location labels and your current storage policies.

Viewing Disk Storage Information

Query the [V_MONITOR.DISK_STORAGE](#) system table for disk storage information on each database node. For more information, see [Using System Tables](#) and [Altering Location Use](#). The [V_MONITOR.DISK_STORAGE](#) system table includes a CATALOG annotation, indicating that the location is used to store catalog files.

Note: You cannot add or remove a catalog storage location. Vertica creates and manages this storage location internally, and the area exists in the same location on each cluster node.

Viewing Location Labels

Three system tables have information about storage location labels in their `location_labels` columns:

- `storage_containers`
- `storage_locations`
- `partitions`

Use a query such as the following for relevant columns of the `storage_containers` system table:

```
VMART=> select node_name,projection_name, location_label from v_monitor.storage_containers;
node_name      | projection_name | location_label
-----+-----+-----
v_vmart_node0001 | states_p       |
v_vmart_node0001 | states_p       |
v_vmart_node0001 | t1_b1          |
v_vmart_node0001 | newstates_b0  | FAST3
v_vmart_node0001 | newstates_b0  | FAST3
v_vmart_node0001 | newstates_b1  | FAST3
v_vmart_node0001 | newstates_b1  | FAST3
v_vmart_node0001 | newstates_b1  | FAST3
.
.
.
```

Use a query such as the following for columns of the `v_catalog.storage_locations` system table:

```
VMart=> select node_name, location_path, location_usage, location_label from storage_locations;
node_name      | location_path   | location_usage | location_label
-----+-----+-----+-----
v_vmart_node0001 | /home/dbadmin/VMart/v_vmart_node0001_data | DATA,TEMP    |
v_vmart_node0001 | home/dbadmin/SSD/schemas | DATA         |
v_vmart_node0001 | /home/dbadmin/SSD/tables | DATA         | SSD
v_vmart_node0001 | /home/dbadmin/SSD/schemas | DATA         | Schema
v_vmart_node0002 | /home/dbadmin/VMart/v_vmart_node0002_data | DATA,TEMP    |
v_vmart_node0002 | /home/dbadmin/SSD/tables | DATA         |
v_vmart_node0002 | /home/dbadmin/SSD/schemas | DATA         |
v_vmart_node0003 | /home/dbadmin/VMart/v_vmart_node0003_data | DATA,TEMP    |
v_vmart_node0003 | /home/dbadmin/SSD/tables | DATA         |
v_vmart_node0003 | /home/dbadmin/SSD/schemas | DATA         |
(10 rows)
```

Use a query such as the following for columns of the `v_monitor.partitions` system table:

```
VMART=> select partition_key, projection_name, location_label from v_monitor.partitions;
partition_key | projection_name | location_label
-----+-----+-----
NH            | states_b0      | FAST3
MA            | states_b0      | FAST3
VT            | states_b1      | FAST3
ME            | states_b1      | FAST3
CT            | states_b1      | FAST3
.
.
```

Viewing Storage Tiers

Query the `storage_tiers` system table to see both the labeled and unlabeled storage containers and information about them:

```
VMart=> select * from v_monitor.storage_tiers;
location_label | node_count | location_count | ros_container_count | total_occupied_size
-----+-----+-----+-----+-----
SSD            |          1 |              2 |                   17 |          297039391
Schema        |          1 |              1 |                   9 |           1506
(3 rows)
```

Viewing Storage Policies

Query the `storage_policies` system table to view the current storage policy in place.

```
VMART=> select * from v_monitor.storage_policies;
schema_name | object_name | policy_details | location_label
-----+-----+-----+-----
public      | public     | Schema        | F4
public      | lineorder  | Partition [4, 4] | M3
(2 rows)
```

Creating Storage Locations

You can add and configure storage locations (other than the required defaults) to provide storage for these purposes:

- Isolating execution engine temporary files from data files.
- Creating labeled locations to use in storage policies.
- Creating storage locations based on predicted or measured access patterns.
- Creating USER storage locations for specific users or user groups.

Important: While no technical issue prevents you from using `CREATE LOCATION` to add one or more Network File System (NFS) storage locations, Vertica does not support

NFS data or catalog storage except for MapR mount points. You will be unable to run queries against any other NFS data. When creating locations on MapR file systems, you must specify `ALL NODES SHARED`.

You can add a new storage location from one node to another node or from a single node to all cluster nodes. However, do not use a shared directory on one node for other cluster nodes to access.

Planning Storage Locations

Adding a storage location requires minimal planning:

1. Verify that the directory you plan to use for a storage location destination is an empty directory with write permissions for the Vertica process.
2. Plan the labels to use if you want to label the location as you create it.
3. Determine the type of information to store in the storage location:
 - `DATA` — Persistent data and temp table data.
 - `TEMP` — Temporary files that are generated and dumped to disk, such as those generated by sort, group by, join, and so on.
 - `DATA,TEMP` — Both data and temp files (the default).
 - `USER` — Gives access to non-dbadmin users so they can use the storage location after being granted read or write privileges. You cannot assign this location type for use in a storage policy.

Tip: Storing temp and data files in different storage locations is advantageous because the two types of data have different disk I/O access patterns. Temp files are distributed across locations based on available storage space. However, data files can be stored on different storage locations, based on storage policy, to reflect predicted or measured access patterns.

If you plan to place storage locations on HDFS, see [Using HDFS Storage Locations](#) in Integrating with Apache Hadoop for additional requirements.

Creating Unlabeled Local Storage Locations

This example shows a three-node cluster, each with a `vertica/SSD` directory for storage.

On each node in the cluster, create a directory where the node stores its data. For example:

```
$ mkdir /home/dbadmin/vertica/SSD
```

Micro Focus recommends that you create the same directory path on each node. Use this path when creating a storage location.

Use the [CREATE LOCATION](#) statement to add a storage location. Specify the following information:

- The path on the node where Vertica stores the data.
- The node where the location is available, or `ALL NODES`.

Important: Specify the node or use the `ALL NODES` keyword. Otherwise, the statement creates the storage locations on all nodes in the cluster in a single transaction.

- The type of information to be stored.

For user access (non-dbadmin users), you must create the storage location with the `USER` usage type. You cannot change an existing storage location to have `USER` access. After you create a `USER` storage location, you can grant one or more users access to it. User areas can store only data files, not temp files. You cannot assign a `USER` storage location to a storage policy.

The following example shows how to add a location available on all nodes to store only data:

```
CREATE LOCATION '/home/dbadmin/vertica/SSD/' ALL NODES USAGE 'DATA';
```

The following example shows how to add a location that is available on node `v_vmart_node0001` to store data and temporary files:

```
CREATE LOCATION '/home/dbadmin/vertica/SSD/' NODE 'v_vmart_node0001';
```

Suppose you are using a storage location for data files and want to create ranked storage locations. In this ranking, columns are stored on different disks based on their measured performance. To create ranked storage locations, see the following sections:

1. [Measuring Storage Performance](#)
2. [Setting Storage Performance](#)

Note: After you create a storage location, you can alter the type of information it stores, with some restrictions. See [Altering Location Use](#).

Storage Location Subdirectories

You cannot create a storage location in a subdirectory of an existing location. Doing so results in an error similar to the following:

```
=> CREATE LOCATION '/tmp/myloc' ALL NODES USAGE 'TEMP';  
CREATE LOCATION  
=> CREATE LOCATION '/tmp/myloc/ssd' ALL NODES USAGE 'TEMP';  
ERROR 5615: Location [/tmp/myloc/ssd] conflicts with existing location  
[/tmp/myloc] on node v_vmart_node0001
```

Creating Labeled Storage Locations

You can add a storage location with a descriptive label using the `CREATE LOCATION` statement's `LABEL` keyword. You use labeled locations to set up storage policies for your site. See [Creating Storage Policies](#).

This example shows how to create a storage location on `v_vmart_node0002` with the label `SSD`:

```
=> CREATE LOCATION '/home/dbadmin/SSD/schemas' NODE 'v_vmart_node0002'  
USAGE 'DATA' LABEL 'SSD';
```

This example shows you how to create a storage location on all nodes. Specifying the `ALL NODES` keyword adds the storage location to all nodes in a single transaction:

```
=> CREATE LOCATION '/home/dbadmin/SSD/schemas' ALL NODES  
    USAGE 'DATA' LABEL 'SSD';
```

The new storage location is listed in the `v_monitor.disk_storage` system table:

```
=> SELECT * FROM v_monitor.disk_storage;  
. .  
-[ RECORD 7 ]-----+-----  
node_name          | v_vmart_node0002  
storage_path       | /home/dbadmin/SSD/schemas  
storage_usage      | DATA  
rank               | 0  
throughput         | 0  
latency            | 0  
storage_status     | Active  
disk_block_size_bytes | 4096  
disk_space_used_blocks | 1549437  
disk_space_used_mb  | 6053  
disk_space_free_blocks | 13380004  
disk_space_free_mb  | 52265  
disk_space_free_percent | 89%  
. . .
```

Creating a Storage Location for USER Access

You can create USER storage locations for a non-dbadmin user to access the storage location after being granted appropriate privileges.

The following example shows how to create a storage location, `BillyBobStore`, with a USER usage argument, on node `v_mcdb_node0007`:

```
=> CREATE LOCATION '/home/dbadmin/UserStorage/BillyBobStore' NODE  
    'v_mcdb_node0007' USAGE 'USER';
```

The following example shows how to grant a user `BillyBob` read and write permissions to the `BillyBobStore` location:

```
=> GRANT ALL ON LOCATION '/home/dbadmin/UserStorage/BillyBobStore' TO BillyBob;  
GRANT PRIVILEGE
```

For more information about configuring user privileges, see [Managing Users and Privileges](#) in the Administrator's Guide and the [GRANT \(Storage Location\)](#) and [REVOKE \(Storage Location\)](#) functions in the SQL Reference Manual.

Altering Location Use

You can make changes to the type of files that Vertica stores at a storage location. To modify a storage location, use the [ALTER_LOCATION_USE](#) function. Normally you use labels only for DATA storage locations, not TEMP.

This example shows how to alter the storage location on `v_vmartdb_node0004` to store only data files:

```
=> SELECT ALTER_LOCATION_USE ('/thirdVerticaStorageLocation/' , 'v_vmartdb_node0004' , 'DATA');
```

Altering HDFS Storage Locations

When altering an HDFS storage location, you must make the change for each node in the Vertica cluster. You can make the change on all nodes at the same time by specifying a node value of "", as in the following example:

```
=> SELECT ALTER_LOCATION_USE('webhdfs://hadoop:50070/user/dbadmin/v_vmart',  
    '', 'TEMP');
```

USER Storage Location Restrictions

You cannot change a storage location from a USER usage type if you created the location that way, or to a USER type if you did not. You can change a USER storage location to specify DATA (storing TEMP files is not supported). However, doing so does not affect the primary objective of a USER storage location, to be accessible by non-dbadmin users with assigned privileges.

Effects of Altering Storage Location Use

Before altering a storage location use type, be aware that at least one location must remain for storing data and temp files on a node. You can store data and temp files in the same, or separate, storage locations.

Altering an existing storage location has the following effects:

Alter use from:	To store only:	Has this effect:
Temp and data files (or data only)	Temp files	Data content is eventually merged out through ATM, per its policies. You can also merge out data from the storage location manually using DO_TM_TASK . The location stores only temp files from that point forward.
Temp and data files (or temp only)	Data files	Vertica continues to run all statements that use temp files (such as queries and loads). Subsequent statements no longer use the changed storage location for temp files, and the location stores only data files from that point forward.

Altering Location Labels

You can change the label for a storage location in the following ways:

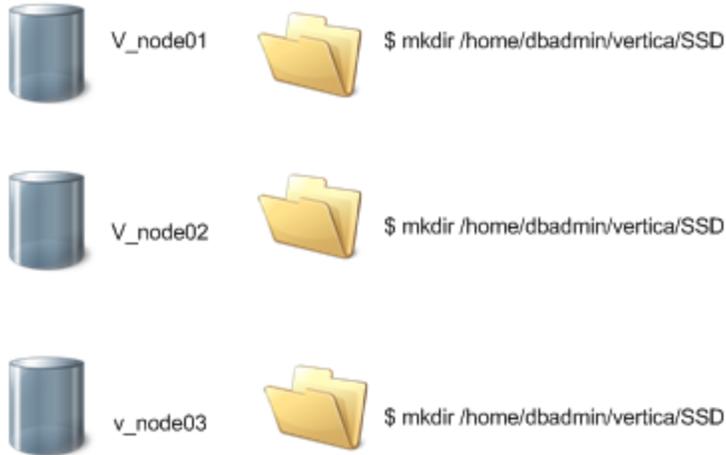

- Add a label to an unlabeled storage location.
- Change an existing label.
- Remove a label.

You can perform this operation on individual nodes (by naming them) or cluster-wide (by specifying an empty string for the node).

Important: You can label an existing storage location that already contains data. However, including the labeled location in one or more storage policies can cause the ATM to relocate existing data. This situation occurs if the ATM determines that data stored on a labeled location does not comply with a storage policy.

Adding a Location Label

To alter a location label, use the [ALTER_LOCATION_LABEL](#) function. The following figure illustrates an unlabeled location that exists on three nodes:

This example shows how to add a location label, 'SSD', to the existing storage locations on all nodes (' '):

```
=> SELECT ALTER_LOCATION_LABEL('/home/dbadmin/vertica/SSD', '', 'SSD');
```

Removing a Location Label

You cannot remove a location label if *both* of the following conditions exist:

- The name being removed is used in a storage policy
- The location from which you are removing the label is the last available storage for its associated objects

The following example removes the SSD label for the storage location on all nodes by specifying empty strings (' ') for both *node* and *location_label* parameters:

```
VMART=> select alter_location_label('/home/dbadmin/SSD/tables','', '');
          alter_location_label
-----
/home/dbadmin/SSD/tables label changed.
(1 row)
```

Effects of Altering a Location Label

Altering a location label has the following effects:

Alter label:	To:	Has this effect:
No name	New label	Lets you use the labeled storage within a storage policy. See note above regarding data storage being moved to other locations if you add a label to a storage location with existing data.
Existing name	New name	You can use the new label in a storage policy. If the existing name is used in a storage policy, you cannot change the label.
Existing name	No name	You cannot use an unlabeled storage in a storage policy. If the existing name is used in a storage policy, you cannot remove the label.

Creating Storage Policies

You create a storage policy to associate a database object with a labeled storage location. To do so, use the [SET_OBJECT_STORAGE_POLICY](#) function. When a storage policy exists, Vertica uses the labeled location as the default storage location for the object data. Storage policies let you determine where to store your critical data. For example, suppose you create a storage location with the label SSD representing the fastest available storage on the cluster nodes. You can then create storage policies to associate tables with that labeled location. One storage policy can exist per database object.

Note: You cannot include temporary files in storage policies. Storage policies are for use only with data files on storage locations for DATA. Storage policies are not valid for USER locations.

You can create a storage policy for any database object (database, schemas, tables, and partition ranges). Each time data is loaded and updated, Vertica checks to see whether the object has a storage policy. If it does, Vertica automatically uses the labeled storage location. If no storage policy exists for an object, or its parent entities, data storage processing continues using standard storage algorithms on available storage locations. If all storage locations are labeled, Vertica uses one of them.

Creating one or more storage policies does not require that policies exist for all database objects. A site can support objects with or without storage policies. You can add storage policies for a discrete set of priority objects, while letting other objects exist without a policy, so they use available storage.

Creating Policies Based on Storage Performance

You can measure the performance of any disk storage location (see [Measuring Storage Performance](#)). Then, using the performance measurements, set the storage location performance. Vertica uses the performance measurements you set to rank its storage locations and, through ranking, to determine which key projection columns to store on higher performing locations, as described in [Setting Storage Performance](#).

If you have already set the performance of your site's storage locations, and decide to use storage policies, any storage location with an associated policy has a higher priority than the storage ranking setting.

Storage Levels and Priorities

Vertica assigns storage levels to database objects. The database is the highest storage level (because nothing exists above the database level), and partition `min_` and `max_` key ranges are considered the lowest level objects. In addition to storage levels, storage priorities exist. The lower the storage level of an object, the higher its storage priority.

Consider this example of database objects, listed in storage level order, with the highest level, Sales database, first:

Object	Storage Level	Storage Policy	Storage Priority	Labeled Location
Sales (database)	Highest	YES	Lower	STANDARD
Region (schema)	Medium	NO	Medium	N/A
Income (table)	Lower	YES	Higher/highest	FAST
Month (partitions)	Lowest	NO	Highest	N/A

Storage policies exist for the database and table objects, with default storage on the locations STANDARD and FAST, respectively.

In this case, when TM operations occur, such as moveout and mergeout, table data has the highest priority. The TM moves data from WOS to ROS to the FAST labeled location.

Any schema data changes are prioritized after table data. Because the Region schema has no storage policy, Vertica searches up the storage levels for a policy. In this case, that is the Sales database itself. If a database storage policy is in effect, Region schema data is moved from

WOS to ROS to the STANDARD storage location, using its parent object's default storage location.

If the Sales database object had no storage policy, the TM operations would use existing storage locations and mechanisms.

Using the SET_OBJECT_STORAGE_POLICY Function

To set a storage policy, use the [SET_OBJECT_STORAGE_POLICY](#) function.

This example shows how to set a storage policy for the table test to use the storage labeled SSD as its default location:

```
=> select set_object_storage_policy('test','ssd', true);
set_object_storage_policy
-----
Object storage policy set.
Task: moving storages
(Table: public.test) (Projection: public.test_b0)
(Table: public.test) (Projection: public.test_b1)

(1 row)
```

You can query existing storage policies, listed in the `location_label` column of the `v_monitor.storage_containers` system table:

```
VMART=> select node_name, projection_name, storage_type, location_label from v_monitor.storage_containers;
 node_name      | projection_name | storage_type | location_label
-----|-----|-----|-----
v_vmart_node0001 | states_p       | ROS         |
v_vmart_node0001 | states_p       | ROS         |
v_vmart_node0001 | t1_b1          | ROS         |
v_vmart_node0001 | newstates_b0   | ROS         | LEVEL3
v_vmart_node0001 | newstates_b0   | ROS         | LEVEL3
v_vmart_node0001 | newstates_b1   | ROS         | LEVEL3
v_vmart_node0001 | newstates_b1   | ROS         | LEVEL3
v_vmart_node0001 | newstates_b1   | ROS         | LEVEL3
v_vmart_node0001 | states_p_v1_node0001 | ROS         | LEVEL3
v_vmart_node0001 | states_b0      | ROS         | SSD
v_vmart_node0001 | states_b0      | ROS         | SSD
v_vmart_node0001 | states_b1      | ROS         | SSD
v_vmart_node0001 | states_b1      | ROS         | SSD
v_vmart_node0001 | states_b1      | ROS         | SSD
.
```

You can use storage policies to move older data to less-expensive storage locations while keeping it available for queries. See [Creating Storage Policies for Low-Priority Data](#).

Effects of Creating Storage Policies

Creating storage policies has the following effects:

Create policy for...	Storage effect:
Database	The highest storage level and the lowest storage priority. This is the default policy when no lower-level or higher priority policies exist. At storage time, Vertica uses the database policy for all objects without storage policies.
Schema	The mid-level storage, also with a medium priority, compared to lower storage level objects. If a table's schema has no policy, the TM searches the next higher level, the database, using that policy, if it exists. If it does not, the TM uses existing storage mechanisms.
Table	A lower storage level than a schema, with the highest storage priority, if no policy exists for the table's partition key ranges. If a table has no storage policy, Vertica checks the next higher storage level (the schema) for a policy and uses that. If the schema has no policy, it checks the next higher level, the database, and uses that. If no database policy exists, the TM uses existing storage mechanisms.
Partition min_key and max_key ranges	The lowest level policy that can be in effect. During storage processing, partition key ranges with a policy have the highest priority. If no policy exists, the parent table is checked, and so on as described for the other database objects.

Creating Storage Policies for Low-Priority Data

If some of your data is in a partitioned table, you can move less-queried partitions to less-expensive storage such as HDFS. The data is still accessible in queries, just at a slower speed. In this scenario, the faster storage is often referred to as "hot storage," and the slower storage is referred to as "cold storage."

Suppose you have a table named `messages` (containing social-media messages) that is partitioned by the year and month of the message's timestamp. You can list the partitions in the table by querying the `PARTITIONS` system table.

```
=> SELECT partition_key, projection_name, node_name, location_label FROM partitions
      ORDER BY partition_key;
partition_key | projection_name | node_name      | location_label
-----+-----+-----+-----
201309       | messages_b1    | v_vmart_node0001 |
201309       | messages_b0    | v_vmart_node0003 |
201309       | messages_b1    | v_vmart_node0002 |
201309       | messages_b1    | v_vmart_node0003 |
201309       | messages_b0    | v_vmart_node0001 |
201309       | messages_b0    | v_vmart_node0002 |
201310       | messages_b0    | v_vmart_node0002 |
201310       | messages_b1    | v_vmart_node0003 |
201310       | messages_b0    | v_vmart_node0001 |
. . .
201405       | messages_b0    | v_vmart_node0002 |
201405       | messages_b1    | v_vmart_node0003 |
201405       | messages_b1    | v_vmart_node0001 |
201405       | messages_b0    | v_vmart_node0001 |
(54 rows)
```

Next, suppose you find that most queries on this table access only the latest month or two of data. You might decide to move the older data to cold storage in an HDFS-based storage location. After you move the data, it is still available for queries, but with lower query performance.

To move partitions to the HDFS storage location, supply the lowest and highest partition key values to be moved in the `SET_OBJECT_STORAGE_POLICY` function call. The following example shows how to move data between two dates. In this example:

- The partition key value 201309 represents September 2013.
- The partition key value 201403 represents March 2014.
- The name, `coldstorage`, is the label of the HDFS-based storage location.
- The final argument, which is optional, is `true`, meaning that the function does not return until the move is complete. By default the function returns immediately and the data is moved when the Tuple Mover next runs. When data is old, however, the Tuple Mover runs less frequently, which would delay recovering the original storage space.

```
=> SELECT SET_OBJECT_STORAGE_POLICY('messages','coldstorage', '201309', '201403', 'true');
```

The partitions within the specified range are moved to the HDFS storage location labeled `coldstorage` the next time the Tuple Mover runs. This location name now displays in the `PARTITIONS` system table's `location_label` column.

```
=> SELECT partition_key, projection_name, node_name, location_label
      FROM partitions ORDER BY partition_key;
partition_key | projection_name | node_name | location_label
-----+-----+-----+-----
201309       | messages_b0    | v_vmart_node0003 | coldstorage
201309       | messages_b1    | v_vmart_node0001 | coldstorage
201309       | messages_b1    | v_vmart_node0002 | coldstorage
201309       | messages_b0    | v_vmart_node0001 | coldstorage
. . .
201403       | messages_b0    | v_vmart_node0002 | coldstorage
201404       | messages_b0    | v_vmart_node0001 |
201404       | messages_b0    | v_vmart_node0002 |
201404       | messages_b1    | v_vmart_node0001 |
201404       | messages_b1    | v_vmart_node0002 |
201404       | messages_b0    | v_vmart_node0003 |
201404       | messages_b1    | v_vmart_node0003 |
201405       | messages_b0    | v_vmart_node0001 |
201405       | messages_b1    | v_vmart_node0002 |
201405       | messages_b0    | v_vmart_node0002 |
201405       | messages_b0    | v_vmart_node0003 |
201405       | messages_b1    | v_vmart_node0001 |
201405       | messages_b1    | v_vmart_node0003 |
(54 rows)
```

After your initial data move, you can move additional data to the HDFS storage location periodically. You can move individual partitions or a range of partitions from the "hot" storage to the "cold" storage location using the same method:

```
=> SELECT SET_OBJECT_STORAGE_POLICY('messages', 'coldstorage', '201404', '201404', 'true');

=> SELECT projection_name, node_name, location_label
      FROM PARTITIONS WHERE PARTITION_KEY = '201404';
projection_name | node_name | location_label
-----+-----+-----
messages_b0     | v_vmart_node0002 | coldstorage
messages_b0     | v_vmart_node0003 | coldstorage
messages_b1     | v_vmart_node0003 | coldstorage
messages_b0     | v_vmart_node0001 | coldstorage
messages_b1     | v_vmart_node0002 | coldstorage
messages_b1     | v_vmart_node0001 | coldstorage
(6 rows)
```

Moving Partitions to a Table Stored on HDFS

Another method of moving partitions from hot storage to cold storage is to move the partitions' data to a separate table in the other storage location. This method breaks the data into two tables, one containing hot data and the other containing cold data. Use this method if you want to prevent queries from inadvertently accessing data stored in cold storage. To query the older data, you must explicitly query the cold table.

To move partitions:

1. Create a new table whose schema matches that of the existing partitioned table.
2. Set the storage policy of the new table to use the HDFS-based storage location.
3. Use the [MOVE_PARTITIONS_TO_TABLE](#) function to move a range of partitions from the hot table to the cold table. The partitions migrate when the Tuple Mover next runs.

The following example demonstrates these steps. You first create a table named `cold_messages`. You then assign it the HDFS-based storage location named `coldstorage`, and, finally, move a range of partitions.

```
=> CREATE TABLE cold_messages LIKE messages INCLUDING PROJECTIONS;  
=> SELECT SET_OBJECT_STORAGE_POLICY('cold_messages', 'coldstorage');  
=> SELECT MOVE_PARTITIONS_TO_TABLE('messages', '201309', '201403', 'cold_messages');
```

Moving Data Storage Locations

You can use the [SET_OBJECT_STORAGE_POLICY](#) function to move data storage from an existing location (whether labeled or not) to another labeled location. You can use this function to accomplish two tasks:

1. Create or update a storage policy:
 - Create new storage policy for the object
 - Update an existing policy to the target labeled location.
2. Move all existing data for the specified objects to the target storage location.

Vertica moves the existing data the next time the Tuple Mover runs. Alternatively, you can enforce the data move to occur in the current transaction using the function's `enforce_storage_move` parameter. Consider setting this parameter to `true` if the Tuple Mover will not run on this data for a while, such as if the data is old.

Before actually moving the object to the target storage location, Vertica calculates the required storage and checks available space at the target. If there is insufficient free space, the function generates an error and stops execution. It does not attempt to find sufficient storage at another location.

Important: You should check available space on the new target location before starting a data move. However, be aware that checking does not guarantee that this space remains available during move execution. Checking target space does prevent attempts to move

any data, if insufficient space is available.

Moving Data Storage While Setting a Storage Policy

The following example shows how to use [SET_OBJECT_STORAGE_POLICY](#) to set a storage policy for the table object `states`. Then, you can move the table's existing stored data to the labeled location, `SSD`. You force the move to occur during the function transaction by specifying the last parameter as `true`:

```
=> select set_object_storage_policy('states', 'SSD', 'true');
       set_object_storage_policy
```

```
-----
Object storage policy set.
Task: moving storages
(Table: public.states) (Projection: public.states_p1)
(Table: public.states) (Projection: public.states_p2)
(Table: public.states) (Projection: public.states_p3)
(1 row)
```

Note: Moving an object's current storage to a new target is a cluster-wide operation, so a failure on any node results in a warning message. The function then attempts to continue executing on other cluster nodes.

You can view the storage policies that are in effect:

```
=> select * from storage_policies;
 schema_name | object_name | policy_details | location_label
-----+-----+-----+-----
 public      | states      | Table          | SSD
(1 row)
```

Effects of Moving a Storage Location

Moving an object from one labeled storage location to another has the following effects:

Object type:	Effect:
Schema or table	If data storage exists, moves data from source to target destination. Source data can reside on a labeled or unlabeled storage location, but will be moved to specified labeled location. Cluster nodes unavailable when existing data is copied are updated by the TM when they rejoin the cluster. Alternately, you can enforce a data

Object type:	Effect:
	<p>move as part of the function transaction, by specifying the last parameter as <code>true</code>.</p> <p>If a storage policy was in effect, the default storage location changes from the source to target location. This change affects all future TM operations, such as moveout and mergeout activities.</p>
Table with specified partition min-keys and max_keys	Sets a policy or moves existing data only for the <code>key_min</code> and <code>key_max</code> ranges. Separate partition key ranges can have different storage policies from other ranges or the parent table.

Clearing Storage Policies

You can clear a storage policy by object name after you have defined storage policies. To see existing policies, query the `storage_policies` system table, described in [Viewing Storage Locations and Policies](#).

To clear a storage policy, use the `CLEAR_OBJECT_STORAGE_POLICY` function, specifying the object name associated with the labeled location:

```
=> select clear_object_storage_policy('lineorder');      clear_object_storage_policy
-----
Default storage policy cleared.
(1 row)
```

Existing data is moved to the parent storage policy's location, or the default storage location if there is no parent policy. Typically, the move occurs the next time the Tuple Mover runs. Alternatively, you can force the data move to occur in the current transaction by setting the optional `enforce_storage_move` parameter to `true`.

You can also use the `ENFORCE_OBJECT_STORAGE_POLICY` meta-function to trigger the move for all storage locations at once. Using this function equates to setting `enforce_storage_move`.

Speeding Up Data Migration

After you clear the storage policy, the Tuple Mover eventually migrates the object's data from the storage location to the database's default storage location. The TM moves the data when

it performs a move-storage operation. This operation runs infrequently at low priority. Therefore, it might be some time before the data migrates out of the storage location.

You can speed up the data-migration process by:

1. Calling the [RETIRE_LOCATION](#) function to retire the storage location on each host that defines it.
2. Calling the [MOVE_RETIRED_LOCATION_DATA](#) function to move the location's data to the database's default storage location.
3. Calling the [RESTORE_LOCATION](#) function to restore the location on each host that defines it. You must perform this step because you cannot drop retired storage locations.

The following example demonstrates clearing the object storage policy of a table stored on HDFS, then performing the steps to move the data off of the location. (See [Using HDFS Storage Locations](#) for additional background.)

```
=> SELECT * FROM storage_policies;
  schema_name | object_name | policy_details | location_label
-----+-----+-----+-----
public      | test       | Table         | hdfs2
(1 row)

=> SELECT clear_object_storage_policy('test');
  clear_object_storage_policy
-----
Object storage policy cleared.
(1 row)

=> SELECT retire_location('webhdfs://hadoop:50070/user/dbadmin/v_vmart_node0001',
  'v_vmart_node0001');
  retire_location
-----
webhdfs://hadoop:50070/user/dbadmin/v_vmart_node0001 retired.
(1 row)

=> SELECT retire_location('webhdfs://hadoop:50070/user/dbadmin/v_vmart_node0002',
  'v_vmart_node0002');
  retire_location
-----

Effects on Same-Name Storage Policies

The effects of clearing a storage policy depend on which policy you clear.

For example, consider the following storage configuration. The table `lineorder` has a storage policy for default storage to the location label F2. The table's partition ranges, also `lineorder` objects, have storage policies for other default storage locations:

```
=> select * from v_monitor.storage_policies;
schema_name      | object_name      | policy_details  | location_label
-----+-----+-----+-----
public           | public           | Schema         | F4
public           | lineorder        | Table          | F2
public           | lineorder        | Partition [0, 0] | F1
public           | lineorder        | Partition [1, 1] | F2
public           | lineorder        | Partition [2, 2] | F4
public           | lineorder        | Partition [3, 3] | M1
public           | lineorder        | Partition [4, 4] | M3
(7 rows)
```

For this example, clearing the storage policy for an object named `lineorder`, removes the policy for the table, while retaining storage policies for its partitions, which have their own policies.

The function determines which `lineorder` object policy to clear because no partition range values are specified in the function call:

```
=> select clear_object_storage_policy('lineorder');
clear_object_storage_policy
-----
Default storage policy cleared.
(1 row)
release=> select * from v_monitor.storage_policies;
schema_name | object_name | policy_details | location_label
-----+-----+-----+-----
public      | public      | Schema         | F4
public      | lineorder   | Partition [0, 0] | F1
public      | lineorder   | Partition [1, 1] | F2
public      | lineorder   | Partition [2, 2] | F4
public      | lineorder   | Partition [3, 3] | M1
public      | lineorder   | Partition [4, 4] | M3
(6 rows)
```

Further, using a partition key range with the `lineorder` object name clears the storage policy for only the specified partition range(s). The storage policy for the parent table objects, and other partition ranges persist:

```
=> select clear_object_storage_policy ('lineorder','0','3');
clear_object_storage_policy
-----
Default storage policy cleared.
(1 row)
release=> select * from storage_policies;
schema_name | object_name | policy_details | location_label
-----+-----+-----+-----
public      | public      | Schema         | F4
public      | lineorder   | Table          | F2
public      | lineorder   | Partition [4, 4] | M3
```

Measuring Storage Performance

Vertica lets you measure disk I/O performance on any storage location at your site. You can use the returned measurements to set performance, which automatically provides rank.

Depending on your storage needs, you can also use performance to determine the storage locations needed for critical data as part of your site's storage policies. Storage performance measurements apply only to data storage locations, not temporary storage locations.

Measuring storage location performance calculates the time it takes to read and write 1 MB of data from the disk, which equates to:

$$\text{IO time} = \text{time to read/write 1MB} + \text{time to seek} = 1/\text{throughput} + 1/\text{Latency}$$

- Throughput is the average throughput of sequential reads/writes (expressed in megabytes per second).
- Latency is for random reads only in seeks (units in seeks per second).

Thus, the I/O time of a faster storage location is less than that of a slower storage location.

Note: Measuring storage location performance requires extensive disk I/O, which is a resource-intensive operation. Consider starting this operation when fewer other operations are running.

Vertica gives you two ways to measure storage location performance, depending on whether the database is running. You can either:

- Measure performance on a running database.
- Measure performance before a cluster is set up.

Both methods return the throughput and latency for the storage location. Record or capture the throughput and latency information so you can use it to set the location performance (see [Setting Storage Performance](#)).

Measuring Performance on a Running Vertica Database

Use the [MEASURE_LOCATION_PERFORMANCE\(\)](#) function to measure performance for a storage location when the database is running. This function has the following requirements:

- The storage path must already exist in the database.
- You need RAM*2 free space available in a storage location to measure its performance. For example, if you have 16 GB RAM, you need 32 GB of available disk space. If you do not have enough disk space, the function returns an error.

Use the system table [DISK_STORAGE](#) to obtain information about disk storage on each database node.

The following example shows how to measure the performance of a storage location on v_vmartdb_node0004:

```
=> SELECT MEASURE_LOCATION_PERFORMANCE('/secondVerticaStorageLocation/', 'v_vmartdb_node0004');  
WARNING: measure_location_performance can take a long time. Please check logs for progress  
measure_location_performance  
-----  
Throughput : 122 MB/sec. Latency : 140 seeks/sec
```

Measuring Performance Before a Cluster Is Set Up

You can measure disk performance before setting up a cluster. This approach is useful when you want to verify that the disk is functioning within normal parameters. To perform this measurement, you must already have Vertica installed.

To measure disk performance, use the following command:

```
opt/vertica/bin/vertica -m <path to disk mount>
```

For example:

```
opt/vertica/bin/vertica -m /secondVerticaStorageLocation/node0004_data
```

Setting Storage Performance

You can use the measurements returned from the [MEASURE_LOCATION_PERFORMANCE](#) function as input values to the [SET_LOCATION_PERFORMANCE\(\)](#) function.

Note: You must set the throughput and latency parameters of this function to 1 or more.

The following example shows how to set the performance of a storage location on `v_`
`vmartdb_node0004`, using values for this location returned from the [MEASURE_LOCATION_](#)
[PERFORMANCE](#) function. Set the throughput to 122 MB/second and the latency to 140
seeks/second. [MEASURE_LOCATION_PERFORMANCE](#)

```
=> SELECT SET_LOCATION_PERFORMANCE('/secondVerticaStorageLocation/', 'node2', '122', '140');
```

Sort Order Ranking by Location Performance Settings

After you set performance-data parameters, , Vertica automatically uses performance data to rank storage locations whenever it stores projection columns.

Vertica stores columns included in the projection sort order on the fastest available storage locations. Columns not included in the projection sort order are stored on slower disks. Columns for each projection are ranked as follows:

- Columns in the sort order are given the highest priority (numbers > 1000).
- The last column in the sort order is given the rank number 1001.
- The next-to-last column in the sort order is given the rank number 1002, and so on until the first column in the sort order is given 1000 + # of sort columns.
- The remaining columns are given numbers from 1000–1, starting with 1000 and decrementing by one per column.

Vertica then stores columns on disk from the highest ranking to the lowest ranking. It places highest-ranking columns on the fastest disks and the lowest-ranking columns on the slowest disks.

Using Location Performance Settings with Storage Policies

You initially measure location performance and set it in the Vertica database. Then, you can use the performance results to determine the fastest storage to use in your storage policies.

- Set the locations with the highest performance as the default locations for critical data.
- Use slower locations as default locations for older, or less-important data. Such slower locations may not require policies at all, if you do not want to specify default locations.

Vertica determines data storage as follows, depending on whether a storage policy exists:

Storage Policy	Label	Number of Locations	Vertica Action
No	No	Multiple	Uses ranking (as described), choosing a location from all locations that exist.
Yes	Yes	Single	Uses that storage location exclusively.
Yes	Yes	Multiple	Ranks storage (as described) among all same-name labeled locations.

Dropping Storage Locations

To drop a storage location, use the [DROP_LOCATION\(\)](#) function. The following example shows how to drop a storage location on `v_vmartdb_node0002` that was used to store temp files:

```
=> SELECT DROP_LOCATION('/secondVerticaStorageLocation/' , 'v_vmartdb_node0002');
```

When you drop a storage location, the operation cascades to associated objects including any granted privileges to the storage.

Caution: Dropping a storage location is a permanent operation and cannot be undone. Subsequent queries on storage used for external table access fail with a COPY COMMAND FAILED message.

Because dropping a storage location cannot be undone, Micro Focus recommends that you first retire a storage location (see [Retiring Storage Locations](#)). Retiring a storage location before dropping it lets you verify that there will be no adverse effects on any data access. Additionally, you can restore a retired storage location (see [Restoring Retired Storage Locations](#)).

Altering Storage Locations Before Dropping Them

You can drop only storage locations containing temp files. Thus, you must alter a storage location to the TEMP usage type before you can drop it. However, if data files still exist on the storage, Vertica prevents you from dropping the storage location. Deleting data files does not clear the storage location and can result in database corruption. To handle a storage area containing data files so that you can drop it, use one of these options:

- Manually merge out the data files.
- Wait for the ATM to mergeout the data files automatically.
- Retire the location, and force the changes to take effect immediately.
- Manually [drop partitions](#)

Dropping USER Storage Locations

Storage locations that you create with the USER usage type can contain only data files, not temp files. However, you can drop a USER location, regardless of any remaining data files. This behavior differs from that of a storage location not designated for USER access.

Checking Location Properties

You can check the properties of a storage location, such as whether it is a USER location or is being used only for TEMP files, in the [STORAGE_LOCATIONS](#) system table. You can also use this table to verify that a location has been retired.

Retiring Storage Locations

To retire a storage location, use the [RETIRE_LOCATION\(\)](#) function.

The following example shows how to retire a storage location on v_vmartdb_node0004:

```
=> SELECT RETIRE_LOCATION('/secondStorageLocation/' , 'v_vmartdb_node0004');
```

To retire a storage location on all nodes, use an empty string (") for the second parameter.

Retiring a location prevents Vertica from storing data or temp files to it, but does not remove the actual location. Any data previously stored on the retired location is eventually merged out by the Automatic Tuple Mover (ATM) per its policies.

If you plan to drop the storage location after retiring it, you can expedite this by setting the optional `enforce_storage_move` parameter to `true`. This setting moves the data out of the storage location instead of waiting for the Tuple Mover, allowing you to drop the location immediately.

You can also use the [ENFORCE_OBJECT_STORAGE_POLICY](#) meta-function to trigger the move for all storage locations at once, and then drop the locations. This approach equates to setting `enforce_storage_move`.

The following example shows how to retire a storage location on all nodes and prepares it for immediate drop:

```
=> SELECT RETIRE_LOCATION('/secondStorageLocation/' , '', true);
```

Note: If the location used in a storage policy is the last available storage for its associated objects, you cannot retire it *unless* you set `enforce_storage_move` to `true`.

Data and temp files can be stored in one, or multiple separate, storage locations.

For further information on dropping a location after retiring it, see [Dropping Storage Locations](#).

Restoring Retired Storage Locations

You can restore a previously retired storage location that continues to be used in queries. After the location is restored, Vertica re-ranks the storage location and uses the restored location to process queries as determined by its rank.

Use the [RESTORE_LOCATION\(\)](#) function to restore a retired storage location.

The following example shows how to restore a retired storage location on `v_vmartdb_node0004`:

```
=> SELECT RESTORE_LOCATION('/secondVerticaStorageLocation/' , 'v_vmartdb_node0004');
```

To restore a storage location on all nodes, use an empty string (") for the second parameter. The following example demonstrates creating, retiring, and restoring a location on all nodes:

```
=> create location '/tmp/ab1' all nodes usage 'TEMP';  
CREATE LOCATION  
  
=> select retire_location('/tmp/ab1', '');
```

```

retire_location
-----
/tmp/ab1 retired.
      (1 row)

=> select * from storage_locations where location_path ilike '/tmp/ab1';
location_id | node_name | location_path | location_usage | is_retired | location_
label | rank | throughput | latency
-----+-----+-----+-----+-----+-----
--+-----+-----+-----+-----+-----+-----

45035996273736728 | v_vmart_node0003 | /tmp/ab1 | TEMP | f |
| 0 | 0 | 0
45035996273736730 | v_vmart_node0004 | /tmp/ab1 | TEMP | f |
| 0 | 0 | 0
      (4 rows)

```

The `RESTORE_LOCATION()` function restores the location only on the nodes where the location exists and is retired. The function does not propagate the storage location to nodes where that location did not previously exist.

Restoring on all nodes fails if the location has been dropped on any of them. If you have dropped the location on some nodes, you have two options:

- If you no longer want to use the dropped node, restore the location individually on each of the other nodes.
- Alternatively, you can re-create the location on the node where you dropped it. To do so, use `CREATE LOCATION()` or `ADD_LOCATION()`. After you have re-created the location, you can then restore it on all nodes.

The following example demonstrates the failure if you try to restore on nodes where you have dropped the location:

```
=> select retire_location('/tmp/ab1', '');
retire_location
-----
/tmp/ab1 retired.
      (1 row)

=> select drop_location('/tmp/ab1', 'v_vmart_node0002');
drop_location
-----
/tmp/ab1 dropped.
      (1 row)

=> select * from storage_locations where location_path ilike '/tmp/ab1';
location_id      | node_name          | location_path | location_usage | is_retired | location_
label | rank | throughput | latency
-----+-----+-----+-----+-----+-----
---+---+---+---+---+---
45035996273736724 | v_vmart_node0001  | /tmp/ab1     | TEMP          | t          |
| 0 | 0 | 0
45035996273736728 | v_vmart_node0003  | /tmp/ab1     | TEMP          | t          |
| 0 | 0 | 0
45035996273736730 | v_vmart_node0004  | /tmp/ab1     | TEMP          | t          |
| 0 | 0 | 0
      (3 rows)

=> select restore_location('/tmp/ab1', '');
ERROR 2081: [/tmp/ab1] is not a valid storage location on node v_vmart_node0002
```

Analyzing Workloads

If queries perform suboptimally, you can get tuning recommendations for them, as well as for hints about optimizing database objects, by using the Workload Analyzer (WLA). WLA is a Vertica utility that analyzes system information in Vertica [system tables](#).

WLA identifies the root causes of poor query performance through intelligent monitoring of query execution, workload history, resources, and configurations. It then returns a set of tuning recommendations based on statistics, system and data collector events, and database/table/projection design. You can use these recommendations to tune query performance, quickly and easily.

You can run WLA in two ways:

- Call the Vertica function [ANALYZE_WORKLOAD](#).
- Use the [Management Console interface](#).

See [Understanding WLA Triggering Conditions](#) for the most common triggering conditions and recommendations.

Getting Tuning Recommendations

Call the function [ANALYZE_WORKLOAD](#) to get tuning recommendations for queries and database objects. The function arguments specify what events to analyze and when.

Setting Scope and Time Span

`ANALYZE_WORKLOAD`'s `scope` argument determines what to analyze:

This argument...	Returns WLA recommendations for...
' ' (empty string)	All database objects
Table name	A specific table
Schema name	All objects in the specified schema

The optional `since-time` argument specifies to return values from all in `-scope` events starting from `since-time` and continuing to the current system status. If you omit `since-time`, `ANALYZE_WORKLOAD` returns recommendations for events since the last recorded time

that you called the function. You must explicitly cast the since-time string value to either `TIMESTAMP` or `TIMESTAMPTZ`.

The following examples show four ways to express the since-time argument with different formats. All queries return the same result for workloads on table `t1` since October 4, 2012:

```
=> SELECT ANALYZE_WORKLOAD('t1', TIMESTAMP '2012-10-04 11:18:15');  
=> SELECT ANALYZE_WORKLOAD('t1', '2012-10-04 11:18:15':TIMESTAMPTZ);  
=> SELECT ANALYZE_WORKLOAD('t1', 'October 4, 2012':TIMESTAMP);  
=> SELECT ANALYZE_WORKLOAD('t1', '10-04-12':TIMESTAMPTZ);
```

Saving Function Results

Instead of analyzing events since a specific time, you can save results from `ANALYZE_WORKLOAD`, by setting the function's second argument to `true`. The default is `false`, and no results are saved. After saving function results, subsequent calls to `ANALYZE_WORKLOAD` analyze only events since you last saved returned data, and ignore all previous events.

For example, the following statement returns recommendations for all database objects in all schemas and records this analysis invocation.

```
=> SELECT ANALYZE_WORKLOAD('', true);
```

The next invocation of `ANALYZE_WORKLOAD` analyzes events from this point forward.

```
-[ RECORD 1 ]-----+-----  
observation_count | 1  
first_observation_time |  
last_observation_time |  
tuning_parameter | public.locations  
tuning_description | run database designer on table public.locations  
tuning_command |  
tuning_cost | HIGH  
-[ RECORD 2 ]-----+-----  
observation_count | 1  
first_observation_time |  
last_observation_time |  
tuning_parameter | public.new_locations  
tuning_description | run database designer on table public.new_locations  
tuning_command |  
tuning_cost | HIGH  
-[ RECORD 3 ]-----+-----  
observation_count | 1  
first_observation_time |  
last_observation_time |  
tuning_parameter | release  
tuning_description | set password for user 'release'  
tuning_command | alter user release identified by 'new_password'  
tuning_cost | LOW
```

Observation Count and Time

The `observation_count` column returns an integer that represents the total number of events Workload Analyzer (WLA) observed for this tuning recommendation. In each case above, WLA is making its first recommendation. Null results in `observation_time` only mean that the recommendations are from the current system status instead of from a prior event.

Tuning Targets

The `tuning_parameter` column returns the object on which WLA recommends that you apply the tuning action. The parameter of `release` in the example above notifies the DBA to set a password for user release.

Tuning Recommendations and Costs

WLA's output returns a brief description of tasks you should consider in the `tuning_description` column, along with a SQL command you can run, where appropriate, in the `tuning_command` column. In records 1 and 2 above, WLA recommends that you run the Database Designer on two tables, and in record 3 recommends setting a user's password. Record 3 also provides the `ALTER USER` command to run because the tuning action is a SQL command.

Output in the `tuning_cost` column indicates the cost of running the recommended tuning command:

- **LOW:** Running the tuning command has minimal impact on resources. You can perform the tuning operation at any time, like changing the user's password in Record 3 above.
- **MEDIUM:** Running the tuning command has moderate impact on resources.
- **HIGH:** Running the tuning command has maximum impact on resources. Depending on the size of your database or table, consider running high-cost operations during off-peak load times.

Examples

The following statement tells WLA to analyze all events for the `locations` table:

```
=> SELECT ANALYZE_WORKLOAD('locations');
```

WLA returns with a recommendation that you run the Database Designer on the table, an operation that, depending on the size of `locations`, might incur a high cost:

```
-[ RECORD 1 ]-----+-----  
observation_count      | 1  
first_observation_time |  
last_observation_time  |  
tuning_parameter      | public.locations  
tuning_description     | run database designer on table public.locations  
tuning_command         |  
tuning_cost           | HIGH
```

The following statement analyzes workloads on all tables in the VMart example database since one week before today:

```
=> SELECT ANALYZE_WORKLOAD('', NOW() - INTERVAL '1 week');
```

WLA returns with the following results:

```
-[ RECORD 1 ]-----+-----  
observation_count      | 4  
first_observation_time | 2012-02-17 13:57:17.799003-04  
last_observation_time  | 2011-04-22 12:05:26.856456-04  
tuning_parameter      | store.store_orders_fact.date_ordered  
tuning_description     | analyze statistics on table column store.store_orders_fact.date_ordered  
tuning_command         | select analyze_statistics('store.store_orders_fact.date_ordered');  
tuning_cost           | MEDIUM  
-[ RECORD 2 ]-----+-----  
...  
-[ RECORD 14 ]-----+-----  
observation_count      | 2  
first_observation_time | 2012-02-19 17:52:03.022644-04  
last_observation_time  | 2012-02-19 17:52:03.02301-04  
tuning_parameter      | SELECT x FROM t WHERE x > (SELECT SUM(DISTINCT x) FROM  
| t GROUP BY y) OR x < 9;  
tuning_description     | consider incremental design on query  
tuning_command         |  
tuning_cost           | HIGH
```

WLA finds two issues:

- In record 1, the `date_ordered` column in the `store.store_orders_fact` table likely has [stale statistics](#), so WLA suggests running [ANALYZE_STATISTICS](#) on that column. The function output also returns the query to run. For example:

```
=> SELECT ANALYZE_STATISTICS('store.store_orders_fact.date_ordered');
```

- In record 14, WLA identifies an under-performing query in the `tuning_parameter` column. It recommends to use the Database Designer to run an incremental design. WLA rates the potential cost as HIGH.

System Table Recommendations

You can also get tuning recommendations by querying system table [TUNING_RECOMMENDATIONS](#), which returns tuning recommendation results from the last `ANALYZE_WORKLOAD` call.

```
=> SELECT * FROM tuning_recommendations;
```

System information that WLA uses for its recommendations is held in [SQL system tables](#), so querying the `TUNING_RECOMMENDATIONS` system table does not run WLA.

See Also

[Collecting Database Statistics](#)

Understanding WLA Triggering Conditions

Workload Analyzer (WLA) monitors suspicious system activity and makes recommendations based on its observations. When you run Workload Analyzer, the utility returns the following information:

- The tuning description
- The objects on which WLA applies tuning action
- The suggested SQL command for you to run (where appropriate)

In rare circumstances, tuning recommendation WLA proposes might not resolve the underlying problem. Because you might occasionally need help understanding WLA's recommendations, the following section lists some of the most common triggering conditions, along with the recommendations to resolve the issue and a pointer to more information, when available.

Common Problems

Problem

Internal configuration parameter is not the same across nodes.

Solution

Reset configuration parameter.

```
=> ALTER DATABASE mydb SET parameter = value;
```

Problem

An unused projection meets the following conditions:

- No queries on projection for more than 30 days but, projection's anchor table has been queried more than 10 times
- Projection's anchor table is not a temp or system table
- Projection's table is not small, where the number of bytes of disk storage in use by the projection (`used_bytes`) is more than 10M

Solution

Drop the projection (*projection-name*).

```
=> DROP PROJECTION public.T1_fact_super_P1_B1;
```

Problem

User with `dbadmin/pseudosuperuser` role has empty password.

Solution

Set the password for user.

```
=> ALTER USER (user) IDENTIFIED BY ('new_password');
```

Problem

Table with too many partition count.

Solution

Alter the table's partition expression.

```
=> ALTER TABLE (schema.table) PARTITION BY (new_partition_expression) REORGANIZE;
```

Problem

LGE threshold setting is lower than the default setting.

Solution

Workload Analyzer does not trigger a tuning recommendation for this scenario unless you altered settings and/or services under the guidance of technical support.

Problem

Tuple Mover's [MoveOutInterval](#) parameter is set greater than the default setting.

Solution

Decrease the [MoveOutInterval](#) configuration parameter setting.

```
=> ALTER DATABASE mydb SET MoveOutInterval = default-value;
```

For more information, see [Monitoring Events](#) and [ACTIVE_EVENTS](#).

Problem

Tuple Mover has been disabled.

Solution

Workload Analyzer does not trigger a tuning recommendation for this scenario unless you altered settings and/or services under the guidance of technical support.

Problem

Too many ROS containers since the last mergeout operation; configuration parameters are set lower than the default.

Solution

Workload Analyzer does not trigger a tuning recommendation for this scenario unless you altered settings and/or services under the guidance of technical support.

Problem

Too many ROS containers since the last mergeout operation; the TM Mergeout service is disabled.

Solution

Workload Analyzer does not trigger a tuning recommendation for this scenario unless you altered settings and/or services under the guidance of technical support.

Problem

Average CPU usage exceeds 95% for 20 minutes.

Solution

Check system processes or change the settings for `PLANNEDCONCURRENCY` and/or `MAXCONCURRENCY` for the resource pool. For details, see [ALTER RESOURCE POOL](#) and [Built-In Pool Configuration](#).

Problem

Partitioned table data is not fully reorganized after repartitioning.

Solution

Reorganize data in partitioned table public.T1.

```
=> ALTER TABLE public.T1 REORGANIZE;
```

Problem

Table has multiple partition keys within the same ROS container.

Solution

Reorganize data in partitioned table public.T1.

```
=> ALTER TABLE public.T1 REORGANIZE;
```

Problem

Excessive swap activity; average memory usage exceeds 99% for 10 minutes.

Solution

Check system processes

Problem

A table does not have any Database Designer-designed projections.

Solution

Run database designer on table public.T1. For details, see [Incremental Design](#).

Problem

Statistics are stale (no histogram or predicate falls outside histogram).

Solution

Run [ANALYZE_STATISTICS](#) on table columns.

```
=> SELECT analyze_statistics ('public.t.a');
```

See also [Collecting Database Statistics](#).

Problem

Data distribution in segmented projection is skewed.

Solution

Re-segment projection public.t_super on high-cardinality column(s). For details, see [Designing for Segmentation](#).

Problem

GROUP BY spill event.

Solution

Consider running an [incremental design](#) on query.

Managing the Database

This section describes how to manage the Vertica database. It includes the following topics:

- [Connection Load Balancing](#)
- [Managing Nodes](#)
- [Adding Disk Space to a Node](#)
- [Tuple Mover Operations](#)
- [Managing the Tuple Mover](#)
- [Managing Workloads](#)

Connection Load Balancing

Each client connection to a host in the Vertica cluster requires a small overhead in memory and processor time. If many clients connect to a single host, this overhead can begin to affect the performance of the database. You can attempt to spread the overhead of client connections by dictating that certain clients connect to specific hosts in the cluster. However, this manual balancing becomes difficult as new clients and hosts are added to your environment.

Connection load balancing helps automatically spread the overhead caused by client connections across the cluster by having hosts redirect client connections to other hosts. By redirecting connections, the overhead from client connections is spread across the cluster without having to manually assign particular hosts to individual clients. Clients can connect to a small handful of hosts, and they are naturally redirected to other hosts in the cluster.

Native Connection Load Balancing Overview

Native connection load balancing is a feature built into the Vertica Analytics Platform server and client libraries as well as vsql. Both the server and the client need to enable load balancing for it to function. If connection load balancing is enabled, a host in the database cluster can redirect a client's attempt to it to another currently-active host in the cluster. This redirection is based on a load balancing policy. This redirection can only take place once, so a client is not bounced from one host to another.

Since native connection load balancing is incorporated into the Vertica client libraries, any client application that connects to Vertica transparently takes advantage of it simply by setting a connection parameter.

How you choose to implement connection load balancing depends on your network environment. Since native load connection balancing is easier to implement, you should use it unless your network configuration requires that clients be separated from the hosts in the Vertica database by a firewall.

For more about native connection load balancing, see [About Native Connection Load Balancing](#).

About Native Connection Load Balancing

Native connection load balancing is a feature built into the Vertica server and client libraries that helps spread the CPU and memory overhead caused by client connections across the hosts in the database. It can prevent unequal distribution of client connections among hosts in the cluster.

Native connection load balancing must be enabled by the server and client. When native connection load balancing is enabled on both, the following process takes place when the client attempts to open a connection to Vertica:

1. The client connects to a host in the database cluster, with a connection parameter indicating that it is requesting a load-balanced connection.
2. The host chooses a host from the list of currently up hosts in the cluster, according to the [current load balancing scheme](#).
3. The host tells the client which host it selected to handle the client's connection.
4. If the host chose another host in the database to handle the client connection, the client disconnects from the initial host. Otherwise, the client jumps to step 6.
5. The client establishes a connection to the host that will handle its connection. The client sets this second connection request so that the second host does not interpret the connection as a request for load balancing.
6. The client connection proceeds as usual, (negotiating encryption if the connection has SSL enabled, and proceeding to authenticating the user).

This process is transparent to the client application. The client driver automatically disconnects from the initial host and reconnects to the host selected for load balancing.

Requirements

- In mixed IPv4 and IPv6 environments, balancing only works for the address family for which you have configured native load balancing. For example, if you have configured load balancing using an IPv4 address, then IPv6 clients cannot use load balancing, however the IPv6 clients can still connect, but load balancing does not occur.
- The native load balancer returns an IP address for the client to use. This address must be one that the client can reach. If your nodes are on a private network, native load-balancing requires you to publish a public address. See `export_address` in the system table [NODES](#).

Load Balancing Schemes

The load balancing scheme controls how a host selects which host to handle a client connection. There are three available schemes:

- **NONE** (default): Disables native connection load balancing.
- **ROUNDROBIN**: Chooses the next host from a circular list of hosts in the cluster that are up—for example, in a three-node cluster, iterates over node1, node2, and node3, then wraps back to node1. Each host in the cluster maintains its own pointer to the next host in the circular list, rather than there being a single cluster-wide state.
- **RANDOM**: Randomly chooses a host from among all hosts in the cluster that are up.

You set the native connection load balancing scheme using the [SET_LOAD_BALANCE_POLICY](#) function. See [Enabling and Disabling Native Connection Load Balancing](#) for instructions.

Driver Notes

- Native connection load balancing works with the ADO.NET driver's connection pooling. The connection the client makes to the initial host, and the final connection to the load-balanced host, use pooled connections if they are available.
- If a client application uses the JDBC and ODBC driver with third-party connection pooling solutions, the initial connection is not pooled because it is not a full client connection. The final connection is pooled because it is a standard client connection.

Connection Failover

The client libraries include a failover feature that allow them to connect to backup hosts if the host specified in the connection properties is unreachable. When using native connection load balancing, this failover feature is only used for the initial connection to the database. If the host to which the client was redirected does not respond to the client's connection request, the client does not attempt to connect to a backup host and instead returns a connection error to the user.

Clients are redirected only to hosts that are known to be up. Thus, this sort of connection failure should only occur if the targeted host goes down at the same moment the client is redirected to it. For more information, see [ADO.NET Connection Failover](#), [JDBC Connection Failover](#), and [ODBC Connection Failover](#) in Connecting to Vertica.

Enabling and Disabling Native Connection Load Balancing

Only a database superuser can enable or disable native connection load balancing. To enable or disable load balancing, use the [SET_LOAD_BALANCE_POLICY](#) function to set the load balance policy. Setting the load balance policy to anything other than 'NONE' enables load balancing on the server. The following example enables native connection load balancing by setting the load balancing policy to ROUNDROBIN.

```
=> SELECT SET_LOAD_BALANCE_POLICY('ROUNDROBIN');
          SET_LOAD_BALANCE_POLICY
-----
Successfully changed the client initiator load balancing policy to: roundrobin
(1 row)
```

To disable native connection load balancing, use `SET_LOAD_BALANCE_POLICY` to set the policy to 'NONE':

```
=> SELECT SET_LOAD_BALANCE_POLICY('NONE');  
SET_LOAD_BALANCE_POLICY  
-----  
Successfully changed the client initiator load balancing policy to: none  
(1 row)
```

Note: When a client makes a connection, the native load-balancer chooses a node and returns the value from the `export_address` column in the `NODES` table. The client then uses the `export_address` to connect. The `node_address` specifies the address to use for inter-node and spread communications. When a database is installed, the `export_address` and `node_address` are set to the same value. If you installed Vertica on a private address, then you must set the `export_address` to a *public* address for each node.

By default, client connections are not load balanced, even when connection load balancing is enabled on the server. Clients must set a connection parameter to indicate they are willing to have their connection request load balanced. See [Enabling Native Connection Load Balancing in ADO.NET](#), [Enabling Native Connection Load Balancing in JDBC](#) and [Enabling Native Connection Load Balancing in ODBC](#) in [Connecting to Vertica](#) for more information.

Important: In mixed IPv4 and IPv6 environments, balancing only works for the address family for which you have configured load balancing. For example, if you have configured load balancing using an IPv4 address, then IPv6 clients cannot use load balancing, however the IPv6 clients can still connect, but load balancing does not occur.

Resetting the Load Balancing State

When the load balancing policy is `ROUNDROBIN`, each host in the Vertica cluster maintains its own state of which host it will select to handle the next client connection. You can reset this state to its initial value (usually, the host with the lowest-node id) using the `RESET_LOAD_BALANCE_POLICY` function:

```
=> SELECT RESET_LOAD_BALANCE_POLICY();  
RESET_LOAD_BALANCE_POLICY  
-----  
Successfully reset stateful client load balance policies: "roundrobin".  
(1 row)
```

Monitoring Native Connection Load Balancing

Query the `LOAD_BALANCE_POLICY` column of the `V_CATALOG.DATABASES` to determine the state of native connection load balancing on your server:

```
=> SELECT LOAD_BALANCE_POLICY FROM V_CATALOG.DATABASES;
LOAD_BALANCE_POLICY
-----
roundrobin
(1 row)
```

Determining to Which Node a Client Has Connected

A client can determine the node to which is has connected by querying the `NODE_NAME` column of the `V_MONITOR.CURRENT_SESSION` table:

```
=> SELECT NODE_NAME FROM V_MONITOR.CURRENT_SESSION;
NODE_NAME
-----
v_vmart_node0002
(1 row)
```

Managing Nodes

Vertica provides the ability to [add](#), [remove](#), and [replace](#) nodes on a live cluster that is actively processing queries. This ability lets you scale the database without interrupting users.

In This Section

Stop Vertica on a Node

In some cases, you need to take down a node to perform maintenance tasks, or upgrade hardware.

1. Check the K-safety level of your cluster:

```
=> SELECT current_fault_tolerance FROM system;
current_fault_tolerance
-----
1
(1 row)
```

Stopping the node might require you to temporarily reduce the K-safety level of the database. For details, see [Lowering K-Safety to Enable Node Removal](#).

Caution: If you must reduce K-safety to 0, first [back up the database](#).

2. Run Administration Tools, select **Advanced Menu**, and click **OK**.
3. Select **Stop Vertica on Host** and click **OK**.
4. Choose the host that you want to stop and click **OK**.
5. Return to the Main Menu, select **View Database Cluster State**, and click **OK**. The host you previously stopped should appear **DOWN**.
6. You can now perform maintenance.

See [Restart Vertica on a Node](#) for details about restarting Vertica on a node.

Restart Vertica on a Node

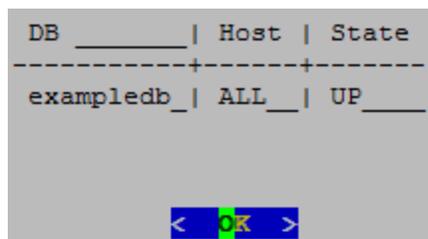

After [stopping a node](#) to perform maintenance, upgrade the hardware, or another similar task, you can bring the node back up. Performing this process reconnects the node with the database.

Restarting Vertica on a Node

1. Run Administration Tools. From the Main Menu select **Restart Vertica on Host** and click **OK**.
2. Select the database and click **OK**.
3. Select the host that you want to restart and click **OK**.

Note: This process may take a few moments.

4. Return to the Main Menu, select **View Database Cluster State**, and click **OK**. The host you restarted now appears as UP, as shown.

```
DB _____ | Host | State
-----+-----+-----
exampledb_ | ALL_ | UP_
```

< OK >

Setting Node Type

When you create a node, Vertica automatically sets its type to PERMANENT. This enables Vertica to use this node to store data. You can change a node's type with [ALTER NODE](#), to one of the following:

- **EPHEMERAL:** A node that is in transition from one type to another—typically, from PERMANENT to either STANDBY or EXECUTE.

- **STANDBY:** A node that is reserved to replace any node when it goes down. When used as a replacement node, Vertica changes its type to **PERMANENT**. A standby node stores no segments or data until it is called to replace a down node. At that time, Vertica changes its type to **PERMANENT**. For more information, see [Active Standby Nodes](#).
- **EXECUTE:** A node that is reserved for computation purposes only. An execute node contains no segments or data.

Active Standby Nodes

An *active standby node* is a specialized type of Vertica [node](#). An active standby node exists as a backup node, ready to replace a failed node. Unlike standard Vertica nodes, an active standby node does not perform computations or contain data. If a standard(permanent) node fails, an active standby node can replace the failed node, after the failed node exceeds the failover time limit. When it take the place of a failed node, the active standby node contains all of the projections and performs all of the calculations of the replaced node.

To deploy active standby nodes automatically, you must first configure the `FailoverToStandbyAfter` parameter. If possible, Vertica selects a standby node from the same fault group as the failed node. Otherwise, Vertica randomly selects an available active standby node.

If you are an administrator, you can manually replace a failed node using the [ALTER NODE](#) command. You can specify a particular standby node to replace a failed node, or you can allow Vertica to choose a node. As with automatic node replacement, Vertica defaults to a standby node from the same fault group as the failed node. If the fault group has no available standby nodes, Vertica selects any available active standby node.

In This Section

Creating an Active Standby Node

You can create active standby nodes at the same time that you create your database or at a later time.

Note: When you create an active standby node, be sure to add any necessary storage locations. For more information, refer to [Adding Storage Locations](#).

Creating an Active Standby Node with a New Database

1. [Create a database](#), including the nodes that you intend to use as active standby nodes.
2. Using vsql, connect to a node **other than** the node that you want to use as an active standby node.
3. Use the [ALTER NODE](#) SQL statement to convert the node from a permanent node to an active standby node. The following example shows a typical alter node command.

```
=> ALTER NODE v_mart_node5 STANDBY;
```

Once you issue the ALTER NODE statement, the affected node goes down and restarts as an active standby node.

Creating an Active Standby Node with an Existing Database

When you are creating a new node with the intent of making it into an active standby node, shift the new node to ephemeral status as quickly as possible to prevent the cluster from moving data to the new node.

1. [Add a new node to your database](#). Do not rebalance the database.
2. Using vsql, connect to a node **other than** the node that you want to use as an active standby node.
3. Use the [ALTER NODE](#) SQL statement to convert the node from a permanent node to an ephemeral node. For example, the following command would set v_mart_node5 to a [node type](#) of ephemeral.

```
=> ALTER NODE v_mart_node5 EPHEMERAL;
```

4. [Rebalance the cluster](#) to move any data from the ephemeral node.
5. Use the [ALTER NODE](#) SQL statement to convert the node from an ephemeral node to an active standby node. The following example shows v_mart_node5 moving from ephemeral status to standby status.

```
=> ALTER NODE v_mart_node5 STANDBY;
```

Replace a Node Using an Active Standby Node

Note: A node must be down for Vertica before you can replace it with an active standby node. If you attempt to replace a functioning node, Vertica displays an error message.

Replacing a Node with Automatic Failover

Vertica can automatically replace a failed node with an active standby node. In the [General Parameters](#) configure the `FailoverToStandbyAfter` parameter to allow automatic failover.

Manually Replacing a Node

1. Connect to the database with [Administration Tools](#) or `vsql`.
2. Enter the command: `ALTER NODE node-name REPLACE WITH standby-node-name;`

Revert from an Active Standby Node

If an active standby node has replaced a Vertica node in your cluster, you can revert from the active standby node on a node-by-node basis or on a cluster-wide basis.

To revert from a single active standby node:

1. Connect to the database with [Administration Tools](#) or via `vsql`.
2. Enter the command: `ALTER NODE (node-name) RESET;`

To revert all cluster nodes from active standby:

1. Connect to the database with [Administration Tools](#) or via `vsql`.
2. Enter the command: `ALTER DATABASE (database-name) RESET STANDBY;`

If a down node cannot resume operation, Vertica ignores the reset request and leaves the standby node in place.

Fault Groups

Fault groups let you configure Vertica for your physical cluster layout. Sharing your cluster topology allows you to use Terrace Routing to reduce the buffer requirements of large queries and helps minimize the risk of correlated failures inherent in your environment, usually caused by shared resources.

Vertica automatically creates fault groups around control nodes (servers that run spread) in large cluster arrangements, placing nodes that share a control node in the same fault group. Automatic and user-defined fault groups do not include ephemeral nodes because such nodes hold no data.

Consider defining your own fault groups specific to your cluster's physical layout if you want to:

- Use Terrace Routing to reduce the buffer requirements of large queries.
- Reduce the risk of correlated failures. For example, by defining your rack layout, Vertica could tolerate a rack failure.
- Influence the placement of control nodes in the cluster.

Vertica supports complex, hierarchical fault groups of different shapes and sizes. The database platform provides a fault group script (DDL generator), SQL statements, system tables, and other monitoring tools.

See [High Availability With Fault Groups](#) for an overview of fault groups with a cluster topology example.

See Also

- [Creating a Fault Group Input File](#)
- [Creating Fault Groups Using the Fault Group Script](#)
- [Dropping Fault Groups](#)
- [Monitoring Fault Groups](#)

About the Fault Group Script

To help you define fault groups on your cluster, Vertica provides a script named `fault_group_ddl_generator.py` in the `/opt/vertica/scripts` directory. This script generates the SQL statements you need to run to create fault groups.

The `fault_group_ddl_generator.py` script does not create fault groups for you, but you can copy the output to a file. Then, when you run the helper script, you can use `\i` or `vsqf-f` commands to pass the cluster topology to Vertica.

The fault group script takes the following arguments:

- The database name
- The fault group input file

For example:

```
$ python /opt/vertica/scripts/fault_group_ddl_generator.py VMartdb fault_grp_input.out
```

See Also

- [Creating a Fault Group Input File](#)
- [Creating Fault Groups Using the Fault Group Script](#)
- [Dropping Fault Groups](#)
- [Monitoring Fault Groups](#)
- [Fault Groups](#)

Creating a Fault Group Input File

Use a text editor to create a fault group input file for the targeted cluster.

The following example shows how you can create a fault group input file for a cluster that has 8 racks with 8 nodes on each rack—for a total of 64 nodes in the cluster.

1. On the first line of the file, list the parent (top-level) fault groups, delimited by spaces.

```
rack1 rack2 rack3 rack4 rack5 rack6 rack7 rack8
```

2. On the subsequent lines, list the parent fault group followed by an equals sign (=). After the equals sign, list the nodes or fault groups delimited by spaces.

```
<parent> = <child_1> <child_2> <child_n...>
```

Such as:

```
rack1 = v_vmart_node0001 v_vmart_node0002 v_vmart_node0003 v_vmart_node0004  
rack2 = v_vmart_node0005 v_vmart_node0006 v_vmart_node0007 v_vmart_node0008  
rack3 = v_vmart_node0009 v_vmart_node0010 v_vmart_node0011 v_vmart_node0012  
rack4 = v_vmart_node0013 v_vmart_node0014 v_vmart_node0015 v_vmart_node0016  
rack5 = v_vmart_node0017 v_vmart_node0018 v_vmart_node0019 v_vmart_node0020  
rack6 = v_vmart_node0021 v_vmart_node0022 v_vmart_node0023 v_vmart_node0024  
rack7 = v_vmart_node0025 v_vmart_node0026 v_vmart_node0027 v_vmart_node0028  
rack8 = v_vmart_node0029 v_vmart_node0030 v_vmart_node0031 v_vmart_node0032
```

After the first row of parent fault groups, the order in which you write the group descriptions does not matter. All fault groups that you define in this file must refer back to a parent fault group. You can indicate the parent group directly or by specifying the child of a fault group that is the child of a parent fault group.

Such as:

```
rack1 rack2 rack3 rack4 rack5 rack6 rack7 rack8  
rack1 = v_vmart_node0001 v_vmart_node0002 v_vmart_node0003 v_vmart_node0004  
rack2 = v_vmart_node0005 v_vmart_node0006 v_vmart_node0007 v_vmart_node0008  
rack3 = v_vmart_node0009 v_vmart_node0010 v_vmart_node0011 v_vmart_node0012  
rack4 = v_vmart_node0013 v_vmart_node0014 v_vmart_node0015 v_vmart_node0016  
rack5 = v_vmart_node0017 v_vmart_node0018 v_vmart_node0019 v_vmart_node0020  
rack6 = v_vmart_node0021 v_vmart_node0022 v_vmart_node0023 v_vmart_node0024  
rack7 = v_vmart_node0025 v_vmart_node0026 v_vmart_node0027 v_vmart_node0028  
rack8 = v_vmart_node0029 v_vmart_node0030 v_vmart_node0031 v_vmart_node0032
```

After you create your fault group input file, you are ready to run the `fault_group_ddl_generator.py`. This script generates the DDL statements you need to create fault groups in Vertica.

If your Vertica database is co-located on a Hadoop cluster, and that cluster uses more than one rack, you can use fault groups to improve performance. See [Configuring Rack Locality](#).

See Also

[Creating Fault Groups Using the Fault Group Script](#)

Creating Fault Groups Using the Fault Group Script

When you define fault groups, Vertica distributes data segments across the cluster. This allows the cluster to be aware of your cluster topology so it can tolerate correlated failures inherent in your environment, such as a rack failure. For an overview, see [High Availability With Fault Groups](#).

Prerequisites for Defining Fault Groups

Defining fault groups requires careful and thorough network planning. You must have a solid understanding of your network topology.

Important: The user who creates fault groups must be a superuser.

Before you can define fault groups, you must:

- A fault group input file. For more information, see [Creating a Fault Group Input File](#).
- An already-existing database

Run the Fault Group Script

1. As the database administrator, run the `fault_group_ddl_generator.py` script and include the following arguments:
 - The database name
 - The fault group input file

For example:

```
$ python /opt/vertica/scripts/fault_group_ddl_generator.py  
VMart fault_groups_VMart.out > fault_group_ddl.sql
```

The preceding command writes the output of `fault_group_ddl_generator.py` to a file (`fault_group_ddl.sql`). This approach allows you to run a single SQL script instead of multiple DDL statements. Also consider saving your input file so you can modify fault groups later, such as after you expand the cluster or change the distribution of control nodes.

- Using `vsql`, run the DDL statements in `fault_group_ddl.sql` or execute the commands in the file using `vsql`.

```
=> \i fault_group_ddl.sql
```

- If you have large cluster enabled, realign the control nodes, as shown. Otherwise, proceed to the next step.

```
=> SELECT REALIGN_CONTROL_NODES();
```

- Save cluster changes to the spread configuration file.

```
=> SELECT RELOAD_SPREAD(true);
```

- Use Administration Tools to restart the database.
- Save changes to the cluster's data layout by calling the `REBALANCE_CLUSTER` function.

```
=> SELECT REBALANCE_CLUSTER();
```

See Also

Monitoring Fault Groups

You can monitor fault groups by querying Vertica system tables or by logging in to the Management Console (MC) interface.

Monitor Fault Groups Using System Tables

Use the following system tables to view information about fault groups and cluster vulnerabilities, such as the nodes the cluster cannot lose without the database going down:

- [V_CATALOG.FAULT_GROUPS](#)—View the hierarchy of all fault groups in the cluster.
- [V_CATALOG.CLUSTER_LAYOUT](#)—Observe the arrangement of the nodes participating in the data business and the fault groups that affect them. Ephemeral nodes do not appear in the cluster layout ring because they hold no data.

Monitoring Fault Groups Using Management Console

An MC administrator can monitor and highlight fault groups of interest by following these steps:

1. Click the running database you want to monitor and click **Manage** in the task bar.
2. Open the **Fault Group View** menu, and select the fault groups you want to view.
3. (Optional) Hide nodes that are not in the selected fault group to focus on fault groups of interest.

Nodes assigned to a fault group each have a colored bubble attached to the upper-left corner of the node icon. Each fault group has a unique color. If the number of fault groups exceeds the number of colors available, MC recycles the colors used previously.

Because Vertica supports complex, hierarchical fault groups of different shapes and sizes, MC displays multiple fault group participation as a stack of different-colored bubbles. The higher bubbles represent a lower-tiered fault group, which means that bubble is closer to the parent fault group, not the child or grandchild fault group.

For more information about fault group hierarchy, see [High Availability With Fault Groups](#).

Dropping Fault Groups

When you remove a fault group from the cluster, be aware that the drop operation removes the specified fault group and its child fault groups. Vertica places all nodes under the parent of the dropped fault group. To see the current fault group hierarchy in the cluster, query the [FAULT_GROUPS](#) system table.

Drop a Fault Group

Use the `DROP FAULT GROUP` statement to remove a fault group from the cluster. The following example shows how you can drop the `group2` fault group:

```
=> DROP FAULT GROUP group2;  
DROP FAULT GROUP
```

Drop All Fault Groups

Use the `ALTER DATABASE` statement to drop all fault groups, along with any child fault groups, from the specified database cluster.

The following command drops all fault groups from the `vmartdb` database.

```
=> ALTER DATABASE exampledb DROP ALL FAULT GROUP;  
ALTER DATABASE
```

Add Nodes Back to a Fault Group

To add a node back to a fault group, you must manually reassign it to a new or existing fault group. To do so, use the `CREATE FAULT GROUP` and `ALTER FAULT GROUP..ADD NODE` statements.

Large Cluster

To support scaling of existing clusters into large clusters and improve control message performance, Vertica delegates control message responsibilities to a subset of Vertica nodes, called **control nodes**. Control nodes communicate with each other. Other cluster nodes are assigned to a control node, which they use for control message communications.

Control nodes on large clusters

On clusters of 120 or more nodes, a large cluster layout is necessary and enabled by default. Vertica makes automatic control node assignments unless you use one of the following options:

If you want to ...	Do this
Install a new cluster before you create a database	Run the Vertica installation script with the <code>--large-cluster <integer></code> arguments. See the following topics for details: <ul style="list-style-type: none">• Installing Vertica with the Installation Script in Installing Vertica• Installing a Large Cluster in this guide
<ul style="list-style-type: none">• Expand an existing cluster for pre-existing databases• Change control nodes on an existing cluster	Use cluster management functions described in Defining and Realigning Control Nodes on an Existing Cluster .
Influence the placement of control nodes in your cluster's physical layout	Define fault groups to configure Vertica for your cluster. See Fault Groups for details.

Control nodes on small clusters

If your cluster has fewer than 120 nodes, large cluster is neither necessary nor automatically applied. As a result, all nodes are control nodes. However, Vertica lets you define control nodes on any sized cluster. Some environments, such as cloud deployments that might have higher network latency, could benefit from a smaller number of control nodes.

For details, see [Planning a Large Cluster Arrangement](#) and [Installing a Large Cluster](#).

Planning a Large Cluster

In a large cluster layout of 120 nodes or more, nodes form a correlated failure group, governed by their control node—the node that runs control messaging (spread). If a control node fails, all nodes in its host group also fail.

This topic provides tips on how to plan for a large cluster arrangement. See [Installing a Large Cluster](#) and [Large Cluster Best Practices](#) for more information.

Planning the number of control nodes

Configuring a large cluster requires careful and thorough network planning. You must have a solid understanding of your network topology before you configure the cluster.

To assess how many cluster nodes should be control nodes, use the square root of the total number of nodes expected to be in the database cluster to help satisfy both data K-Safety and rack fault tolerance for the cluster. Depending on the result, you might need to adjust the number of control nodes to account for your physical hardware/rack count. For example, if you have 121 nodes (with a result of 11), and your nodes will be distributed across 8 racks, you might want to increase the number of control nodes to 16 so you have two control nodes per rack.

Specifying the number of control nodes

Vertica provides different tools to help you define the number of control nodes, depending on your current configuration. Consider the following scenarios, in which cluster nodes are distributed among three racks in different configurations:

If you cluster fits this scenario ...	Consider this setup
Three control nodes. All other nodes are evenly distributed among the three racks.	Specify one control node per rack.
Five control nodes and three racks.	Specify two control nodes on two racks each and one control node on the final rack.
Four control nodes. One rack has twice as many nodes as the other racks.	Specify two control nodes on the larger rack and one control node each on the other two racks.

Installing a Large Cluster

Whether you are forming a new large cluster (adding all nodes for the first time) or expanding an existing cluster to a large cluster, Vertica provides two methods that let you specify the number of control nodes (the nodes that run control messaging). See the following sections for details:

- [If you want to install a new large cluster](#)
- [If you want to expand an existing cluster](#)

If you want to install a new large cluster

To configure Vertica for a new, large cluster, pass the `install_vertica` script the `--large-cluster <integer>` argument. Vertica selects the first `<integer>` number of hosts from the comma-separated `--hosts host_list` as control nodes and assigns all other hosts you specify in the `--hosts` argument to a control node based on a round-robin model.

Note: The number of hosts you include in the `--hosts` argument determines a large cluster layout, not the number of nodes you later include in the database. If you specify 120 or more hosts in the `--hosts` list, but you do not specifically enable large cluster by providing the `--large-cluster` argument, Vertica automatically enables large cluster and configures control nodes for you.

To help control nodes and the nodes assigned to them be configured for the highest possible fault tolerance, you must specify hosts in the `--hosts host_list` in a specific order. For example, if you have four sets of hosts on four racks, the first four nodes in the `--hosts host_list` must be one host from each rack in order to have one control node per rack. Then the list must consist of four hosts from each rack in line with the first four hosts. You'll continue to use this pattern of host listing for all targeted hosts. See [Sample rack-based cluster hosts topology](#) below for examples.

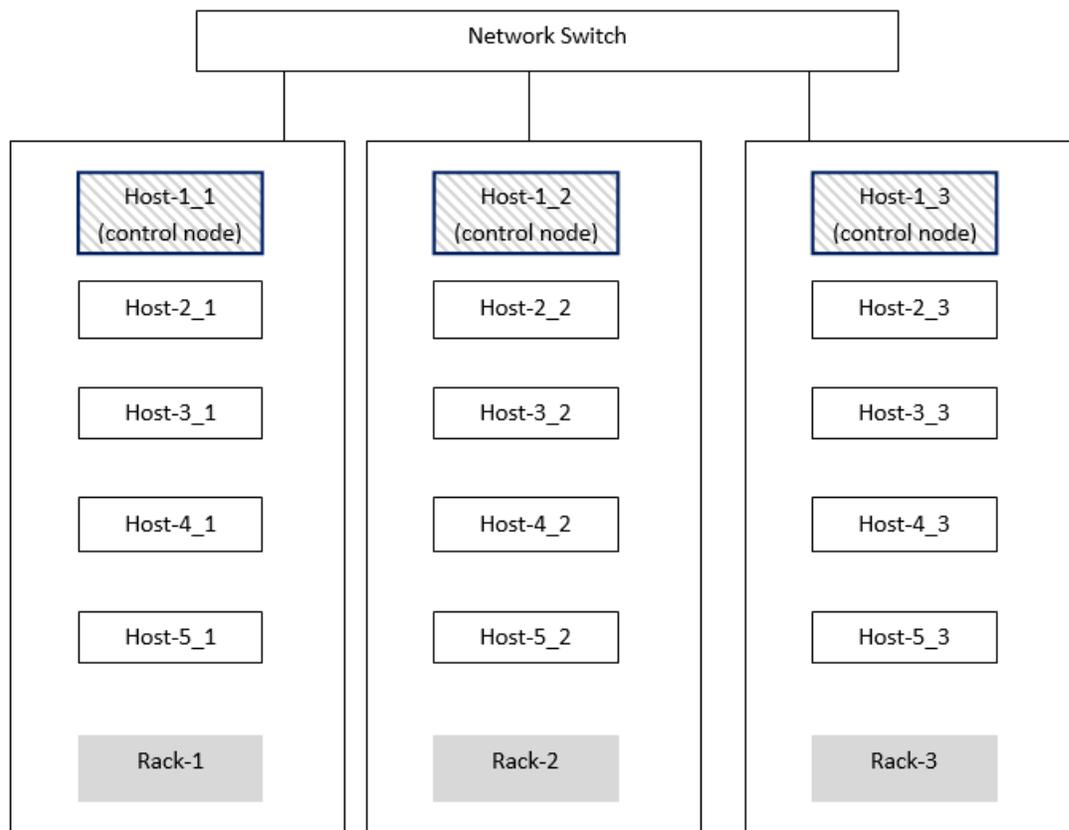

Tip: If you pass the `--large-cluster` argument a DEFAULT value instead of an `<integer>` value, Vertica calculates a number of control nodes based on the total number of nodes specified in the `--hosts host_list` argument. If you want a specific number of control nodes on the cluster, you must use the `<integer>` value.

For more information, see the following topics:

- [Planning a Large Cluster Arrangement](#)
- [Installing Vertica with the Installation Script](#) in Installing Vertica

Sample rack-based cluster hosts topology

This example shows a simple, multi-rack cluster layout, in which cluster nodes are evenly distributed across three racks. Each rack has one control node.

In the rack-based example:

- Rack-1, Rack-2, and Rack-3 are managed by a single network switch
- Host-1_1, Host-1_2, and Host-1_3 are control nodes
- All hosts on Rack-1 are assigned to control node Host-1_1
- All hosts on Rack-2 are assigned to control node Host-1_2
- All hosts on Rack-3 are assigned to control node Host-1_3

In the following `install_vertica` script fragment, note the order of the hosts in the `--hosts` list argument. The final arguments specifically enable large cluster and provide the number of control nodes (3):

```
... install_vertica --hosts Host-1-1,Host-1-2,Host-1-3,  
Host-2-1,Host-2-2,Host-2-3,Host-3-1,Host-3-2,Host-3-3,  
Host-4-1,Host-4-2,Host-4-3,Host-5-1,Host-5-2,Host-5-3 -rpm  
<vertica-package-name> <other-required-options>  
--large-cluster 3
```

After the installation process completes, use the Administration Tools to create a database. This operation generates a Vertica cluster with three control nodes and their respective associated hosts that reside on the same racks as the control node.

If you want to expand an existing cluster

When you add a node to an existing cluster, Vertica places the new node in an appropriate location within the cluster ring. Vertica then assigns the newly-added node to a control node, based on the cluster's current allocations.

To give you more flexibility and control over which nodes run Spread, you can use the `SET_CONTROL_SET_SIZE(integer)` function. This function works like the installation script's `--large-cluster <integer>` option. See [Defining and Realigning Control Nodes on an Existing Cluster](#) for details.

Important: The Vertica installation script cannot alter the database cluster.

Defining and Realigning Control Nodes on an Existing Cluster

This topic describes how to set up or change control node assignments on an existing cluster using a series of [cluster management functions](#). It assumes you already know how many control nodes the cluster needs for failover safety. See [Planning a Large Cluster Arrangement](#) for more information.

Note: If you are adding control nodes for the first time, run the Vertica installation script using the `--large-cluster <integer>` argument. See [Installing Vertica with the Installation Script](#) in [Installing Vertica](#).

Setting up control nodes on an existing cluster makes the following changes to the cluster:

- Configures the number of nodes that run spread.
- Assigns each non-control cluster node to a control node.

- Saves the new layout to the spread configuration file.
- Redistributes data across the cluster to improve fault tolerance.

How to set up control nodes on an existing cluster

After you add, remove, or swap nodes on an existing cluster, perform the following steps. This procedure helps the cluster maintain adequate control messaging distribution for failover safety. For more details, see "Control node assignment/realignment" in [Large Cluster Best Practices](#).

1. As the database administrator, log in to the Administration Tools and connect to the database.
2. Call the `SET_CONTROL_SET_SIZE(integer)` function with an integer argument that specifies the number of control nodes you want. For example, 4:

```
=> SELECT SET_CONTROL_SET_SIZE(4);
```

3. Call the `REALIGN_CONTROL_NODES()` function without arguments:

```
=> SELECT REALIGN_CONTROL_NODES();
```

4. Call the `RELOAD_SPREAD(true)` function to save changes to the spread configuration file:

```
=> SELECT RELOAD_SPREAD(true);
```

5. After the `RELOAD_SPREAD()` operation finishes, log back in to the Administration Tools, and restart the database.
6. Call the `REBALANCE_CLUSTER()` function to distribute data across the cluster:

```
=> SELECT REBALANCE_CLUSTER();
```

Important: You must run `REBALANCE_CLUSTER` for fault tolerance to be realized.

For more details about the functions used in this procedure, see [Cluster Management Functions](#) in the SQL Reference Manual.

Expanding the Database to a Large Cluster

If you have an existing database cluster that you want to expand to a large cluster (more than 120 nodes), follow these steps:

1. Log in to the Administration Tools as the database administrator and stop the database.
2. As root or a user with sudo privileges, open a BASH shell and run the `install_vertica` script with the `--add-hosts` argument, providing a comma-separated list of hosts you want to add to an existing Vertica cluster. See [Installing Vertica with the Installation Script](#) in [Installing Vertica](#).
3. Exit the shell and re-establish a `vsq` connection as the database administrator.
4. Log in to the Administration Tools and start the database.
5. Use the Administration Tools **Advanced Menu > Cluster Management > Add Hosts** option to add the standby hosts you created in Step 2.
6. Run `SET_CONTROL_SET_SIZE(integer)` to specify the number of control nodes you want on the cluster. See [Defining and Realigning Control Nodes on an Existing Cluster](#).
7. Optionally create fault groups to further define the layout of the control nodes within the physical cluster. See [Fault Groups](#).

Terrace Routing

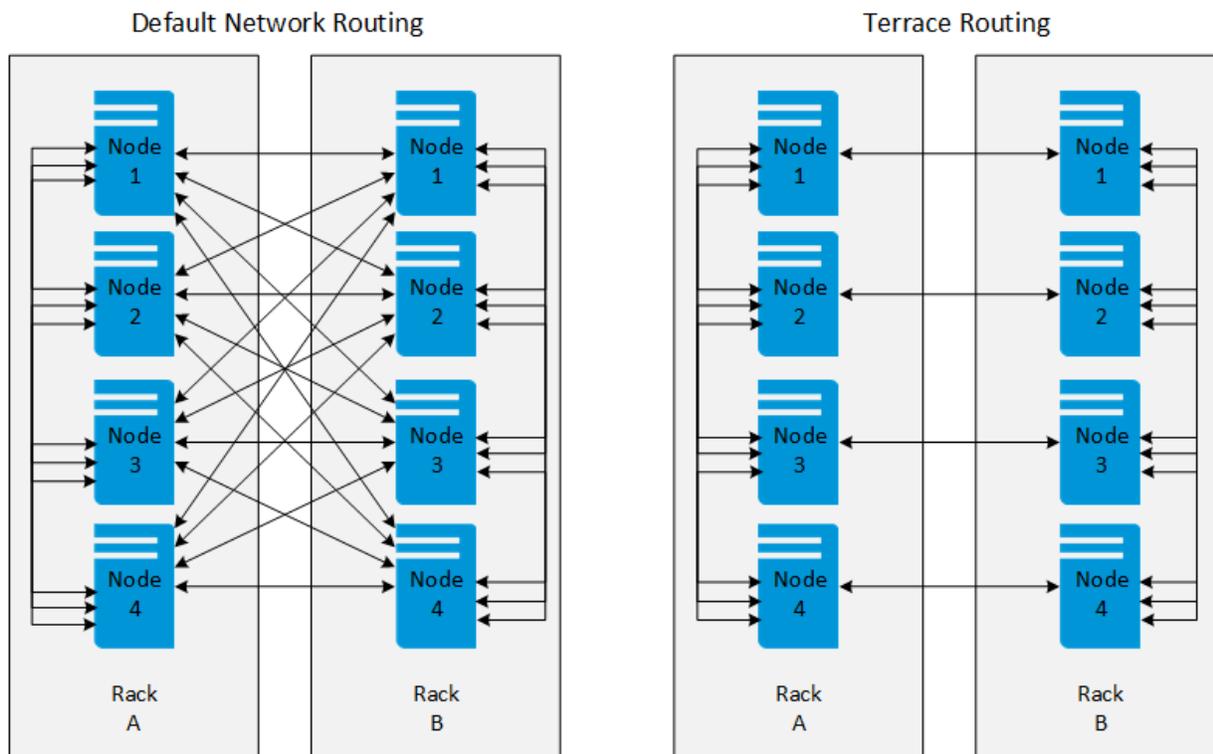

By default, nodes in a Vertica cluster form a fully connected network (complete graph). Therefore, large Vertica clusters contain an extremely large number of connections between nodes. Each connection requires buffering. Thus, your current system can have many connections, causing queries to have extremely large data requirements on each node.

Terrace routing is a feature that can reduce the buffer requirements of large queries. Use terrace routing in situations where you have large queries and clusters with a large number of nodes. Without terrace routing, these situations would otherwise require excessive buffer space.

How Terrace Routing Changes Routing Behavior

In the case when data needs to be sent from each node across an entire network. In this case, Vertica uses the n^{th} node in each rack to send to all the nodes in all the racks. Terrace routing

changes this behavior. Instead of sending to all nodes in all racks, the n^{th} node in each rack sends to the n^{th} nodes in all the other racks. It additionally sends to all the nodes in its own rack.

Before Enabling Terrace Routing

Before you apply terrace routing to your database make sure you have read the following topics and completed the tasks described:

- [Fault Groups](#)
- [Creating a Fault Group Input File](#)
- [Creating Fault Groups Using the Fault Group Script](#)
- [High Availability with Fault Groups](#)

How to Apply Terrace Routing

Your Vertica Analytics Platform is not aware of the topology of the cluster on which your Vertica database is running. By applying fault groups to your database, you can make your Vertica Analytics Platform aware of your network's topology.

Implementing terrace routing requires use of fault groups. Terrace routing uses the fault-group definitions to represent the topology of the network of the cluster, because rack membership

is a natural division for fault groups. In a terrace-routing approach, Vertica first distributes data within the rack (fault group) before forwarding it between racks. For information about creating fault groups, see [Creating Fault Groups Using the Fault Group Script](#).

For this reason, terrace routing uses the network within the rack to reduce the buffering requirements for queries. Networks between racks can have a higher capacity so there is a performance tradeoff when a connection goes off-rack.

Calculate the TerraceRoutingFactor

TerraceRoutingFactor is a general parameter that sets the ratio of connections without terrace routing to the number of connections with terrace routing.

You can calculate the TerraceRoutingFactor value using this formula:

$$((RackCount * RackPopulation) - 1) / (RackCount + RackPopulation - 2) = TerraceRoutingFactor$$

RackCount is the number of racks or fault groups in your cluster, and *RackPopulation* is the number of nodes in each rack or fault group.

Enable Terrace Routing

The TerraceRoutingFactor is set to a default value of 1000.0, which is large enough to disable the parameter for even the largest clusters. Micro Focus recommends enabling terrace routing when your cluster contains 64 or more nodes or if your queries require excessive buffer space.

The following examples show how you can enable terrace routing for varying node and rack configurations and then disable it.

Set the TerraceRoutingFactor on a 64 node cluster with 8 racks and 8 nodes in each rack:

```
=> ALTER DATABASE MyDB SET TerraceRoutingFactor = 4.5;
```

Set the TerraceRoutingFactor on a 80 node cluster with 10 racks and 8 nodes in each rack in the current session:

```
=> ALTER SESSION SET TerraceRoutingFactor = 4.94;
```

Disable terrace routing:

```
=> ALTER DATABASE MyDB SET TerraceRoutingFactor = 1000;
```

Monitoring Large Clusters

Monitor large cluster traits by querying the following system tables:

- [V_CATALOG.LARGE_CLUSTER_CONFIGURATION_STATUS](#)—Shows the current spread hosts and the control designations in the catalog so you can see if they match.
- [V_MONITOR.CRITICAL_HOSTS](#)—Lists the hosts whose failure would cause the database to become unsafe and force a shutdown.

Tip: The `CRITICAL_HOSTS` view is especially useful for large cluster arrangements. For non-large clusters, query the [CRITICAL_NODES](#) table.

You might also want to query the following system tables:

- [V_CATALOG.FAULT_GROUPS](#)—Shows fault groups and their hierarchy in the cluster.
- [V_CATALOG.CLUSTER_LAYOUT](#)—Shows the relative position of the actual arrangement of the nodes participating in the database cluster and the fault groups that affect them.

Large Cluster Best Practices

Keep the following best practices in mind when you are planning and managing a large cluster implementation.

Planning the number of control nodes

To assess how many cluster nodes should be control nodes, use the square root of the total number of nodes expected to be in the database cluster to help satisfy both data K-Safety and rack fault tolerance for the cluster. Depending on the result, you might need to adjust the number of control nodes to account for your physical hardware/rack count. For example, if you have 121 nodes (with a result of 11), and your nodes will be distributed across 8 racks, you might want to increase the number of control nodes to 16 so you have two control nodes per rack.

See [Planning a Large Cluster Arrangement](#).

Control node assignment/realignment

After you specify the number of control nodes, you must update the control host's (spread) configuration files to reflect the catalog change. Certain [cluster management functions](#) might require that you run other functions or restart the database or both.

If, for example, you drop a control node, cluster nodes that point to it are reassigned to another control node. If that node fails, all the nodes assigned to it also fail, so you need to use

the Administration Tools to restart the database. In this scenario, you'd call the `REALIGN_CONTROL_NODES()` and `RELOAD_SPREAD(true)` functions, which notify nodes of the changes and realign fault groups. Calling `RELOAD_SPREAD(true)` connects an existing cluster node to a newly-assigned control node.

On the other hand, if you run `REALIGN_CONTROL_NODES()` multiple times in a row, the layout does not change beyond the initial setup, so you don't need to restart the database. But if you add or drop a node and then run `REALIGN_CONTROL_NODES()`, the function call could change many node assignments.

Here's what happens with control node assignments when you add or drop nodes, whether those nodes are control nodes or non-control nodes:

- **If you add a cluster node**—Vertica assigns a control node to the newly-added node based on the current cluster configuration. If the new node joins a fault group, it is assigned to a control node from that fault group and requires a database restart to reconnect to that control node. See [Fault Groups](#) for more information.
- **If you drop a non-control node**—Vertica quietly drops the cluster node. This operation could change the cluster and spread layout, so you must call `REBALANCE_CLUSTER()` after you drop a node.
- **If you drop a control node**—All nodes assigned to the control node go down. In large cluster implementations, however, the database remains up because the down nodes are not buddies with other cluster nodes.

Dropping a control node results in $(n-1)$ control nodes. You must call `REALIGN_CONTROL_NODES()` to reset the cluster so it has n control nodes, which might or might not be the same number as before you dropped the control node. Remaining nodes are assigned new control nodes. In this operation, Vertica makes control node assignments based on the cluster layout. When it makes the new assignments, it respects user-defined fault groups, if any, which you can view by querying the `V_CATALOG.CLUSTER_LAYOUT` system table, a view that also lets you see the proposed new layout for nodes in the cluster. If you want to influence the layout of control nodes in the cluster, you should define fault groups.

For more information, see [Defining and Realigning Control Nodes on an Existing Cluster](#) and [Rebalancing Data Across Nodes](#).

Allocate standby nodes

Have as many standby nodes available as you can, ideally on racks you are already using in the cluster. If a node suffers a non-transient failure, use the Administration Tools "Replace Host" utility to swap in a standby node.

Standby node availability is especially important for control nodes. If you are swapping a node that's a control node, all nodes assigned to the control node's host grouping will need to be taken offline while you swap in the standby node. For details on node replacement, see [Replacing Nodes](#).

Plan for cluster growth

If you plan to expand an existing cluster to 120 or more nodes, you can configure the number of control nodes for the cluster after you add the new nodes. See [Defining and Realigning Control Nodes](#).

Write custom fault groups

When you deploy a large cluster, Vertica automatically creates fault groups around control nodes, placing nodes that share a control node into the same fault group. Alternatively, you can specify which cluster nodes should reside in a particular correlated failure group and share a control node. See [High Availability With Fault Groups](#) in Vertica Concepts.

Use segmented projections

On large-cluster setups, minimize the use of unsegmented projections in favor of segmented projections. When you use segmented projections, Vertica creates buddy projections and distributes copies of segmented projections across database nodes. If a node fails, data remains available on the other cluster nodes.

Use the Database Designer

Micro Focus recommends that you use the Database Designer to create your physical schema. If you choose to design projections manually, you should segment large tables across all database nodes and replicate (unsegment) small table projections on all database nodes.

Elastic Cluster

You can scale your cluster up or down to meet the needs of your database. The most common case is to add nodes to your database cluster to accommodate more data and provide better query performance. However, you can scale down your cluster if you find that it is overprovisioned or if you need to divert hardware for other uses.

You scale your cluster by adding or removing nodes. Nodes can be added or removed without having to shut down or restart the database. After adding a node or before removing a node,

Vertica begins a rebalancing process that moves data around the cluster to populate the new nodes or move data off of nodes about to be removed from the database. During this process, data can be exchanged between nodes that are not being added or removed to maintain robust intelligent K-safety. If Vertica determines that the data cannot be rebalanced in a single iteration due to a lack of disk space, then the rebalance is done in multiple iterations.

To help make data rebalancing due to cluster scaling more efficient, Vertica locally segments data storage on each node so it can be easily moved to other nodes in the cluster. When a new node is added to the cluster, existing nodes in the cluster give up some of their data segments to populate the new node and exchange segments to keep the number of nodes that any one node depends upon to a minimum. This strategy keeps to a minimum the number of nodes that may become critical when a node fails (see [Critical Nodes/K-Safety](#)). When a node is being removed from the cluster, all of its storage containers are moved to other nodes in the cluster (which also relocates data segments to minimize nodes that may become critical when a node fails). This method of breaking data into portable segments is referred to as elastic cluster, since it makes enlarging or shrinking the cluster easier.

The alternative to elastic cluster is to resegment all of the data in the projection and redistribute it to all of the nodes in the database evenly any time a node is added or removed. This method requires more processing and more disk space, since it requires all of the data in all projections to essentially be dumped and reloaded.

Elastic Cluster Scaling Factor

In a new installation, each node has a *scaling factor* that specifies the number of local segments (see [Scaling Factor](#)). Rebalance efficiently redistributes data by relocating local segments provided that, after nodes are added or removed, there are sufficient local segments in the cluster to redistribute the data evenly (determined by [MAXIMUM_SKEW_PERCENT](#)). For example, if the scaling factor = 8, and there are initially 5 nodes, then there are a total of 40 local segments cluster wide.

If you add two additional nodes (7 nodes) Vertica relocates 5 local segments on 2 nodes, and 6 such segments on 5 nodes, resulting in roughly a 16.7% skew. Rebalance chooses relocates local segments only if the resulting skew is less than the allowed threshold, as determined by [MAXIMUM_SKEW_PERCENT](#). Otherwise, segmentation space (and hence data, if uniformly distributed over this space) is evenly distributed among the 7 nodes, and new local segment boundaries are drawn for each node, such that each node again has 8 local segments.

Note: By default, the scaling factor only has an effect while Vertica rebalances the database. While rebalancing, each node breaks the projection segments it contains into storage containers, which it then moves to other nodes if necessary. After rebalancing, the data is recombined into ROS containers. It is possible to have Vertica always group data

into storage containers. See [Local Data Segmentation](#) for more information.

Enabling and Disabling Elastic Cluster

You enable and disable elastic cluster using functions. See the entries for the [ENABLE_ELASTIC_CLUSTER](#) and [DISABLE_ELASTIC_CLUSTER](#) functions in the SQL Reference Manual.

Query the [ELASTIC_CLUSTER](#) system table to determine if elastic cluster is enabled:

```
=> SELECT is_enabled FROM ELASTIC_CLUSTER;
is_enabled
-----
t
(1 row)
```

Scaling Factor

To avoid an increased number of ROS containers, do not disable local segmentation and do not change the scaling factor.

Viewing Scaling Factor Settings

To view the scaling factor, query the [ELASTIC_CLUSTER](#) table:

```
=> SELECT scaling_factor FROM ELASTIC_CLUSTER;
scaling_factor
-----
4
(1 row)

=> SELECT SET_SCALING_FACTOR(6);
SET_SCALING_FACTOR
-----
SET
(1 row)

=> SELECT scaling_factor FROM ELASTIC_CLUSTER;
scaling_factor
-----
6
(1 row)
```

Setting the Scaling Factor

The scaling factor determines the number of storage containers that Vertica uses to store each projection across the database during rebalancing when local segmentation is enabled. When setting the scaling factor, follow these guidelines:

- The number of storage containers should be greater than or equal to the number of partitions multiplied by the number of local segments:

$$\text{num-storage-containers} \geq (\text{num-partitions} * \text{num-Local-segments})$$

- Set the scaling factor high enough so rebalance can transfer local segments to satisfy the skew threshold, but small enough so the number of storage containers does not result in too many ROS containers, and cause ROS *pushback*. The maximum number of ROS containers is 1024.

Use the [SET_SCALING_FACTOR](#) function to change your database's scaling factor. The scaling factor can be an integer between 1 and 32.

```
=> SELECT SET_SCALING_FACTOR(12);  
SET_SCALING_FACTOR  
-----  
SET  
(1 row)
```

Local Data Segmentation

By default, the scaling factor only has an effect when Vertica rebalances the database. During rebalancing, nodes break the projection segments they contain into storage containers which they can quickly move to other nodes.

This process is more efficient than re-segmenting the entire projection (in particular, less free disk space is required), but it still has significant overhead, since storage containers have to be separated into local segments, some of which are then transferred to other nodes. This overhead is not a problem if you rarely add or remove nodes from your database.

However, if your database is growing rapidly and is constantly busy, you may find the process of adding nodes becomes disruptive. In this case, you can enable local segmentation, which tells Vertica to always segment its data based on the scaling factor, so the data is always broken into containers that are easily moved. Having the data segmented in this way dramatically speeds up the process of adding or removing nodes, since the data is always in a state that can be quickly relocated to another node. The rebalancing process that Vertica

performs after adding or removing a node just has to decide which storage containers to relocate, instead of first having to first break the data into storage containers.

Local data segmentation increases the number of storage containers stored on each node. This is not an issue unless a table contains many partitions. For example, if the table is partitioned by day and contains one or more years. If local data segmentation is enabled, then each of these table partitions is broken into multiple local storage segments, which potentially results in a huge number of files which can lead to ROS "pushback." Consider your table partitions and the effect enabling local data segmentation may have before enabling the feature.

Enabling and Disabling Local Segmentation

To enable local segmentation, use the [ENABLE_LOCAL_SEGMENTS](#) function. To disable local segmentation, use the [DISABLE_LOCAL_SEGMENTATION](#) function:

```
=> SELECT ENABLE_LOCAL_SEGMENTS();
ENABLE_LOCAL_SEGMENTS
-----
ENABLED
(1 row)

=> SELECT is_local_segment_enabled FROM elastic_cluster;
is_enabled
-----
t
(1 row)

=> SELECT DISABLE_LOCAL_SEGMENTS();
DISABLE_LOCAL_SEGMENTS
-----
DISABLED
(1 row)

=> SELECT is_local_segment_enabled FROM ELASTIC_CLUSTER;
is_enabled
-----
f
(1 row)
```

Elastic Cluster Best Practices

The following are some best practices with regard to local segmentation.

Note: You should always perform a database backup before and after performing any of the operations discussed in this topic. You need to back up before changing any elastic cluster or local segmentation settings to guard against a hardware failure causing the rebalance process to leave the database in an unusable state. You should perform a full backup of the database after the rebalance procedure to avoid having to rebalance the

database again if you need to restore from a backup.

When to Enable Local Data Segmentation

[Local Data Segmentation](#) can significantly speed up the process of resizing your cluster. You should enable local data segmentation if:

- your database does not contain tables with hundreds of partitions.
- the number of nodes in the database cluster is a power of two.
- you plan to expand or contract the size of your cluster.

Local segmentation can result in an excessive number of storage containers with tables that have hundreds of partitions, or in clusters with a non-power-of-two number of nodes. If your database has these two features, take care when enabling local segmentation.

Monitoring Elastic Cluster Rebalancing

Vertica includes system tables that can be used to monitor the rebalance status of an elastic cluster and gain general insight to the status of elastic cluster on your nodes.

- The [REBALANCE_TABLE_STATUS](#) table provides general information about a rebalance. It shows, for each table, the amount of data that has been separated, the amount that is currently being separated, and the amount to be separated. It also shows the amount of data transferred, the amount that is currently being transferred, and the remaining amount to be transferred (or an estimate if storage is not separated).

Note: If multiple rebalance methods were used for a single table (for example, the table has unsegmented and segmented projections), the table may appear multiple times - once for each rebalance method.

- [REBALANCE_PROJECTION_STATUS](#) can be used to gain more insight into the details for a particular projection that is being rebalanced. It provides the same type of information as above, but in terms of a projection instead of a table.

In each table, *separated_percent* and *transferred_percent* can be used to determine overall progress.

Historical Rebalance Information

Historical information about work completed is retained, so use the predicate "*where is_latest*" to restrict the output to only the most recent or current rebalance activity. The historical data may include information about dropped projections or tables. If a table or projection has been dropped and information about the anchor table is not available, then NULL is displayed for the `table_id` and "<unknown>" is displayed for the `table_name`. Information on dropped tables is still useful, for example, in providing justification for the duration of a task.

Adding Nodes

There are many reasons for adding one or more nodes to an installation of Vertica:

- **Increase system performance.** Add additional nodes due to a high query load or load latency or increase disk space without adding storage locations to existing nodes.

Note: The database response time depends on factors such as type and size of the application query, database design, data size and data types stored, available computational power, and network bandwidth. Adding nodes to a database cluster does not necessarily improve the system response time for every query, especially if the response time is already short, e.g., less than 10 seconds, or the response time is not hardware bound.

- **Make the database K-safe** (K-safety=1) or increase K-safety to 2. See [Failure Recovery](#) for details.
- **Swap a node for maintenance.** Use a spare machine to temporarily take over the activities of an existing node that needs maintenance. The node that requires maintenance is known ahead of time so that when it is temporarily removed from service, the cluster is not vulnerable to additional node failures.
- **Replace a node.** Permanently add a node to remove obsolete or malfunctioning hardware.

Important: : If you installed Vertica on a single node without specifying the IP address or hostname (or you used localhost), you cannot expand the cluster. You must reinstall Vertica and specify an IP address or hostname that is not localhost/127.0.0.1.

Adding nodes consists of the following general tasks:

1. [Back up the database.](#)

Micro Focus strongly recommends that you back up the database before you perform this significant operation because it entails creating new projections, refreshing them, and then deleting the old projections. See [Backing Up and Restoring the Database](#) for more information.

The process of migrating the projection design to include the additional nodes could take a while; however during this time, all user activity on the database can proceed normally, using the old projections.

2. Configure the hosts you want to add to the cluster.

See [Before you Install Vertica](#) in Installing Vertica. You will also need to edit the hosts configuration file on all of the existing nodes in the cluster to ensure they can resolve the new host.

3. [Add one or more hosts to the cluster.](#)
4. [Add the hosts](#) you added to the cluster (in step 3) to the database.

Note: When you add a "host" to the database, it becomes a "node." You can add nodes to your database using either the Administration Tools or the Management Console (See [Monitoring Vertica Using Management Console.](#))

You can also add nodes using the `admintools` command line, which allows you to preserve the specific order of the nodes you add.

After you add one or more nodes to the database, Vertica automatically distributes updated configuration files to the rest of the nodes in the cluster and starts the process of rebalancing data in the cluster. See [Rebalancing Data Across Nodes](#) for details.

Adding Hosts to a Cluster

After you have backed up the database and configured the hosts you want to add to the cluster, you can now add hosts to the cluster using the `update_vertica` script.

You can use MC to add standby nodes to a database, but you cannot add hosts to a cluster using MC.

Prerequisites and Restrictions

- If you installed Vertica on a single node without specifying the IP address or hostname (you used `localhost`), it is not possible to expand the cluster. You must reinstall Vertica and specify an IP address or hostname.
- If your database has more than one node already, you can add a node without stopping the server. However, if you are adding a node to a single-node installation, then you must shut down both the database and spread. If you do not, the system returns an error like the following:

```
$ sudo /opt/vertica/sbin/update_vertica --add-hosts v_vmart_node0005 --rpm vertica_8.1.x.x86_64.RHEL6.rpm
Vertica 7.0.x Installation Tool
Starting installation tasks...
Getting system information for cluster (this may take a while)...
Spread is running on ['v_vmart_node0001']. Vertica and spread must be stopped before adding nodes to a 1 node cluster.
Use the admin tools to stop the database, if running, then use the following command to stop spread:
    /etc/init.d/spread stop (as root or with sudo)
Installation completed with errors.
Installation failed.
```

Procedure to Add Hosts

From one of the existing cluster hosts, run the `update_vertica` script with a minimum of the `--add-hosts host(s)` parameter (where *host(s)* is the hostname or IP address of the system (s) that you are adding to the cluster) and the `--rpm` or `--deb` parameter:

```
# /opt/vertica/sbin/update_vertica --add-hosts host(s) --rpm package
```

Note: See [Installing Vertica with the Installation Script](#) for the full list of parameters. You must also provide the same options you used when originally installing the cluster.

The `update_vertica` script uses all the same options as `install_vertica` and:

- Installs the Vertica RPM on the new host.
- Performs post-installation checks, including RPM version and N-way network connectivity checks.
- Modifies spread to encompass the larger cluster.
- Configures the [Administration Tools](#) to work with the larger cluster.

Important Tips:

- Consider using `--large-cluster` with more than 50 nodes.
- A host can be specified by the hostname or IP address of the system you are adding to the cluster. However, internally Vertica stores all host addresses as IP addresses.
- Do not use include spaces in the hostname/IP address list provided with `--add-hosts` if you specified more than one host.

- If a package is specified with `--rpm/--deb`, and that package is newer than the one currently installed on the existing cluster, then, Vertica first installs the new package on the existing cluster hosts before the newly-added hosts.
- Use the same command line parameters for the database administrator username, password, and directory path you used when you installed the cluster originally. Alternatively, you can create a properties file to save the parameters during install and then re-using it on subsequent install and update operations. See [Installing Vertica Silently](#).
- If you are installing using `sudo`, the database administrator user (`dbadmin`) must already exist on the hosts you are adding and must be configured with passwords and home directory paths identical to the existing hosts. Vertica sets up passwordless ssh from existing hosts to the new hosts, if needed.
- If you initially used the `--point-to-point` option to configure spread to use direct, point-to-point communication between nodes on the subnet, then use the `--point-to-point` option whenever you run `install_vertica` or `update_vertica`. Otherwise, your cluster's configuration is reverted to the default (*broadcast*), which may impact future databases.
- The maximum number of spread daemons supported in point-to-point communication and broadcast traffic is 80.
 - It is possible to have more than 80 nodes by using large cluster mode, which does not install a spread daemon on each node.

Examples:

```
--add-hosts host01 --rpm
--add-hosts 192.168.233.101
--add-hosts host02,host03
```

Adding Nodes to a Database

Once you have added one or more hosts to the cluster, you can add them as nodes to the database.

You can add nodes to a database using these methods:

- The Management Console interface
- The Administration Tools interface

- The `admintools` command line (to preserve the specific order of the nodes you add)

Note: When you add nodes to a database using either the MC or the Administration Tools interface (GUI), Vertica does not always preserve the order of the host and node names. You can preserve the order of the nodes you add by using the `admintools` command line with the `db_add_node` tool. An example follows, where the `-s` option allows you to specify the order of the nodes you are adding.

```
$ admintools -t db_add_node -d sampleDB -p 'password' -s  
192.0.2.1,192.0.2.2,192.0.2.3
```

To Add Nodes to a Database Using MC

Only nodes in STANDBY state are eligible for addition. STANDBY nodes are nodes included in the cluster but not yet assigned to the database.

You add nodes to a database on MC's **Manage** page. Click the node you want to act upon, and then click **Add node** in the Node List.

When you add a node, the node icon in the cluster view changes color from gray (empty) to green as the node comes online. Additionally, a task list displays detailed progress of the node addition process.

To Add Nodes to a Database Using the Administration Tools:

1. Open the Administration Tools. (See [Using the Administration Tools.](#))
2. On the **Main Menu**, select **View Database Cluster State** to verify that the database is running. If it is not, start it.
3. From the **Main Menu**, select **Advanced Tools Menu** and click **OK**.
4. In the **Advanced Menu**, select **Cluster Management** and click **OK**.
5. In the **Cluster Management** menu, select **Add Host(s)** and click **OK**.
6. Select the database to which you want to add one or more hosts, and then select **OK**.
A list of unused hosts is displayed.
7. Select the hosts you want to add to the database and click **OK**.
8. When prompted, click **Yes** to confirm that you want to add the hosts.

9. When prompted, enter the password for the database, and then select **OK**.
10. When prompted that the hosts were successfully added, select **OK**.
11. Vertica now automatically starts the rebalancing process to populate the new node with data. When prompted, enter the path to a temporary directory that the Database Designer can use to rebalance the data in the database and select **OK**.
12. Either press enter to accept the default K-Safety value, or enter a new higher value for the database and select **OK**.
13. Select whether Vertica should immediately start [rebalancing the database](#), or whether it should create a script to rebalance the database later. You should select the option to automatically start rebalancing unless you want to delay rebalancing until a time when the database has a lower load. If you choose to automatically rebalance the database, the script is still created and saved where you can use it later.
14. Review the summary of the rebalancing process and select **Proceed**.
15. If you chose to automatically rebalance, the rebalance process runs. If you chose to create a script, the script is generated and saved. In either case, you are shown a success screen, and prompted to select **OK** to end the Add Node process.

Removing Nodes

Although less common than adding a node, permanently removing a node is useful if the host system is obsolete or over-provisioned.

Note: You cannot remove nodes if doing so leaves your cluster without the minimum number of nodes required to maintain your database's current K-safety level (3 nodes for a database with a K-safety level of 1, and 5 nodes for a K-safety level of 2). If you really wish to remove the node or nodes from the database, you first must reduce the K-safety level of your database.

This section includes:

Automatic Eviction of Unhealthy Nodes

To decrease the impact of an unhealthy node in your Vertica database, Vertica performs regular health checks. The health checks are performed on a regular schedule. The time between each interval is set by the user using the DatabaseHeartBeatInterval parameter. This parameter specifies the time intervals between internal health checks performed by each node. After a successful health check, the node sends a heartbeat. If a heartbeat is not detected by the time five intervals have elapsed, then the node is evicted from the database cluster.

The formula for the amount of time allowed before an eviction is

$$TOT = DHBI * 5$$

where *TOT* is the total time (in seconds) allowed without a heartbeat before eviction, and *DHBI* is equal to the value of DatabaseHeartBeatInterval.

By default DatabaseHeartBeatInterval is set to 120, which allows five 120-second intervals to pass without a heartbeat. If you set the DatabaseHeartBeatInterval too low, it can cause evictions in cases of brief node health issues. Sometimes, such premature evictions result in lower availability and performance of the Vertica database.

See Also

DatabaseHeartbeatInterval in [General Parameters](#)

Lowering K-Safety to Enable Node Removal

A database with a K-safety level of 1 requires at least three nodes to operate, and a database with a K-Safety level 2 requires at least 5 nodes to operate. To remove a node from a cluster that is at the minimum number of nodes for its database's K-safety level, first lower the K-safety level with [MARK_DESIGN_KSAFE](#).

Caution: Lowering the K-safety level of a database to 0 eliminates Vertica's fault tolerance features. If you must reduce K-safety to 0, first [back up the database](#).

To lower the K-safety level of the database:

1. Connect to the database with [Administration Tools](#) or `vsq`.
2. Call the function `MARK_DESIGN_KSAFE`:

```
SELECT MARK_DESIGN_KSAFE(n);
```

where *n* is the new K-safety level for the database.

Removing Nodes From a Database

As long as there are enough nodes remaining to satisfy the K-Safety requirements, you can remove the node from a database. You cannot drop nodes that are critical for K-safety. See [Lowering K-Safety to Enable Node Removal](#)

You can remove nodes from a database using one of the following methods:

- The Management Console interface
- The Administration Tools interface

Prerequisites

Before attempting to remove a node from the database, ensure the following prerequisites are met:

- Your database must be running.
- You must [back up the database](#).

- If necessary, [lower the K-safety of your database](#) if the cluster will not be large enough to support its current level of K-safety after you remove nodes. Remember you must have enough nodes to satisfy K-Safety requirements.

Remove Hosts From the Database with Management Console

Remove nodes with Management Console from the **Manage** page. You can only remove nodes that belong to the database cluster and have a DOWN state (red). Remove nodes as follows:

1. Select the node you want to remove.
2. Click **Remove node** in the Node List.

When you remove a node the state changes to STANDBY. You can add STANDBY nodes back to the database later, see [Using the Management Console to Replace Nodes](#).

Remove Hosts From the Database with Administration Tools

To remove unused hosts from the database using Administration Tools:

1. Open the Administration Tools. See [Using the Administration Tools](#) for information about accessing the Administration Tools.
2. On the **Main Menu**, select **View Database Cluster State** to verify that the database is running. If the database is not running, start it.
3. From the **Main Menu**, select **Advanced Tools Menu** and select **OK**.
4. In the **Advanced** menu, select **Cluster Management** and select **OK**.
5. In the **Cluster Management** menu, select **Remove Host(s) from Database** and select **OK**.
6. When warned that you must redesign your database and create projections that exclude the hosts you are going to drop, select **Yes**.
7. Select the database from which you want to remove the hosts and select **OK**.

A list of currently active hosts appears.

8. Select the hosts you want to remove from the database and select **OK**.
9. When prompted, select **OK** to confirm that you want to remove the hosts.
10. When informed that the hosts were successfully removed, select **OK**.

11. If you removed a host from a [Large Cluster](#) configuration, open a vsql session and run the following command:

```
SELECT realign_control_nodes();
```

For more details, see [REALIGN_CONTROL_NODES](#).

12. If this host is not used by any other database in the cluster, you can remove the host from the cluster. See [Removing Hosts From a Cluster](#).

Removing Hosts From a Cluster

If a host that you removed from the database is not used by any other database, you can remove it from the cluster using the `update_vertica` script. You can leave the database running (UP) during this operation.

You can [remove hosts from a database](#) on the MC interface, but you cannot remove those hosts from a cluster.

Prerequisites

The host must not be used by any database.

Procedure to Remove Hosts

From one of the hosts in the cluster, run `update_vertica` with the `--remove-hosts` switch. Provide a comma-separated list of hosts to remove from an existing Vertica cluster. You can specify a host by the host name or IP address of the system.

This example removes `host01`, `host02`, and `host03` from the cluster:

```
# /opt/vertica/sbin/update_vertica --remove-hosts host01,host02,host03
```

Note: See [Installing Vertica with the Installation Script](#) for the full list of parameters.

The `update_vertica` script uses all the same options as `install_vertica` and:

- Modifies the spread to match the smaller cluster.
- Configures the Administration Tools to work with the smaller cluster.

Important Tips

- Do not include spaces in the hostname list provided with `--remove-hosts` if you specified more than one host.
- If a new RPM is specified with `--rpm`, then Vertica will first install it on the existing cluster hosts before proceeding.
- Use the same command line parameters as those used when you installed the original cluster. Specifically if you used non-default values for the database administrator username, password, or directory path, provide the same when you remove hosts; otherwise, the procedure fails. Consider creating a properties file in which you save the parameters during the installation, which you can reuse on subsequent install and update operations. See [Installing Vertica Silently](#).

Replacing Nodes

If you have a K-Safe database, you can replace nodes, as necessary, without bringing the system down. For example, you might want to replace an existing node if you:

- Need to repair an existing host system that no longer functions and restore it to the cluster
- Want to exchange an existing host system for another more powerful system

Note: Vertica does not support replacing a node on a K-safe=0 database. Use the procedures to [add](#) and [remove](#) nodes instead.

The process you use to replace a node depends on whether you are replacing the node with:

- A host that uses the same name and IP address
- A host that uses a different name and IP address
- An active standby node

Prerequisites

- Configure the replacement hosts for Vertica. See [Before you Install Vertica](#) in [Installing Vertica](#).
- Read the Important **Tips** sections under [Adding Hosts to a Cluster](#) and [Removing Hosts From a Cluster](#).
- Ensure that the database administrator user exists on the new host and is configured identically to the existing hosts. Vertica will setup passwordless ssh as needed.
- Ensure that directories for Catalog Path, Data Path, and any storage locations are added to the database when you create it and/or are mounted correctly on the new host and have read and write access permissions for the database administrator user. Also ensure that there is sufficient disk space.
- Follow the best practice procedure below for introducing the failed hardware back into the cluster to avoid spurious full-node rebuilds.

Best Practice for Restoring Failed Hardware

Following this procedure will prevent Vertica from misdiagnosing missing disk or bad mounts as data corruptions, which would result in a time-consuming, full-node recovery.

If a server fails due to hardware issues, for example a bad disk or a failed controller, upon repairing the hardware:

1. Reboot the machine into runlevel 1, which is a root and console-only mode.

Runlevel 1 prevents network connectivity and keeps Vertica from attempting to reconnect to the cluster.

2. In runlevel 1, validate that the hardware has been repaired, the controllers are online, and any RAID recover is able to proceed.

Note: You do not need to initialize RAID recover in runlevel 1; simply validate that it can recover.

3. Once the hardware is confirmed consistent, only then reboot to runlevel 3 or higher.

At this point, the network activates, and Vertica rejoins the cluster and automatically recovers any missing data. Note that, on a single-node database, if any files that were associated with a projection have been deleted or corrupted, Vertica will delete all files associated with that projection, which could result in data loss.

Replacing a Host Using the Same Name and IP Address

If a host of an existing Vertica database is removed you can replace it while the database is running.

Note: Remember a host in Vertica consists of the hardware and operating system on which Vertica software resides, as well as the same network configurations.

You can replace the host with a new host that has the following same characteristics as the old host:

- Name
- IP address

- Operating system
- The OS administrator user
- Directory location

Replacing the host while your database is running prevents system downtime. Before replacing a host, backup your database. See [Backing Up and Restoring the Database](#) for more information.

Replace a host using the same characteristics as follows:

1. Run `install_vertica` from a functioning host using the `--rpm` or `--deb` parameter:

```
$ /opt/vertica/sbin/install_vertica --rpm <rpm_package>
```

For more information see [Installing Vertica](#).

2. Use Administration Tools from an existing node to restart the new host. See [Restart Vertica on a Node](#).

The node automatically joins the database and recovers its data by querying the other nodes in the database. It then transitions to an UP state.

Replacing a Failed Node Using a Node with a Different IP Address

Replacing a failed node with a host system that has a different IP address from the original consists of the following steps:

1. [Back up the database](#).

Micro Focus recommends that you back up the database before you perform this significant operation because it entails creating new projections, deleting old projections, and reloading data.

2. Add the new host to the cluster. See [Adding Hosts to a Cluster](#).
3. If Vertica is still running in the node being replaced, then use the Administration Tools to *Stop Vertica on Host* on the host being replaced.

4. Use the Administration Tools to [replace the original host](#) with the new host. If you are using more than one database, replace the original host in all the databases in which it is used. See [Replacing Hosts](#).
5. Use the procedure in [Distributing Configuration Files to the New Host](#) to transfer metadata to the new host.
6. [Remove the host from the cluster](#).
7. Use the Administration Tools to restart Vertica on the host. On the **Main Menu**, select **Restart Vertica on Host**, and click **OK**. See [Start the Database](#) for more information.

Once you have completed this process, the replacement node automatically recovers the data that was stored in the original node by querying other nodes within the database.

Replacing a Functioning Node Using a Different Name and IP Address

Replacing a node with a host system that has a different IP address and host name from the original consists of the following general steps:

1. [Back up the database](#).

Micro Focus recommends that you back up the database before you perform this significant operation because it entails creating new projections, deleting old projections, and reloading data.

2. [Add the replacement hosts to the cluster](#).

At this point, both the original host that you want to remove and the new replacement host are members of the cluster.

3. Use the Administration Tools to Stop *Vertica on Host* on the host being replaced.
4. Use the Administration Tools to [replace the original host](#) with the new host. If you are using more than one database, replace the original host in all the databases in which it is used. See [Replacing Hosts](#).
5. [Remove the host from the cluster](#).
6. Restart Vertica on the host.

Once you have completed this process, the replacement node automatically recovers the data that was stored in the original node by querying the other nodes within the database. It then transitions to an UP state.

Note: If you do not remove the original host from the cluster and you attempt to restart the database, the host is not invited to join the database because its node address does not match the new address stored in the database catalog. Therefore, it remains in the INITIALIZING state.

Using the Administration Tools to Replace Nodes

If you are replacing a node with a host that uses a different name and IP address, use the Administration Tools to replace the original host with the new host. Alternatively, you can [use the Management Console to replace a node](#).

Replace the Original Host with a New Host Using the Administration Tools

To replace the original host with a new host using the Administration Tools:

1. Back up the database. See [Backing Up and Restoring the Database](#).
2. From a node that is up, and is not going to be replaced, open the Administration Tools.
3. On the **Main Menu**, select **View Database Cluster State** to verify that the database is running. If it's not running, use the Start Database command on the Main Menu to restart it.
4. On the **Main Menu**, select **Advanced Menu**.
5. In the **Advanced Menu**, select **Stop Vertica on Host**.
6. Select the host you want to replace, and then click **OK** to stop the node.
7. When prompted if you want to stop the host, select **Yes**.
8. In the **Advanced Menu**, select **Cluster Management**, and then click **OK**.
9. In the **Cluster Management** menu, select **Replace Host**, and then click **OK**.
10. Select the database that contains the host you want to replace, and then click **OK**.

A list of all the hosts that are currently being used displays.

11. Select the host you want to replace, and then click **OK**.
12. Select the host you want to use as the replacement, and then click **OK**.
13. When prompted, enter the password for the database, and then click **OK**.
14. When prompted, click **Yes** to confirm that you want to replace the host.
15. When prompted that the host was successfully replaced, click **OK**.
16. In the **Main Menu**, select **View Database Cluster State** to verify that all the hosts are running. You might need to start Vertica on the host you just replaced. Use **Restart Vertica on Host**.

The node enters a RECOVERING state.

Caution: If you are using a K-Safe database, keep in mind that the recovering node counts as one node down even though it might not yet contain a complete copy of the data. This means that if you have a database in which $K \text{ safety}=1$, the current fault tolerance for your database is at a critical level. If you lose one more node, the database shuts down. Be sure that you do not stop any other nodes.

Using the Management Console to Replace Nodes

On the MC **Manage** page, you can quickly replace a DOWNS node in the database by selecting one of the STANDBY nodes in the cluster.

A DOWNS node shows up as a red node in the cluster. Click the DOWNS node and the Replace node button in the Node List becomes activated, as long as there is at least one node in the cluster that is not participating in the database. The STANDBY node will be your replacement node for the node you want to retire; it will appear gray (empty) until it has been added to the database, when it turns green.

Tip: You can resize the Node List by clicking its margins and dragging to the size you want.

When you highlight a node and click **Replace**, MC provides a list of possible STANDBY nodes to use as a replacement. After you select the replacement node, the process begins. A node replacement could be a long-running task.

MC transitions the DOWNS node to a STANDBY state, while the node you selected as the replacement will assume the identity of the original node, using the same node name, and will be started.

Assuming a successful startup, the new node will appear orange with a status of RECOVERING until the recovery procedure is complete. When the recovery process completes, the replacement node will turn green and show a state of UP.

Rebalancing Data Across Nodes

Vertica can rebalance your database when you add or remove nodes. As a superuser, you can manually trigger a rebalance with [Administration Tools](#), [SQL functions](#), or the [Management Console](#).

A rebalance operation can take some time, depending on the cluster size, and the number of projections and the amount of data they contain. You should allow the process to complete uninterrupted. If you must cancel the operation, call [CANCEL_REBALANCE_CLUSTER](#).

Why Rebalance?

Rebalancing is useful or even necessary after you perform one of the following operations:

- Change the size of the cluster by adding or removing nodes.
- Mark one or more nodes as ephemeral in preparation of removing them from the cluster.
- Change the [scaling factor](#) of an elastic cluster, which determines the number of storage containers used to store a projection across the database.
- Set the control node size or realign control nodes on a [large cluster](#) layout.
- Specify more than 120 nodes in your initial Vertica cluster configuration.
- Modify a [fault group](#) by adding or removing nodes.

General Rebalancing Tasks

When you rebalance a database cluster, Vertica performs the following tasks for all projections, segmented and unsegmented alike:

- Distributes data based on:
 - User-defined [fault groups](#), if specified
 - [Large cluster](#) automatic fault groups
- Ignores node-specific distribution specifications in projection definitions. Node rebalancing always distributes data across all nodes.

- When rebalancing is complete, sets the Ancient History Mark the greatest allowable epoch (now).

Vertica rebalances segmented and unsegmented projections differently, as described below.

Rebalancing Segmented Projections

For each segmented projection, Vertica performs the following tasks:

1. Copies and renames projection buddies and distributes them evenly across all nodes. The renamed projections share the same base name.
2. Refreshes the new projections.
3. Drops the original projections.

Rebalancing Unsegmented Projections

For each unsegmented projection, Vertica performs the following tasks:

If adding nodes:

- Creates projection buddies on them.
- Maps the new projections to their shared name in the database catalog.

If dropping nodes: drops the projection buddies from them.

K-safety and Rebalancing

Until rebalancing completes, Vertica operates with the existing K-safe value. After rebalancing completes, Vertica operates with the K-safe value specified during the rebalance operation.

The new K-safe value must be equal to or higher than current K-safety. Vertica does not support downgrading K-safety and returns a warning if you try to reduce it from its current value. For more information, see [Lowering K-Safety to Enable Node Removal](#).

Rebalancing Failure and Projections

If a failure occurs while rebalancing the database, you can rebalance again. If the cause of the failure has been resolved, the rebalance operation continues from where it failed. However, a

failed data rebalance can result in projections becoming out of date.

To locate any such projections, query the system table [PROJECTIONS](#) as follows:

```
=> SELECT projection_name, anchor_table_name, is_prejoin, is_up_to_date FROM projections  
WHERE is_up_to_date = false;
```

To remove out-of-date projections, use [DROP PROJECTION](#).

Temporary Tables

Node rebalancing has no effect on projections of temporary tables.

Rebalancing Data Using the Administration Tools UI

To rebalance the data in your database:

1. Open the Administration Tools. (See [Using the Administration Tools](#).)
2. On the **Main Menu**, select **View Database Cluster State** to verify that the database is running. If it is not, start it.
3. From the **Main Menu**, select **Advanced Menu** and click **OK**.
4. In the **Advanced Menu**, select **Cluster Management** and click **OK**.
5. In the **Cluster Management** menu, select **Re-balance Data** and click **OK**.
6. Select the database you want to rebalance, and then select **OK**.
7. Enter the directory for the Database Designer outputs (for example `/tmp`) and click **OK**.
8. Accept the proposed K-safety value or provide a new value. Valid values are 0 to 2.
9. Review the message and click **Proceed** to begin rebalancing data.

The Database Designer modifies existing projections to rebalance data across all database nodes with the K-safety you provided. A script to rebalance data, which you can run manually at a later time, is also generated and resides in the path you specified; for example `/tmp/extend_catalog_rebalance.sql`.

Important: Rebalancing data can take some time, depending on the number of projections and the amount of data they contain. Micro Focus recommends that you allow the process to complete. If you must cancel the operation, use Ctrl+C.

The terminal window notifies you when the rebalancing operation is complete.

10. Press **Enter** to return to the Administration Tools.

Rebalancing Data Using Management Console

Vertica can rebalance the database when you add or remove nodes. If you notice data skew where one node shows more activity than another (for example, most queries processing data on a single node), you can manually rebalance the database using MC if that database is imported into the MC interface.

On the **Manage** page, click **Rebalance** in the toolbar to initiate the rebalance operation.

During a rebalance, you cannot perform any other activities on the database cluster, such as start, stop, add, or remove nodes.

Rebalancing Data Using SQL Functions

Vertica has three SQL functions for starting and stopping a cluster rebalance. You can call these functions from a script that runs during off-peak hours, rather than manually trigger a rebalance through Administration Tools.

- [REBALANCE_CLUSTER](#) rebalances the database cluster synchronously as a session foreground task.
- [START_REBALANCE_CLUSTER](#) asynchronously rebalances the database cluster as a background task.
- [CANCEL_REBALANCE_CLUSTER](#) stops any rebalance task that is currently in progress or is waiting to execute.

Redistributing Configuration Files to Nodes

The add and remove node processes automatically redistribute the Vertica configuration files. You rarely need to redistribute the configuration files to help resolve configuration issues.

To distribute configuration files to a host:

1. Log on to a host that contains these files and start the Administration Tools.

See [Using the Administration Tools](#) for information about accessing the Administration Tools.

2. On the **Main Menu** in the Administration Tools, select **Configuration Menu** and click **OK**.
3. On the **Configuration Menu**, select **Distribute Config Files** and click **OK**.
4. Select **Database Configuration**.
5. Select the database where you want to distribute the files and click **OK**.

The `vertica.conf` file is distributed to all the other hosts in the database. If it previously existed on a host, it is overwritten.

6. On the **Configuration Menu**, select **Distribute Config Files** and click **OK**.
7. Select **SSL Keys**.

The certifications and keys for the host are distributed to all the other hosts in the database. If they previously existed on a host, they are overwritten.

8. On the **Configuration Menu**, select **Distribute Config Files** and click **OK**.

Select **AdminTools Meta-Data**.

The Administration Tools metadata is distributed to every host in the cluster.

9. [Restart the database](#).

Note: To distribute configuration files from the command line or via scripts, use the `admintools` option `distribute_config_files`:

```
admintools -t distribute_config_files
```

Stopping and Starting Nodes on MC

You can start and stop one or more database nodes through the **Manage** page by clicking a specific node to select it and then clicking the Start or Stop button in the Node List.

Note: The Stop and Start buttons in the toolbar start and stop the database, not individual nodes.

On the **Databases and Clusters** page, you must click a database first to select it. To stop or start a node on that database, click the **View** button. You'll be directed to the Overview page. Click **Manage** in the applet panel at the bottom of the page and you'll be directed to the database node view.

The Start and Stop database buttons are always active, but the node Start and Stop buttons are active only when one or more nodes of the same status are selected; for example, all nodes are UP or DOWN.

After you click a Start or Stop button, Management Console updates the status and message icons for the nodes or databases you are starting or stopping.

Mapping New IP Addresses

There are times when existing, operational Vertica database cluster nodes need to run on different IP addresses. Cluster nodes may also need to run based on different IP protocols, for example, when changing the protocol from broadcast to point-to-point. To run Vertica in these situations, use the `re_ip` function to re-IP and map the old addresses to the new addresses:

```
$ admintools -t re_ip -f mapfile
```

The *mapfile* references the file that you must create. A map file contains the old and new IP addresses. For details see [Re-IP Addresses with a Mapping File](#).

Use this function to re-IP in one of the following situations:

- If your Vertica database cluster has the same data and control messaging address, do one of the following:
 - Re-IP all the database cluster node IP addresses.
 - Re-IP only one or some of the database cluster node IP addresses.

```
$ admintools -t re_ip -f mapfile
```

- Re-IP the Vertica database cluster from broadcast mode to point-to-point (unicast) mode:

```
$ admintools -t re_ip -d db name -T
```

- Re-IP the Vertica database cluster from point-to-point (unicast) mode to broadcast mode :

```
$ admintools -t re_ip -d db name -U
```

Note: For information on changing communications protocols, see the -U and -T options under [install_vertica Options](#)

- Re-IP the control address of the database cluster. In this case the mapping file must contain the control messaging IP address and associated broadcast address.

```
$ admintools -t re_ip -f mapfile
```

- Re-IP only one database address without changing the admintools configuration. See [Mapping IP Addresses on the Database only](#).

Note: The database only re-ip is useful for error recovery. The node names and IP addresses must be the same as the node information in admintools.conf. You can also run `SELECT * from vs_nodes order by name` to display the node information.

For more information on the options used in the above commands, see [Re-IP Command-Line Options](#).

Re-IP and the Export IP address

By default, the node IP address and the export IP address are configured with the same IP address. The export address is the IP address of the node on the network with access to other DBMS systems. Use the export address for importing and exporting data from DBMS systems. You can manually change the export address using the instructions found [here](#).

If you change the export address and run the re-ip command, the export address remains the same.

Example

Run the following command:

```
=> SELECT node_name, node_address, export_address FROM nodes;
   node_name      | node_address  | export_address
-----|-----|-----
v_VMartDB_node0001 | 192.168.100.101 | 192.168.100.101
v_VMartDB_node0002 | 192.168.100.102 | 192.168.100.101
v_VMartDB_node0003 | 192.168.100.103 | 192.168.100.101
v_VMartDB_node0004 | 192.168.100.104 | 192.168.100.101
(4 rows)
```

In the above example the `export_address` is the default. In this case, when you run the re-ip command the `export_address` changes to the new `node_address`.

If you manually change the export address as [described here](#), you may have something like the following:

```
=> SELECT node_name, node_address, export_address FROM nodes;
   node_name      | node_address      | export_address
-----|-----|-----
v_VMartDB_node0001 | 192.168.100.101 | 10.10.10.1
v_VMartDB_node0002 | 192.168.100.102 | 10.10.10.2
v_VMartDB_node0003 | 192.168.100.103 | 10.10.10.3
v_VMartDB_node0004 | 192.168.100.104 | 10.10.10.4
(4 rows)
```

In this case, when you run the re-ip command the export_address does not change.

Finding IP Addresses

IP addresses for the hosts and nodes are stored in `opt/vertica/config/admintools.conf`:

```
[Cluster]
hosts = 203.0.113.111, 203.0.113.112, 203.0.113.113

[Nodes]
node0001 = 203.0.113.111/home/dbadmin,/home/dbadmin
node0002 = 203.0.113.112/home/dbadmin,/home/dbadmin
node0003 = 203.0.113.113/home/dbadmin,/home/dbadmin
```

You can also display a list of IP addresses with the following:

```
$ admintools -t list_allnodes
Node          | Host          | State | Version          | DB
-----|-----|-----|-----|-----
v_vmart_node0001 | 203.0.113.111 | UP    | vertica-8.1.1.20170511 | VMart
v_vmart_node0002 | 203.0.113.112 | UP    | vertica-8.1.1.20170511 | VMart
v_vmart_node0003 | 203.0.113.113 | UP    | vertica-8.1.1.20170511 | VMart
```

Tip: Run the `list_allnodes` tool to help identify any issues you may be having accessing Vertica. For example, if the hosts are not communicating with each other, `Unavailable` appears in the `Version` column.

Re-IP Addresses with a Mapping File

Mapping new IP addresses includes:

- Creating a mapping file that maps the old IP addresses to the new IP addresses.
- Using the mapping file to update configuration files and the database catalog.

Note: If you are using control messaging for communication between hosts, you may also need to update IPs with the new controlAddress and controlBroadcast IP addresses.

The embedded messages subsystem operates based on the controlAddress IP and controlBroadcast IP when you use the -U option.

Create Mapping File

Before creating a mapping file you need to know the new IP addresses. Create a mapping file as follows:

1. If you do not already have them, obtain the new IP addresses and save them in a text file. You can save the file anywhere on your system.
2. Run the following command to obtain the old IP addresses.

```
$ admintools -t list_allnodes
Node          | Host          | State | Version          | DB
-----+-----+-----+-----+-----
v_vmart_node0001 | 192.0.2.254 | UP    | vertica-8.1.1.20170511 | VMart
v_vmart_node0002 | 192.0.2.255 | UP    | vertica-8.1.1.20170511 | VMart
v_vmart_node0003 | 192.0.2.256 | UP    | vertica-8.1.1.20170511 | VMart
```

3. Copy the contents of the Host column into the same text file as the new IP addresses. The file is in the format old address, new address:

```
192.0.2.254 198.51.100.255
192.0.2.255 198.51.100.256
192.0.2.256 198.51.100.257
```

You can have the following map file formats:

Re-IP from an old IP address to a new IP address:

```
oldIPAddress newIPAddress, controlAddress (optional), controlBroadcast (optional)
```

In this scenario, the controlAddress and controlBroadcast are optional. If you do not include them in the map file:

- The controlAddress defaults to the newIPAddress.
- The controlBroadcast defaults to the host of the newIPAddress's broadcast IP address.

For example:

```
192.0.2.254 198.51.100.255, 198.51.100.255, 203.0.113.255  
192.0.2.255 198.51.100.256, 198.51.100.256, 203.0.113.255  
192.0.2.256 198.51.100.257, 198.51.100.257, 203.0.113.255
```

The command for performing this Re-IP process is as follows:

```
$ admintools -t re_ip -f <mapfile>
```

Re-IP from an old IP address to a new IP address and change the control messaging mode

```
oldIPAddress newIPAddress, controlAddress, controlBroadcast
```

For example:

```
192.0.2.254 198.51.100.255, 203.0.113.255, 203.0.113.258  
192.0.2.255 198.51.100.256, 203.0.113.256, 203.0.113.258  
192.0.2.256 198.51.100.257, 203.0.113.257, 203.0.113.258
```

Note that the map file uses comma separators after the new IP address and controlAddress.

The command for performing this re-IP process and changing the control messaging mode to point-to-point is as follows:

```
$ admintools -t re_ip -d db name -T
```

The command for performing this re-IP process and changing the control messaging mode to broadcast is as follows:

```
$ admintools -t re_ip -d db name -U
```

Re-IP the node control address on the database only (see [Mapping IP Addresses on the Database only](#)).

```
nodeName nodeIPAddress controlAddress, controlBroadcast
```

For example:

```
v_vmart_node0001 192.0.2.254, 203.0.113.255, 203.0.113.258  
v_vmart_node0002 192.0.2.255, 203.0.113.256, 203.0.113.258
```

```
v_vmart_node0003 192.0.2.256, 203.0.113.257, 203.0.113.258
```

The command for performing database-only re-IP is as follows:

```
$ admintools -t re_ip -f <mapfile> -O -d database
```

Re-IP the IP Addresses

After creating the mapping file you can re-IP the new IP addresses. The re-IP process automatically backs up `admintools.conf` so you can recover the original settings if necessary.

1. Stop the database.
2. Run the following command to map the old IP addresses to the new IP addresses:

```
$ admintools -t re_ip -f mapfile
```

Note: This example uses the command for performing a re-IP from an old IP address to a new IP address.

A warning occurs if:

- Any of the IP addresses is incorrectly formatted
- a duplicate old or new IP address exists in the file. For example, `192.0.2.256` appears twice in the old IP set.

If the syntax is correct and mapping begins:

- Re-maps the IP addresses as listed in the mapping file.
- Prompts you to confirm the updates to the database, unless you use the `-i` option.
- Updates the required local configuration files with the new IP addresses.
- Distributes the updated configuration files to the hosts using the new IP addresses.

Track these steps using the following prompts:

```
Parsing mapfile...  
New settings for Host 192.0.2.254 are:  
  
address: 198.51.100.255
```

```
New settings for Host 192.0.2.255 are:
address: 198.51.100.256

New settings for Host 192.0.2.254 are:
address: 198.51.100.257

The following databases would be affected by this tool: Vmart

Checking DB status ...
Enter "yes" to write new settings or "no" to exit > yes
Backing up local admintools.conf ...
Writing new settings to local admintools.conf ...

Writing new settings to the catalogs of database Vmart ...
The change was applied to all nodes.
Success. Change committed on a quorum of nodes.

Initiating admintools.conf distribution ...
Success. Local admintools.conf sent to all hosts in the cluster.
```

3. Restart the database.

Mapping IP Addresses on the Database only

You can map IP addresses for just the database. This task involves mapping the name of the nodes in the database to the new IP addresses. This is useful for error recovery because `admintools.conf` does not get updated. Vertica updates only `spread.conf` and the catalog with the changes.

You can also map IP addresses on the database only to set `controlAddress` and `controlBroadcast` on a single database. This task allows nodes on the same host to have a different data and `controlAddress`.

1. Stop the database.
2. Create a mapping file in the following format:

```
nodeName IPaddress, controlAddress, controlBroadcast
```

For example:

```
192.0.2.254, 203.0.113.255, 203.0.113.258 192.0.2.256, 203.0.113.257, 203.0.113.258
```

```
vertica_node001 192.0.2.254, 203.0.113.255, 203.0.113.258
vertica_node002 192.0.2.255, 203.0.113.256, 203.0.113.258
vertica_node003 192.0.2.256, 203.0.113.257, 203.0.113.258
```

3. Run the following command to map the new IP addresses:

```
$ admintools -t re_ip -f <mapfile> -O -d database
```

4. Restart the database.

Re-IP Command-Line Options

The table below lists the command-line options you can use with the `re_ip` command.

Option	Description
- h or --help	Displays the online help for <code>re_ip</code> .
-f <mapfile> or --file=<mapfile>	The name of the mapping text file. What this file contains depends on the type of re-IP you want to perform. See Mapping New IP Addresses .
-O or --dba-only	Used for error recovery. Updates and replaces data on the database cluster catalog and control messaging system. If the map text file fails, Vertica automatically recreates it when you re-run the command. The format of the map text file is: <pre>NodeName AssociatedNodeIPAddress, new ControlAddress, new ControlBroadcast</pre> <p>NodeName and AssociatedNodeIPAddress must be the same as those in <code>admintools.conf</code>.</p> <p>This option updates only one database at a time so you must use the <code>-d</code> option:</p> <pre>\$ admintools -t re_ip -f mapfile -O -d database</pre>
-i or --noprompts	Specifies that the system does not prompt for the validation of the new settings before performing the re-IP. Prompting is on by default.
-T or --point-to-point	Sets the control messaging to point-to-point (unicast) protocol. This option updates only one database at a time so you must use the <code>-d</code>

Option	Description
	<p>option. You do not need a mapping text file with this option.</p> <p>For information on setting point-to-point communication, see the -T option in install_vertica Options</p>
<p>-U or --broadcast</p>	<p>Sets the control messaging to broadcast protocol. This option updates only one database at a time so you must use the -d option. You do not need a mapping text file with this option.</p> <p>For information on setting broadcast communication, see the -U option in install_vertica Options</p>
<p>-d <database name> or --database=<database name></p>	<p>The database name. This option is required with the following re-IP options:</p> <ul style="list-style-type: none">• -O• -T• -U

Managing Disk Space

Vertica detects and reports low disk space conditions in the log file so that the issue can be addressed before serious problems occur. It also detects and reports low disk space conditions via [SNMP traps](#) if enabled.

Critical disk space issues are reported sooner than other issues. For example, running out of catalog space is fatal; therefore, Vertica reports the condition earlier than less critical conditions. To avoid database corruption when the disk space falls beyond a certain threshold, Vertica begins to reject transactions that update the catalog or data.

Caution: A low disk space report indicates one or more hosts are running low on disk space or have a failing disk. It is imperative to add more disk space (or replace a failing disk) as soon as possible.

When Vertica reports a low disk space condition, use the [DISK_RESOURCE_REJECTIONS](#) system table to determine the types of disk space requests that are being rejected and the hosts on which they are being rejected.

For descriptions of all the system tables, see [Using System Tables](#).

To add disk space, see [Adding Disk Space to a Node](#). To replace a failed disk, see [Replacing Failed Disks](#).

Monitoring Disk Space Usage

You can use these system tables to monitor disk space usage on your cluster:

System table	Description
DISK_STORAGE	Monitors the amount of disk storage used by the database on each node.
COLUMN_STORAGE	Monitors the amount of disk storage used by each column of each projection on each node.
PROJECTION_STORAGE	Monitors the amount of disk storage used by each projection on each node.

Adding Disk Space to a Node

This procedure describes how to add disk space to a node in the Vertica cluster.

Note: If you are adding disk space to multiple nodes in the cluster, then use the following procedure for each node, one node at a time.

To add disk space to a node:

1. If you must shut down the hardware to which you are adding disk space, then first shut down Vertica on the host where disk space is being added.
2. Add the new disk to the system as required by the hardware environment. Boot the hardware if it is was shut down.
3. Partition, format, and mount the new disk, as required by the hardware environment.
4. Create a data directory path on the new volume.

For example:

```
mkdir -p /myNewPath/myDB/host01_data2/
```

5. If you shut down the hardware, then restart Vertica on the host.
6. Open a database connection to Vertica and add a storage location to add the new data directory path. Specify the node in the [CREATE LOCATION](#), otherwise Vertica assumes you are creating the storage location on all nodes.

See [Creating Storage Locations](#) in this guide and the [CREATE LOCATION](#) statement in the SQL Reference Manual.

Replacing Failed Disks

If the disk on which the data or catalog directory resides fails, causing full or partial disk loss, perform the following steps:

1. Replace the disk and recreate the data or catalog directory.
2. Distribute the configuration file (`vertica.conf`) to the new host. See [Distributing Configuration Files to the New Host](#) for details.
3. Restart the Vertica on the host, as described in [Restart Vertica On Host](#).

See [Catalog and Data Files](#) for information about finding your `DATABASE_HOME_DIR`.

Catalog and Data Files

For the recovery process to complete successfully, it is essential that catalog and data files be in the proper directories.

In Vertica, the catalog is a set of files that contains information (metadata) about the objects in a database, such as the nodes, tables, constraints, and projections. The catalog files are replicated on all nodes in a cluster, while the data files are unique to each node. These files are installed by default in the following directories:

```
/DATABASE_HOME_DIR/DATABASE_NAME/v_db_nodexxxx_catalog/ /DATABASE_HOME_DIR/DATABASE_NAME/v_db_nodexxxx_catalog/
```

Note: `DATABASE_HOME_DIR` is the path, which you can see from the Administration Tools. See [Using the Administration Tools](#) in the Administrator's Guide for details on using the interface.

To view the path of your database:

1. Run the Administration Tools.

```
$ /opt/vertica/bin/admintools
```

2. From the Main Menu, select **Configuration Menu** and click **OK**.
3. Select **View Database** and click **OK**.
4. Select the database you want would like to view and click **OK** to see the database profile.

See [Understanding the Catalog Directory](#) for an explanation of the contents of the catalog directory.

Understanding the Catalog Directory

The catalog directory stores metadata and support files for your database. Some of the files within this directory can help you troubleshoot data load or other database issues. See [Catalog and Data Files](#) for instructions on locating your database's catalog directory. By default, it is located in the database directory. For example, if you created the VMart database in the database administrator's account, the path to the catalog directory is:

```
/home/dbadmin/VMart/v_vmart_nodennn_catalog
```

where `nodennn` is the name of the node you are logged into. The name of the catalog directory is unique for each node, although most of the contents of the catalog directory are identical on each node.

The following table explains the files and directories that may appear in the catalog directory.

Note: Do not change or delete any of the files in the catalog directory unless asked to do so by Vertica support.

File or Directory	Description
<code>bootstrap-catalog.log</code>	A log file generated as the Vertica server initially creates the database (in which case, the log file is only created on the node used to create the database) and whenever the database is restored from a backup.
<code>Catalog/</code>	Contains catalog information about the database, such as checkpoints.
<code>CopyErrorLogs/</code>	The default location for the COPY exceptions and rejections files generated when data in a bulk load cannot be inserted into the database. See Capturing Load Rejections and Exceptions for more information.
<code>DataCollector/</code>	Log files generated by the Data Collector.
<code>debug_log.conf</code>	Debugging information configuration file. For Micro Focus use only.
<code>Epoch.log</code>	Used during recovery to indicate the latest epoch that

File or Directory	Description
	contains a complete set of data.
ErrorReport.txt	A stack trace written by Vertica if the server process exits unexpectedly.
Libraries/	Contains user defined library files that have been loaded into the database See Developing User-Defined Extensions (UDxs) in Extending Vertica. Do not change or delete these libraries through the file system. Instead, use the CREATE LIBRARY , DROP LIBRARY , and ALTER LIBRARY statements.
Snapshots/	The location where backups are stored.
tmp/	A temporary directory used by Vertica's internal processes.
UDxLogs/	Log files written by user defined functions that run in fenced mode. See Fenced Mode in Extending Vertica for more information.
vertica.conf	The configuration file for Vertica.
vertica.log	The main log file generated by the Vertica server process.
vertica.pid	The process ID and path to the catalog directory of the Vertica server process running on this node.

Reclaiming Disk Space From Deleted Table Data

You can reclaim disk space from deleted table data in several ways:

- [Purge deleted records.](#)
- [Rebuild the table.](#)
- [Drop table partition.](#)

Managing Memory

`glibc` enhances performance by aggressively holding onto memory, even if that memory is not being used at the time by a process. The Linux kernel's Out of Memory (OOM) Killer may terminate the Vertica process if it uses too much memory.

You can avoid this by setting the `MALLOC_ARENA_MAX` environment variable to a nonzero value, which limits the number of arenas (memory pools available to `malloc()`) a process can use.

If you have write privileges on `~/ .bashrc`, perform the following steps on all nodes:

1. Run the following command to set `MALLOC_ARENA_MAX`:

```
$ export MALLOC_ARENA_MAX=4
```

2. Log out and back in.
3. Restart the Vertica database.
4. Verify that `MALLOC_ARENA_MAX` is set:

```
$ set | grep ARENA  
MALLOC_ARENA_MAX=4
```

If you don't have write privileges on `~/ .bashrc`, you must always start the database with the `VERTICA_ADMINTOOLS_PASSTHROUGH` environment variable.

1. Always run the following command to start the database:

```
$ export VERTICA_ADMINTOOLS_PASSTHROUGH=MALLOC_ARENA_MAX=4 admintools -t start_db -d database_name
```

2. Verify on each node that MALLOC_ARENA_MAX is set for the process:

```
$ xargs --null --max-args=1 echo < /proc/$(pgrep vertica$)/environ | grep ARENA  
MALLOC_ARENA_MAX=4
```

Tuple Mover Operations

The Tuple Mover manages WOS and ROS data storage. It performs two operations:

- [Moveout](#) moves data from WOS to ROS. During moveout operations, the Tuple Mover also enforces storage policies for the storage location.
- [Mergeout](#) combines small ROS containers into larger ones and purges deleted data.

The Tuple Mover automatically performs these tasks in the background, at intervals that are set by its [configuration parameters](#).

Each of these operations occurs at different intervals across all nodes. The Tuple Mover runs independently on each node, ensuring that storage is managed appropriately even in the event of data skew.

Tuple Mover operations are automatic and transparent, and typically require no intervention. However, Vertica provides various ways to control Tuple Mover behavior. For details, see [Managing the Tuple Mover](#).

Mergeout

Mergeout is the Tuple Mover process that consolidates ROS containers and purges deleted records. Over time, the number of ROS containers increases enough to affect performance. It is then necessary to merge some of the ROS containers to avoid performance degradation. At that point, the Tuple Mover performs an automatic mergeout, combining two or more ROS containers into a single container. You can think of this process as a way of *defragmenting* the ROS.

Vertica keeps data from different partitions separate on disk. The Tuple Mover adheres to this separation policy when it consolidates ROS containers. Tuple Move does not merge ROS containers from different partitions. When a partition is first created, it typically has frequent data loads and requires regular activity from the Tuple Mover. As a partition ages, it commonly transitions to a mostly read-only workload and requires much less activity.

The Tuple Mover has two different policies for managing these different partition workloads:

- *Active partition* is the partition that was most recently created. The Tuple Mover uses a [STRATA](#) mergeout policy that keeps a collection of ROS container sizes to minimize the number of times any individual tuple is subjected to mergeout. The `ActivePartitionCount` parameter identifies how many partitions are being actively created.
- *Inactive partitions* are those that were not most recently created. The Tuple Mover consolidates the ROS containers to a minimal set while avoiding merging containers whose size exceeds `MaxMrgOutROSSizeMB`.

Partitions are not explicitly marked by the user as active or inactive; instead, the Tuple Mover uses the following algorithm to order the partitions from oldest to newest:

- If one partition was created before the other partition, it is older.
- If two partitions were created at the same time, but one partition was last updated earlier than the other partition, it is older.
- If two partitions were created and last updated at the same time, the partition with the smaller key is considered older.

If you perform a manual mergeout using the `DO_TM_TASK` function, *all* partitions are consolidated into the smallest possible number of containers, regardless of the value of the `ActivePartitionCount` parameter.

Mergeout Strata Algorithm

The mergeout operation uses a strata-based algorithm to verify that each tuple is subjected to a mergeout operation a small, constant number of times, despite the process used to load the data. The mergeout operation uses this algorithm to choose which ROS containers to merge for non-partitioned tables and for active partitions in partitioned tables.

Vertica builds strata for each active partition and for projections anchored to non-partitioned tables. The number of strata, the size of each stratum, and the maximum number of ROS containers in a stratum is computed based on disk size, memory, and the number of columns in a projection.

Merging small ROS containers before merging larger ones provides the maximum benefit during the mergeout process. The algorithm begins at stratum 0 and moves upward. It checks to see if the number of ROS containers in a stratum has reached a value equal to or greater than the maximum ROS containers allowed per stratum. The default value is 32. If the algorithm finds that a stratum is full, it marks the projections and the stratum as eligible for mergeout.

Mergeout of Deletion Markers

When you delete data from the database, Vertica does not remove it. Instead, it marks the data as deleted. Using many `DELETE` statements to mark a small number of rows relative to the size of a table can result in creating many small containers, the delete vectors, to hold data marked for deletion. Each delete vector container consumes resources, so a large number of such containers can impact performance, especially during recovery.

After the Tuple Mover performs a mergeout, it looks for deletion marker containers that hold few entries. If such containers exist, the Tuple Mover merges them together into a single, larger container. This process helps lower the overhead of tracking deleted data by freeing resources used by multiple, individual containers. The Tuple Mover does not purge or otherwise affect the deleted data, but consolidates delete vectors for greater efficiency.

Note: You can see the number and size of the containers holding the deletion marks by viewing the `V_MONITOR.DELETE_VECTORS` system table.

Automatic and Manual Mergeout

Vertica periodically checks ROS storage containers to determine whether delete vectors are eligible for purge, as follows:

1. Counts the number of 'aged-out' delete vectors in each container—that is, delete vectors that are as 'old' or older than the ancient history mark (AHM) epoch.
2. Calculates the percentage of aged-out delete vectors relative to the total number of records in the same ROS container.
3. If this percentage exceeds the threshold set by configuration parameter `PurgeMergeoutPercent` (by default, 20 percent), Vertica automatically performs a mergeout on the ROS container, and permanently removes all aged-out delete vectors from the ROS container.

You can also manually remove all aged-out delete vectors from ROS containers with two Vertica meta-functions:

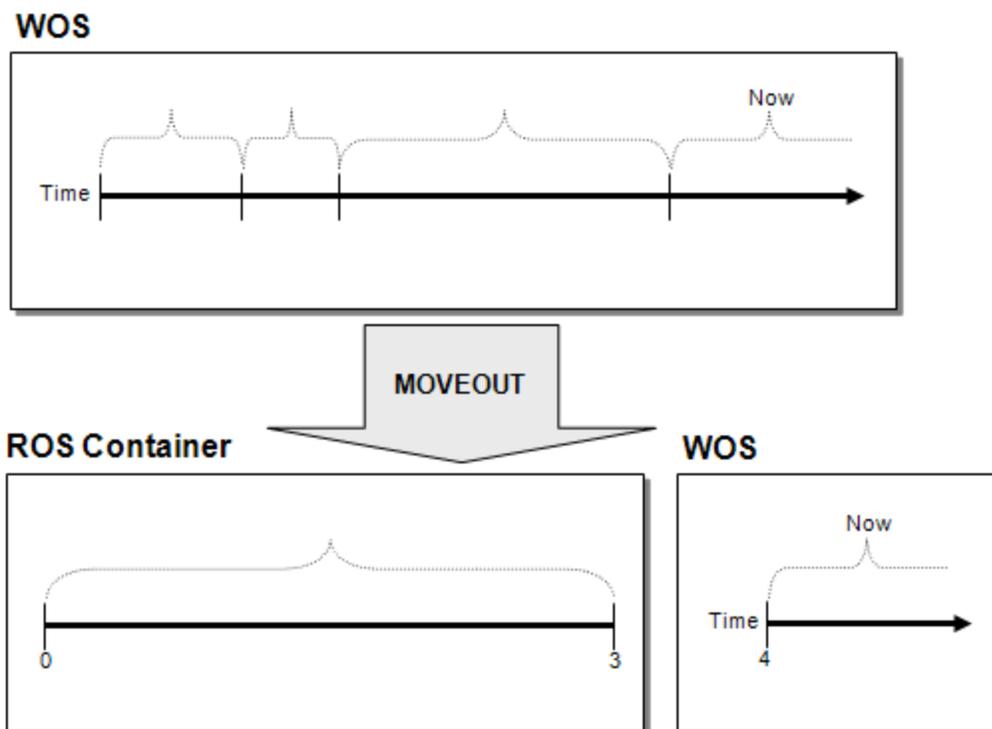

- `DO_TM_TASK('mergeout')`
- `PURGE`

Both functions remove all aged-out delete vectors from ROS containers, regardless of how many are in a given container.

Moveout

Moveout operations move data from memory (WOS) into a new ROS container. A moveout *flushes* all historical data from the WOS to the ROS.

The following illustration shows the effect of a projection moveout on a single node:

ROS Containers

A ROS (Read Optimized Store) container is a set of rows stored in a particular group of files. ROS containers are created by operations like Moveout or COPY DIRECT. You can query the `STORAGE_CONTAINERS` system table to see ROS containers. The ROS container layout can

differ across nodes due to data variance. Segmentation can deliver more rows to one node than another. Two data loads could fit in the WOS on one node and spill on another.

Managing the Tuple Mover

The Tuple Mover is preconfigured to handle typical workloads. However, some situations can require you to adjust Tuple Mover behavior. You can do so in various ways:

- [Configure resource pools](#)
- [Manage data loading](#)
- [Add threads](#)
- [Manage active data partitions](#)

Configuring Resource Pools

The Tuple Mover draws its resources from the TM resource pool. Adding more resources (RAM) to this pool, and changing its concurrency setting, can make the Tuple Mover more effective in dealing with high load rates.

The TM resource pool concurrency setting is determined by subtracting one from the value of `MAXCONCURRENCY`. This calculates the number of merges that can occur simultaneously through multiple threads. As a side effect of the concurrency setting, the Tuple Mover dedicates some threads to aggressively address small ROS containers, while other threads are reserved to work only on merges of ROS containers in the lower strata.

For the TM pool, `PLANNEDCONCURRENCY` must be proportional to the size of the RAM, the CPU, and the storage subsystem. Depending on the storage type, if you increase `PLANNEDCONCURRENCY` for the Tuple Mover threads, you might create a storage I/O bottleneck. Monitor the storage subsystem; if it becomes saturated with long I/O queues, more than two I/O queues, and long latency in read and write, adjust the `PLANNEDCONCURRENCY` parameter to keep the storage subsystem resources below saturation level. In addition, you might need to:

- Partition storage data files
- Adjust block-size optimization on storage subsystems such as RAID 5 or RAID 10
- Identify the optimal number of disks in the RAID array

The following statement illustrates how to increase the size of the TM resource pool and set the concurrency settings for the pool:

```
=> ALTER RESOURCE POOL tm MEMORYSIZE '4G' PLANNEDCONCURRENCY 4 MAXCONCURRENCY 5;
```

The WOSDATA resource pool settings also indirectly affect the Tuple Mover. In automatic mode, INSERT and COPY commands use the concurrency setting to determine whether data is small enough to store in WOS or if it should be written to ROS. Therefore, set this value to be the number of concurrent loads you expect to perform in your database. The WOSDATA resource pool also determines how much RAM the WOS can use.

```
=> ALTER RESOURCE POOL wosdata MAXMEMORYSIZE '4G' PLANNEDCONCURRENCY 3;
```

See [Managing Workloads](#) and [Resource Pool Architecture](#) in this guide and [ALTER RESOURCE POOL](#) and [Built-In Pools](#) in the SQL Reference Manual.

Managing Data Loads

By default, Vertica automatically decides whether the data should be placed in WOS or stored directly in ROS containers based on the amount of data processed by a COPY or INSERT command. Vertica stores large loads directly to disk and stores smaller loads in memory, which it later moves to disk.

For low-latency access to data, use small loads. The automatic Tuple Mover settings are the best option for handling such smaller loads. One exception is for single-node deployments, where a system failure would cause in-memory data to be lost. In this case, you might want to force all data loads to go directly to disk.

For high load rates, you might want the Tuple Mover to check for jobs more frequently by changing the `MergeOutInterval` and `MoveOutInterval` configuration parameters. Reduce the `MoveOutInterval` if you expect the peak load rate to fill the WOS quickly. Reduce `MergeOutInterval` if you anticipate performing many DIRECT loads or inserts.

In some cases, you might wish to control how Vertica loads data into ROS or WOS. Vertica provides various options for controlling how it loads data for specific tables and DML operations. This can also affect Tuple Mover behavior. For more information, see [Choosing a Load Method](#).

Adding Threads

If your database is receiving a large volume of data to load or if it is performing many DIRECT loads or inserts, consider allowing the Tuple Mover to perform more operations concurrently

by increasing the TM resource pool until it can keep up with anticipated peak loads. For example:

```
=> ALTER RESOURCE POOL TM MEMORYSIZE '4G' PLANNEDCONCURRENCY 4 MAXCONCURRENCY 5;
```

See [ALTER RESOURCE POOL](#) and [Built-In Pools](#) in the SQL Reference Manual.

Managing Active Data Partitions

By default, the Tuple Mover assumes that all loads and updates for partitioned tables are going to the same *active* partition. For example, if a table is partitioned by month, the Tuple Mover expects that after the start of a new month, no data is loaded into the partition for the prior month.

If loads and updates occur to more than one partition, set the `ActivePartitionCount` parameter to reflect the number of partitions that will be loading data. For example, if your database receives data for the current month as well as updates to the prior month, set `ActivePartitionCount` to 2. For tables partitioned by non-temporal attributes, set `ActivePartitionCount` to reflect the number of partitions that will be loaded simultaneously.

For more information, see [Managing Partitions](#).

- [Best Practices for Managing Workload Resources](#)

Managing Workloads

Vertica's resource management scheme allows diverse, concurrent workloads to run efficiently on the database. For basic operations, Vertica pre-configures the built-in [GENERAL pool](#) based on RAM and machine cores. You can customize the General pool to handle specific concurrency requirements.

You can also define new resource pools that you configure to limit memory usage, concurrency, and query priority. You can then optionally assign each database user to use a specific resource pool, which controls memory resources used by their requests.

User-defined pools are useful if you have competing resource requirements across different classes of workloads. Example scenarios include:

- A large batch job takes up all server resources, leaving small jobs that update a web page without enough resources. This can degrade user experience.

In this scenario, create a resource pool to handle web page requests and ensure users get resources they need. Another option is to create a limited resource pool for the batch job, so the job cannot use up all system resources.

- An application has lower priority than other applications and you want to limit the amount of memory and number of concurrent users for the low-priority application.

In this scenario, create a resource pool with an upper limit on the query's memory and associate the pool with users of the low-priority application.

You can also use resource pools to manage resources assigned to running queries. You can assign a run-time priority to a resource pool, as well as a threshold to assign different priorities to queries with different durations. See [Managing Resources At Query Run Time](#) for more information.

For detailed syntax of creating and managing resource pools see the following topics in the SQL Reference Manual:

Statements

- [ALTER RESOURCE POOL](#) alters a resource pool.
- [ALTER USER](#) associates a user with the RESOURCE POOL and MEMORYCAP parameters.
- [CREATE RESOURCE POOL](#) creates a resource pool.
- [CREATE USER](#) adds a name to the list of authorized database users and specifies that user's RESOURCE POOL and MEMORYCAP parameters.
- [DROP RESOURCE POOL](#) drops a user-created resource pool.
- [SET SESSION MEMORYCAP](#) sets the limit on amount of memory that any request issued by the session can consume.
- [SET SESSION RESOURCE POOL](#) associates a user session with specified resource pool.

System Tables

- [RESOURCE_ACQUISITIONS](#) provides details of resources (memory, open file handles, threads) acquired by each request for each resource pool in the system.
- [RESOURCE_POOL_DEFAULTS \(systab\)](#) lists default values for parameters in each internal and user-defined resource pool.
- [RESOURCE_POOL_STATUS](#) provides configuration settings of the various resource pools in the system, including internal pools.
- [RESOURCE_POOLS](#) displays information about the parameters the resource pool was configured with.
- [RESOURCE_QUEUES](#) provides information about requests pending for various resource pools.
- [RESOURCE_REJECTIONS](#) monitors requests for resources that are rejected by the Resource Manager.
- [RESOURCE_REJECTION_DETAILS](#) records an entry for each resource request that Vertica denies. This is useful for determining if there are resource space issues, as well as which users/pools encounter problems
- [SYSTEM_RESOURCE_USAGE](#) provides history about system resources, such as memory, CPU, network, disk, I/O.

Resource Manager

On a single-user environment, the system can devote all resources to a single query, getting the most efficient execution for that one query. More likely, your environment needs to run several queries at once, which can cause tension between providing each query the maximum amount of resources (fastest run time) and serving multiple queries simultaneously with a reasonable run time.

The Vertica Resource Manager (RM) lets you resolve this tension, while ensuring that every query is eventually serviced and that true system limits are respected at all times.

For example, when the system experiences resource pressure, the Resource Manager might queue queries until the resources become available or a timeout value is reached. In addition,

when you configure various RM settings, you can tune each query's target memory based on the expected number of concurrent queries running against the system.

This section discusses the detailed architecture and operation of the Resource Manager.

Resource Manager Impact on Query Execution

The Resource Manager (RM) impacts individual query execution in various ways. When a query is submitted to the database, the following series of events occur:

1. The query is parsed, optimized to determine an execution plan, and distributed to the participating nodes.
2. The Resource Manager is invoked on each node to estimate resources required to run the query and compare that with the resources currently in use. One of the following will occur:
 - If the memory required by the query alone would exceed the machine's physical memory, the query is rejected - it cannot possibly run. Outside of significantly under-provisioned nodes, this case is very unlikely.
 - If the resource requirements are not currently available, the query is queued. The query will remain on the queue until either sufficient resources are freed up and the query runs or the query times out and is rejected.
 - Otherwise the query is allowed to run.
3. The query starts running when all participating nodes allow it to run.

Note: Once the query is running, the Resource Manager further manages resource allocation using `RUNTIMEPRIORITY` and `RUNTIMEPRIORITYTHRESHOLD` parameters for the resource pool. See [Managing Resources At Query Run Time](#) for more information.

Apportioning resources for a specific query and the maximum number of queries allowed to run depends on the resource pool configuration. See [Resource Pool Architecture](#).

On each node, no resources are reserved or held while the query is in the queue. However, multi-node queries queued on some nodes will hold resources on the other nodes. Vertica makes every effort to avoid deadlocks in this situation.

Resource Pool Architecture

The Resource Manager handles resources as one or more resource pools, which are a pre-allocated subset of the system resources with an associated queue.

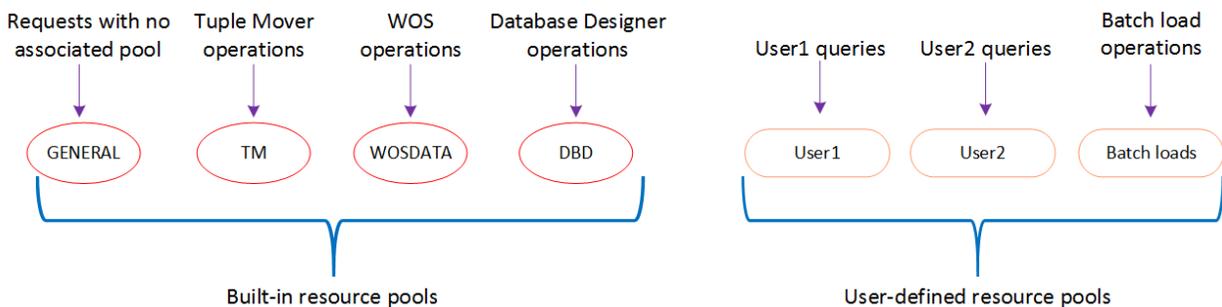

Vertica is preconfigured with a set of [Built-In Pools](#) that allocate resources to different request types, where the GENERAL pool allows for a certain concurrency level based on the RAM and cores in the machines.

Modifying and Creating Resource Pools

You can configure the built-in GENERAL pool based on actual concurrency and performance requirements, as described in [Built-In Pools](#). You can also create custom pools to handle various classes of workloads and optionally restrict user requests to your custom pools.

You create a pool using the [CREATE RESOURCE POOL](#) command.

You can create new resource pools and configure them for memory usage, concurrency, and queue priority. In addition, you can restrict a database user or user session to use a specific resource pool. Doing so allows you to control how memory, CPU, and other resources are allocated. If you have competing resource requirements across different classes of workloads, create user-defined pools. The following graphic illustrates what database operations are executed in which resource pool. Only four of the built-in pools are shown.

Defining Secondary Resource Pools

You can define secondary resource pools to which running queries can cascade if they exceed the initial pool's `RUNTIMECAP`.

Identifying a Secondary Pool

Defining secondary resource pools allows you to designate a place where queries that exceed the `RUNTIMECAP` of the pool on which they are running can execute. This way, if a query exceeds a pool's `RUNTIMECAP`, the query can cascade to a pool with a larger `RUNTIMECAP` instead of causing an error. When a query cascades to another pool, the original pool regains the memory used by that query.

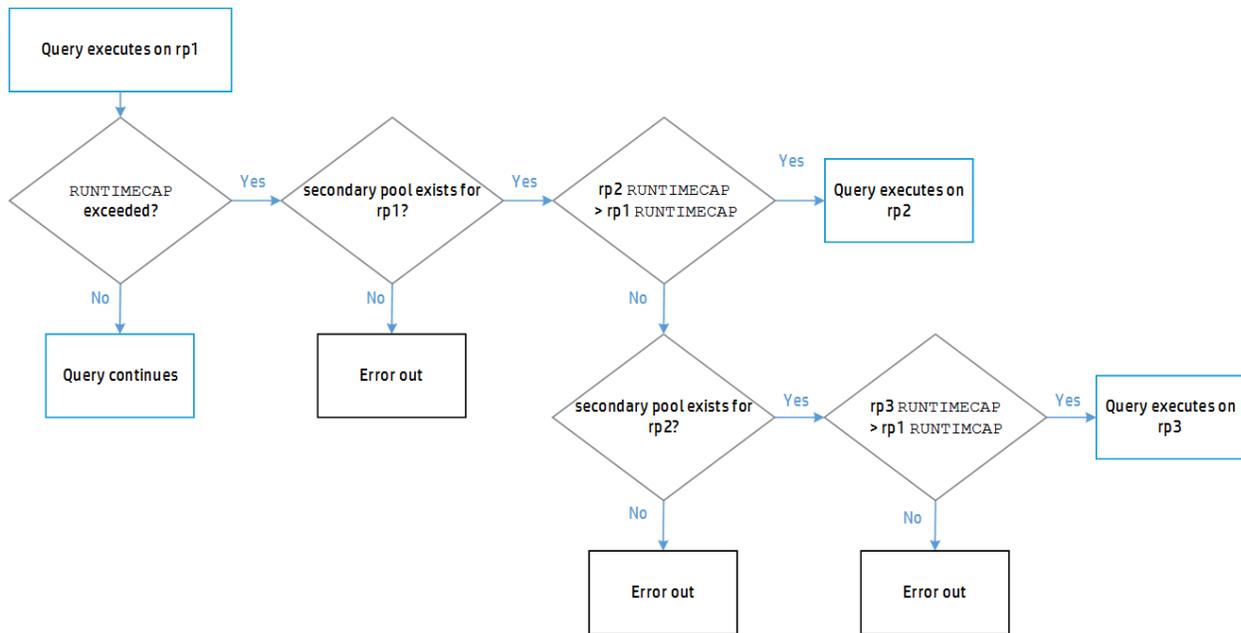

Because grant privileges are not considered on secondary pools, you can use this functionality to designate secondary resource pools for user queries without giving users explicit permission to run queries on that pool.

You can also use secondary pools as a place to store long-running queries for later. Using the `PRIORITY_HOLD` option, you can designate a secondary pool that re-queues the queries until `QUEUETIMEOUT` is reached or the pool's priority is changed to a non-hold value.

Query Cascade Path

Vertica routes queries to a secondary pool when the `RUNTIMECAP` on an initial pool is reached. Vertica then checks the secondary pool's `RUNTIMECAP` value. If the secondary pool's `RUNTIMECAP` is greater than the initial pool's value, the query executes on the secondary pool. If the secondary pool's `RUNTIMECAP` is less than or equal to the initial pool's value, Vertica retries the query on the next pool in the chain until it finds a pool on which the `RUNTIMECAP` is greater than the initial pool's value. If the secondary pool does not have sufficient resources available to execute the query at that time, `SELECT` queries may re-queue, re-plan, and abort on that pool. Other types of queries will fail due to insufficient resources. If no appropriate secondary pool exists for a query, the query will error out.

The following diagram demonstrates the path a query takes to execution.

Query Execution Time Allocation

After Vertica finds an appropriate pool on which to run the query, it continues to execute that query uninterrupted. The query now has the difference of the two pools' RUNTIMECAP limits in which to complete:

```
query execution time allocation = rp2 RUNTIMECAP - rp1 RUNTIMECAP
```

Using the CASCADE TO Parameter

As a superuser, you can identify the secondary pool by using the `CASCADE TO` parameter in the `CREATE RESOURCE POOL` or `ALTER RESOURCE POOL` statement. The secondary pool must already exist as a user-defined pool or the `GENERAL` pool. When using `CASCADE TO`, you cannot create a resource pool loop.

This example demonstrates a situation where the administrator wants `user1`'s queries to start on the `user_0` resource pool, but cascade to the `userOverflow` pool if the queries are too long.

```
=> CREATE RESOURCE POOL userOverflow RUNTIMECAP '5 minutes';
=> CREATE RESOURCE POOL user_0 RUNTIMECAP '1 minutes' CASCADE TO userOverflow;
=> CREATE USER "user1" RESOURCE POOL user_0;
```

In this scenario, `user1` cannot start his or her queries on the `userOverflow` resource pool, but because grant privileges are not considered for secondary pools, `user1`'s queries can cascade to the `userOverflow` pool if they exceed the `user_0` pool RUNTIMECAP. Using the secondary pool frees up space in the primary pool so short queries can run.

This example shows a situation where the administrator wants long-running queries to stay queued on a secondary pool.

```
=> CREATE RESOURCE POOL rp2 PRIORITY HOLD;  
=> CREATE RESOURCE POOL rp1 RUNTIMECAP '2 minutes' CASCADE TO rp2;  
=> SET SESSION RESOURCE_POOL = rp1;
```

In this scenario, queries that run on rp1 for more than 2 minutes will queue on rp2 until QUEUETIMEOUT is reached, at which point the queries will be rejected.

Dropping a Secondary Pool

If you try to drop a resource pool that is a secondary pool for another resource pool, Vertica returns an error. The error lists the resource pools that depend on the secondary pool you tried to drop. To drop a secondary resource pool, first set the `CASCADE TO` parameter to `DEFAULT` on the primary resource pool, and then drop the secondary pool.

For example, you can drop resource pool rp2, which is a secondary pool for rp1, as follows:

```
=> ALTER RESOURCE POOL rp1 CASCADE TO DEFAULT;  
=> DROP RESOURCE POOL rp2;
```

Parameter Considerations

The secondary resource pool's `CPUAFFINITYSET` and `CPUAFFINITYMODE` is applied to the query when it enters the pool.

The query adopts the secondary pool's `RUNTIMEPRIORITY` at different times, depending on the following circumstances:

- If the `RUNTIMEPRIORITYTHRESHOLD` timer was not started when the query was running in the primary pool, the query adopts the secondary resource pools' `RUNTIMEPRIORITY` when it cascades. This happens either when the `RUNTIMEPRIORITYTHRESHOLD` is not set for the primary pool or the `RUNTIMEPRIORITY` is set to `HIGH` for the primary pool.
- If the `RUNTIMEPRIORITYTHRESHOLD` was reached in the primary pool, the query adopts the secondary resource pools' `RUNTIMEPRIORITY` when it cascades.
- If the `RUNTIMEPRIORITYTHRESHOLD` was not reached in the primary pool and the secondary pool has no threshold, the query adopts the new pool's `RUNTIMEPRIORITY` when it cascades.
- If the `RUNTIMEPRIORITYTHRESHOLD` was not reached in the primary pool and the secondary pool has a threshold set.

- If the primary pool's `RUNTIMEPRIORITYTHRESHOLD` is greater than or equal to the secondary pool's `RUNTIMEPRIORITYTHRESHOLD`, the query adopts the secondary pool's `RUNTIMEPRIORITY` after the query reaches the `RUNTIMEPRIORITYTHRESHOLD` of the primary pool.

For example:

```
RUNTIMECAP of primary pool = 5 sec  
RUNTIMEPRIORITYTHRESHOLD of primary pool = 8 sec  
RUNTIMTPRIORITYTHRESHOLD of secondary pool = 7 sec
```

In this case, the query runs for 5 seconds on the primary pool and then cascades to the secondary pool. After another 3 seconds, 8 seconds total, the query adopts the `RUNTIMEPRIORITY` of the secondary pool.

- If the primary pool's `RUNTIMEPRIORITYTHRESHOLD` is less than the secondary pool's `RUNTIMEPRIORITYTHRESHOLD`, the query adopts the secondary pool's `RUNTIMEPRIORITY` after the query reaches the `RUNTIMEPRIORITYTHRESHOLD` of the secondary pool.

For example,

```
RUNTIMECAP of primary pool = 5 sec  
RUNTIMEPRIORITYTHRESHOLD of primary pool = 8 sec  
RUNTIMTPRIORITYTHRESHOLD of secondary pool = 12 sec
```

In this case, the query runs for 5 seconds on the primary pool and then cascades to the secondary pool. After another 7 seconds, 12 seconds total, the query adopts the `RUNTIMEPRIORITY` of the secondary pool.

Using Queries to Monitor Resource Pool Size and Usage

You can use the [Linux top command](#) to determine the overall CPU usage and I/O wait time across the system. However, because of file system caching, the resident memory size indicated by `top` is not a good indicator of actual memory use or available reserve.

Instead, Vertica provides several monitoring tables that provide detailed information about resource pools, their current memory usage, resources requested and acquired by various requests, and the state of the queues.

The [RESOURCE_POOLS](#) table lets you view various resource pools defined in the system (both internal and user-defined), and the [RESOURCE_POOL_STATUS](#) table lets you view the current state of the resource pools.

Examples

This example shows how to find the various resource pools defined in the system.

```
=> SELECT name, memorysize, maxmemorysize FROM V_CATALOG.RESOURCE_POOLS;
```

name	memorysize	maxmemorysize
general		Special: 95%
sysquery	64M	
sysdata	100M	10%
wosdata	0%	25%
tm	200M	
refresh	0%	
recovery	0%	
dbd	0%	
jvm	0%	10%

(9 rows)

Viewing Only User-Defined Resource Pools

To see only the user-defined resource pools, you can limit your query to return records where `IS_INTERNAL` is false.

Note: The user-defined pools shown in these examples also appear in subsequent sections related to Workload Management.

This example shows how to find information on user-defined resource pools:

```
=> SELECT name, memorysize, maxmemorysize, priority, maxconcurrency  
FROM V_CATALOG.RESOURCE_POOLS where is_internal = 'f';
```

name	memorysize	maxmemorysize	priority	maxconcurrency
load_pool	0%		10	
ceo_pool	250M		10	
ad hoc_pool	200M	200M	0	
billing_pool	0%		0	3
web_pool	25M		10	5
batch_pool	150M	150M	0	10
dept1_pool	0%		5	
dept2_pool	0%		8	

(8 rows)

Viewing the Status of All Resource Pools

The following example shows how to access the `V_MONITOR.RESOURCE_POOL_STATUS` table to return the current state of all resource pools on node0001:

```
=>\x
Expanded display is on
=> SELECT pool_name, memory_size_kb, memory_size_actual_kb, memory_inuse_kb,
       general_memory_borrowed_kb, running_query_count
       FROM V_MONITOR.RESOURCE_POOL_STATUS where node_name ilike '%node0001';

-[ RECORD 1 ]-----+-----
pool_name          | general
memory_size_kb     | 2983177
memory_size_actual_kb | 2983177

memory_inuse_kb            | 0
general_memory_borrowed_kb | 0
running_query_count        | 0

```

Viewing Query Resource Acquisitions

The following example displays all resources granted to the queries that are currently running. The information shown is stored in the `V_MONITOR.RESOURCE_ACQUISITIONS` table. You can see that the query execution used 708504 KB of memory from the GENERAL pool.

```

=> SELECT pool_name, thread_count, open_file_handle_count, memory_inuse_kb,
       queue_entry_timestamp, acquisition_timestamp
       FROM V_MONITOR.RESOURCE_ACQUISITIONS WHERE node_name ILIKE '%node0001';

-[ RECORD 1 ]-----+-----
pool_name           | sysquery
thread_count        | 4
open_file_handle_count | 0
memory_inuse_kb     | 4103
queue_entry_timestamp | 2013-12-05 07:07:08.815362-05
acquisition_timestamp | 2013-12-05 07:07:08.815367-05
-[ RECORD 2 ]-----+-----
...
-[ RECORD 8 ]-----+-----
pool_name           | general
thread_count        | 12
open_file_handle_count | 18
memory_inuse_kb     | 708504
queue_entry_timestamp | 2013-12-04 12:55:38.566614-05
acquisition_timestamp | 2013-12-04 12:55:38.566623-05
-[ RECORD 9 ]-----+-----
...

```

You can determine how long a query waits in the queue before it can run. To do so, you obtain the difference between the `acquisition_timestamp` and the `queue_entry_timestamp` using a query as this example shows:

```
=> SELECT pool_name, queue_entry_timestamp, acquisition_timestamp,  
       (acquisition_timestamp-queue_entry_timestamp) AS 'queue wait'  
FROM V_MONITOR.RESOURCE_ACQUISITIONS WHERE node_name ILIKE '%node0001';
```

```
-[ RECORD 1 ]-----+-----  
pool_name      | sysquery  
queue_entry_timestamp | 2013-12-05 07:07:08.815362-05  
acquisition_timestamp | 2013-12-05 07:07:08.815367-05  
queue wait     | 00:00:00.000005  
-[ RECORD 2 ]-----+-----  
pool_name      | sysquery  
queue_entry_timestamp | 2013-12-05 07:07:14.714412-05  
acquisition_timestamp | 2013-12-05 07:07:14.714417-05  
queue wait     | 00:00:00.000005  
-[ RECORD 3 ]-----+-----  
pool_name      | sysquery  
queue_entry_timestamp | 2013-12-05 07:09:57.238521-05  
acquisition_timestamp | 2013-12-05 07:09:57.281708-05  
queue wait     | 00:00:00.043187  
-[ RECORD 4 ]-----+-----  
...
```

- See [Monitoring Resource Pools](#) for descriptions of other ways to monitor resource usage.

User Profiles

User profiles are attributes associated with a user that control that user's access to several system resources. These resources include:

- Resource pool to which a user is assigned (RESOURCE POOL)
- Maximum amount of memory a user's session can use (MEMORYCAP)
- Maximum amount of temporary file storage a user's session can use (TEMPSPACECAP)
- Maximum amount of time a user's query can run (RUNTIMECAP)

You can set these attributes with the [CREATE USER](#) statement and modify the attributes later with [ALTER USER](#).

Two strategies limit a user's access to resources: Setting attributes on the user directly to control resource use, or assigning the user to a resource pool. The first method lets you fine

tune individual users, while the second makes it easier to group many users together and set their collective resource usage.

The following examples illustrate how to set a user's resource pool attributes. For additional examples, see the scenarios described in [Using User-Defined Pools and User-Profiles for Workload Management](#).

Example

Set the user's RESOURCE POOL attribute to assign the user to a resource pool. To create a user named `user1` who has access to the resource pool `my_pool`, use the command:

```
=> CREATE USER user1 RESOURCE POOL my_pool;
```

To limit the amount of memory for a user without designating a pool, set the user's MEMORYCAP to either a particular unit or a percentage of the total memory available. For example, to create a user named `user2` whose sessions are limited to using 200 MBs memory each, use the command:

```
=> CREATE USER user2 MEMORYCAP '200M';
```

To limit the time a user's queries are allowed to run, set the RUNTIMECAP attribute. To prevent queries for `user2` from running more than five minutes, use this command:

```
=> ALTER USER user2 RUNTIMECAP '5 minutes';
```

To limit the amount of temporary disk space that the user's sessions can use, set the TEMPSPACECAP to either a particular size or a percentage of temporary disk space available. For example, the next statement creates `user3`, and limits her to using 1 GB of temporary space:

```
=> CREATE USER user3 TEMPSPACECAP '1G';
```

You can combine different attributes into a single command. For example, to limit the MEMORYCAP and RUNTIMECAP for `user3`, include both attributes in an [ALTER USER](#) statement:

```
=> ALTER USER user3 MEMORYCAP '750M' RUNTIMECAP '10 minutes';
ALTER USER
=> \x
Expanded display is on.
=> SELECT * FROM USERS;
-[ RECORD 1 ]-----+-----
user_id      | 45035996273704962
user_name    | release
is_super_user | t
resource_pool | general
memory_cap_kb | unlimited
temp_space_cap_kb | unlimited
```

```
run_time_cap      | unlimited
-[ RECORD 2 ]-----+-----
user_id           | 45035996273964824
user_name         | user1

Target Memory Determination for Queries in Concurrent Environments

The resource pool parameters `MEMORYSIZE`, `MAXMEMORYSIZE`, and `PLANNEDCONCURRENCY` allow you to tune the target memory allocated to queries.

Note: For details about these parameters, see [CREATE RESOURCE POOL](#) in the SQL Reference Manual.

What is the Query Budget?

Each resource pool has a *query budget*, which is the target memory for queries executed on the associated pool. Vertica stores this value in the `query_budget_kb` column in the `V_MONITOR.RESOURCE_POOL_STATUS` system table.

Computing the Query Budget

The formula for computing a pool's query budget is as follows:

GENERAL pool:

- Query budget = Queuing threshold of the GENERAL pool / PLANNEDCONCURRENCY

If MEMORYSIZE is set to 0 and MAXMEMORYSIZE is NOT set:

- Query budget = Queuing threshold of the GENERAL pool / PLANNEDCONCURRENCY

If MEMORYSIZE is set to 0 and MAXMEMORYSIZE is set to a value other than the default:

- Query budget = Queuing threshold of the pool / PLANNEDCONCURRENCY

If MEMORYSIZE is set to a value other than the default:

- Query budget = MEMORYSIZE / PLANNEDCONCURRENCY of the pool

The consequence of this is by carefully tuning the MEMORYSIZE and PLANNEDCONCURRENCY parameters, it is possible to restrict the amount of memory used by a query to a desired size.

For a detailed example of query budget calculations, see [Do You Need to Put Your Query on a Budget?](#) in the [Vertica User Community](#).

Note: Vertica calculates the queuing threshold for a pool is 95% of a pool's MAXMEMORYSIZE.

Tuning the Query Budget

Normally, query budgets do not require any specific tuning. However, if you reduce the MAXMEMORYSIZE because you need memory for other purposes, be aware that you are also reducing the query budget. Reducing the query budget negatively impacts the query performance, particularly if the queries are complex.

To maintain the original query budget for the resource pool, if you reduce MAXMEMORYSIZE, be sure to also reduce the value of PLANNEDCONCURRENCY.

Parameter Values

The [RESOURCE_POOL_STATUS](#) system table contains the values for parameters for all Vertica resource pools.

Managing Resources At Query Run Time

The Resource Manager estimates the resources required for queries to run, and then determines when to run queries and when to queue them.

The Resource Manager also lets you manage resources that are assigned to queries that are already running using either of these methods:

- [Setting Runtime Priority for the Resource Pool](#)--Use resource pool parameters to set the run time priority for queries running within the resource pool.
- [Changing Runtime Priority of a Running Query](#)--Manually change the run time priority of a running query.

Setting Runtime Priority for the Resource Pool

For each resource pool, you can manage resources that are assigned to queries that are already running. You assign each resource pool a runtime priority of HIGH, MEDIUM, or LOW. These settings determine the amount of runtime resources (such as CPU and I/O bandwidth) assigned to queries in the resource pool when they run. Queries in a resource pool with a HIGH priority are assigned greater runtime resources than those in resource pools with MEDIUM or LOW runtime priorities.

Prioritizing Queries Within a Resource Pool

While runtime priority helps to manage resources for the resource pool, there may be instances where you want some flexibility within a resource pool. For instance, you may want to ensure that very short queries run at a high priority, while also ensuring that all other queries run at a medium or low priority.

The Resource Manager allows you this flexibility by letting you set a *runtime priority threshold* for the resource pool. With this threshold, you specify a time limit (in seconds) by which a query must finish before it is assigned the runtime priority of the resource pool. All queries begin running with a HIGH priority; once a query's duration exceeds the time limit specified in the runtime priority threshold, it is assigned the runtime priority of the resource pool.

Setting Runtime Priority and Runtime Priority Threshold

You specify runtime priority and runtime priority threshold by setting two resource pool parameters with [CREATE RESOURCE POOL](#) or [ALTER RESOURCE POOL](#):

- `RUNTIMEPRIORITY`
- `RUNTIMEPRIORITYTHRESHOLD`

Changing Runtime Priority of a Running Query

[CHANGE_CURRENT_STATEMENT_RUNTIME_PRIORITY](#) lets you to change a query's runtime priority. You can change the runtime priority of a query that is already executing.

This function takes two arguments:

- The query's transaction ID, obtained from the system table [SESSIONS](#)
- The desired priority, one of the following string values: HIGH, MEDIUM, or LOW

Restrictions

Superusers can change the runtime priority of any query to any priority level. The following restrictions apply to other users:

- They can only change the runtime priority of their own queries.
- They cannot raise the runtime priority of a query to a level higher than that of the resource pools.

Procedure

Changing a query's runtime priority is a two-step procedure:

1. Get the query's transaction ID by querying the system table [SESSIONS](#). For example, the following statement returns information about all running queries:

```
=> SELECT transaction_id, runtime_priority, transaction_description from SESSIONS;
```

2. Run [CHANGE_CURRENT_STATEMENT_RUNTIME_PRIORITY](#), specifying the query's

transaction ID and desired runtime priority:

```
=> SELECT CHANGE_CURRENT_STATEMENT_RUNTIME_PRIORITY(45035996273705748, 'low')
```

Manually Moving Queries to Different Resource Pools

If you are the database administrator, you can move queries to another resource pool mid-execution using the [MOVE_STATEMENT_TO_RESOURCE_POOL](#) meta-function.

You might want to use this feature if a single query is using a large amount of resources, preventing smaller queries from executing.

What Happens When a Query Moves to a Different Resource Pool

When a query is moved from one resource pool to another, it continues executing, provided the target pool has enough resources to accommodate the incoming query. If sufficient resources cannot be assigned in the target pool on at least one node, Vertica cancels the query and attempts to re-plan the query. If Vertica cannot re-plan the query, the query is canceled indefinitely.

When you successfully move a query to a target resource pool, its resources will be accounted for by the target pool and released on the first pool.

If you move a query to a resource pool with `PRIORITY HOLD`, Vertica cancels the query and queues it on the target pool. This cancellation remains in effect until you change the `PRIORITY` or move the query to another pool without `PRIORITY HOLD`. You can use this option if you want to store long-running queries for later use.

You can view the [RESOURCE_ACQUISITIONS](#) or [RESOURCE_POOL_STATUS](#) system tables to determine if the target pool can accommodate the query you want to move. Be aware that the system tables may change between the time you query the tables and the time you invoke the `MOVE_STATEMENT_TO_RESOURCE_POOL` meta-function.

When a query successfully moves from one resource pool to another mid-execution, it executes until the greater of the existing and new `RUNTIMECAP` is reached. For example, if the `RUNTIMECAP` on the initial pool is greater than that on the target pool, the query can execute until the initial `RUNTIMECAP` is reached.

When a query successfully moves from one resource pool to another mid-execution the CPU affinity will change.

Using the MOVE_STATEMENT_TO_RESOURCE_POOL Function

To manually move a query from its current resource pool to another resource pool, use the `MOVE_STATEMENT_TO_RESOURCE_POOL` meta-function. Provide the session id, transaction id, statement id, and target resource pool name, as shown:

```
=> SELECT MOVE_STATEMENT_TO_RESOURCE_POOL ('v_vmart_node0001.example.-31427:0x82fbm',  
45035996273711993, 1, 'my_target_pool');
```

Restoring Resource Manager Defaults

The system table `V_CATALOG.RESOURCE_POOL_DEFAULTS` stores default values for all parameters for all built-in and user-defined resource pools.

If you have changed the value of any parameter in any of your resource pools and want to restore it to its default, you can simply alter the table and set the parameter to `DEFAULT`. For example, the following statement sets the `RUNTIMEPRIORITY` for the resource pool `sysquery` back to its default value:

```
VMart=> ALTER RESOURCE POOL sysquery RUNTIMEPRIORITY DEFAULT;
```

Best Practices for Managing Workload Resources

This section provides general guidelines and best practices on how to set up and tune resource pools for various common scenarios.

Note: The exact settings for resource pool parameters are heavily dependent on your query mix, data size, hardware configuration, and concurrency requirements. VERTICA recommends performing your own experiments to determine the optimal configuration for your system.

Basic Principles for Scalability and Concurrency Tuning

An Vertica database runs on a cluster of commodity hardware. All loads and queries running against the database take up system resources, such as CPU, memory, disk I/O bandwidth, file handles, and so forth. The performance (run time) of a given query depends on how much resource it has been allocated.

When running more than one query concurrently on the system, both queries are sharing the resources; therefore, each query could take longer to run than if it was running by itself. In an efficient and scalable system, if a query takes up all the resources on the machine and runs in X time, then running two such queries would double the run time of each query to $2X$. If the query runs in $> 2X$, the system is not linearly scalable, and if the query runs in $< 2X$ then the single query was wasteful in its use of resources. Note that the above is true as long as the query obtains the minimum resources necessary for it to run and is limited by CPU cycles. Instead, if the system becomes bottlenecked so the query does not get enough of a particular resource to run, then the system has reached a limit. In order to increase concurrency in such cases, the system must be expanded by adding more of that resource.

In practice, Vertica should achieve near linear scalability in run times, with increasing concurrency, until a system resource limit is reached. When adequate concurrency is reached without hitting bottlenecks, then the system can be considered as ideally sized for the workload.

Note: Typically Vertica queries on segmented tables run on multiple (likely all) nodes of the cluster. Adding more nodes generally improves the run time of the query almost linearly.

Setting a Runtime Limit for Queries

You can set a limit for the amount of time a query is allowed to run. You can set this limit at three levels, listed in descending order of precedence:

1. The resource pool to which the user is assigned.
2. User profile with RUNTIMECAP configured by [CREATE USER/ALTER USER](#)
3. Session queries, set by [SET SESSION RUNTIMECAP](#)

In all cases, you set the runtime limit with an [interval](#) value that does not exceed one year. When you set runtime limit at multiple levels, Vertica always uses the shortest value. If a runtime limit is set for a non-superuser, that user cannot set any session to a longer runtime limit. Superusers can set the runtime limit for other users and for their own sessions, to any value up to one year, inclusive.

Example

user1 is assigned to the ad_hoc_queries resource pool:

```
=> CREATE USER user1 RESOURCE POOL ad_hoc_queries;
```

RUNTIMECAP for user1 is set to 1 hour:

```
=> ALTER USER user1 RUNTIMECAP '60 minutes';
```

RUNTIMECAP for the ad_hoc_queries resource pool is set to 30 minutes:

```
=> ALTER RESOURCE POOL ad_hoc_queries RUNTIMECAP '30 minutes';
```

In this example, Vertica terminates user1's queries if they exceed 30 minutes. Although the user1's runtime limit is set to one hour, the pool on which the query runs, which has a 30-minute runtime limit, has precedence.

Note: If a secondary pool for the ad_hoc_queries pool is specified using the CASCADE TO function, the query executes on that pool when the RUNTIMECAP on the ad_hoc_queries pool is surpassed.

- [RESOURCE_POOLS](#)
- [Defining Secondary Resource Pools](#)

Handling Session Socket Blocking

A session socket can be blocked while awaiting client input or output for a given query. Session sockets are typically blocked for numerous reasons—for example, when the Vertica execution engine transmits data to the client, or a [COPY LOCAL](#) operation awaits load data from the client.

In rare cases, a session socket can remain indefinitely blocked. For example, a query times out on the client, which tries to forcibly cancel the query, or relies on the session [RUNTIMECAP setting](#) to terminate it. In either case, if the query ends while awaiting messages or data, the socket can remain blocked and the session hang until it is forcibly closed.

Configuring a Grace Period

You can configure the system with a grace period, during which a lagging client or server can catch up and deliver a pending response. If the socket is blocked for a continuous period that exceeds the grace period setting, the server shuts down the socket and throws a fatal error. The session is then terminated. If no grace period is set, the query can maintain its block on the socket indefinitely.

You should set the session grace period high enough to cover an acceptable range of latency and avoid closing sessions prematurely—for example, normal client-side delays in responding to the server. Very large load operations might require you to adjust the session grace period as needed.

You can set the grace period at four levels, listed in descending order of precedence:

1. Session (highest)
2. User
3. Node
4. Database

Setting Grace Periods for the Database and Nodes

At the database and node levels, you set the grace period to any [interval](#) up to 20 days, through configuration parameter `BlockedSocketGracePeriod`:

- `ALTER DATABASE db-name SET BlockedSocketGracePeriod = 'interval';`
- `ALTER NODE node-name SET BlockedSocketGracePeriod = 'interval';`

By default, the grace period for both levels is set to an empty string, which allows unlimited blocking.

Setting Grace Periods for Users and Sessions

You can set the grace period for individual users and for a given session, as follows:

- `{ CREATE | ALTER USER } user-name GRACEPERIOD { 'interval' | NONE };`
- `SET SESSION GRACEPERIOD { 'interval' | = DEFAULT | NONE };`

A user can set a session to any interval equal to or less than the grace period set for that user. Superusers can set the grace period for other users, and for their own sessions, to any value up to 20 days, inclusive.

Examples

Superuser `dbadmin` sets the database grace period to 6 hours. This limit only applies to non-superusers. `dbadmin` can set the session grace period for herself to any value up to 20 days—in this case, 10 hours:

```
=> ALTER DATABASE VMart SET BlockedSocketGracePeriod = '6 hours';
ALTER DATABASE
=> SHOW CURRENT BlockedSocketGracePeriod;
  level |          name          | setting
-----+-----+-----
DATABASE | BlockedSocketGracePeriod | 6 hours
(1 row)

=> SET SESSION GRACEPERIOD '10 hours';
SET
=> SHOW GRACEPERIOD;
  name      | setting
-----+-----
graceperiod | 10:00
(1 row)
```

dbadmin creates user user777 created with no grace period setting. Thus, the effective grace period for user777 is derived from the database setting of BlockedSocketGracePeriod, which is 6 hours. Any attempt by user777 to set the session grace period to a value greater than 6 hours returns with an error:

```
=> CREATE USER user777;
=> \c - user777
You are now connected as user "user777".
=> SHOW GRACEPERIOD;
   name      | setting
-----+-----
 graceperiod | 06:00
(1 row)

=> SET SESSION GRACEPERIOD '7 hours';
ERROR 8175: The new period 07:00 would exceed the database limit of 06:00
```

dbadmin sets a grace period of 5 minutes for user777. Now, user777 can set the session grace period to any value equal to or less than the user-level setting:

```
=> \c
You are now connected as user "dbadmin".
=> ALTER USER user777 GRACEPERIOD '5 minutes';
ALTER USER
=> \c - user777
You are now connected as user "user777".
=> SET SESSION GRACEPERIOD '6 minutes';
ERROR 8175: The new period 00:06 would exceed the user limit of 00:05
=> SET SESSION GRACEPERIOD '4 minutes';
SET
```

Using User-Defined Pools and User-Profiles for Workload Management

The scenarios in this section describe common workload-management issues, and provide solutions with examples.

Periodic Batch Loads

Scenario

You do batch loads every night, or occasionally (infrequently) during the day. When loads are running, it is acceptable to reduce resource usage by queries, but at all other times you want all resources to be available to queries.

Solution

Create a separate resource pool for loads with a higher priority than the preconfigured setting on the build-in GENERAL pool.

In this scenario, nightly loads get preference when borrowing memory from the GENERAL pool. When loads are not running, all memory is automatically available for queries.

Note: If you are using the WOS, tune the PLANNEDCONCURRENCY parameter of the WOSDATA pool to the number of concurrent loads. This ensures that AUTO spill to ROS is configured in an optimal fashion.

Example

Create a resource pool with the `PRIORITY` of the pool set higher than the `GENERAL` pool.

For example, to create a pool designated for loads that has a higher priority than the `GENERAL` pool, set `load_pool` with a priority of 10:

```
=> CREATE RESOURCE POOL load_pool PRIORITY 10;
```

Edit the `WOSDATA` pool `PLANNEDCONCURRENCY`:

```
=> ALTER RESOURCE POOL WOSDATA PLANNEDCONCURRENCY 6;
```

Modify the user's resource pool:

```
=> ALTER USER load_user RESOURCE POOL load_pool;
```

CEO Query

Scenario

The CEO runs a report every Monday at 9AM, and you want to be sure that the report always runs.

Solution

To ensure that a certain query or class of queries always gets resources, you could create a dedicated pool for it as follows:

1. Using the [PROFILE](#) command, run the query that the CEO runs every week to determine how much memory should be allocated:

```
=> PROFILE SELECT DISTINCT s.product_key, p.product_description
-> FROM store.store_sales_fact s, public.product_dimension p
-> WHERE s.product_key = p.product_key AND s.product_version = p.product_version
-> AND s.store_key IN (
->   SELECT store_key FROM store.store_dimension
->   WHERE store_state = 'MA')
-> ORDER BY s.product_key;
```

2. At the end of the query, the system returns a notice with resource usage:

```
NOTICE: Statement is being profiled.HINT: select * from v_monitor.execution_engine_profiles
where
transaction_id=45035996273751349 and statement_id=6;
NOTICE: Initiator memory estimate for query: [on pool general: 1723648 KB,
minimum: 355920 KB]
```

3. Create a resource pool with MEMORYSIZE reported by the above hint to ensure that the CEO query has at least this memory reserved for it:

```
=> CREATE RESOURCE POOL ceo_pool MEMORYSIZE '1800M' PRIORITY 10;
CREATE RESOURCE POOL
=> \x
Expanded display is on.
=> SELECT * FROM resource_pools WHERE name = 'ceo_pool';
-[ RECORD 1 ]-----+-----
name                | ceo_pool
is_internal          | f
memorysize           | 1800M
maxmemorysize        |
priority             | 10
queuetimeout         | 300
plannedconcurrency   | 4
maxconcurrency       |
singleinitiator      | f
```

4. Assuming the CEO report user already exists, associate this user with the above resource pool using ALTER USER statement.

```
=> ALTER USER ceo_user RESOURCE POOL ceo_pool;
```

5. Issue the following command to confirm that the `ceo_user` is associated with the `ceo_pool`:

```
=> SELECT * FROM users WHERE user_name = 'ceo_user';  
-[ RECORD 1 ]-----  
user_id      | 45035996273713548  
user_name    | ceo_user  
is_super_user | f  
resource_pool | ceo_pool  
memory_cap_kb | unlimited
```

If the CEO query memory usage is too large, you can ask the Resource Manager to reduce it to fit within a certain budget. See [Target Memory Determination for Queries in Concurrent Environments](#).

Preventing Runaway Queries

Scenario

Joe, a business analyst often runs big reports in the middle of the day that take up the whole machine's resources. You want to prevent Joe from using more than 100MB of memory, and you want to also limit Joe's queries to run for less than 2 hours.

Solution

[User Profiles](#) provides a solution to this scenario. To restrict the amount of memory Joe can use at one time, set a MEMORYCAP for Joe to 100MB using the [ALTER USER](#) command. To limit the amount of time that Joe's query can run, set a RUNTIMECAP to 2 hours using the same command. If any query run by Joe takes up more than its cap, Vertica rejects the query.

If you have a whole class of users whose queries you need to limit, you can also create a resource pool for them and set RUNTIMECAP for the resource pool. When you move these users to the resource pool, Vertica limits all queries for these users to the RUNTIMECAP you specified for the resource pool.

Example

```
=> ALTER USER analyst_user MEMORYCAP '100M' RUNTIMECAP '2 hours';
```

If Joe attempts to run a query that exceeds 100MB, the system returns an error that the request exceeds the memory session limit, such as the following example:

```
\i vmart_query_04.sqlvsq1:vmart_query_04.sql:12: ERROR: Insufficient resources to initiate plan  
on pool general [Request exceeds memory session limit: 137669KB > 102400KB]
```

Only the system database administrator (dbadmin) can increase only the MEMORYCAP setting. Users cannot increase their own MEMORYCAP settings and will see an error like the following if they attempt to edit their MEMORYCAP or RUNTIMECAP settings:

```
ALTER USER analyst_user MEMORYCAP '135M';  
ROLLBACK: permission denied
```

Restricting Resource Usage of Ad Hoc Query Application

Scenario

You recently made your data warehouse available to a large group of users who are not experienced SQL users. Some of the users run reports that operate on a large number of rows and overwhelm the system. You want to throttle usage of the system by these users.

Solution

The simplest solution is to create a standalone resource pool for the ad hoc applications so that the total MEMORYSIZE is fixed. Recall that in a standalone pool, MAXMEMORYSIZE is set equal to MEMORYSIZE so no memory can be borrowed from the GENERAL pool. Associate this user pool with database users from which the application uses to connect to the database. Also set RUNTIMECAP to limit the maximum duration of an ad hoc query.

Other solutions include limiting the memory usage of individual users such as in the [Preventing Runaway Queries](#).

Example

To create a standalone resource pool for the ad hoc users, set the MEMORYSIZE equal to the MAXMEMORYSIZE:

```
=> CREATE RESOURCE POOL adhoc_pool MEMORYSIZE '200M' MAXMEMORYSIZE '200M' PRIORITY 0 QUEUETIMEOUT
300 PLANNEDCONCURRENCY 4;
=> SELECT pool_name, memory_size_kb, queueing_threshold_kb
FROM V_MONITOR.RESOURCE_POOL_STATUS w
WHERE is_standalone = 'true' AND is_internal = 'false';
pool_name | memory_size_kb | queueing_threshold_kb
-----+-----+-----
adhoc_pool |          204800 |             153600
(1 row)
```

After the pool has been created, associate the ad hoc users with the adhoc_pool:

```
=> ALTER USER app1_user RESOURCE POOL adhoc_pool;
=> ALTER RESOURCE POOL adhoc_pool MEMORYSIZE '10M' MAXMEMORYSIZE '10M';
\i vmart_query_04.sql
vsq1:vmart_query_04.sql:12: ERROR: Insufficient resources to initiate plan
on pool adhoc_pool [Request Too Large:Memory(KB)
Exceeded: Requested = 84528, Free = 10240 (Limit = 10240, Used = 0)]
```

The query will not borrow memory from the GENERAL pool and gets rejected with a 'Request Too Large' message.

Setting a Hard Limit on Concurrency for an Application

Scenario

For billing purposes, analyst Jane would like to impose a hard limit on concurrency for this application. How can she achieve this?

Solution

The simplest solution is to create a separate resource pool for the users of that application and set its `MAXCONCURRENCY` to the desired concurrency level. Any queries beyond `MAXCONCURRENCY` are queued.

Tip: Micro Focus recommends leaving `PLANNEDCONCURRENCY` to the default level so the queries get their maximum amount of resources. The system as a whole thus runs with the highest efficiency.

Example

In this example, there are four billing users associated with the billing pool. The objective is to set a hard limit on the resource pool so a maximum of three concurrent queries can be executed at one time. All other queries will queue and complete as resources are freed.

```
=> CREATE RESOURCE POOL billing_pool MAXCONCURRENCY 3 QUEUETIMEOUT 2;
=> CREATE USER bill1_user RESOURCE POOL billing_pool;
=> CREATE USER bill2_user RESOURCE POOL billing_pool;
=> CREATE USER bill3_user RESOURCE POOL billing_pool;
=> CREATE USER bill4_user RESOURCE POOL billing_pool;
=> \x
Expanded display is on.

=> select maxconcurrency,queuetimeout from resource_pools where name = 'billing_pool';
maxconcurrency | queuetimeout
-----+-----
                3 |                2
(1 row)
> SELECT reason, resource_type, rejection_count FROM RESOURCE_REJECTIONS
WHERE pool_name = 'billing_pool' AND node_name ilike '%node0001';
reason | resource_type | rejection_count
-----+-----+-----
Timeout waiting for resource request | Queries | 16
(1 row)
```

If queries are running and do not complete in the allotted time (default timeout setting is 5 minutes), the next query requested gets an error similar to the following:

```
ERROR: Insufficient resources to initiate plan on pool billing_pool [Timeout waiting for resource
request: Request exceeds limits:
Queries Exceeded: Requested = 1, Free = 0 (Limit = 3, Used = 3)]
```

The table below shows that there are three active queries on the billing pool.

```
=> SELECT pool_name, thread_count, open_file_handle_count, memory_inuse_kb FROM RESOURCE_ACQUISITIONS
WHERE pool_name = 'billing_pool';
pool_name | thread_count | open_file_handle_count | memory_inuse_kb
-----+-----+-----+-----
billing_pool | 4 | 5 | 132870
billing_pool | 4 | 5 | 132870
billing_pool | 4 | 5 | 132870
(3 rows)

Handling Mixed Workloads: Batch versus Interactive

Scenario

You have a web application with an interactive portal. Sometimes when IT is running batch reports, the web page takes a long time to refresh and users complain, so you want to provide a better experience to your web site users.

Solution

The principles learned from the previous scenarios can be applied to solve this problem. The basic idea is to segregate the queries into two groups associated with different resource pools. The prerequisite is that there are two distinct database users issuing the different types of queries. If this is not the case, do consider this a best practice for application design.

Method 1

Create a dedicated pool for the web page refresh queries where you:

- Size the pool based on the average resource needs of the queries and expected number of concurrent queries issued from the portal.
- Associate this pool with the database user that runs the web site queries. See [CEO Query](#) for information about creating a dedicated pool.

This ensures that the web site queries always run and never queue behind the large batch jobs. Leave the batch jobs to run off the GENERAL pool.

For example, the following pool is based on the average resources needed for the queries running from the web and the expected number of concurrent queries. It also has a higher PRIORITY to the web queries over any running batch jobs and assumes the queries are being tuned to take 250M each:

```
=> CREATE RESOURCE POOL web_pool
    MEMORYSIZE '250M'
    MAXMEMORYSIZE NONE
    PRIORITY 10
    MAXCONCURRENCY 5
    PLANNEDCONCURRENCY 1;
```

Method 2

Create a standalone pool to limit the batch reports down to a fixed memory size so memory is always left available for other purposes. For details, see [Restricting Resource Usage of Ad Hoc Query Application](#).

For example:

```
=> CREATE RESOURCE POOL batch_pool
    MEMORYSIZE '4G'
    MAXMEMORYSIZE '4G'
    MAXCONCURRENCY 10;
```

The same principle can be applied if you have three or more distinct classes of workloads.

Setting Priorities on Queries Issued By Different Users

Scenario

You want user queries from one department to have a higher priority than queries from another department.

Solution

The solution is similar to the [mixed workload case](#). In this scenario, you do not limit resource usage; you set different priorities. To do so, create two different pools, each with MEMORYSIZE=0% and a different PRIORITY parameter. Both pools borrow from the GENERAL pool, however when competing for resources, the priority determine the order in which each pool's request is granted. For example:

```
=> CREATE RESOURCE POOL dept1_pool PRIORITY 5;  
=> CREATE RESOURCE POOL dept2_pool PRIORITY 8;
```

If you find this solution to be insufficient, or if one department's queries continuously starves another department's users, you can add a reservation for each pool by setting MEMORYSIZE so some memory is guaranteed to be available for each department.

For example, both resources use the GENERAL pool for memory, so you can allocate some memory to each resource pool by using ALTER RESOURCE POOL to change MEMORYSIZE for each pool:

```
=> ALTER RESOURCE POOL dept1_pool MEMORYSIZE '100M';  
=> ALTER RESOURCE POOL dept2_pool MEMORYSIZE '150M';
```

Continuous Load and Query

Scenario

You want your application to run continuous load streams, but many have up concurrent query streams. You want to ensure that performance is predictable.

Solution

The solution to this scenario depends on your query mix. In all cases, the following approach applies:

1. Determine the number of continuous load streams required. This may be related to the desired load rate if a single stream does not provide adequate throughput, or may be more directly related to the number of sources of data to load. Also determine if automatic storage is best, or if DIRECT is required. Create a dedicated resource pool for the loads, and associate it with the database user that will perform them. See [CREATE RESOURCE POOL](#) for details.

In general, concurrency settings for the load pool should be less than the number of cores per node. Unless the source processes are slow, it is more efficient to dedicate more memory per load, and have additional loads queue. Adjust the load pool's QUEUETIMEOUT setting if queuing is expected.

2. If using automatic targeting of [COPY](#) and [INSERT](#), set the PLANNEDCONCURRENCY parameter of the WOSDATA pool to the number of concurrent loads expected. Also, set MEMORYSIZE of the WOS to the expected size of the loaded data to ensure that small loads don't spill to ROS immediately. See [Built-In Pools](#) for details.
3. Run the load workload for a while and observe whether the load performance is as expected. If the Tuple Mover is not tuned adequately to cover the load behavior, see [Managing the Tuple Mover](#) in Administrator's Guide.
4. If there is more than one kind of query in the system—for example, some queries must be answered quickly for interactive users, while others are part of a batch reporting process—follow the guidelines in [Handling Mixed Workloads: Batch versus Interactive](#).
5. Let the queries run and observe performance. If some classes of queries do not perform as desired, then you might need to tune the GENERAL pool as outlined in [Restricting Resource Usage of Ad Hoc Query Application](#), or create more dedicated resource pools for those queries. See more information, see [CEO Query](#) and [Handling Mixed Workloads: Batch versus Interactive](#).

See the sections on [Managing Workloads](#) and [CREATE RESOURCE POOL](#) for information on obtaining predictable results in mixed workload environments.

Prioritizing Short Queries at Run Time

Scenario

You recently created a resource pool for users who are not experienced with SQL and who frequently run ad hoc reports. You have managed resource allocation by creating a standalone resource pool that will prevent these queries from borrowing resources from the GENERAL pool, but now you want to manage resources at run time and ensure that short queries always run with a high priority and are never queued as a result of limited run-time resources.

Solution

Set the `RUNTIMEPRIORITY` for the resource pool to `MEDIUM` or `LOW`. Set the `RUNTIMEPRIORITYTHRESHOLD` for the resource pool to the duration of queries you want to ensure always run at a high priority. For instance, if you set this value to 5, all queries that complete within 5 seconds will run at high priority. Any other query that exceeds 5 seconds will drop down to the `RUNTIMEPRIORITY` assigned to the resource pool (`MEDIUM` or `LOW`).

Example

To ensure that all queries with a duration of less than 5 seconds always run at a high priority, modify `adhoc_pool` as follows:

- Set the `RUNTIMEPRIORITY` to `MEDIUM`
- Set the `RUNTIMETHRESHOLD` to 5

```
=> ALTER RESOURCE POOL ad_hoc_pool RUNTIMEPRIORITY medium RUNTIMEPRIORITYTHRESHOLD 5;
```

Dropping the Runtime Priority of Long Queries

Scenario

You want most queries in a resource pool to run at a HIGH runtime priority; however, you'd like to be able to drop jobs longer than 1 hour to a lower priority.

Solution

Set the `RUNTIMEPRIORITY` for the resource pool to `LOW` and set the `RUNTIMEPRIORITYTHRESHOLD` to a number that cuts off only the longest jobs.

Example

To ensure that all queries with a duration of more than 3600 seconds (1 hour) are assigned a low runtime priority, modify the resource pool as follows:

- Set the `RUNTIMEPRIORITY` to `LOW`.
- Set the `RUNTIMETHRESHOLD` to `3600`

```
=> ALTER RESOURCE POOL ad_hoc_pool RUNTIMEPRIORITY low RUNTIMEPRIORITYTHRESHOLD 3600;
```

Tuning Built-In Pools

The scenarios in this section describe how to tune built-in pools.

- [Restricting Vertica to Take Only 60% of Memory](#)
- [Tuning for Recovery](#)
- [Tuning for Refresh](#)
- [Tuning Tuple Mover Pool Settings](#)
- [Tuning for Machine Learning](#)

Restricting Vertica to Take Only 60% of Memory

Scenario

You have a single node application that embeds Vertica, and some portion of the RAM needs to be devoted to the application process. In this scenario, you want to limit Vertica to use only 60% of the available RAM.

Solution

Set the MAXMEMORYSIZE parameter of the GENERAL pool to the desired memory size. See [Resource Pool Architecture](#) for a discussion on resource limits.

Tuning for Recovery

Scenario

You have a large database that contains a single large table with two projections, and with default settings, recovery is taking too long. You want to give recovery more memory to improve speed.

Solution

Set the `PLANNEDCONCURRENCY` and `MAXCONCURRENCY` setting of the recovery pool to 1 so that recovery can take as much memory as possible from the `GENERAL` pool and run only one thread at once.

Note: This setting could slow down other queries in your system.

Tuning for Refresh

Scenario

When a refresh operation is running, system performance is affected and user queries get rejected. You want to reduce the memory usage of the refresh job.

Solution

Set the MEMORYSIZE parameter of the refresh pool to a fixed value. The Resource Manager then tunes the refresh query to only use this amount of memory.

Tip: Remember to reset the refresh pool MEMORYSIZE back to 0% after the refresh operation completes so memory can be used for other operations.

Tuning Tuple Mover Pool Settings

Scenario

During loads, you occasionally notice spikes in the number of ROS containers, and you would like to make the Tuple Mover more aggressive.

Solution

Increase the `MAXCONCURRENCY` parameter of the TM pool to 3 or higher. This setting ensures that the Tuple Mover can run more than one mergeout thread, so if a large mergeout is in progress, smaller ROS containers can also be merged, thus preventing a buildup of ROS containers.

Tuning for Machine Learning

Scenario

You have a large number of machine learning algorithms running, and you want to improve the performance of the queries. In this scenario, you want to give machine learning functions more memory to improve their performance.

Solution

Vertica executes the machine learning functions in the BLOBDATA resource pool. To improve the performance of the machine learning functions increase the MAXMEMORYSIZE parameter of the BLOBDATA pool. If a query using the BLOBDATA pool exceeds its query planning budget, then it spills to disk.

For more information about tuning your query budget, see [Target Memory Determination for Queries in Concurrent Environments](#).

- [ALTER RESOURCE POOL](#)
- [Managing Resources At Query Run Time](#)
- [Built-In Pool Configuration](#)
- [Built-In Pools](#)

Reducing Query Run Time

The run time of queries depends on the complexity of the query, the number of operators in the plan, data volumes, and projection design. If the system is bottlenecked on either I/O or CPU, queries could run more slowly than expected. In most cases, high CPU usage can be alleviated by better projection design, and high I/O is usually due to contention because of operations like joins and sorts that spill to disk. However, there is no single solution to fix high CPU or high I/O usage, so queries must be examined and tuned individually.

You can evaluate a slow-running query in two ways:

- Prefix the query with [EXPLAIN](#) to view the optimizer's query plan.
- Examine the execution profile by querying the system table [EXECUTION_ENGINE_PROFILES](#)

Examining the query plan often reveals one or more of the following:

- Suboptimal projection sort order
- Predicate evaluation on an unsorted or unencoded column
- Use of `GROUPBY HASH` instead of `GROUPBY PIPE`

See [Creating Custom Designs](#) to understand projection design techniques. The Database Designer automatically applies these techniques to suggest optimal designs for queries.

Profiling

Vertica provides profiling mechanisms that let you determine how well the database is performing. For example, Vertica can collect profiling data for a single statement, a single session, or for all sessions on all nodes. For details, see [Profiling Database Performance](#).

Managing System Resource Usage

You can use the [Using System Tables](#) to track overall resource usage on your cluster. These and the other system tables are described in the [Vertica System Tables](#).

If your queries are experiencing errors due to resource unavailability, you can use the following system tables to obtain more details:

System Table	Description
RESOURCE_REJECTIONS	Monitors requests for resources that are rejected by the Resource Manager.
DISK_RESOURCE_REJECTIONS	Monitors requests for resources that are rejected due to disk space shortages. See Managing Disk Space for more information.

When requests for resources of a certain type are being rejected, do one of the following:

- Increase the resources available on the node by adding more memory, more disk space, and so on. See [Managing Disk Space](#).
- Reduce the demand for the resource by reducing the number of users on the system (see [Managing Sessions](#)), rescheduling operations, and so on.

The `LAST_REJECTED_VALUE` field in `RESOURCE_REJECTIONS` indicates the cause of the problem. For example:

- The message `Usage of a single requests exceeds high limit` means that the system does not have enough of the resource available for the single request. A common example occurs when the file handle limit is set too low and you are loading a table with a large number of columns.
- The message `Timed out or Canceled waiting for resource reservation` usually means that there is too much contention for the resource because the hardware platform cannot support the number of concurrent users using it.

Managing Sessions

Vertica provides several methods for database administrators to view and control sessions. The methods vary according to the type of session:

- External (user) sessions are initiated by vsql or programmatic (ODBC or JDBC) connections and have associated client state.
- Internal (system) sessions are initiated by Vertica and have no client state.

Configuring Maximum Sessions

The maximum number of per-node user sessions is set by the configuration parameter `MaxClientSessions` parameter, by default 50. You can set `MaxClientSessions` parameter to any value between 0 and 1000. In addition to this maximum, Vertica also allows up to five administrative sessions per node.

For example:

```
=> ALTER DATABASE mydb SET MaxClientSessions = 100;
```

Note: If you use the Administration Tools "Connect to Database" option, Vertica will attempt connections to other nodes if a local connection does not succeed. These cases can result in more successful "Connect to Database" commands than you would expect given the `MaxClientSessions` value.

Viewing Sessions

The system table [SESSIONS](#) contains detailed information about user sessions and returns one row per session. Superusers have unrestricted access to all database metadata. Access for other users varies according to their [privileges](#).

Interrupting and Closing Sessions

You can interrupt a running statement with the Vertica function [INTERRUPT_STATEMENT](#). Interrupting a running statement returns a session to an idle state:

- No statements or transactions are running.
- No locks are held.
- The database is doing no work on behalf of the session.

Closing a user session interrupts the session and disposes of all state related to the session, including client socket connections for the target sessions. The following Vertica functions close one or more user sessions:

- [CLOSE_SESSION](#)
- [CLOSE_ALL_SESSIONS](#)
- [CLOSE_USER_SESSIONS](#)
- [SHUTDOWN](#)

SELECT statements that call these functions return after the interrupt or close message is delivered to all nodes. The function might return before Vertica completes execution of the interrupt or close operation. Thus, there might be a delay after the statement returns and the interrupt or close takes effect throughout the cluster. To determine if the session or transaction ended, query the `SESSIONS` system table.

In order to shut down a database, you must first close all user sessions. For more about database shutdown, see [Stopping the Database](#).

Managing Load Streams

You can use the [Using System Tables](#) to keep track of data being loaded on your cluster.

System Table	Description
LOAD_STREAMS	Monitors load metrics for each load stream on each node.

For details about Vertica system tables, see [Vertica System Tables](#).

When a `COPY` statement using the `DIRECT` option is in progress, the `ACCEPTED_ROW_COUNT` value can increase during parsing. This value can reach the maximum number of rows in the input file.

If `COPY` reads input data from multiple named pipes, the `PARSE_COMPLETE_PERCENT` value remains at zero (0) until *all* named pipes return an EOF. While `COPY` awaits an EOF from multiple pipes, it can appear to be hung. However, before canceling the `COPY` statement, check your [system CPU and disk accesses](#) to determine if any activity is in progress.

In a typical load, the `PARSE_COMPLETE_PERCENT` value can either increase slowly or jump quickly to 100%, if you are loading from named pipes or `STDIN`. However, `SORT_COMPLETE_PERCENT` remains at 0 when loading from named pipes or `STDIN`. After `PARSE_COMPLETE_PERCENT` reaches 100%, `SORT_COMPLETE_PERCENT` increases to 100%. Depending on the data sizes, a significant lag can occur between the time `PARSE_COMPLETE_PERCENT` reaches 100% and the time `SORT_COMPLETE_PERCENT` begins to increase.

Monitoring Vertica

This section describes some of the ways in which you can monitor the health of your database.

You can also monitor the Vertica database using MC, as described in [Monitoring Using MC](#).

Monitoring Log Files

When a Database Is Running

When a Vertica database is running, each node in the cluster writes messages into a file named `vertica.log`. For example, the Tuple Mover and the transaction manager write INFO messages into `vertica.log` at specific intervals even when there is no WOS activity.

Note: Vertica often changes the format or content of log files in subsequent releases to benefit both customers and customer support.

To monitor one node in a running database in real time:

1. Log in to the database administrator account on any node in the cluster.
2. In a terminal window enter:

```
$ tail -f catalog-path/database-name/node-name_catalog/vertica.log
```

Note: To monitor your overall database (rather than an individual node/host), use the Data Collector, which records system activities and performance. See [Retaining Monitoring Information](#) for more on Data Collector.

<i>catalog-path</i>	The catalog pathname specified when you created the database. See Creating a Database in the Administrator's Guide.
<i>database-name</i>	The database name (case sensitive)
<i>node-name</i>	The node name, as specified in the database definition. See Viewing a Database in the Administrator's Guide.

When the Database / Node Is Starting up

During system startup, before the vertica log has been initialized to write messages, each node in the cluster writes messages into a file named dbLog. This log is useful to diagnose situations where the database fails to start before it can write messages into vertica.log. The dblog is located at the following path, using catalog-path and database-name as described above:

```
catalog-path/database-name/dbLog
```

See Also

- [Rotating Log Files](#)

Rotating Log Files

Most Linux distributions include the logrotate utility. Using this utility simplifies log file administration. By setting up a logrotate configuration file, you can use the utility to complete one or more of these tasks automatically:

- Compress and rotate log files
- Remove log files automatically
- Email log files to named recipients

You can configure logrotate to complete these tasks at specific intervals, or when log files reach a particular size.

If logrotate is present when Vertica is installed, then Vertica automatically sets this utility to look for configuration files. Thus, logrotate searches for configuration files in the /opt/vertica/config/logrotate directory on each node.

When you create a database, Vertica creates database-specific logrotate configurations on each node in your cluster, which are used by the logrotate utility. It then creates a file with the path /opt/vertica/config/logrotate/<dbname> for each individual database.

For information about additional settings, use the man logrotate command.

Executing the Python script Through the dbadmin logrotate cron Job

During the installation of Vertica, the installer configures a cron job for the dbadmin user. This cron job is configured to execute a Python script that runs the `logrotate` utility. You can view the details of this cron job by viewing the `dbadmin.cron` file, which is located in the `/opt/vertica/config` directory.

If you want to customize a cron job to configure logrotate for your Vertica database, you *must* create the cron job under the dbadmin user.

Using the Administration Tools Logrotate Utility

You can use the `admintools logrotate` option to help configure logrotate scripts for a database and distribute the scripts across the cluster. The `logrotate` option allows you to specify:

- How often to rotate logs
- How large logs can become before being rotated
- How long to keep the logs

Example:

The following example shows you how to set up log rotation on a weekly schedule and keeps for three months (12 logs).

```
$ admintools -t logrotate -d <dbname> -r weekly -k 12
```

See [Writing Administration Tools Scripts](#) for more usage information.

Rotating Logs Manually

To implement a custom log rotation process, follow these steps:

1. Rename or archive the existing *vertica.log* file. For example:

```
$ mv vertica.log vertica.log.1
```

2. Send the Vertica process the USR1 signal, using either of the following approaches:

```
$ killall -USR1 vertica
```

or

```
$ ps -ef | grep -i vertica  
$ kill -USR1 process-id
```

See Also

- [Monitoring Log Files](#)

Monitoring Process Status (ps)

You can use `ps` to monitor the database and Spread processes running on each node in the cluster. For example:

```
$ ps aux | grep /opt/vertica/bin/vertica
$ ps aux | grep /opt/vertica/spread/sbin/spread
```

You should see one Vertica process and one Spread process on each node for common configurations. To monitor Administration Tools and connector processes:

```
$ ps aux | grep vertica
```

There can be many connection processes but only one Administration Tools process.

Monitoring Linux Resource Usage

You should monitor system resource usage on any or all nodes in the cluster. You can use System Activity Reporting (SAR) to monitor resource usage.

Micro Focus recommends that you install `pstack` and `sysstat` to help monitor Linux resources. The `SYSSTAT` package contains utilities for monitoring system performance and usage activity, such as `sar`, as well as tools you can schedule via `cron` to collect performance and activity data. See the [SYSSTAT Web page](#) for details.

The `pstack` utility lets you print a stack trace of a running process. See the [PSTACK man page](#) for details.

1. Log in to the database administrator account on any node.
2. Run the `top` utility

```
$ top
```

A high CPU percentage in `top` indicates that Vertica is CPU-bound. For example:

```
top - 11:44:28 up 53 days, 23:47, 9 users, load average: 0.91, 0.97, 0.81
Tasks: 123 total, 1 running, 122 sleeping, 0 stopped, 0 zombie
Cpu(s): 26.9%us, 1.3%sy, 0.0%ni, 71.8%id, 0.0%wa, 0.0%hi, 0.0%si, 0.0%st
Mem: 4053136 total, 3882020k used, 171116 free, 407688 buffers
Swap: 4192956 total, 176k used, 4192780 free, 1526436 cached
  PID USER      PR  NI  VIRT  RES  SHR  S %CPU %MEM    TIME+  COMMAND
 13703 dbadmin    1   0 1374m 678m 55m  S 99.9 17.1   6:21.70 vertica
  2606 root       16   0 32152  11m 2508  S  1.0  0.3    0:16.97 X
    1 root       16   0  4748   552  456  S  0.0  0.0    0:01.51 init
    2 root       RT  -5     0     0     0  S  0.0  0.0    0:04.92 migration/0
    3 root       34  19     0     0     0  S  0.0  0.0    0:11.75 ksoftirqd/0
...
```

Some possible reasons for high CPU usage are:

- The Tuple Mover runs automatically and thus consumes CPU time even if there are no connections to the database.
- Log in as root and change the Linux parameter `swappiness` to 1.

```
# echo 1 > /proc/sys/vm/swappiness
```

Setting swappiness in this manner does not save the value after a reboot. To permanently set the swappiness value, add or update the following in `/etc/sysctl.conf`:

```
vm.swappiness = 1
```

You can also check the swappiness value as follows:

```
cat /proc/sys/vm/swappiness
```

■ Some information sources:

- [Red Hat](#)
- [Indiana University Unix Systems Support Group](#)

3. Run the `iostat` utility. A high idle time in `top` at the same time as a high rate of blocks read in `iostat` indicates that Vertica is disk-bound. For example:

```
$ /usr/bin/iostat
Linux 2.6.18-164.el5 (qa01)      02/05/2011
avg-cpu:  %user   %nice %system %iowait  %steal   %idle
           0.77    2.32   0.76    0.68    0.00   95.47

Device:            tps    Blk_read/s  Blk_wrtn/s  Blk_read  Blk_wrtn
hda                 0.37         3.40         10.37     2117723   6464640
sda                 0.46         1.94         18.96     1208130   11816472
sdb                 0.26         1.79         15.69     1114792   9781840
sdc                 0.24         1.80         16.06     1119304   10010328
sdd                 0.22         1.79         15.52     1117472   9676200
md0                 8.37         7.31         66.23     4554834   41284840
```

Monitoring Disk Space Usage

You can use these system tables to monitor disk space usage on your cluster:

System table	Description
DISK_STORAGE	Monitors the amount of disk storage used by the database on each node.
COLUMN_STORAGE	Monitors the amount of disk storage used by each column of each projection on each node.
PROJECTION_STORAGE	Monitors the amount of disk storage used by each projection on each

System table	Description
	node.

Monitoring Database Size for License Compliance

Your Vertica license can include a data storage allowance. The allowance can consist of data in columnar tables, flex tables, or both types of data. The `AUDIT()` function estimates the columnar table data size and any flex table materialized columns. The `AUDIT_FLEX()` function estimates the amount of `__raw__` column data in flex or columnar tables. In regards to license data limits, data in `__raw__` columns is calculated at 1/10th the size of structured data. Monitoring data sizes for columnar and flex tables lets you plan either to schedule deleting old data to keep your database in compliance with your license, or to consider a license upgrade for additional data storage.

Note: An audit of columnar data includes flex table real and materialized columns, but not `__raw__` column data.

Viewing Your License Compliance Status

Vertica periodically runs an audit of the columnar data size to verify that your database is compliant with your license terms. You can view the results of the most recent audit by calling the `GET_COMPLIANCE_STATUS` function.

```
=> select GET_COMPLIANCE_STATUS();
          GET_COMPLIANCE_STATUS
-----
Raw Data Size: 2.00GB +/- 0.003GB
License Size : 4.000GB
Utilization  : 50%
Audit Time   : 2011-03-09 09:54:09.538704+00
Compliance Status : The database is in compliance with respect to raw data size.
License End Date: 04/06/2011
Days Remaining: 28.59
(1 row)
```

Periodically running `GET_COMPLIANCE_STATUS` to monitor your database's license status is usually enough to ensure that your database remains compliant with your license. If your database begins to near its columnar data allowance, you can use the other auditing functions

described below to determine where your database is growing and how recent deletes affect the database size.

Manually Auditing Columnar Data Usage

You can manually check license compliance for all columnar data in your database using the [AUDIT_LICENSE_SIZE](#) function. This function performs the same audit that Vertica periodically performs automatically. The [AUDIT_LICENSE_SIZE](#) check runs in the background, so the function returns immediately. You can then query the results using [GET_COMPLIANCE_STATUS](#).

Note: When you audit columnar data, the results include any flex table real and materialized columns, but not data in the `__raw__` column. Materialized columns are virtual columns that you have promoted to real columns. Columns that you define when creating a flex table, or which you add with `ALTER TABLE . . . ADD COLUMN` statements are real columns. All `__raw__` columns are real columns. However, since they consist of unstructured or semi-structured data, they are audited separately.

An alternative to `AUDIT_LICENSE_SIZE` is to use the [AUDIT](#) function to audit the size of the columnar tables in your entire database by passing an empty string to the function. This function operates synchronously, returning when it has estimated the size of the database.

```
=> SELECT AUDIT('');  
  AUDIT  
-----  
  76376696  
(1 row)
```

The size of the database is reported in bytes. The `AUDIT` function also allows you to control the accuracy of the estimated database size using additional parameters. See the entry for the [AUDIT](#) function in the SQL Reference Manual for full details. Vertica does not count the `AUDIT` function results as an official audit. It takes no license compliance actions based on the results.

Note: The results of the `AUDIT` function do not include flex table data in `__raw__` columns. Use the [AUDIT_FLEX](#) function to monitor data usage flex tables.

Manually Auditing `__raw__` Column Data

You can use the [AUDIT_FLEX](#) function to manually audit data usage for flex or columnar tables with a `__raw__` column. The function calculates the encoded, compressed data stored in ROS containers for any `__raw__` columns. Materialized columns in flex tables are calculated by the

AUDIT function. The [AUDIT_FLEX](#) results do not include data in the `__raw__` columns of temporary flex tables.

Targeted Auditing

If audits determine that the columnar table estimates are unexpectedly large, consider schemas, tables, or partitions that are using the most storage. You can use the AUDIT function to perform targeted audits of schemas, tables, or partitions by supplying the name of the entity whose size you want to find. For example, to find the size of the `online_sales` schema in the [VMart](#) example database, run the following command:

```
=> SELECT AUDIT('online_sales');  
  AUDIT  
-----  
 35716504  
(1 row)
```

You can also change the granularity of an audit to report the size of each object in a larger entity (for example, each table in a schema) by using the `granularity` argument of the AUDIT function. See the [AUDIT](#) function in the SQL Reference Manual.

Using Management Console to Monitor License Compliance

You can also get information about data storage of columnar data (for columnar tables and for materialized columns in flex tables) through the Management Console. This information is available in the database Overview page, which displays a grid view of the database's overall health.

- The needle in the license meter adjusts to reflect the amount used in megabytes.
- The grace period represents the term portion of the license.
- The Audit button returns the same information as the `AUDIT()` function in a graphical representation.
- The Details link within the License grid (next to the Audit button) provides historical information about license usage. This page also shows a progress meter of percent used toward your license limit.

Monitoring Elastic Cluster Rebalancing

Vertica includes system tables that can be used to monitor the rebalance status of an elastic cluster and gain general insight to the status of elastic cluster on your nodes.

- The [REBALANCE_TABLE_STATUS](#) table provides general information about a rebalance. It shows, for each table, the amount of data that has been separated, the amount that is currently being separated, and the amount to be separated. It also shows the amount of data transferred, the amount that is currently being transferred, and the remaining amount to be transferred (or an estimate if storage is not separated).

Note: If multiple rebalance methods were used for a single table (for example, the table has unsegmented and segmented projections), the table may appear multiple times - once for each rebalance method.

- [REBALANCE_PROJECTION_STATUS](#) can be used to gain more insight into the details for a particular projection that is being rebalanced. It provides the same type of information as above, but in terms of a projection instead of a table.

In each table, *separated_percent* and *transferred_percent* can be used to determine overall progress.

Historical Rebalance Information

Historical information about work completed is retained, so use the predicate "*where is_latest*" to restrict the output to only the most recent or current rebalance activity. The historical data may include information about dropped projections or tables. If a table or projection has been dropped and information about the anchor table is not available, then NULL is displayed for the *table_id* and "<unknown>" is displayed for the *table_name*. Information on dropped tables is still useful, for example, in providing justification for the duration of a task.

Monitoring Parameters

The following table describes the monitoring parameters for configuring Vertica.

Parameters	Description
SnmpTrapDestinationsList	<p>Defines where Vertica sends traps for SNMP. See Configuring Reporting for SNMP.</p> <p>Default Value: none</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET SnmpTrapDestinationsList = 'localhost 162 public';</pre>
SnmpTrapsEnabled	<p>Enables event trapping for SNMP. See Configuring Reporting for SNMP.</p> <p>Default Value: 0</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET SnmpTrapsEnabled = 1;</pre>
SnmpTrapEvents	<p>Define which events Vertica traps through SNMP. See Configuring Reporting for SNMP.</p> <p>Default Value: Low Disk Space, Read Only File System, Loss of K Safety, Current Fault Tolerance at Critical Level, Too Many ROS Containers, WOS Over Flow, Node State Change, Recovery Failure, Stale Checkpoint, and CRC Mismatch.</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET SnmpTrapEvents = 'Low Disk Space, Recovery Failure';</pre>
SyslogEnabled	<p>Enables event trapping for syslog. See Configuring Reporting for Syslog.</p> <p>Default Value: 0</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET SyslogEnabled = 1);</pre>
SyslogEvents	<p>Defines events that generate a syslog entry. See Configuring Reporting for Syslog.</p> <p>Default Value: none</p> <p>Example:</p> <pre>ALTER DATABASE mydb SET SyslogEvents = 'Low Disk Space, Recovery Failure';</pre>
SyslogFacility	<p>Defines which SyslogFacility Vertica uses. See Configuring</p>

Parameters	Description
	<p data-bbox="576 283 844 315">Reporting for Syslog.</p> <p data-bbox="576 336 836 367">Default Value: user</p> <p data-bbox="576 388 706 420">Example:</p> <pre data-bbox="576 441 1128 472">ALTER DATABASE mydb SET SyslogFacility = 'ftp';</pre>

Monitoring Events

To help you monitor your database system, Vertica traps and logs significant events that affect database performance and functionality if you do not address their root causes. This section describes where events are logged, the types of events that Vertica logs, how to respond to these events, the information that Vertica provides for these events, and how to configure event monitoring.

Event Logging Mechanisms

Vertica posts events to the following mechanisms:

Mechanism	Description
vertica.log	All events are automatically posted to vertica.log. See Monitoring the Log Files .
ACTIVE_EVENTS	This SQL system table provides information about all open events. See Using System Tables and ACTIVE_EVENTS .
SNMP	To post traps to SNMP, enable global reporting in addition to each individual event you want trapped. See Configuring Event Reporting .
Syslog	To log events to syslog, enable event reporting for each individual event you want logged. See Configuring Event Reporting .

Event Severity Types

Event names are sensitive to case and spaces. Vertica logs the following events:

Event Name	Event Type	Description	Action
Low Disk Space	0	The database is running out of disk space or a disk is failing or there is a I/O hardware failure.	It is imperative that you add more disk space or replace the failing disk or hardware as soon as possible.

Event Name	Event Type	Description	Action
			<p>Check <code>dmesg</code> to see what caused the problem.</p> <p>Also, use the DISK_RESOURCE_REJECTIONS system table to determine the types of disk space requests that are being rejected and the hosts on which they are being rejected. See Managing Disk Space for more information about low disk space.</p>
Read Only File System	1	The database does not have write access to the file system for the data or catalog paths. This can sometimes occur if Linux remounts a drive due to a kernel issue.	Modify the privileges on the file system to give the database write access.
Loss Of K Safety	2	<p>The database is no longer K-Safe because there are insufficient nodes functioning within the cluster. Loss of K-safety causes the database to shut down.</p> <p>In a four-node cluster, for example, $K\text{-safety}=1$. If one node fails, the fault tolerance is at a critical level. If two nodes fail, the system loses K-safety.</p>	If a system shuts down due to loss of K-safety, you need to recover the system. See Failure Recovery in the Administrator's Guide.
Current Fault Tolerance at Critical Level	3	One or more nodes in the cluster have failed. If the database loses one more node, it is no longer K-Safe and it shuts down. (For	Restore any nodes that have failed or been shut down.

Event Name	Event Type	Description	Action
		example, a four-node cluster is no longer K-safe if two nodes fail.)	
Too Many ROS Containers	4	Due to heavy data load conditions, there are too many ROS containers. This occurs when the Tuple Mover falls behind in performing mergeout operations. The resulting excess number of ROS containers can exhaust all available system resources. To prevent this, Vertica automatically rolls back all transactions that would load data until the Tuple Mover has time to catch up.	<p>You might need to adjust the Tuple Mover's configuration parameters to compensate for the load pattern or rate. See Managing the Tuple Mover in the Administrator's Guide for details.</p> <p>You can query the TUPLE_MOVER_OPERATIONS table to monitor mergeout activity. However, the Tuple Mover does not immediately start a mergeout when a projection reaches the limit of ROS containers, so you may not see a mergeout in progress when receiving this error.</p> <p>If waiting for a mergeout does not resolve the error, the problem probably is related to insufficient RAM.. A good rule of thumb is that system RAM in MB divided by 6 times the number of columns in the largest table should be greater than 10. For example, for a 100 column table you would want at least 6GB of RAM ($6144\text{MB} / (6 * 100) = 10.24$) to handle continuous loads.</p>
WOS Over Flow	5	The WOS cannot hold all the data that you are attempting to load. This means that the	Consider loading the data to disk (ROS) instead of memory (WOS) or splitting the fact

Event Name	Event Type	Description	Action
		copy fails and the transaction rolls back.	table load file into multiple pieces and then performing multiple loads in sequence. You might also consider making the Tuple Mover's moveout operation more aggressive. See Managing the Tuple Mover in Administrator's Guide.
Node State Change	6	The node state has changed.	Check the status of the node.
Recovery Failure	7	The database was not restored to a functional state after a hardware or software related failure.	The reason for recovery failure can vary. See the event description for more information about your specific situation.
Recovery Error	8	The database encountered an error while attempting to recover. If the number of recovery errors exceeds Max Tries, the Recovery Failure event is triggered. See Recovery Failure within this table.	The reason for a recovery error can vary. See the event description for more information about your specific situation.
Recovery Lock Error	9	A recovering node could not obtain an S lock on the table. If you have a continuous stream of COPY commands in progress, recovery might not be able to obtain this lock even after multiple re-tries.	Either momentarily stop the loads or pick a time when the cluster is not busy to restart the node and let recovery proceed.
Recovery Projection Retrieval Error	10	Vertica was unable to retrieve information about a projection.	The reason for a recovery projection retrieval error can vary. See the event description

Event Name	Event Type	Description	Action
			for more information about your specific situation.
Refresh Error	11	The database encountered an error while attempting to refresh.	The reason for a refresh error can vary. See the event description for more information about your specific situation.
Refresh Lock Error	12	The database encountered a locking error during refresh.	The reason for a refresh error can vary. See the event description for more information about your specific situation.
Tuple Mover Error	13	The database encountered an error while attempting to move the contents of the Write Optimized Store (WOS) into the Read Optimized Store (ROS).	The reason for a Tuple Mover error can vary. See the event description for more information about your specific situation.
Timer Service Task Error	14	An error occurred in an internal scheduled task.	Internal use only
Stale Checkpoint	15	Data in the WOS has not been completely moved out in a timely manner. An UNSAFE shutdown could require reloading a significant amount of data.	Be sure that Moveout operations are executing successfully. Check the <code>vertica.log</code> files for errors related to Moveout.
CRC Mismatch	16	The Cyclic Redundancy Check returned an error or errors while fetching data.	Review the <code>vertica.log</code> file or the SNMP trap utility to review the errors. For more information see Handling CRC Errors .

Event Data

To help you interpret and solve the issue that triggered an event, each event provides a variety of data, depending upon the event logging mechanism used.

The following table describes the event data and indicates where it is used.

vertica.log	ACTIVE_EVENTS (column names)	SNMP	Syslog	Description
N/A	NODE_NAME	N/A	N/A	The node where the event occurred.
Event Code	EVENT_CODE	Event Type	Event Code	A numeric ID that indicates the type of event. See Event Types in the previous table for a list of event type codes.
Event Id	EVENT_ID	Event OID	Event Id	A unique numeric ID that identifies the specific event.
Event Severity	EVENT_SEVERITY	Event Severity	Event Severity	The severity of the event from highest to lowest. These

vertica.log	ACTIVE_EVENTS (column names)	SNMP	Syslog	Description
				<p>events are based on standard syslog severity types:</p> <ul style="list-style-type: none"> 0 - Emergency 1 - Alert 2 - Critical 3 - Error 4 - Warning 5 - Notice 6 - Info 7 - Debug
PostedTimestamp	EVENT_POSTED_TIMESTAMP	N/A	PostedTimestamp	<p>The year, month, day, and time the event was reported. Time is provided as military time.</p>
ExpirationTimestamp	EVENT_EXPIRATION	N/A	ExpirationTimestamp	<p>The time at which this event expires. If the same</p>

vertica.log	ACTIVE_ EVENTS (column names)	SNMP	Syslog	Description
				event is posted again prior to its expiration time, this field gets updated to a new expiration time.
EventCodeDescription	EVENT_ CODE_ DESCRIPTION	Description	EventCodeDescription	A brief description of the event and details pertinent to the specific situation.
ProblemDescription	EVENT_ PROBLEM_ DESCRIPTION	Event Short Description	ProblemDescription	A generic description of the event.
N/A	REPORTING_ NODE	Node Name	N/A	The name of the node within the cluster that reported the event.
DatabaseName	N/A	Database Name	DatabaseName	The name of the database that is impacted by the event.
N/A	N/A	Host Name	Hostname	The name of

<code>vertica.log</code>	<code>ACTIVE_EVENTS</code> (column names)	SNMP	Syslog	Description
				the host within the cluster that reported the event.
N/A	N/A	Event Status	N/A	The status of the event. It can be either: 1 - Open 2 - Clear

Configuring Event Reporting

Event reporting is automatically configured for `vertica.log`, and current events are automatically posted to the `ACTIVE_EVENTS` system table. You can also configure Vertica to post events to `syslog` and `SNMP`.

Configuring Reporting for Syslog

Syslog is a network-logging utility that issues, stores, and processes meaningful log messages. It is designed so DBAs can keep machines up and running, and it is a useful way to get heterogeneous data into a single data repository.

To log events to syslog, enable event reporting for each individual event you want logged. Messages are logged, by default, in `/var/log/messages`.

Configuring event reporting to syslog consists of:

1. Enabling Vertica to trap events for syslog.
2. Defining which events Vertica traps for syslog.

Micro Focus strongly suggests that you trap the Stale Checkpoint event.

3. Defining which syslog facility to use.

Enabling Vertica to Trap Events for Syslog

To enable event trapping for syslog, issue the following SQL command:

```
=> ALTER DATABASE mydb SET SyslogEnabled = 1;
```

To disable event trapping for syslog, issue the following SQL command:

```
=> ALTER DATABASE mydb SET SyslogEnabled = 0;
```

Defining Events to Trap for Syslog

To define events that generate a syslog entry, issue the following SQL command, where `Event_Name` is one of the events described in the list below the command:

```
=> ALTER DATABASE mydb SET SyslogEvents = 'Event_Name, Event_Name';
```

- Low Disk Space
- Read Only File System
- Loss Of K Safety
- Current Fault Tolerance at Critical Level
- Too Many ROS Containers
- WOS Over Flow
- Node State Change
- Recovery Failure
- Recovery Error
- Recovery Lock Error
- Recovery Projection Retrieval Error
- Refresh Error

- Refresh Lock Error
- Tuple Mover Error
- Timer Service Task Error
- Stale Checkpoint

The following example generates a syslog entry for low disk space and recovery failure:

```
=> ALTER DATABASE mydb SET SyslogEvents = 'Low Disk Space, Recovery Failure';
```

Defining the SyslogFacility to Use for Reporting

The syslog mechanism allows for several different general classifications of logging messages, called facilities. Typically, all authentication-related messages are logged with the `auth` (or `authpriv`) facility. These messages are intended to be secure and hidden from unauthorized eyes. Normal operational messages are logged with the `daemon` facility, which is the collector that receives and optionally stores messages.

The `SyslogFacility` directive allows all logging messages to be directed to a different facility than the default. When the directive is used, *all* logging is done using the specified facility, both authentication (secure) and otherwise.

To define which `SyslogFacility` Vertica uses, issue the following SQL command:

```
=> ALTER DATABASE mydb SET SyslogFacility = 'Facility_Name';
```

Where the facility-level argument `<Facility_Name>` is one of the following:

<ul style="list-style-type: none">• <code>auth</code>	<ul style="list-style-type: none">• <code>uucp</code> (UUCP subsystem)
<ul style="list-style-type: none">• <code>authpriv</code> (Linux only)	<ul style="list-style-type: none">• <code>local0</code> (local use 0)
<ul style="list-style-type: none">• <code>cron</code>	<ul style="list-style-type: none">• <code>local1</code> (local use 1)
<ul style="list-style-type: none">• <code>daemon</code>	<ul style="list-style-type: none">• <code>local2</code> (local use 2)
<ul style="list-style-type: none">• <code>ftp</code> (Linux only)	<ul style="list-style-type: none">• <code>local3</code> (local use 3)
<ul style="list-style-type: none">• <code>lpr</code> (line printer subsystem)	<ul style="list-style-type: none">• <code>local4</code> (local use 4)
<ul style="list-style-type: none">• <code>mail</code> (mail system)	<ul style="list-style-type: none">• <code>local5</code> (local use 5)

<ul style="list-style-type: none">• news (network news subsystem)	<ul style="list-style-type: none">• local6 (local use 6)
<ul style="list-style-type: none">• user (default system)	<ul style="list-style-type: none">• local7 (local use 7)

Configuring Reporting for SNMP

Configuring event reporting for SNMP consists of:

1. Configuring Vertica to enable event trapping for SNMP as described below.
2. Importing the Vertica Management Information Base (MIB) file into the SNMP monitoring device.

The Vertica MIB file allows the SNMP trap receiver to understand the traps it receives from Vertica. This, in turn, allows you to configure the actions it takes when it receives traps.

Vertica supports the SNMP V1 trap protocol, and it is located in `/opt/vertica/sbin/VERTICA-MIB`. See the documentation for your SNMP monitoring device for more information about importing MIB files.

3. Configuring the SNMP trap receiver to handle traps from Vertica.

SNMP trap receiver configuration differs greatly from vendor to vendor. As such, the directions presented here for configuring the SNMP trap receiver to handle traps from Vertica are generic.

Vertica traps are single, generic traps that contain several fields of identifying information. These fields equate to the event data described in [Monitoring Events](#). However, the format used for the field names differs slightly. Under SNMP, the field names contain no spaces. Also, field names are pre-pended with “vert”. For example, Event Severity becomes `vertEventSeverity`.

When configuring your trap receiver, be sure to use the same hostname, port, and community string you used to configure event trapping in Vertica.

Examples of network management providers:

- IBM Tivoli
- AdventNet
- Net-SNMP (Open Source)
- Nagios (Open Source)
- Open NMS (Open Source)

See Also

- [Configuration Parameters](#)

Configuring Event Trapping for SNMP

The following events are trapped by default when you configure Vertica to trap events for SNMP:

- Low Disk Space
- Read Only File System
- Loss of K Safety
- Current Fault Tolerance at Critical Level
- Too Many ROS Containers
- WOS Over Flow
- Node State Change
- Recovery Failure
- Stale Checkpoint
- CRC Mismatch

To Configure Vertica to Trap Events for SNMP

1. Enable Vertica to trap events for SNMP.
2. Define where Vertica sends the traps.
3. Optionally redefine which SNMP events Vertica traps.

Note: After you complete steps 1 and 2 above, Vertica automatically traps the default SNMP events. Only perform step 3 if you want to redefine which SNMP events are trapped. Micro Focus recommends that you trap the `Stale Checkpoint` event even if you decide to reduce the number events Vertica traps for SNMP. The specific settings you define have no effect on traps sent to the log. All events are trapped to the log.

To Enable Event Trapping for SNMP

Use the following SQL command:

```
=> ALTER DATABASE mydb SET SnmpTrapsEnabled = 1;
```

To Define Where Vertica Send Traps

Use the following SQL command, where `Host_name` and `port` identify the computer where SNMP resides, and `CommunityString` acts like a password to control Vertica's access to the server:

```
=> ALTER DATABASE mydb SET SnmpTrapDestinationsList = 'host_name port CommunityString';
```

For example:

```
=> ALTER DATABASE mydb SET SnmpTrapDestinationsList = 'localhost 162 public';
```

You can also specify multiple destinations by specifying a list of destinations, separated by commas:

```
=> ALTER DATABASE mydb SET SnmpTrapDestinationsList = 'host_name1 port1 CommunityString1, hostname2 port2 CommunityString2';
```

Note: : Setting multiple destinations sends any SNMP trap notification to all destinations listed.

To Define Which Events Vertica Traps

Use the following SQL command, where `Event_Name` is one of the events in the list below the command:

```
=> ALTER DATABASE mydb SET SnmpTrapEvents = 'Event_Name1, Even_Name2';
```

- Low Disk Space
- Read Only File System
- Loss Of K Safety
- Current Fault Tolerance at Critical Level
- Too Many ROS Containers
- WOS Over Flow
- Node State Change
- Recovery Failure
- Recovery Error
- Recovery Lock Error
- Recovery Projection Retrieval Error
- Refresh Error
- Tuple Mover Error
- Stale Checkpoint
- CRC Mismatch

Note: The above values are case sensitive.

The following example specifies two event names:

```
=> ALTER DATABASE mydb SET SnmpTrapEvents = 'Low Disk Space, Recovery Failure';
```

Verifying SNMP Configuration

To create a set of test events that checks SNMP configuration:

1. Set up SNMP trap handlers to catch Vertica events.
2. Test your setup with the following command:

```
SELECT SNMP_TRAP_TEST();
       SNMP_TRAP_TEST
-----
Completed SNMP Trap Test
(1 row)
```

Event Reporting Examples

Vertica.log

The following example illustrates a Too Many ROS Containers event posted and cleared within vertica.log:

```

```

Using System Tables

Vertica provides an API (application programming interface) for monitoring various features and functions within a database in the form of system tables. These tables provide a robust, stable set of views that let you monitor information about your system's resources, background processes, workload, and performance, allowing you to more efficiently profile, diagnose, and view historical data equivalent to load streams, query profiles, tuple mover operations, and more. Because Vertica collects and retains this information automatically, you don't have to manually set anything.

You can write queries against system tables with full SELECT support the same way you perform query operations on base and temporary tables. You can query system tables using expressions, predicates, aggregates, analytics, subqueries, and joins. You can also save system table query results into a user table for future analysis. For example, the following query creates a table, `mynode`, selecting three node-related columns from the `V_CATALOG.NODES` system table:

```
VMart=> CREATE TABLE mynode AS SELECT node_name, node_state, node_address
FROM nodes;
CREATE TABLE
VMart=> SELECT * FROM mynode;
   node_name      | node_state | node_address
-----+-----+-----
v_vmart_node0001 | UP         | 192.168.223.11
(1 row)
```

Note: You cannot query system tables if the database cluster is in a recovering state. The database refuses connection requests and cannot be monitored. Vertica also does not support DDL and DML operations on system tables.

Where System Tables Reside

System tables are grouped into the following schemas:

- `V_CATALOG` – information about persistent objects in the catalog
- `V_MONITOR` – information about transient system state

These schemas reside in the default search path so there is no need to specify `schema.table` in your queries unless you [change the search path](#) to exclude `V_MONITOR` or `V_CATALOG` or both.

The system tables that make up the monitoring API are described fully in the [SQL Reference Manual](#). You can also use the following command to view all the system tables and their schema:

```
SELECT * FROM system_tables ORDER BY table_schema, table_name;
```

How System Tables Are Organized

Most of the tables are grouped into the following areas:

- System information
- System resources
- Background processes
- Workload and performance

Vertica reserves some memory to help monitor busy systems. Using simple system table queries makes it easier to troubleshoot issues. See also `SYSQUERY` and `SYSDATA` pools under [Built-in pools](#) topic in SQL Reference Manual.

Note: You can use external monitoring tools or scripts to query the system tables and act upon the information, as necessary. For example, when a host failure causes the K-safety level to fall below the desired level, the tool or script can notify the database administrator and/or appropriate IT personnel of the change, typically in the form of an e-mail.

Querying Case-Sensitive Data in System Tables

Some system table data might be stored in mixed case. For example, Vertica stores mixed-case [identifier](#) names the way you specify them in the `CREATE` statement, even though case is ignored when you reference them in queries. When these object names appear as data in the system tables, you'll encounter errors if you use the equality (`=`) predicate because the case must match the stored identifier. In particular, `V_CATALOG.TABLES.TABLE_SCHEMA` and `V_CATALOG.TABLES.TABLE_NAME` columns are case sensitive with equality predicates.

If you don't know how the identifiers are stored, use the case-insensitive operator [ILIKE](#) instead of equality predicates.

For example, given the following schema:

```
=> CREATE SCHEMA SS;  
=> CREATE TABLE SS.TT (c1 int);  
=> CREATE PROJECTION SS.TTP1 AS SELECT * FROM ss.tt UNSEGMENTED ALL NODES;  
=> INSERT INTO ss.tt VALUES (1);
```

If you run a query using the = predicate, Vertica returns 0 rows:

```
=> SELECT table_schema, table_name FROM v_catalog.tables WHERE table_schema ='ss';  
table_schema | table_name  
-----+-----  
(0 rows)
```

Using the case-insensitive ILIKE predicate returns the expected results:

```
=> SELECT table_schema, table_name FROM v_catalog.tables WHERE table_schema ILIKE 'ss';  
table_schema | table_name  
-----+-----  
SS           | TT  
(1 row)
```

Examples

The following query uses the VMart example database (see [Introducing the VMart Example Database](#)) to obtain the number of rows and size occupied by each table in the database.

```
=> SELECT t.table_name AS table_name,  
       SUM(ps.wos_row_count + ps.ros_row_count) AS row_count,  
       SUM(ps.wos_used_bytes + ps.ros_used_bytes) AS byte_count  
FROM tables t  
JOIN projections p ON t.table_id = p.anchor_table_id  
JOIN projection_storage ps on p.projection_name = ps.projection_name  
WHERE (ps.wos_used_bytes + ps.ros_used_bytes) > 500000  
GROUP BY t.table_name  
ORDER BY byte_count DESC;  
table_name | row_count | byte_count  
-----+-----+-----  
online_sales_fact | 5000000 | 171987438  
store_sales_fact | 5000000 | 108844666  
store_orders_fact | 300000 | 9240800  
product_dimension | 60000 | 2327964  
customer_dimension | 50000 | 2165897  
inventory_fact | 300000 | 2045900  
(6 rows)
```

The rest of the examples illustrate simple ways to use system tables in queries.

```
=> SELECT table_name FROM columns WHERE data_type ILIKE 'Numeric' GROUP BY table_name;  
table_name  
-----  
n1  
(1 row)  
=> SELECT current_epoch, designed_fault_tolerance, current_fault_tolerance
```

```
FROM SYSTEM;
  current_epoch | designed_fault_tolerance | current_fault_tolerance
-----+-----+-----
          492 |                1 |                1
(1 row)
=> SELECT node_name, total_user_session_count, executed_query_count FROM
query_metrics;
  node_name          | total_user_session_count | executed_query_count
-----+-----+-----
v_vmart_node0001    |                53 |                42
v_vmart_node0002    |                53 |                 0
v_vmart_node0003    |                42 |               120
v_vmart_node0004    |                53 |                 0
(4 rows)
=> SELECT table_schema FROM primary_keys;
table_schema
-----
public
store
online_sales
online_sales
(12 rows)
```

Retaining Monitoring Information

When you query a Vertica system table (described in [Using System Tables](#)), you can get information about currently running queries, the state of various components, and other run-time information. During query execution, Vertica examines the current state of the system and returns information in the result set.

Data Collector

Vertica also provides a utility called the Data Collector (DC), which collects and retains history of important system activities and records essential performance and resource utilization counters.

Data Collector extends system table functionality by:

- Providing a framework for recording events
- Making the information available in system tables
- Requiring few configuration parameter tweaks
- Having negligible impact on performance

You can use the information the Data Collector retains to query the past state of system tables and extract aggregate information, as well as do the following:

- See what actions users have taken
- Locate performance bottlenecks
- Identify potential improvements to Vertica configuration

DC does not collect data for nodes that are down, so no historical data would be available for that node.

Data Collector works in conjunction with the Workload Analyzer (WLA), an advisor tool that intelligently monitors the performance of SQL queries and workloads and recommends tuning actions based on observations of the actual workload history. See [Analyzing Workloads](#) for more information about WLA.

Where Is DC Information retained?

Collected data is stored on disk in the DataCollector directory under the Vertica /catalog path. This directory also contains instructions on how to load the monitoring data into another Vertica database. See [Working with Data Collection Logs](#) for details.

DC retains the data it gathers based on retention policies, which a superuser can configure. See [Configuring Data Retention Policies](#).

Data Collector is on by default, but a superuser can disable it if performance issues arise. See [Data Collector Parameters](#) and [Enabling and Disabling Data Collector](#).

DC Tables

Caution: Data Collector tables (prefixed by dc_) reside in the V_INTERNAL schema and are provided for informational purposes only. They are provided as-is and are subject to removal or change without notice. If you use Data Collector tables in scripts or monitoring tools, you might need to change your scripts and tools after a Vertica upgrade. Micro Focus recommends that you use the [Workload Analyzer](#) instead of accessing the Data Collector tables directly.

- [ANALYZE_WORKLOAD](#)
- [TUNING_RECOMMENDATIONS](#)

Enabling and Disabling Data Collector

Data Collector is on by default and retains information for all sessions. If performance issues arise, a superuser can disable Data Collector at any time.

To disable the Data Collector:

```
=> ALTER DATABASE mydb SET EnableDataCollector = 0;
```

To re-enable the Data Collector:

```
=> ALTER DATABASE mydb SET EnableDataCollector = 1;
```

See Also

- [Data Collector Parameters](#)

Viewing Current Data Retention Policy

To view the current retention policy for a Data Collector component, use the [GET_DATA_COLLECTOR_POLICY\(\)](#) function and supply the component name as the function's argument.

To retrieve a list of all current component names, query the [V_MONITOR.DATA_COLLECTOR](#) system table, which returns Data Collector components, their current retention policies, and statistics about how much data is retained. For example:

```
mddb=> \xExpanded display is on.
mddb=> SELECT * from data_collector;
-[ RECORD 1 ]-----+-----
node_name          | v_mddb_node0001
component          | AllocationPoolStatistics
table_name         | dc_allocation_pool_statistics
description        | Information about global memory pools, which generally cannot be recovered
without restart
access_restricted | t
in_db_log          | f
in_vertica_log     | f
memory_buffer_size_kb | 64
disk_size_kb       | 256
record_too_big_errors | 0
lost_buffers       | 0
lost_records       | 0
retired_files      | 1429
retired_records    | 647358
current_memory_records | 0
current_disk_records | 1493
current_memory_bytes | 0
current_disk_bytes  | 215737
first_time         | 2012-11-30 07:04:30.000726-05
last_time          | 2012-11-30 07:16:56.000631-05
kb_per_day         | 24377.3198211312
-[ RECORD 2 ]-----+-----
```

The following command returns the retention policy for a specific component, NodeState.

```
=> SELECT get_data_collector_policy('NodeState');
```

The results let you know that 10KB is retained in memory and 100KB on disk:

```
get_data_collector_policy-----  
10KB kept in memory, 100KB kept on disk.  
(1 row)
```

Configuring Data Retention Policies

Data Collector retention policies hold the following information:

- Which component to monitor
- How much memory to retain
- How much disk space to retain

A superuser can modify policies, such as change the amount of data to retain, by invoking the [SET_DATA_COLLECTOR_POLICY\(\)](#) function, as follows:

```
SET_DATA_COLLECTOR_POLICY('component', 'memoryKB', 'diskKB' )
```

The `SET_DATA_COLLECTOR_POLICY()` function sets the retention policy for the specified component on all nodes, and lets you specify memory and disk size to retain in kilobytes. Failed nodes receive the new setting when they rejoin the cluster.

For example, the following statement specifies that the `NodeState` component be allocated 50KB of memory and 250KB of disk space:

```
=> SELECT SET_DATA_COLLECTOR_POLICY('NodeState', '50', '250');  
SET_DATA_COLLECTOR_POLICY  
-----  
SET  
(1 row)
```

Before you change a retention policy, you can view the current setting by calling the `GET_DATA_COLLECTOR_POLICY()` function.

You can also use the `GET_DATA_COLLECTOR_POLICY()` function to verify changed settings. For example, the following query retrieves a brief statement about the retention policy for the `NodeState` component:

```
=> SELECT GET_DATA_COLLECTOR_POLICY('NodeState');  
GET_DATA_COLLECTOR_POLICY  
-----  
50KB kept in memory, 250KB kept on disk.  
(1 row)
```

Tip: If you do not know the name of a component, you can query the [V_MONITOR.DATA_COLLECTOR](#) system table to get a full list. For example, the following query returns all current Data Collector components and a description of each: => `SELECT DISTINCT component, description FROM data_collector ORDER BY 1 ASC;`

- [SET_DATA_COLLECTOR_POLICY](#)

Working with Data Collection Logs

Upon startup, a Vertica database creates a DataCollector directory within the /catalog directory.

The DataCollector directory holds the disk-based data collection logs, where retained data is kept in files named `<component>.<timestamp>.log`. Vertica might maintain several log files, per component, at any given time. See [Querying Data Collector Tables](#) for an example of how to view this information.

Also upon startup, Vertica creates two additional files, per component, in the DataCollector directory. These are SQL files that contain examples on how to load Data Collector data into another Vertica instance. These files are:

- `CREATE_<component>_TABLE.sql` — contains the SQL DDL needed to create a table into which Data Collector logs for the component can be loaded.
- `COPY_<component>_TABLE.sql` — contains example SQL to load (using [COPY](#) commands) the data log files into the table that the CREATE script creates.

Two functions let you manipulate these log files.

If you want to ...	See these topics in the SQL Reference Manual
Clear memory and disk records from Data Collector retention and reset collection statistics	CLEAR_DATA_COLLECTOR()

If you want to ...	See these topics in the SQL Reference Manual
Flush the Data Collector logs	FLUSH_DATA_COLLECTOR()
Retrieve a list of all current Data Collector components	V_MONITOR.DATA_COLLECTOR

Clearing the Data Collector

If you want to clear the Data Collector of all memory and disk records and reset the collection statistics in the V_MONITOR.DATA_COLLECTOR system table, call the CLEAR_DATA_COLLECTOR() function. You can clear records for all components on all nodes or you can specify individual components, one at a time.

To clear records on a single component, pass the function the component argument. For example, the following command clears records for the ResourceAcquisitions component only, returning a result of CLEAR (success):

```
=> SELECT clear_data_collector('ResourceAcquisitions');
clear_data_collector
-----
CLEAR
(1 row)
```

The following command clears the Data Collector records for all components on all nodes:

```
=> SELECT clear_data_collector();
clear_data_collector
-----
CLEAR
(1 row)
```

Note: After you clear the DataCollector log, the information is no longer available for querying.

Flushing Data Collector Logs

If you want to flush Data Collector information for all components or for an individual component, use the FLUSH_DATA_COLLECTOR() function. This function waits until memory logs are moved to disk and flushes the Data Collector, synchronizing the log with the disk storage:

To flush data collection for all components on all nodes:

```
=> SELECT flush_data_collector();
flush_data_collector
-----
FLUSH
(1 row)
```

To flush records on a single component, pass a component argument to the function. For example, the following command flushes the ResourceAcquisitions component:

```
=> SELECT flush_data_collector('ResourceAcquisitions');
flush_data_collector
-----
FLUSH
(1 row)
```

See Also

- [Data Collector Functions](#)
- [DATA_COLLECTOR](#)

Monitoring Data Collection Components

Query the V_MONITOR.DATA_COLLECTOR system table to get a list of Data Collector components, their current retention policies, and statistics about how much data is retained and how much has been discarded for various reasons. DATA_COLLECTOR also calculates the approximate collection rate, to aid in sizing calculations.

The following is a simple query that returns all the columns in this system table. See [V_MONITOR.DATA_COLLECTOR](#) in the SQL Reference Manual for additional details.

```
=> \xExpanded display is on.
=> SELECT * FROM data_collector;
-[ RECORD 1 ]-----+-----
node_name          | v_vmartdb_node0001
component          | AllocationPoolStatistics
table_name         | dc_allocation_pool_statistics
description        | Information about global memory pools, ...
in_db_log          | f
in_vertica_log     | f
memory_buffer_size_kb | 64
disk_size_kb       | 256
record_too_big_errors | 0
lost_buffers       | 0
lost_records       | 0
retired_files      | 120
retired_records    | 53196
current_memory_records | 0
```

```
current_disk_records | 1454
current_memory_bytes | 0
current_disk_bytes   | 214468
first_time           | 2011-05-26 12:25:52.001109-04
last_time            | 2011-05-26 12:31:55.002762-04
kb_per_day           | 49640.4151810525
-[ RECORD 2 ]-----+-----
...
```

Querying Data Collector Tables

Caution: Data Collector tables (prefixed by `dc_`) reside in the `V_INTERNAL` schema and are provided for informational purposes only. They are provided as-is and are subject to removal or change without notice. If you use Data Collector tables in scripts or monitoring tools, you might need to change your scripts and tools after a Vertica upgrade. Micro Focus recommends that you use the [Workload Analyzer](#) instead of accessing the Data Collector tables directly.

Here's one useful example you can use to check on the state of your database. Upon startup, the Vertica database creates, under its catalog directory, a DataCollector directory. This directory holds the disk-based data collection logs. The main data is kept in files named `<component>.<timestamp>.log`.

When you start your database an entry is created in the `dc_startups` table. The following is the result of querying this table.

```
=> SELECT * FROM dc_startups;
-[ RECORD 1 ]-----+-----
time           | 2011-05-26 17:35:40.588589-04

Monitoring Query Plan Profiles

See [Profiling Query Plans](#).

Monitoring Partition Reorganization

When you use `ALTER TABLE . . . REORGANIZE`, the operation reorganizes the data in the background.

You can monitor details of the reorganization process by polling the following system tables:

- [V_MONITOR.PARTITION_STATUS](#) displays the fraction of each table that is partitioned correctly.
- [V_MONITOR.PARTITION_REORGANIZE_ERRORS](#) logs errors issued by the reorganize process.
- [V_MONITOR.PARTITIONS](#) displays NULL in the `partition_key` column for any ROS that was not reorganized.

Note: The corresponding foreground process to `ALTER TABLE . . . REORGANIZE` is [PARTITION_TABLE](#).

Using Queries to Monitor Resource Pool Size and Usage

You can use the [Linux top command](#) to determine the overall CPU usage and I/O wait time across the system. However, because of file system caching, the resident memory size indicated by `top` is not a good indicator of actual memory use or available reserve.

Instead, Vertica provides several monitoring tables that provide detailed information about resource pools, their current memory usage, resources requested and acquired by various requests, and the state of the queues.

The [RESOURCE_POOLS](#) table lets you view various resource pools defined in the system (both internal and user-defined), and the [RESOURCE_POOL_STATUS](#) table lets you view the current state of the resource pools.

Examples

This example shows how to find the various resource pools defined in the system.

```
=> SELECT name, memorysize, maxmemorysize FROM V_CATALOG.RESOURCE_POOLS;
```

name	memorysize	maxmemorysize
general		Special: 95%
sysquery	64M	
sysdata	100M	10%
wosdata	0%	25%
tm	200M	
refresh	0%	

```

recovery | 0%      |
dbd      | 0%      |
jvm      | 0%      | 10%
(9 rows)

```

Viewing Only User-Defined Resource Pools

To see only the user-defined resource pools, you can limit your query to return records where `IS_INTERNAL` is false.

Note: The user-defined pools shown in these examples also appear in subsequent sections related to Workload Management.

This example shows how to find information on user-defined resource pools:

```

=> SELECT name, memorysize, maxmemorysize, priority, maxconcurrency
      FROM V_CATALOG.RESOURCE_POOLS where is_internal = 'f';

```

name	memorysize	maxmemorysize	priority	maxconcurrency
load_pool	0%		10	
ceo_pool	250M		10	
ad hoc_pool	200M	200M	0	
billing_pool	0%		0	3
web_pool	25M		10	5
batch_pool	150M	150M	0	10
dept1_pool	0%		5	
dept2_pool	0%		8	

(8 rows)

Viewing the Status of All Resource Pools

The following example shows how to access the `V_MONITOR.RESOURCE_POOL_STATUS` table to return the current state of all resource pools on node0001:

```

=>\x
Expanded display is on
=> SELECT pool_name, memory_size_kb, memory_size_actual_kb, memory_inuse_kb,
      general_memory_borrowed_kb, running_query_count
      FROM V_MONITOR.RESOURCE_POOL_STATUS where node_name ilike '%node0001';

```

pool_name	general
[RECORD 1]	

```

memory_size_kb          | 2983177
memory_size_actual_kb  | 2983177
memory_inuse_kb        | 0
general_memory_borrowed_kb | 0
running_query_count    | 0
-[ RECORD 2 ]-----+-----

memory_size_actual_kb | 0
memory_inuse_kb       | 0
general_memory_borrowed_kb | 0
running_query_count   | 0
-[ RECORD 9 ]-----+-----
pool_name              | jvm
memory_size_kb        | 0
memory_size_actual_kb | 0
memory_inuse_kb       | 0
general_memory_borrowed_kb | 0

```

```
running_query_count      | 0
```

Viewing Query Resource Acquisitions

The following example displays all resources granted to the queries that are currently running. The information shown is stored in the `V_MONITOR.RESOURCE_ACQUISITIONS` table. You can see that the query execution used 708504 KB of memory from the GENERAL pool.

```
=> SELECT pool_name, thread_count, open_file_handle_count, memory_inuse_kb,
       queue_entry_timestamp, acquisition_timestamp
       FROM V_MONITOR.RESOURCE_ACQUISITIONS WHERE node_name ILIKE '%node0001';

-[ RECORD 1 ]-----+-----
pool_name      | sysquery
thread_count   | 4
open_file_handle_count | 0
memory_inuse_kb | 4103
queue_entry_timestamp | 2013-12-05 07:07:08.815362-05
acquisition_timestamp | 2013-12-05 07:07:08.815367-05
-[ RECORD 2 ]-----+-----
...
-[ RECORD 8 ]-----+-----
pool_name      | general
thread_count   | 12
open_file_handle_count | 18
memory_inuse_kb | 708504
queue_entry_timestamp | 2013-12-04 12:55:38.566614-05
acquisition_timestamp | 2013-12-04 12:55:38.566623-05
-[ RECORD 9 ]-----+-----
...
```

You can determine how long a query waits in the queue before it can run. To do so, you obtain the difference between the `acquisition_timestamp` and the `queue_entry_timestamp` using a query as this example shows:

```
=> SELECT pool_name, queue_entry_timestamp, acquisition_timestamp,
       (acquisition_timestamp-queue_entry_timestamp) AS 'queue wait'
       FROM V_MONITOR.RESOURCE_ACQUISITIONS WHERE node_name ILIKE '%node0001';

-[ RECORD 1 ]-----+-----
pool_name      | sysquery
queue_entry_timestamp | 2013-12-05 07:07:08.815362-05

See Also

- See the [SQL Reference Manual](#) for detailed descriptions of the monitoring tables.
- See [Monitoring Resource Pools](#) for descriptions of other ways to monitor resource usage.

Monitoring Recovery

There are several ways to monitor database recovery:

- [Log files on each host](#)
- [Admintools \(View Database Cluster State\)](#)
- [System tables](#)
- [Cluster Status after recovery](#)

Viewing Log Files on Each Node

During database recovery, Vertica adds logging information to the `vertica.log` on each host. Each message is identified with a `[Recover]`string.

Use the `tail` command to monitor recovery progress by viewing the relevant status messages, as follows.

```
$ tail -f catalog-path/database-name/node-name_catalog/vertica.log  
01/23/08 10:35:31 thr:Recover:0x2a98700970 [Recover] <INFO> Changing host v_vmart_node0001 startup  
state from INITIALIZING to RECOVERING  
01/23/08 10:35:31 thr:CatchUp:0x1724b80 [Recover] <INFO> Recovering to specified epoch 0x120b6  
01/23/08 10:35:31 thr:CatchUp:0x1724b80 [Recover] <INFO> Running 1 split queries  
01/23/08 10:35:31 thr:CatchUp:0x1724b80 [Recover] <INFO> Running query: ALTER PROJECTION proj_  
tradesquotes_0 SPLIT v_vmart_node0001 FROM 73911;
```

Using System Tables to Monitor Recovery

Use the following system tables to monitor recover:

- [RECOVERY_STATUS](#)
- [PROJECTION_RECOVERIES](#)

Specifically, the `recovery_status` system table includes information about the node that is recovering, the epoch being recovered, the current recovery phase, and running status:

```
=>select node_name, recover_epoch, recovery_phase, current_completed, is_running from recovery_status;
```

node_name	recover_epoch	recovery_phase	current_completed	is_running
v_vmart_node0001			0	f
v_vmart_node0002	0	historical pass 1	0	t
v_vmart_node0003	1	current	0	f

The `projection_recoveries` system table maintains history of projection recoveries. To check the recovery status, you can summarize the data for the recovering node, and run the same query several times to see if the counts change. Differing counts indicate that the recovery is working and in the process of recovering all missing data.

```
=> select node_name, status , progress from projection_recoveries;
```

node_name	status	progress
v_vmart_node0001	running	61

To see a single record from the `projection_recoveries` system table, add `limit 1` to the query.

After a recovery has completed, Vertica continues to store information from the most recent recovery in these tables.

Viewing Cluster State and Recovery Status

Use the admintools `view_cluster` tool from the command line to see the cluster state:

```
$ /opt/vertica/bin/admintools -t view_cluster
```

DB	Host	State
<data_base>	112.17.31.10	RECOVERING
<data_base>	112.17.31.11	UP
<data_base>	112.17.31.12	UP

```
<data_base> | 112.17.31.17 | UP
```

Monitoring Cluster Status After Recovery

When recovery has completed:

1. Launch Administration Tools.
2. From the Main Menu, select **View Database Cluster State** and click **OK**.

The utility reports your node's status as UP.

Note: You can also monitor the state of your database nodes on the Management Console Overview page under the Database section, which tells you the number of nodes that are up, critical, recovering, or down. To get node-specific information, click Manage at the bottom of the page.

Clearing PROJECTION_REFRESHES History

Information about a refresh operation—whether successful or unsuccessful—is maintained in system table `PROJECTION_REFRESHES` until the function `CLEAR_PROJECTION_REFRESHES` executes or the storage quota for the table is exceeded. The table's `IS_EXECUTING` column returns a boolean value that indicates whether the refresh is running now (t) or occurred earlier (f).

To immediately purge this information, use the `CLEAR_PROJECTION_REFRESHES()` function:

```
=> SELECT clear_projection_refreshes();
clear_projection_refreshes
-----
CLEAR
(1 row)
```

Note: Only the rows where the `PROJECTION_REFRESHES.IS_EXECUTING` column equals *false* are cleared.

- [CLEAR_PROJECTION_REFRESHES](#)
- [PROJECTION_REFRESHES](#)

Monitoring Vertica Using Notifiers

A Vertica notifier is a push-based mechanism capable of sending messages from Vertica to endpoints such as Apache Kafka. For example, you could configure a long-running script to send notifications at various stages and then at the completion of a task.

To use a notifier, follow these steps:

1. Create a notifier with [CREATE NOTIFIER](#).
2. Use the notifier to send messages from Vertica to the end point with the meta-function [NOTIFY](#).

See Also

[ALTER NOTIFIER](#)

Backing Up and Restoring the Database

Creating regular database backups is an important part of basic maintenance tasks at your site. Vertica supplies a comprehensive utility, called `vbr`, for this purpose. This utility lets you back up, restore, list backups, and copy your database to another cluster. You can create full and incremental database backups, and backups of schemas or tables (object-level backups) for use with a multi-tenanted database. When a full backup exists, you can restore one or more objects from the backup or the entire database, as required.

Using `vbr`, you can save your data to a variety of locations:

- A local directory on the nodes in the cluster
- One or more hosts outside of the cluster
- A different Vertica cluster (effectively cloning your database)
- Amazon S3 storage

Impact of Backups on Vertica Nodes

While a backup is taking place, the backup process can consume additional storage. The amount of space consumed depends on the size of your catalog and any objects that you drop during the backup. The backup process releases this storage once the backup is complete.

Compatibility Requirements for Restore and Replication

Creating backups with `vbr` requires restoring backups with the same utility. Vertica 6.x and later supports object-level backups.

Vertica supports restore, replication, and `copycluster` actions only to the same exact version of Vertica that created the backup. For example, you cannot restore, replicate objects, or `copycluster` a version 7.0.2-3 backup to a version 7.0.2-5 database.

Additional Considerations for HDFS Storage Locations

If your database has any storage locations on HDFS, you must do additional configuration to enable those storage locations to be backed up. See [Backing Up HDFS Storage Locations](#) in [Integrating with Apache Hadoop](#).

Supported File Systems

Vertica supports the following file systems for backup and temporary directory locations:

- ext3
- ext4
- NFS
- Amazon S3 Standard

The file system at your backup and temporary directory locations must support `fcntl` lockf (POSIX) file locking. [Backups to Amazon S3](#) use a secondary location to handle file locking.

Creating vbr Configuration Files

The vbr utility uses a configuration file for the information required to back up and restore a full- or object-level backup or copy a cluster. You cannot run vbr without a configuration file because no default file exists. You can, however:

- Create a configuration file. See [Start the vbr Configuration Script](#).
- Copy and edit an existing configuration file and save the changes to a different file name.
- Copy and edit one of the [sample configuration files](#) included with Vertica.

Note: You must be logged on as the database administrator, not root, to create the vbr configuration file.

Start the vbr Configuration Script

To create a configuration file, enter this command:

```
> /opt/vertica/bin/vbr --setupconfig
```

The script prompts you to answer several questions, as shown in the following summarized example:

```
[dbadmin@localhost ~]$ /opt/vertica/bin/vbr --setupconfig
Snapshot name (backup_snapshot): fullbak1
Number of restore points (1): 3
Specify objects (no default):
Object restore mode (coexist, createOrReplace or create) (createOrReplace):
Vertica user name (dbadmin):
Save password to avoid runtime prompt? (n) [y/n]: y
Password to save in vbr config file (no default):
Node v_vmart_node0001
Backup host name (no default): 194.66.82.11
Backup directory (no default): /home/dbadmin/backups
Config file name (fullbak1.ini):
Password file name (no default value) (no default):pwdfile
Change advanced settings? (n) [y/n]: n
Saved vbr configuration to fullbak1.ini.
Saved vbr database password to pwdfile.ini.
```

For further information on how to answer these questions, see:

See the following instructions to complete the questions in the configuration script:

- Specify a Backup Name
- Specify Restore Points
- Specify Object Restore Mode
- Specify Full or Object-Level Backups
- Enter the User Name
- Save the Account Password
- Specify the Backup Host and Directory
- Save the Configuration File
- Continue to Advanced Settings

Specify a Backup Name

Specify the name of the backup for `vbr` to create:

```
Snapshot name (backup_snapshot):
```

You must provide a name for the backup that clearly identifies the specific backup. The backup name is used in the directory tree structure that `vbr` creates for each node. Because Vertica automatically augments the backup subdirectories with date and time indicators, do not add dates to the backup name.

Create different configuration files with specific backup names for full and object-level backups, but use the same backup directory for both types of backups. For example, the configuration file for a full database backup, named `fullbak.ini`, has these `snapshotName` and `backupDir` parameter values:

```
snapshotName=fullbak  
backupDir=/home/dbadmin/data/backups
```

The configuration file for the object-level backup, named `objectbak.ini`, has these parameter values:

```
snapshotName=objectbak  
backupDir=/home/dbadmin/data/backups
```

Specify Restore Points

Specify how many backups to save as a number of restore points:

```
Number of restore points (1):
```

The default value is 1, indicating that `vbr` always retains one additional restore point.

Saving multiple restore points gives you the option to recover from one of several backups. For example, if you specify 3, you have 1 current backup, and 3 backup archives. Vertica stores the value you enter as the `restorePointLimit` parameter in the `vbr` configuration file.

Specify Object Restore Mode

Specify how Vertica should handle restored objects, as this example shows:

```
Object restore mode (coexist, createOrReplace or create)
(createOrReplace):
```

Vertica supports the following object restore modes:

- `createOrReplace` (default) — Vertica creates any objects that do not exist. If the object does exist, `vbr` overwrites it with the version from the archive.
- `create` — Vertica creates any objects that do not exist. If an object being restored does exist, Vertica displays an error message and skips that object.
- `coexist` — Vertica creates all restored objects with the form `<backup>_<timestamp>_<object_name>`. This approach allows existing and restored objects to exist simultaneously. If the appended information pushes the schema name past the maximum length of 128 characters, HP Vertica truncates the name. You can perform a reverse lookup of the original schema name by querying the system table [TRUNCATED_SCHEMATA](#).

In all modes, Vertica restores data with the current epoch. Object restore mode settings do not apply to backups and full restores.

Specify Full or Object-Level Backups

Indicate whether you want to create a full- or object-level backup:

Specify objects (no default):

- For full database backup: Press Enter to continue creating a configuration file for a full database backup.
- For object-level backup: Enter the names of any schema or table for which you want to create an object-level backup configuration file. Enter table names in the form `schema.objectname`.

For example, to make backups of the table, `customers` from the schema, `finance`, enter `finance.customers`. Separate each name with a comma (,). The objects you enter appear listed in the `Objects` parameter of the configuration file.

Enter the User Name

Enter the user name of the person who invoking `vbr`:

Vertica user name (dbadmin):

Note: This user name must be the user identified as the database administrator for the entire database. No other user has permission to invoke this action, even if the user has `dbadmin` permissions within portions of the database.

Save the Account Password

Specify whether `vbr` prompts for an account password at run time:

Save password to avoid runtime prompt? (n) [y/n]:

Press **Enter** to accept the default (n) and continue. Because you are not saving the password, you must enter it when you run `vbr`.

To save your password to a [password configuration file](#), enter `y`. The utility prompts for you to enter the password but does not display the text as you type:

Save password to avoid runtime prompt? (n) [y/n]:

The parameter name in the configuration file that indicates whether to prompt for a password is `dbPromptForPassword`.

Specify the Backup Host and Directory

Vbr lists each node name for your cluster. Enter the backup host name and directory for each cluster node at the prompts:

```
Node v_vmart_node0001  
Backup host name (no default):  
Backup directory (no default):
```

No defaults exist for either the host name or the backup directory.

In the configuration file, all cluster nodes appear listed by name under the [Mapping] section. Each cluster node contains a line that includes the cluster node, backup host, and backup directory location:

```
[Mapping]  
v_vmart_node0001 = 194.66.82.11:/home/dbadmin/backups
```

Save the Configuration File

To save the configuration file with its default name, enter a configuration file name of your choice, or press (Enter):

```
Config file name (fullbak.ini):
```

The default name consists of:

- The backup name you supplied (fullbak in this example)
- An .ini file extension

The vbr utility confirms that it saved the file:

```
Saved vbr configuration to fullbak.ini.
```

By default, Vertica saves the file in the current working directory. You can include a fully qualified or relative path to save the configuration file to an alternate location.

Note: The backup configuration file is typically stored on the cluster you are backing up. Therefore, Micro Focus recommends that you also save a copy of the configuration file on the backup host. If you do so, the configuration file remains available, even if the cluster

```
node is lost.
```

Continue to Advanced Settings

To continue with advanced configuration settings, enter `y`:

```
Change advanced settings? (n) [y/n]:
```

To continue *without* advanced settings and save the configuration file with the information you just entered, press **Enter**.

Changing the `objectRestoreMode` Parameter Value

After you create the configuration file, you can also specify an `objectRestoreMode` parameter. The `objectRestoreMode` parameter is associated only with restoring object-level backups.

Related Tasks

- [Configuring Advanced VBR Options](#)

Configuring Required VBR Parameters

To invoke the `vbr` utility to create a configuration file, enter this command:

```
> /opt/vertica/bin/vbr --setupconfig
```

The utility prompts you to answer the following questions. Each is followed by its default value, if any exists. Type **Enter** to accept a default value.

The second table column lists the name of the parameter associated with the question, as it appears in the configuration file.

Setupconfig Prompt	Parameter Name
Snapshot name: (backup_snapshot)	snapshotName
Number of restore points? (1):	restorePointLimit

Specify objects (no default):	objects
Object restore mode (coexist, createOrReplace or create)(createOrReplace):	objectRestoreMode
Vertica user name (current user):	dbUser
Save password to avoid runtime prompt (n) [y/n]	dbPromptForPassword
Database user password to save in vbr password config file (no default):	dbPassword
Backup host name (no default):	Backup host
Backup directory (no default):	Backup directory
Config file name (backup_snapshot.ini):	N/A
Password file name (no default):	PasswordFile
Change advanced settings? (n) [y/n]:	N/A

To change any advanced parameters, respond to the last question, Change advanced settings? by entering y.

After you successfully complete all of the required questions, vbr generates a configuration file with the information you supplied. Create separate configuration files for a full backup and each object-level backup. Use distinct backup names in each configuration file.

When the setup completes processing, enter a configuration file name. Use this file name when you run the `--task backup` or other commands. The utility uses the configuration file contents for both backup and restore tasks, and also for the `--copycluster` task.

If you do not successfully complete all of the required questions, vbr lists error messages and hints but does not create a configuration file. You can then run the `--setupconfig` command again to specify any missing or incorrect information.

Sample Session Configuring Required Parameters

The following sample test session shows the required configuration file parameters needed to create a configuration file. The utility detects the Vertica node names in the cluster, so you do not have to supply them (v_example_node0001, v_example_node0002, and v_exampleledb_node0003):

```
> /opt/vertica/bin/vbr --setupconfig
Snapshot name (snapshotName): ExampleBackup
Backup Vertica configurations? (n) [y/n] y
Number of restore points? (1): 5
Specify objects (no default): dim, dim2
Object restore mode (coexist, createOrReplace or create) (createOrReplace): coexist
```

```
Vertica user name (current_user): dbadmin
Save password to avoid runtime prompt? (n)[y/n]: y
Database user password to save in vbr password config file (no default): mypw234
Node v_example_node0001
Backup host name (no default): backup01
Backup directory (no default): /home/dbadmin/backups
Node v_example_node0002
Backup host name: backup02
Backup directory: /home/dbadmin/backups
Node v_example_node0003
Backup host name: backup03
Backup directory: /home/dbadmin/backups
Config file name: exampleBackup.ini
Password file name: StoredPasswords
Change advanced settings? (n)[y/n]: n
Saved vbr configuration to ExampleBackup.ini.
```

- [Copying the Database to Another Cluster](#)

Configuring Advanced VBR Options

When you use `vbr` to create your configuration file, you can configure advanced parameters after configuring the basic ones that are required. The first time you invoke this utility, enter the command:

```
> /opt/vertica/bin/vbr --setupconfig
```

After you complete the required parameter options, continue to advanced settings. Respond to the last question by entering `y` in response:

```
Change advanced settings? (n)[y/n]: y
```

The completed configuration file includes the following list of the advanced parameters, their description, and their default values:

Configuration Parameter	Description and Default Value
bwlimit	(Deprecated) The transfer bandwidth limit in kilobytes per second for a backup or a restore operation. This parameter is replaced by total_bwlimit_backup and total_bwlimit_restore.
checksum	When set to y, this parameter uses checksum for data integrity instead of file date and size. The default value is n.
concurrency_backup	The maximum number of backup TCP rsync connections per node. The default value is 1.
concurrency_restore	The maximum number of restore TCP rsync connections per node. The default value is 1.
encrypt	When set to y, encrypts data during transmission. The default value is n.
port_rsync	The Port number for the rsync daemon. The default value is 50000.
retryCount	The number of times to retry if a connection attempt fails. The default value is 2.
retryDelay	The number of seconds to wait between connection retry attempts. The default value is 1.
serviceAccessUser	The user name used for simple authentication of rsync connections. Vertica stores the password for this user name in a separate configuration file .
tempDir	The temporary directory (/tmp/vbr). For additional information about the tempDir configuration parameter, see [Misc] Miscellaneous Settings .
total_bwlimit_backup	The total bandwidth limit in kilobytes per second per node for backup connections. Vertica distributes this bandwidth among the number of connections set in concurrency_backup. The total network load allowed by this value is the number of nodes multiplied by the value of this parameter. For example, a three node cluster and a total_bwlimit_backup value of 100 would allow 300Kbytes/sec of network traffic. The default value of 0 allows unlimited bandwidth.

Configuration Parameter	Description and Default Value
total_bwlimit_restore	The total bandwidth limit in kilobytes per second per node for restore connections. Vertica distributes this bandwidth among the number of connections set in <code>concurrency_restore</code> . The total network load allowed by this value is the number of nodes multiplied by the value of this parameter. For example, a three node cluster and a <code>total_bwlimit_restore</code> value of 100 would allow 300Kbytes/sec of network traffic. The default value of 0 allows unlimited bandwidth.

Example of Configuring Advanced Parameters

This example shows how you might set some of the advanced configuration file parameters to configure your backup and restore settings:

```
Change advanced settings? (n)[y/n]: y
Temp directory (/tmp/vbr):
Number of times to retry backup? (2): 5
Seconds between retry attempts? (1): 3
Encrypt data during transmission? (n) [y/n] n
Use checksum for data integrity (not file date and size)? (n)[y/n]: n
Port number for Rsync daemon (50000):
User name to access rsync daemon (no default): rsyncaccount
Password of the user who accesses rsync daemon:
Transfer bandwidth limit in KBPS or 0 for unlimited (0): 0
Saved vbr configuration to exampleBackup.ini.
```

Related Tasks

- [Configuring Backup Hosts](#)

Configuring the Hard-Link Local Parameter

Creating hard link local backups requires that you manually add the `hardLinkLocal=True` parameter to the `[Transmission]` section of the `vbr` configuration file.

Any configuration file you generate with the `vbr --setupconfig` always includes a `[Transmission]` section. If you have an existing `vbr` configuration file (*backup_name.ini*), add the `hardLinkLocal` parameter to the `[Transmission]` section.

Generating a Configuration File

To generate a configuration file *without* advanced options:

1. Add the parameter as the sole entry in the `[Transmission]` section:

```
[Transmission]
hardLinkLocal = True
```

2. Save the configuration file.

You can also generate a configuration file *with* advanced options.

1. Add the `hardLinkLocal` parameter as the last entry in the `[Transmission]` section:

```
[Transmission]
encrypt = False
checksum = False
port_rsync = 50000
total_bwlimit_backup = 0
total_bwlimit_restore = 0
hardLinkLocal = True
```

2. Save the configuration file.

Restrictions for the Backup Encryption Option

You cannot use `encrypt` parameter advanced option when creating a hard link local backup. If you add `hardLinkLocal=true` to a configuration file that includes `encrypt=true`, `vbr` issues a warning and then ignores the encryption parameter.

Configuring a Local Backup File Without Hard Links

To create a local backup without hard file links, omit the `hardLinkLocal=True` parameter from the configuration file. Specify the `backupDir` parameter as a location on the same file system as the database catalog and data files. Then, the `vbr` utility creates a backup by copying the files, even when they are located on the same file system.

Example Password Configuration File

The following example password configuration file shows the options for configuring VBR passwords. If you have chosen not to store passwords, this file remains empty. Only the `dbadmin` or members of that user's permission group can view the contents of the file.

```
[Passwords]
dbPassword = DBsecurity
serviceAccessPass = rsyncpwd
;Specifies password for remote database. Used only for restoring to alternate cluster.
dest_dbPassword = DestinationPwd
```

Sample VBR .ini Files

To assist users with the task of configuring the `vbr` utility, Vertica includes sample configuration files that you can copy, edit, and deploy for your various `vbr` tasks. Vertica automatically installs these files at `/opt/vertica/share/vbr/example_configs`.

Vertica includes the following files:

- [Database Copy to an Alternate Cluster](#) - `copycluster.ini`
- [External Central Backup/Restore](#) - `backup_restore_full_external.ini`
- [Full Hardlink Backup/Restore](#) - `backup_restore_full_hardlink.ini`
- [Full Local Backup/Restore](#) - `backup_restore_full_local.ini`
- [Object-Level Local Backup/Restore](#) - `backup_restore_object_local.ini`
- [Object Replication to an Alternate Database](#) - `replicate.ini`

- [Full Backup and Restore to an Alternate Cluster](#) - restore_to_other_cluster.ini
- [Backup/Restore To Amazon S3](#) - backup_restore_s3.htm

Database Copy to an Alternate Cluster

```
; This sample vbr configuration file is configured for the copycluster vbr task.
; Copycluster supports full database copies only, not specific objects.
; Section headings are enclosed by square brackets.
; Comments have leading semicolons (;) or pound signs (#).
; An equal sign separates options and values.
; Specify arguments marked '!!Mandatory!!' explicitly.
; All commented parameters are set to their default value.

; ----- ;
;;; BASIC PARAMETERS ;;;
; ----- ;

[Mapping]
; For each node of the source database, there must be a [Mapping] entry specifying the corresponding
hostname of the destination database node.
; !!Mandatory!! node_name = new_host/ip (no defaults)
v_exampledb_node0001 = new_host1.example
v_exampledb_node0002 = new_host2.example
v_exampledb_node0003 = new_host3.example
v_exampledb_node0004 = new_host4.example
; v_exampledb_node0001 = 10.0.90.17
; v_exampledb_node0002 = 10.0.90.18
; v_exampledb_node0003 = 10.0.90.19
; v_exampledb_node0004 = 10.0.90.20

[Database]
; !!Recommended!! If you have more than one database defined on this Vertica cluster, use this
parameter to specify which database to copy.
; dbName = current_database

; If this parameter is True, vbr prompts the user for the database password every time.
; If False, specify the location of password config file in 'passwordFile' parameter in [Misc]
section.
; dbPromptForPassword = True

; ----- ;
;;; ADVANCED PARAMETERS ;;;
; ----- ;

[Misc]
; The temp directory location on all database hosts.
; The directory must be readable and writeable by the dbadmin, and must implement POSIX style fcntl
lockf locking.
; tempDir = /tmp/vbr

; How many times to retry operations if an error occurs.
; retryCount = 2

; Specifies the number of seconds to wait between retry attempts, if a failure occurs.
```

```
; retryDelay = 1

; Full path to the password configuration file containing database password credentials
; Store this file in directory readable only by the dbadmin.
; (no default)
; passwordFile = /path/to/vbr/pw.txt

; The maximum
; acceptable difference, in seconds, between the current epoch and the backup epoch.
; If the time between the current epoch and the backup epoch exceeds the value
; specified in this parameter, Vertica displays an error message.
; SnapshotEpochLagFailureThreshold = 3600

[Transmission]
; Changes the default port number for the rsync protocol.
; port_rsync = 50000

; Total bandwidth limit for all copycluster connections in KBPS, 0 for unlimited. Vertica distributes
; this bandwidth evenly among the number of connections set in concurrency_backup.
; total_bwlimit_backup = 0

; The maximum number of copycluster TCP rsync connection threads per node.
; Results vary depending on environment, but values between 2 and 16 are sometimes quite helpful.
; concurrency_backup = 1

; The total bandwidth limit for all restore connections in KBPS, 0 for unlimited
; total_bwlimit_restore = 0

; The maximum number of restore TCP rsync connection threads per node.
; Results vary depending on environment, but values between 2 and 16 are sometimes quite helpful.
; concurrency_restore = 1

[Database]
; Vertica user name for vbr to connect to the database.
; This is rarely needed since dbUser is normally identical to the database administrator
; dbUser = current_username
```

External Central Backup/Restore

```
; This sample vbr configuration file shows full or object backup and restore to a separate remote
backup-host for each respective database host.
; Section headings are enclosed by square brackets.
; Comments have leading semicolons (;) or pound signs (#).
; An equal sign separates options and values.
; Specify arguments marked '!!Mandatory!!' explicitly.
; All commented parameters are set to their default value.

; ----- ;
;;; BASIC PARAMETERS ;;;
; ----- ;

[Mapping]
; !!Mandatory!! This section defines what host and directory will store the backup for each node.
; node_name = backup_host:backup_dir
```

```
; In this "parallel backup" configuration, each node backs up to a distinct external host.
; To backup all database nodes to a single external host, use that single hostname/IP address in each
entry below.

[Misc] Miscellaneous Settings

This section collects basic settings, including the name and location of your backup. The section also indicates whether you are keeping more than a single backup file, as specified by the `restorePointLimit` parameter.

Parameter	Default	Configuration Setting and Description
<code>snapshotName</code>	<code>snapshotName</code>	<p>Specifies the name of the directory vbr creates for the full or object-level backup. This directory appears beneath a top-level directory named for the node being backed up.</p> <p>Valid Values:</p> <ul style="list-style-type: none">• a–z• A – Z• 0 – 9• Hyphen (-)• Underscore (_)
<code>tempDir</code>	<code>/tmp/vbr</code>	<p>Specifies an absolute path to a temporary storage area on the cluster nodes. The <code>tmp</code> path must be the same on all nodes in the cluster. The vbr utility uses this directory as a temporary location while it is copying files from the source cluster node to the destination backup location.</p>

Parameter	Default	Configuration Setting and Description
		<p>Vertica also writes backup logs to this location. The vbr utility uses this directory as a temporary location for log files, lock files and other bookkeeping information during the execution of a task.</p> <p>Do not specify the same location as your database's data or catalog directory. Any unexpected files or directories in your data or catalog location can cause errors during database start or restore.</p> <p>The file system at this location must support <code>fcntl lockf</code> (POSIX) file locking.</p>
restorePointLimit	1	<p>Specifies the number of historical backups to retain in addition to the most recent backup. For example, if you set <code>restorePointLimit=3</code>, Vertica saves three historical backups, in addition to the most recent backup, for a total of four backups. By default, Vertica maintains a current backup and one historical backup. Saving multiple backups lets you back up incrementally. Enter a positive integer.</p> <p>Saves multiple backups to the same location, which are shared through hard links. In such cases, <code>listbackup</code> displays the common backup prefix but indicates unique time and date suffixes:</p> <pre>my_archive20111111_205841</pre>
objects	None	<p>Specifies whether vbr creates a full or object-level backup. If you do not specify any objects, vbr creates a full backup. Otherwise, specify the object names (schemas or tables) to include in a</p>

Parameter	Default	Configuration Setting and Description
		<p>backup. To enter more than one object, enter multiple names in a comma-separated list.</p> <p>Enter table names in the form <code>schema.objectname</code>. For example, to make backups of the table <code>customers</code> from the schema <code>finance</code>, enter <code>finance.customers</code>. If a public table and a schema have the same name, <code>vbr</code> backs up only the schema. Use the <code>schema.objectname</code> convention to avoid confusion.</p> <p>Object names can include UTF-8 alphanumeric characters. Object names cannot include escape characters, single quote (') or double quote (") characters.</p> <p>To use non-alphanumeric characters, use a backslash (\) followed by a hex value. For instance, if the table name is a <code>my table</code> (<code>my</code> followed by a space character, then <code>table</code>), enter the object name as follows:</p> <pre>objects=my\20table</pre> <p>This parameter also identifies objects that you want to replicate to an alternate cluster.</p>
objectRestoreMode	createOrReplace	<p>Specifies how Vertica handles objects of the same name when restoring schema or table backups.</p> <p>Valid Values:</p> <ul style="list-style-type: none"> • createOrReplace • create • coexist

Parameter	Default	Configuration Setting and Description
		For descriptions of these settings, refer to Creating vbr Configuration Files .
retryCount	2	Specifies the number of backup attempts to complete execution after an error occurs. If the backup fails after exceeding the number of retry attempts, the utility reports an error and stops processing.
retryDelay	1	Specifies the number of seconds to wait between backup retry attempts, if a failure occurs.
passwordFile	None	Specifies the file name of the password configuration file .
enableFreeSpaceCheck	True	When enabled, Vertica confirms that the specified backup locations contain sufficient free space and inodes to allow a successful backup. If a backup location has insufficient resources, Vertica displays an error message and cancels the backup. If Vertica cannot determine the amount of available space or number of inodes in the backupDir, it displays a warning and continues with the backup. If you do not include this setting in your configuration file, Vertica performs the space check by default.
SnapshotEpochLagFailureThreshold	3600	When performing a backup, replication, or copycluster, specifies the maximum acceptable difference, in seconds, between the current epoch and the backup epoch. If the time between the current epoch and the backup epoch exceeds the value specified in this parameter, Vertica displays an error message. A value of 0 disables this check. If you do not include this setting in your

Parameter	Default	Configuration Setting and Description
		configuration file, Vertica performs this check using the default value. Backups do not contain information committed after the backup epoch.

[Database] Database Access Settings

Sets options for accessing the database.

Parameter	Default	Description
dbName	N/A	Specifies the name of the database to back up. If you do not supply a database name, the vbr utility selects the current database to back up. Micro Focus recommends that you provide a database name.
dbUser	Current user name	Identifies the Vertica user used for database operations performed by vbr. In the case of the replicate task, this user is the source database user. The vbr utility obtains this information automatically as the current user of the person who invoked the <code>--setupconfig</code> command. You must be logged on as the database administrator to back up the database. The password, if you choose to save it, is stored in the Password Configuration File .
dbPromptForPassword	True	Controls whether the utility prompts for a password. If you set this parameter to <code>False</code> (indicating no prompt at run time), then you must also enter the database administrator password in the <code>dbPassword</code> parameter. If you do not supply a password in the configuration file, the utility prompts for one at run time.

Vertica uses destination database parameters only to replicate objects to alternate clusters. By default, these parameters do not exist in your vbr configuration files. You must manually [edit your database configuration](#) file to add them.

Parameter	Default	Description
dest_dbName	N/A	Specifies the name of the destination database.
dest_dbUser	N/A	Identifies the Vertica user name in the destination database to be used for loading the replicated data. This Vertica user must have default super user privileges.
dest_dbPromptForPassword	N/A	Controls whether the utility prompts for a password for the destination database. If you set this parameter to <code>False</code> (indicating no prompt at run time), then you must also enter the destination database administrator password in the <code>dest_dbPassword</code> parameter. If you do not supply a password in the configuration file, the utility prompts for one at run time.

[Transmission] Data Transmission

Sets options for transmitting the data when using backup hosts.

Parameter	Default	Description
encrypt	False	Controls whether the transmitted data is encrypted while it is being copied to the target backup location. Choose this option if you are performing a backup over an untrusted network (for example, backing up to a remote host across the Internet). Note: Encrypting data transmission causes significant processing overhead and slows transfer. One of the processor cores of each database node is consumed during the encryption process. Use this option only if you are concerned about the security of the network used when transmitting backup data.
checksum	False	Controls whether the <code>vbr</code> utility has <code>rsync</code> use the <code>md5</code> checksum to determine whether files are identical before and after network transmission. By default, <code>rsync</code> does not perform checksum. Instead, it

Parameter	Default	Description
		<p>performs minimal file checking, confirming that the file size and time of last modification are identical before and after transmission.</p> <p>Note: Calculating checksum values increases processor usage during the backup process.</p>
port_rsync	50000	Changes the default port number for the rsync protocol. Change this value if the default rsync port is in use on your cluster, or you need rsync to use another port to avoid a firewall restriction.
total_bwlimit_backup	0	The total bandwidth limit in KBps for backup connections. Vertica distributes this bandwidth evenly among the number of connections set in concurrency_backup. The default value of 0 allows unlimited bandwidth.
concurrency_backup	1	The maximum number of backup TCP rsync connection threads per node. To improve local and remote backup, replication, and copy cluster performance, you can increase the number of threads available to perform backups. Increasing the number of threads allocates more CPU resources to the backup task and can, for remote backups, increase the amount of bandwidth used. The optimal value for this setting depends greatly on your specific configuration and requirements. Values higher than 16 produce no additional benefit.
total_bwlimit_restore	0	The total bandwidth limit in KBps for restore connections. Vertica distributes this bandwidth evenly among the number of connections set in concurrency_restore. The default value of 0 allows unlimited bandwidth.
concurrency_restore	1	<p>The maximum number of restore TCP rsync connections per node.</p> <p>The maximum number of restore TCP rsync connection threads per node. To improve local and</p>

Parameter	Default	Description
		remote restore, replication, and copy cluster performance, you can increase the number of threads available to perform restores. Increasing the number of threads allocates more CPU resources to the restore task and can, for restores of remote backups, increase the amount of bandwidth used. The optimal value for this setting depends greatly on your specific configuration and requirements. Values higher than 16 produce no additional benefit.
serviceAccessUser	None	The user name used for simple authentication of rsync connections. This user is neither a Linux nor Vertica user name. It is simply an arbitrary identifier used by the rsync protocol. If you do not provide a user name, Vertica leaves rsync running without authentication, creating a potential security risk. If you choose to save the password, Vertica stores it in the Password Configuration File .
hardLinkLocal	False	Creates a full- or object-level backup using hard file links on the local file system, rather than copying database files to a remote backup host. Add this configuration parameter manually to the Transaction section of the configuration file, as described in Configuring the Hard-Link Local Parameter .
port_ssh_backup	22	<p>Overrides the default SSH port setting (22) for the backup hosts. Enter the required SSH port for your site.</p> <p>Changing the default SSH port is supported only when using the backup and restore tasks. Using a non-default SSH port with the copyCluster task is not supported.</p> <p>NOTE: This parameter is not included in the configuration file automatically. For more information, see Configuring Backup Hosts.</p>

[Mapping]

You have one [Mapping] section for all of the nodes in your database cluster. The section must appear in your configuration file because it specifies asl database nodes being included in the backup. It also includes the backup host and directory for each node. If you have objects being replicated to an alternate database, the [Mapping] section also maps the target database nodes to the source database backup locations.

- If you edit an existing configuration file to add a Mapping in the current style, you must combine information from all existing Mappings into the new section.
- Alternatively, you can use vbr with the --setupconfig option to generate a new configuration file, as described in [Creating vbr Configuration Files](#).

Note: The [S3] and [Mapping] configuration sections are mutually exclusive. If you include both, your backup fails with the error message "Config has conflicting sections (Mapping, S3), specify only one of them."

Parameter	Default	Description
backupHost	None	<p>Indicates the target host name or IP address on which to store this node's backup. The backupHost name is different from dbNode. The copycluster command uses this value to identify the target database node host name.</p> <p>Performance Consideration:</p> <p>Although supported, backups to an NFS host may have poor performance, particularly on networks shared with rsync operations.</p>
backupDir	None	<p>Identifies the full path to the directory on the backup host or node where the backup will be stored.</p> <p>Directory Requirements:</p> <ul style="list-style-type: none"> • Must already exist when you run the utility with the --task backup option • Must be writable by the user account used to run the backup utility.

Parameter	Default	Description
		<ul style="list-style-type: none">• Must be unique to the database you are backing up. Multiple databases cannot share the same backup directory.• The file system at this location must supportfcntl lockf file locking.
dbNode	None	<p>The name of the database node, as recognized by Vertica. This value is not the node's host name, but rather the name Vertica uses internally to identify the node, usually in the form of:</p> <pre>v_node00xx</pre> <p>To find database node names in your cluster, query the node_name column of the NODES system table.</p>

Map to the localhost

Vertica vbr does not support the special localhost name as a backup host. To backup a database node to its own disk, use empty square brackets for the hostname in the [Mapping] section of the configuration file.

```
[Mapping]
NodeName = []:/backup/path
```

Your mapping section should resemble this example:

```
[Mapping]
v_node0001 = []:/scratch_drive/archive/backupdir
v_node0002 = []:/scratch_drive/archive/backupdir
v_node0003 = []:/scratch_drive/archive/backupdir
```

Map to the Same Database

The following example shows how you can specify a Mapping section that indicates a single node to be backed up (v_vmart_node0001). The node is assigned to the backup host (v_srv01), and the backup directory (/home/dbadmin/backups). Although you are backing up

a single node cluster, and the backup host and the database node are the same system, you specify them differently.

Specify the backup host and directory, using a colon (:) as a separator:

```
[Mapping]
v_vmart_node0001 = srv01:/home/dbadmin/backups
```

Although the configuration file `[Mapping]` section no longer uses named parameters, you still use the elements of the simplified format continue to represent the following parameters:

```
dbNode = backupHost:backupDir
```

Map to an Alternate Database

Before you can replicate objects to an alternate database, you must also create a [\[NodeMapping\]](#) section in your vbr configuration file. The `NodeMapping` section points source nodes to their target database nodes.

Restore an alternate database, by adding mapping information in the following form:

```
[Mapping]
targetNode: sourceDBNode_backuphost:sourceDB_backuppath
```

Your mapping section should resemble this example:

```
[Mapping]
v_sec_node0001 = pri_bsrv01:/archive/backup
v_sec_node0002 = pri_bsrv02:/archive/backup
v_sec_node0003 = pri_bsrv03:/archive/backup
```

[NodeMapping]

Vertica uses the node mapping section exclusively to restore a full backup from one database to another, different, database. Be sure to update the [\[Mapping\]](#) section of your configuration file to point your target Vertica nodes to their source backup locations.

Important: Vertica does not automatically generate the [NodeMapping] section of the vbr configuration file. You must edit the file manually to add a node mapping section. Refer to [Full Backup and Restore to an Alternate Cluster](#) as an example.

Use the following form to specify node mapping:

```
source_vertica_node = target_vertica_host
```

For example, you can use the following mapping to restore content from one 4-node database to an alternate 4-node database.

```
[NodeMapping]
v_exampledb_node0001 = new_host0001
v_exampledb_node0002 = new_host0002
v_exampledb_node0003 = new_host0003
v_exampledb_node0004 = new_host0004
```

[S3]

Sets options for storing backup data on Amazon S3.

Note: The [S3] and [Mapping] configuration sections are mutually exclusive. If you include both, your backup fails with the error message "Config has conflicting sections (Mapping, S3), specify only one of them."

Parameter	Default	Description
s3_backup_file_system_path		<p>Specifies the host and path that you are using to handle file locking during the backup process. Vertica must be able to create a passwordless ssh connection to the location that you specify here.</p> <p>To use a local NFS file system, specify a value of:</p> <pre>s3_backup_file_system_path = [:path]</pre> <p>To use an EC2 instance, specify a value of:</p> <pre>s3_backup_file_system_path = [host_name]:path</pre>
s3_backup_path		<p>Specifies the S3 bucket name and backup path for the backup to S3. When you backup to S3, all nodes back up to same S3 bucket. You must create the backup location on S3</p>

Parameter	Default	Description
		before performing a backup. This value takes the following form: <pre>s3_backup_path = s3://backup_bucket/database_backup_path/</pre>
s3_encrypt_transport	True	When True, uses SSL encryption to encrypt moving between your Vertica cluster and your S3 instance. If you are backing up or restoring from an Amazon EC2 cluster, you must set this parameter to True.
s3_concurrency_backup	10	The maximum number of concurrent backup threads for backup to S3.
s3_concurrency_restore	10	The maximum number of concurrent restore threads for restoring from S3.

Backup and Restore Utility Reference

This section provides reference information about both the `vbr` utility commands, and its associated configuration file parameters.

VBR Utility Reference

Allows you to back up and restore either the full database, or one or more schema and table objects of interest. You can also copy a cluster and list backups you created previously.

The utility is located in the Vertica binary directory (`/opt/vertica/bin/vbr` on most installations).

Syntax

```
    /opt/vertica/bin/vbr { command }  
... [ --archive timestamp ]  
... [ --config-file file ]  
... [ --debug level ]  
... [ --nodes node1 [, noden, ...] ]  
... [ --showconfig ]
```

Where *command* is one of the following:

Full Command	Short Command	Description
<code>--help</code>	<code>-h</code>	Shows a brief usage guide for the command.
<code>--showconfig</code>		Displays the current configuration settings.
<code>--setupconfig</code>		Asks a series of questions and generates a configuration file.
<code>--task {backup 7.2_upgrade collect-garbage copycluster full-check init listbackup quick-check quick-repair remove replicate</code>	<code>-t</code>	Performs the specified task: <ul style="list-style-type: none">7.2_upgrade — Upgrades an existing 7.1 or earlier backup to the manifest-based backup introduced in version 7.2.backup — Creates a full database or object-level backup, depending on configuration file

Full Command	Short Command	Description
restore }		<p>specification.</p> <ul style="list-style-type: none"> • <code>collect-garbage</code> — Rebuilds the backup manifest and deletes any unreferenced objects in the backup location. • <code>copycluster</code> — Copies the database to another Vertica cluster. • <code>full-check</code> — Verifies all objects listed in the backup manifest against file system metadata, outputting missing and unreferenced objects. • <code>init</code> — Creates a new backup directory, or prepares an existing one, for use and creates necessary backup manifests. You must perform this task before the first time you create a backup in a directory. • <code>listbackup</code> — Displays the existing backups associated with the configuration file you supply. View this display to get the name of a backup that you want to restore. • <code>quick-check</code> Confirms that all backed-up objects appear in the backup manifest. Outputs any discrepancies between objects in the backup location and objects listed in the backup manifest. • <code>quick-repair</code> — Builds a replacement backup manifest, based on storage locations and objects. • <code>remove</code> — Removes the specified backup or restore point. • <code>replicate</code>— Copies objects from one cluster to an alternate cluster. • <code>restore</code> — Restores a full or object-level database backup. Requires the configuration file that created the backup.

Parameters

Parameter	Description
<code>--archive <i>timestamp</i></code>	Used with the <code>--task restore</code> and <code>--task remove</code> commands. Specifies the timestamp of the backup to restore or remove: > <code>vbr --task restore --config-file myconfig.ini --archive=20160115_182640</code>
<code>-c <i>file</i></code> <code>--config-file <i>file</i></code>	Indicates the configuration file to use as an absolute or relative path to the location from which you start the backup utility. If no file exists, an error occurs and the utility cannot continue.
<code>--nodes <i>node1[,...]</i></code>	Specifies any nodes, in a comma-separated list, on which to perform a vbr task. The nodes listed match the names in the Mapping section of the configuration file. Caution: Do not try to restore the entire database cluster from a partial database backup created from a subset of the nodes. Data loss could result.
<code>--debug <i>level</i></code>	Specifies the level of debugging messages (from 0 to 3) that the vbr utility provides. Level 3 indicates verbose, while level 0, the default, indicates no messages.
<code>--report-file <i>path/filename</i></code>	Optional. Outputs a delimited JSON file that describes the results of the associated full backup integrity check or garbage collection task.
<code>--restore-objects <i>objects</i></code>	Specifies the individual objects to restore from a full or object-level backup.
<code>--s3-force-init</code>	Used with the <code>--task init</code> command. Forces the <code>init</code> task to succeed on S3 storage targets when there is an identity/lock file mismatch. For more information, refer to Creating Backups on Amazon S3 .
<code>--showconfig</code>	The configuration values being used to perform the task, displayed in raw JSON format before vbr starts begins.

Parameter	Description
<code>--list-all</code>	Used with the <code>--task listbackup</code> command. Displays a list of all backups stored on the hosts and paths listed in the specified configuration file.
<code>--json</code>	Used with the <code>--task listbackup</code> command. Displays a JSON delimited list of all backups stored on the hosts and paths listed in the specified configuration file.
<code>--list-output-file <i>path/filename</i></code>	Used with the <code>--task listbackup</code> command. Outputs a file containing a JSON delimited list of all backups stored on the hosts and paths listed in the specified configuration file.

Password Configuration File Reference

The `vbr` utility automatically creates the password configuration file to store any saved passwords. Only the database administrator or members of that user's permission group can view the contents of the file. If you alter the file permissions from their default values (xx0), Vertica backup or restore actions fail with an error message.

Vertica creates the password file, even if you do not save any passwords. In this case, the file exists but remains empty. Vertica stores this file in the same location that you choose to save your backup and restore configuration file.

[Passwords] Password Settings

Parameter	Default	Description
dbPassword	None	<p>Identifies the database administrator's password. If you set <code>dbPromptForPassword</code> to <code>False</code>, enter a password. Doing so prevents you from being prompted at run time. You do not need to specify additional settings.</p> <p>Empty strings:</p> <p>You cannot enter an empty string for the <code>dbPassword</code> in the configuration file. Micro Focus does not recommend using an empty string as a superuser password. If you do so, you must:</p> <ol style="list-style-type: none">1. Set the <code>dbPromptForPassword</code> parameter to <code>True</code>.2. Leave the <code>dbPassword</code> option blank.3. Enter the empty string at the prompt each time you run the backup utility.
serviceAccessPass	None	Identifies the password for the <code>rsync</code> user account.
dest_dbPassword	None	The password for the <code>dest_dbuser</code> Vertica account. Vertica uses this value for replication tasks only.

When to Back up the Database

In addition to any guidelines established by your enterprise, Micro Focus recommends that you back up your database in the following circumstances:

Before:

- You upgrade Vertica to another release.
- You drop a partition.

- You add, remove, or replace nodes in your database cluster.

After:

- You load a large volume of data.
- You add, remove, or replace nodes in your database cluster.
- You recover a cluster from a crash.

If:

The epoch in the latest backup is earlier than the current ancient history mark.

Note: Always create a new full backup after adding, removing, or replacing nodes. When you restore a full database backup, you must restore to a cluster that is identical to the one on which you created the backup.

Ideally, schedule ongoing backups to back up your data. You can run the Vertica `vbr` from a cron job or other task scheduler.

Related Terms

- Ancient history mark (AHM).

Configuring Backup Hosts

The `vbr` utility lets you back up your database to one or more hosts (known as *backup hosts*), that can be outside of your database cluster.

You can use one or more backup hosts or a single S3 bucket to back up your database. Use the `vbr` configuration file to specify which backup host each node in your cluster should use.

Before you back up to hosts outside of the local cluster, configure the target backup locations to work with the `vbr` utility. The backup hosts you use must:

- [Have sufficient backup disk space.](#)
- Be accessible from your database cluster through SSH.
- Have passwordless SSH access for the Database Administrator account.

- Set `AllowTcpForwarding = Yes` in your `sshd_config` file. If TCP forwarding is not enabled, backups fail with the following message:

"Errors connecting to remote hosts: Check SSH settings, and that the same Vertica version is installed on all nodes. "

- Have either the Vertica rpm or Python 2.7 and rsync 3.0.5 or later installed.
- If you are using a stateful firewall, configure your `tcp_keepalive_time` and `tcp_keepalive_intvl` `sysctl` settings to use values less than your firewall timeout value.

Creating Configuration Files for Backup Hosts

Create separate configuration files for full or object-level backups, using distinct names for each configuration file. Also, use the same node, backup host, and directory location pairs. Specify different backup directory locations for each database.

Note: For optimal network performance when creating a backup, Micro Focus recommends that you give each node in the cluster its own dedicated backup host.

Preparing Backup Host Directories

Before `vbr` can back up a database, you must prepare the target backup directory. Run `vbr` with a task type of `init` to create the necessary manifests for the backup process. You need to perform the `init` process only once. After that, Vertica maintains the manifests automatically.

Estimating Backup Host Disk Requirements

Wherever you plan to save data backups, consider the disk requirements for incremental backups at your site. Also, if you use more than one archive, multiple archives potentially require more disk space. Micro Focus recommends that each backup host have space for at least twice the database node footprint size. Follow this recommendation regardless of the specifics of your site's backup schedule and retention requirements.

To estimate the database size from the `used_bytes` column of the `storage_containers` system table:

```
VMart=> select sum(used_bytes) from storage_containers where node_name='v_mydb_node0001';
total_size
-----
      302135743
(1 row)
```

If your site uses multiple backup host locations, you can estimate the database size requirements per node. Use a query, such as the following, substituting a backup host name for *node_name*:

```
select node_name,sum(used_bytes) as size_in_bytes from v_monitor.storage_containers group by node_name;
```

Making Backup Hosts Accessible

You must verify that any firewalls between the source database nodes and the target backup hosts allow connections for SSH and rsync on port 50000.

The backup hosts must be running identical versions of rsync and Python as those supplied in the Vertica installation package.

Setting Up Passwordless SSH Access

To access a backup host, the database administrator must meet two requirements to run the vbr utility:

- Have an account on each backup host, with write permissions to the backup directory.
- Have passwordless SSH access from each database cluster host to the corresponding backup host.

How you fulfill these requirements depends on your platform and infrastructure.

SSH access among the backup hosts and access from the backup host to the database node is not necessary.

If your site does not use a centralized login system (such as LDAP), you can usually add a user with the `useradd` command or through a GUI administration tool. See the documentation for your Linux distribution for details.

If your platform supports it, you can enable passwordless SSH logins using the `ssh-copy-id` command to copy a database administrator's SSH identity file to the backup location from one of your database nodes. For example, to copy the SSH identity file from a node to a backup host named `backup01`:

```
> ssh-copy-id -i dbadmin@backup01|  
Password:
```

Try logging into the machine with "ssh 'dbadmin@backup01' ". Then, check the contents of the `~/.ssh/authorized_keysfile` to verify that you have not added extra keys that you did not intend to include.

```
> ssh backup01  
Last login: Mon May 23 11:44:23 2011 from host01
```

Repeat the steps to copy a database administrator's SSH identity to all backup hosts you use to back up your database.

After copying a database administrator's SSH identity, you should be able to log in to the backup host from any of the nodes in the cluster. You are not prompted for a password.

Increasing the SSH Maximum Connection Settings for a Backup Host

If your configuration requires backing up multiple nodes to one backup host (n:1), increase the number of concurrent SSH connections to the SSH daemon (`sshd`). By default, the number of concurrent SSH connections on each host is 10, as set in the `sshd_config` file with the `MaxStartups` keyword. The `MaxStartups` value for each backup host should be greater than the total number of hosts being backed up to this backup host.

To increase the `MaxStartups` value:

1. Log on as root to access the config file.
2. Open the SSH configuration file (`/etc/ssh/sshd_config`) in a text editor.
3. If the `MaxStartups` line is commented out with `#`, delete that character. Replace the current value, which may be a single integer or three integers like `10:30:60` with the new value. For example, to back up a 50 node cluster to one machine, use a value of 60:

```
MaxStartups 60
```

For more information on configuring `MaxStartups`, [refer to the man page for that parameter](#).

4. Save the file.
5. Reload the file using the following command:

```
sudo /etc/init.d/sshd reload
```

If you are using Red Hat 7/CentOS 7, use the following command instead: `sudo /bin/systemctl reload sshd.service`

6. Exit from root.

Types of Backups

The `vbr` utility supports several kinds of backups:

- [Full backups](#)
- [Object-level backups](#)
- [Hard-link local backups](#)

You can refer to full or object-level backups by a user-defined descriptive name, such as `FullDBSnap`, `Schema1Bak`, or `Table1Bak`.

Full Backups

A *full backup* is a complete copy of the database catalog, its schemas, tables, and other objects. This type of backup provides a consistent image of the database at the time the backup occurred. You can use a full backup for disaster recovery to restore a damaged or incomplete database. You can also [restore individual objects from a full backup](#).

When a full backup exists, `vbr` creates incremental backups as successive backups following the full-backup. Incremental backups contain new or changed data since the last full, or incremental, backup occurred.

Archives contain a collection of same-name backups. Each archive can have a different retention policy. For example, suppose that `TBak` is the name of an object-level backup of table `T`, and you create a daily backup each week. These seven backups become part of the `TBak` archive. Keeping a backup archive lets you revert back to any one of the saved backups.

Full and object-level backups reside on *backup hosts*, the computer systems on which backups and archives are stored.

Vertica saves backups in a specific *backup location*, the directory on a backup host. This location can contain multiple backups, including associated archives. The backups are also compatible, allowing you to restore any objects from a full database backup.

Object-Level Backups

An *object-level backup* consists of one or more schemas or tables or a group of such objects. The conglomerate parts of the object-level backup do not contain the entire database. When an object-level backup exists, you can restore all of its contents or [individual objects](#).

Note: Vertica does not support object level backups on Hadoop Distributed File System (HDFS) storage.

Object-level backups contain the following object types:

Selective objects	Objects you choose to be part of an object-level backup. For example, if you specify tables <code>T1</code> and <code>T2</code> to include in an object-level backup, they are the selected objects.
Dependent objects	Objects that must be included as part of an object-level backup, due to dependencies. Suppose you want to create an object-level backup that includes a table with a foreign key. To do so, table constraints require that you include the primary key table, and <code>vbr</code> enforces this requirement. Projections anchored on a table in the selected objects are also <i>dependent objects</i> .
Principal objects	The objects on which both selected and dependent objects depend are called <i>principal objects</i> . For example, each table and projection has an owner, and each is a <i>principal object</i> .

Vertica 6.x and later provides support for object-level backups.

Hard Link Local Backups

A *hard-link local backup* can be a full- or object-level backup. It consists of a complete copy of the database catalog, and a set of hard file links to corresponding data files. You must save a hard-link local backup on the file system used by the catalog and database files.

Backup Contents

Backups contain all committed data for the backed up objects as of the start time of the backup. Backups do not contain uncommitted data or data committed during the backup. Backups do not delay mergeout or load activity.

Related Tasks

- [Configuring Backup Hosts](#)

Creating Backups on Amazon S3

Vertica supports the creation of backups on Amazon S3 Standard cloud storage. You can create these backups from your local cluster or from Amazon EC2 virtual servers.

Note: Vertica supports backup and restore from S3. Copycluster and replication to S3 targets is not supported.

Creating an S3 Configuration File

To backup to Amazon S3, you must add an [S3] section to your backup configuration file. For more information, refer to [\[S3\]](#). Vertica also provides a [sample S3 configuration file](#) that you can copy and edit.

Configuring Amazon S3 Storage for Backup

Vertica supports using Amazon S3 cloud storage as a backup location. As with all Vertica backups, Vertica creates incremental backups, meaning each subsequent backup contains only changes that have occurred since you created the first backup. As with any storage location, you must initialize an S3 storage location with the `vbr task init`.

Because S3 storage does not support file locking, Vertica uses either your local file system or an Amazon EC2 file system to handle file locks during a backup. You identify this location using the `s3_backup_file_system_path` [parameter](#) in your `vbr` configuration file. During a backup, Vertica creates a locked identity file on your local or EC2 instance, and a duplicate file in your S3 backup location. As long as the files match, Vertica proceeds with the backup, releasing the lock once the backup is complete. As long as the files remain identical, you can use the S3 location for backup and restore tasks.

If the files in your locking location become out of sync with the files in your backup location, backup and restore tasks fail with an error message. You can resolve locking inconsistencies by rerunning the `init` task with the `--s3-force-init` parameter.

A typical S3 locking file reset command takes the following form:

```
/opt/vertica/bin/vbr --task init --s3-force-init -c filename.ini
```

Note: If a backup fails, confirm that your Vertica cluster has permission to access your S3 storage location.

Configuring EC2 Authentication for Amazon S3

If you are backing to S3 from an EC2-based cluster, you must provide authentication to your S3 host. Regardless of the authentication type you choose, your credentials do not leave your EC2 cluster. Vertica supports the following authentication types:

- AWS credential file
- IAM role
- Environmental variables

AWS credential file - You can manually create a configuration file on your EC2 initiator host at `~/.aws/credentials`.

```
[default]  
aws_access_key_id = YOUR_ACCESS_KEY  
aws_secret_access_key = YOUR_SECRET_KEY
```

For more information on credential files, refer to [Amazon's Web Services documentation](#).

IAM role - Create an AWS IAM role and grant that role permission to access your EC2 cluster and S3 resources. For more information, refer to [Amazon's Web Services documentation](#).

Environmental variables - (Recommended) Amazon Web Services provides the following environmental variables:

- AWS_ACCESS_KEY_ID
- AWS_SECRET_ACCESS_KEY

Use these variables on your initiator to provide authentication to your S3 host. Once your session ends, AWS deletes these variables. For more information, refer to the [AWS documentation](#).

Creating Object-Level Backups

The database administrator can create object-level backups consisting of one or more schemas and tables. Object-level backups are especially useful for multi-tenanted database sites. For example, an international airport could use a multi-tenanted database to represent different airlines in its schemas. Then, tables could maintain various types of information for the airline, including ARRIVALS, DEPARTURES, and PASSENGER information. With such an organization, creating object-level backups of the specific schemas would let you restore by airline tenant, or any other important data segment.

The following configuration file parameters are specific to object-level backups:

- Objects
- objectRestoreMode (used in restore operations only)

For more information about creating configuration files for full or object-level backups, see [Configuring Required VBR Parameters](#).

Note: Apache Kafka uses internal configuration settings to maintain the integrity of your data. When backing up your Kafka data, Micro Focus recommends that you perform a [full database backup](#), rather than an object-level backup.

Preparing Your Backup Directory

Before you can create a backup, you must prepare your backup directory with the [vbr -init task](#).

Invoking vbr Backup

After creating the configuration file specifying which objects to backup, you can create an object-level backup. The following example shows how you can use the `objectbak.ini` command in a configuration file:

```
[dbadmin@v_vmart_node0001 ~]$ vbr --task backup --config-file objectbak.ini
Preparing...
Found Database port: 5433
Copying...
[=====] 100%
All child processes terminated successfully.
Committing changes on all backup sites...
backup done!
[dbadmin@v_vmart_node0001 ~]$
```

Backup Locations and Naming

You can use one top-level backup directory to store both full and object-level backups.

Note: Micro Focus does not recommend concurrent backups. If you must run multiple backups concurrently, use separate backup and temp directories for each. Having separate backup directories detracts from the advantage of sharing data among incremental backups.

To see existing full and object-level backups, see [Viewing Backups](#) in the [See Also](#) section below.

Best Practices for Object-Level Backups

To create one or more object-level backups, create a configuration file specifying the backup location, the object-level backup name, and a list of objects to include (one or more schemas and tables). When creating configuration backup files:

- Create one configuration file for each object-level backup
- Create a different configuration file to create a full database backup
- For best network performance, use one backup host per cluster node
- Use one directory on each backup-node to store successive backups
- For future reference, append the major Vertica version number to the configuration file name (mybackup7x)

Using the same backup host directory location for full and object-level backups results in the backups sharing disk space. Shared disk space makes backups compatible when performing a restore. Each cluster node must also use the same directory location on its designated backup host.

The selected objects of a backup can include one or more schemas or tables, or a combination of both. For example, you can include schema S1 and tables T1 and T2 in an object-level backup. Multiple backups can be combined into a single backup. A schema-level backup can be integrated with a database backup (and a table backup integrated with a schema-level backup, and so on).

Naming Conventions

Give each object-level backup configuration file a distinct and descriptive name. For instance, at an airport terminal, schema-based backup configuration files use a naming convention with an airline prefix, followed by further description, such as:

AIR1_daily_arrivals_backup

AIR2_hourly_arrivals_backup

AIR2_hourly_departures_backup

AIR3_daily_departures_backup

When database and object-based backups exist, you can recover the backup of your choice.

Caution: Do not change object names in an object-level configuration file if a backup already exists. Doing so overwrites the original configuration file, and you cannot restore it from the earlier backup. Instead, create a different configuration file.

Determining Backup Frequency

Micro Focus recommends, as a best practice, that you take frequent backups if database contents diverge in significant ways.

Always take backups after any event that significantly modifies the database, such as performing a rebalance. Mixing many backups with significant differences can weaken data K-safety. For example, taking backups both before and after a rebalance is not a recommended practice in cases where the backups are all part of one archive.

Understanding Object-Level Backup Contents

Object-level backups comprise only the elements necessary to restore the schema or table, including the selected, dependent, and principal objects. An object-level backup includes the following contents:

- Storage: Data files belonging to any specified objects
- Metadata: Including the cluster topology, timestamp, epoch, AHM, and so on
- Catalog snippet: Persistent catalog objects serialized into the principal and dependent objects

Some of the elements that comprise AIR2, for instance, include its parent schema, tables, named sequences, primary key and foreign key constraints, and so on. To create such a backup, `vbr` script saves the objects directly associated with the table. It also saves any dependencies, such as foreign key (FK) tables, and creates an object map from which to restore the backup.

Note: Because the data in local temp tables persists only within a session, local temporary tables are excluded when you create an object-level schema. For global temporary tables, `vbr` stores the table's definition.

Making Changes After an Object-Level Backup

Be aware how changes made after an object-level backup affect subsequent backups. Suppose you create an object-level backup and later drop schemas and tables from the database. In this case, the objects you dropped are also be dropped from subsequent backups. If you do not save an archive of the object backup, such objects could be lost permanently.

Changing a table name after creating a table backup does not persist after restoring the backup. Suppose that, after creating a backup, you drop a user who owns any selected or dependent objects in that backup. In this case, restoring the backup re-creates the object and assigns ownership to the user performing the restore. If the owner of a restored object still exists, that user retains ownership of the restored object.

To restore a dropped table from a backup:

1. Rename the newly created table from t1 to t2.
2. Restore the backup containing t1.
3. Restore t1. Tables t1 and t2 now coexist.

For information on how Vertica handles object overwrites, refer to "Specifying Object Restore Mode" in [Creating vbr Configuration Files](#).

K-safety may increase after an object backup. Restoration of a backup fails if *both* of the following conditions occur:

- An increase in K-safety occurs.
- Any table in the backup has insufficient projections.

Changing Principal and Dependent Objects

If you create a backup and then drop a principal object, restoring the backup restores that principal object. If the owner of the restored object has also been dropped, Vertica assigns the restored object to the current dbadmin.

You can specify how Vertica handles object overwrites in the vbr configuration file. For more information, refer to "Specifying Object Restore Mode" in [Creating vbr Configuration Files](#).

Identity and auto-increment sequences are dependent objects because they cannot exist without their tables. An object-level backup includes such objects, along with the tables on which they depend.

Named sequences are not dependent objects because they exist autonomously. A named sequence remains after you drop the table in which the sequence is used. In this case, the named sequence is a principal object. Thus, you must back up the named sequence with the table. Then, you regenerate it, if it does not already exist when you restore the table. If the sequence does exist, vbr uses it, unmodified. Sequence values could repeat, if you restore the full database and then restore a table backup to a newer epoch.

Considering Constraint References

You must backup all database objects that are related through constraints. For example, suppose you have a schema with tables whose constraints reference only tables in the same schema can be backed up. However, a schema containing a table with an FK/PK constraint on a table in another schema cannot. To back up the second table, you must include the other schema in the list of selected objects.

Configuration Files for Object-Level Backups

The `vbr` utility automatically associates configurations with different backup names but uses the same backup location.

Always create a cluster-wide configuration file and one or more object-level configuration files pointing to the same backup location. Storage between backups is shared, preventing multiple copies of the same data. For object-level backups, using the same backup location causes `vbr` to encounter fewer OID conflict prevention techniques. Avoiding OID conflict prevention results in fewer problems when restoring the backup.

By using cluster and object configuration files with the same backup location, the utility includes additional provisions to ensure that the object-level backups can be used following a full cluster restore. One approach to restoring a full cluster is to use a full database backup to bootstrap the cluster. After the cluster is operational again, you can restore the most recent object-level backups for schemas and tables.

Attempting to restore a full database using an object-level configuration file fails, resulting in this error:

Note:

```
VMart=> /tmp/vbr --config-file=Table2.ini -t restore
Preparing...
Invalid metadata file. Cannot restore.
restore failed!
```

Backup Epochs

Each backup includes the epoch to which its contents can be restored. When `vbr` restores data, Vertica updates to the current epoch.

The `vbr` utility attempts to create an object-level backup five times before an error occurs and the backup fails.

Creating Hard-Link Local Backups

Before creating a full hard-link local database backup, verify the following:

- Your database is running. All nodes need not be up in a K-safe database for `vbr` to run. However, be aware that any nodes that are DOWN are not backed up.
- The user account that starts the utility (`dbadmin` or other) has write access to the target backup directories.

When you create a full or object-level hard link local backup, that backup contains the following contents.

Backup	Catalog	Database files
Full backup	Full copy	Hard-file links to all database files
Object-level backup	Full copy	Hard-file links for all objects listed in the configuration file, and any of their dependent objects

Run the vbr script from a terminal using the database administrator account from a node in your database cluster. You cannot run the utility as root.

To create a full or object-level backup, enter the following command:

```
> /opt/vertica/bin/vbr --task backup --config fullbak.ini
```

Note: While not required, Micro Focus recommends that you first create a full backup before creating any object-level backups.

Common Errors in Specifying the Hard-Link Local Backup Location

When you specify the hard-link backup location, be sure to avoid these common errors when adding the `hardLinkLocal=True` parameter to the configuration file:

If ...	Then...	Solution
You specify a backup directory on a <i>different</i> node	vbr issues an error message and stops processing the backup.	Change the configuration file to include a backup directory on the same host and file system as the database and catalog files. Then, run the backup utility again.
You specify <i>both</i> of the following: <ul style="list-style-type: none">A backup destination directory on a <i>different</i> file system from the database and catalog files.That backup destination is on the <i>same</i> node.	vbr issues a warning message Performs backup by copying the files on the node from	No action required. No action required.

If ...	Then...	Solution
	one file system to the other.	

Creating Hard-Link Local Backups for Tape Storage

You can use hard-link local backups as a staging mechanism to backup to tape or other forms of storage media. You can also use the hard-link local backup to restore the hard file links to the database files.

The following steps present a simplified approach to saving, and then restoring, hard-link local backups from tape storage:

1. Create a configuration file using a command such as:

```
/opt/vertica/bin/vbr --setupconfig
```

2. Edit the configuration file (`localbak.ini` in this example) to include the `hardLinkLocal=True` parameter in the `[Transmission]` section.
3. Run the backup utility with the configuration file:

```
/opt/vertica/bin/vbr --task backup --config-file localbak.ini
```

4. Copy the hard-link local backup directory with a separate process (not `vbr`) to tape or other external media.
5. If the database becomes corrupted, create the directory structure that existed when you created the hard-link local backup.
6. Transfer the backup files from tape to their original backup directory.
7. Using the configuration file you used to create the hard-link local backup (Step 3), restore the database using the following command:

```
/opt/vertica/bin/vbr --task restore --config-file localbak.ini
```

When you restore from a hard-link local backup (copied from tape), `vbr` creates hard links from the backup files to the database directory, if possible. This approach saves significant disk space and time.

Creating Full Backups

Before you create a database backup, verify the following:

- You have prepared your backup directory with the [vbr -init task](#).
- Your database is running. It is unnecessary for all nodes to be up in a K-safe database. However, any nodes that are DOWN are not backed up.
- All of the backup hosts are up and available.
- The backup host (either on the database cluster or elsewhere) has sufficient disk space to store the backups.
- The user account of the user who starts the utility has write access to the target directories on the host backup location. This user can be the `dbadmin` or another assigned role. However, you cannot run the utility as root.
- Each backup has a unique file name.

Run the `vbr` script from a terminal. Use the database administrator account from an initiator node in your database cluster.

Running `vbr` Without Optional Commands

You can run the `vbr` using only its required commands:

- `--task backup`
- `--config-file config_file`

If your configuration file does not contain the database administrator password, `vbr` prompts you to enter the password. However, it does not display what you type.

The utility requires no further interaction after you invoke it.

To run the `vbr` utility:

Use the `--task backup` and `--config-file filename` directives as shown in this example:

```
[release@qco55srv01:/scratch_b/qa/vertica/QA/VT_Scenario 0]$ vbr -t backup --config $FULLBAK_CONFIG
Starting backup of database VTDB.
Participating nodes: v_vmart_node0001, v_vmart_node0002, v_vmart_node0003, v_vmart_node0004.
Snapshotting database.
Snapshot complete.
Approximate bytes to copy: 2315056043 of 2356089422 total.
[=====] 100%
Copying backup metadata.
Finalizing backup.
Backup complete!
```

By default, no output appears, other than the progress bar. To include additional progress information, use the `--debug` option, with a value between 1–3.

If the utility does not locate the configuration you specify, it searches for one at `opt/vertica/config/vbr.ini`. If no file exists, the backup fails with an error.

Best Practices for Creating Backups

When creating backup configuration files:

- Create separate configuration files to create full- and object-level backups.
- Use the same backup host directory location for both kinds of backups:
 - Because the backups share disk space, they are compatible when performing a restore.
 - Each cluster node must also use the same directory location on its designated backup host.
- For best network performance, use one backup host per cluster node.
- Use one directory on each backup node to store successive backups.
- For future reference, append the major Vertica version number to the configuration file name (`mybackup7x`).

The selected objects of a backup can include one or more schemas or tables, or a combination of both. For example, you can include schema `S1` and tables `T1` and `T2` in an object-level backup. Multiple backups can be combined into a single backup. A schema-level backup can be integrated with a database backup (and a table backup integrated with a schema-level backup, and so on).

Incremental Backups

Each time you back up your database with the same configuration file, `vbr` creates an incremental backup. This incremental backup copies new storage containers, which can include:

- Data that existed the last time you performed a database backup
- New and changed data since the last full backup

You can configure the `restorePointLimit` parameter to increase the number of stored backups.

vbr Process for Deleting Backups

Running the `vbr` utility with the `--task backup` command deletes the oldest backup. This command run whenever the total number that exist exceeds the `restorePointLimit` value in the configuration file. Suppose the `restorePointLimit = 5`, and five archives exist. In this case, running the `vbr --task backup` utility again deletes the backup with the oldest *date_timestamp*, when `vbr` completes the current backup command.

When you invoke `vbr` to create a backup:

1. The utility obtains the value of the `restorePointLimit` parameter value to determine how many backups should exist in the archive.
2. If creating the next backup exceeds the restore point limit, `vbr` deletes the oldest archived backup.
3. `vbr` continues processing and initially creates the backup on the database cluster.
4. When the new backup is complete, `vbr` copies it from the database cluster to the designated backup location.
5. After the new backup is successfully copied to the backup location, `vbr` removes the backup from the database cluster.

- [Creating Object-Level Backups](#)

Interrupting the Backup Utility

To cancel a backup, use **Ctrl+C** or send a SIGINT to the Python process running the backup utility. The utility stops the backup procedure after it has completed copying the data. Canceling a `vbr` backup with **Ctrl+C** immediately closes the session. Uninterrupted incremental backups may run more quickly as a result.

The files generated by an interrupted backup process remain in the target backup location directory. The next backup process picks up where the interrupted process left off.

Backup operations are atomic, so that interrupting a backup operation does not affect the previous backup. Vertica replaces the previous backup only as the very last step of backing up your database.

The `restore` or `copy-cluster` operations overwrite the database catalog directory. Thus, interrupting either of these processes leaves the database unusable until you restart the process and allow it to finish.

Backup and Restore Resource Allocation

Vertica allows administrators to allocate bandwidth and TCP rsync connection resources to backup and restore operations. By default, Vertica allows a single connection and unlimited bandwidth for any backup or restore operation. By changing the default allocations in your vbr configuration file, you can:

- Increase the number of available connections. If you have many Vertica files, more connections can provide a significant performance boost as each connection increases the number of concurrent file transfers.
- Assign a limit to the total amount of bandwidth that a particular operation uses. If your files are fewer and larger, additional bandwidth can provide a performance boost.

For more information, refer to the `total_bwlimit_backup`, `total_bwlimit_restore`, `concurrency_backup`, and `concurrency_restore` settings in [Configuring Advanced VBR Options](#).

Increasing Queue Transport

Each connection creates an additional process that can transport an additional queue of files. When you start a backup or restore operation, Vertica creates a list of all the files requiring transport. As a connection completes a transfer, it takes the next file on the list until the list has been completed. If any file fails to transfer, Vertica assigns that file to another process.

The `retryCount` setting in the vbr configuration file determines the number of times vbr attempts to transfer a file. If the number of failures for a particular file exceeds the limit specified in the `retryCount` setting, the entire operation fails. Vbr then terminates processing.

Bandwidth Limits

Vertica can limit its network bandwidth use through the `total_bwlimit_backup` and `total_bwlimit_restore` data transmission parameters. For more information, refer to [\[Transmission\] Data Transmission](#).

Viewing Backups

You can view backups in any of three ways:

- Use `vbr` to list the backups that reside on the local or remote backup host (requires a configuration file).
- View historical information about backups using the `DATABASE_BACKUPS` systems table. Because the `database_backups` system table contains historical information, it is not updated when you delete the backups.
- Open the `vbr` log file to check the status of a backup. The log file resides on the node where you have run `vbr`, in the directory specified by the [tempDir vbr configuration parameter](#). The default name of this directory is `/tmp/vbr`.

List Backups with `vbr`

To list backups on the backup hosts, use `vbr --task listbackup` with a specific configuration file. The following example shows how you can list backups, using a full backup configuration file, `bak.ini`:

```
dbadmin@doch01 ~]$ vbr --task listbackup --config-file /home/dbadmin/bak.ini
```

The `vbr` output information includes the following:

- `backup` — The name of the generated backup. Vertica names the backup by combining the name of the `vbr` configuration file with a timestamp. Use the timestamp to identify an archive when you perform a restore.
- `backup_type` — The type of the backup, either full or object.
- `epoch` — The epoch when the backup was created.
- `objects` — The objects being backed up. For a full backup, this field is blank.
- `nodes (hosts)` — The hosts that received the backup and the database node names that provided the backups.

- `file_system_type` — The storage location file system of the Vertica hosts that comprise this backup, either Linux or HDFS. For information on backing up HDFS hosts, refer to [Backing Up HDFS Storage Locations](#) .

The following example shows a list of full backups of a three node cluster to a single backup host, bkhost.

```

backup          backup_type epoch  objects  nodes (hosts)
                file_system_type
bak_20160414_134452  full      749      (bkhost), v_vmart_node0003(bkhost) [Linux]
bak_20160413_174544  full      659      (bkhost), v_vmart_node0003(bkhost) [Linux]

```

Note: The `listbackup` task fails if you attempt to view backups on a cluster without a database when the backups were made to local hosts using the [\[\] shortcut](#). `vbr` requires a database to provide the location of the mapped local host.

Viewing All Backups in a Location

You can use the `--list-all` parameter with the `listbackup` task to view a list of all the snapshots stored on the hosts and paths listed in the specified configuration file.

```
dbadmin@doca01 ~]$ vbr --task listbackup --list-all --config-file /home/dbadmin/Nightly.ini
```

The following example shows a `--list-all` task using the configuration file `Nightly.ini`. That configuration file references the hosts `doca01`, `doca02`, and `doca03` and the path `/vertica/backup`. The output shows that these locations contain not just the backups created using `Nightly`, but also backups created using a configuration file called `Weekly.ini`.

```

backup          backup_type epoch  objects  nodes(hosts)
                file_system_type
Weekly_20170508_183249  full      3449      vmart_1(doca01), vmart_2(doca01), vmart_3
(doca01) [Linux]
Weekly_20170508_182816  full      2901      vmart_1(doca01), vmart_2(doca02), vmart_3
(doca03) [Linux]
Weekly_20170508_182754  full      2649      vmart_1(doca01), vmart_2(doca02), vmart_3
(doca03) [Linux]
Nightly_20170508_183034  object    1794      sales_schema vmart_1(doca01), vmart_2(doca02), vmart_3
(doca03) [Linux]
Nightly_20170508_181808  object    1469      sales_schema vmart_1(doca01), vmart_2(doca02), vmart_3
(doca03) [Linux]
Nightly_20171117_193906  object    173       sales_schema vmart_1(doca01), vmart_2(doca02), vmart_3
(doca03) [Linux]

```

You can also use the the `--json` and `--list-output-file` parameters with the `listbackup` task to output the same content in JSON delimited format to a display or to an output file. For more information, refer to [VBR Utility Reference](#).

Query database_backups

Use the following query to list historical information about backups. The `objects` column lists which objects were included in object-level backups. Do not use the `backup_timestamp` value when restoring an archive. Instead, Use the values provided by `vbr --task listbackup`, when restoring an archive.

```
VMart=> SELECT * FROM v_monitor.database_backups;
-[ RECORD 1 ]-----+-----

- [DATABASE_BACKUPS](#)

Estimating Log File Disk Requirements

When you run the `vbr --setupconfig` command to create the configuration file and configure advanced parameters, one of the parameters is `tempDir`. This parameter specifies the database host location where `vbr` writes its log files and some other temp files (of negligible size). The default location is the `/tmp/vbr` directory on each database host. You can change the default location by specifying a different path in the configuration file.

The temporary storage directory also contains local log files describing the progress, throughput, and any errors encountered for each node. Each time you run `vbr`, the script creates a separate log file, each named with a timestamp. When using default settings, the log file typically uses about 4KB of space per node per backup.

The `vbr` log files are not removed automatically, so you must delete older log files manually, as necessary.

Checking Backup Integrity

Vertica can confirm the integrity of your backup files and the manifest that identifies them. By default, backup integrity checks output their results to the command line.

Perform a Quick Check

A *quick check* gathers all backup metadata from the backup location specified in the configuration file and compares that metadata to the backup manifest. A quick check does not verify the objects themselves. Instead, this task outputs an exceptions list of any discrepancies between objects in the backup location and objects listed in the backup manifest.

Use the following form to perform quick check task:

```
vbr -t quick-check -c configfile.ini
```

For example:

```
vbr -t quick-check -c backupconfig.ini --report-file=logging/quickintegritycheck.json
```

Perform a Full Check

A *full check* verifies all objects listed in the backup manifest against file system metadata. A full check includes the same steps as a quick check. You can include the optional `--report-file` parameter to output results to a delimited JSON file. This task outputs an exceptions list that identifies the following inconsistencies:

- Incomplete restore points
- Damaged restore points
- Missing backup files
- Unreferenced files

Use the following form to perform a full check task:

```
vbr -t full-check -c configfile.ini --report-file=path/filename
```

For example:

```
vbr -t full-check -c backupconfig.ini --report-file=logging/fullintegritycheck.json
```

Repairing Backups

Vertica can reconstruct backup manifests and remove unneeded backup objects. You can include the optional `--report-file` parameter to output results to a delimited JSON file.

Performing a Quick Repair

The `quick-repair` task rebuilds the backup manifest, based on the manifests contained in the backup location.

Use the following form to perform a quick repair task:

```
vbr -t quick-repair -c configfile.ini
```

Performing Garbage Collection

The `collect-garbage` task rebuilds your backup manifest and deletes any backup objects that do not appear in the manifest. You can include the optional `--report-file` parameter to output results to a delimited JSON file.

Use the following form to perform a garbage collection task:

```
vbr -t collect-garbage -c configfile.ini --report-file=path/filename
```

Removing Backups

You can remove existing backups and restore points using the `vbr` utility. When you use the `vbr` task, `remove`, Vertica updates the manifests affected by the removal and maintains their integrity. If the backup archive contains multiple restore points, removing one does not affect the others. When you remove the last restore point, Vertica removes the backup entirely.

Note: Vertica does not support removing backups through the file system.

To remove a backup or a restore point, use the `vbr` task `remove`. Specify this task in the following form:

```
vbr -t remove -c configfile.ini --archive timestamp
```

You can remove multiple restore points using the `archive` parameter. To obtain the timestamp for a particular restore point, [use the `listbackup` task](#).

- To remove multiple restore points, use a comma separator:
`--archive="restore_point1, restore_point2"`
- To remove an inclusive range of restore points, use a colon:
`--archive="restore_point1: restore_point2"`
- To remove all restore points, specify an archive value of `all`:
`--archive="all"`

The following example shows how you can remove a restore point from an existing backup.

```
[dbadmin@doch01 ~]$ vbr -t remove -c backup.ini --archive 20160414_134452  
Removing restore points: 20160414_134452  
Remove complete!
```

Upgrading Pre-7.2 Backups

In version 7.2 and later, Vertica no longer relies on hard links to perform backups. As a result, pre-7.2 backups are not compatible with later Vertica versions. To resolve this issue, `vbr` includes the `vbr` task `7.2_upgrade`. This task copies an existing pre-7.2 backup and creates a 7.2.x-compatible version of it.

Note: Micro Focus recommends that you run this task before performing the first backup of the upgraded database.

To upgrade a backup:

1. Specify the `vbr` task `7.2_upgrade` in the following form:

```
vbr -t 7.2_upgrade --old-config-file outdated-configfile.ini -c new-configfile.ini
```

2. Verify that the `snapshotName` parameter is the same in the old and new configuration files.

The new configuration file assigns new backup locations for the upgraded backup. This approach preserves the existing backup so you can continue to perform incremental backups on the upgraded backup. After the upgrade is complete, Vertica no longer requires the old configuration file.

Using HardFile Link Local Backups

You can use the `vbr` utility `hardLinkLocal` option to create a full- or object-level backups with hard file links on a local database host.

Creating hard-link local backups can provide the following advantages over a remote host backup:

- **Speed** — Hard link local backups are significantly faster than a remote host backup. When backing up, `vbr` does not copy files if the backup directory exists on the same file system as

the database catalog and data directories.

- Reduced network activities — The hard-link local backup minimizes network load because it does not require rsync to copy files to a remote backup host.
- Less disk space — The backup includes a copy of the catalog and hard file links. Therefore, the local backup uses significantly less disk space than a backup with copies of database data files. However, a hard-link local backup saves a full copy of the catalog each time you run `vbr`. Thus, the disk size increases with the catalog size over time.

Hard-link local backups can help you during experimental designs and development cycles. Database designers and developers can create hard-link local object backups of schemas and tables on a regular schedule during design and development phases. If any new developments are unsuccessful, developers can restore one or more objects from the backup.

Note: Running `vbr` does not affect active database applications. The `vbr` utility supports creating backups while concurrently running applications that execute DML statements, including `COPY`, `INSERT`, `UPDATE`, `DELETE`, and `SELECT`.

Planning Hard-Link Local Backups

If you plan to use hard-link local backups as a standard site procedure, design your database and hardware configuration appropriately. Consider storing all of the data files on one file system per node. Such a configuration has the advantage of being automatically set up for hard-link local backups. However, be aware that using one file system per node to support hard-link local backups does preclude the use of external storage locations on separate file systems.

Specifying Backup Directory Locations

The `backupDir` parameter of the configuration file specifies the location of the top-level backup directory. Hard-link local backups require that the backup directory be located on the same Linux file system as the database data and catalog files. The Linux operating system cannot create hard file links to another file system.

Do not create the hard-link local backup directory in a database data storage location. For example, as a best practice, the database data directory should not be at the top level of the file system, as it is in the following example:

```
/home/dbadmin/data/VMart/v_vmart_node0001
```

Instead, Micro Focus recommends adding another subdirectory for data above the database level, such as in this example:

```
/home/dbadmin/data/dbdata/VMart/v_vmart_node0001
```

You can then create the hard-link local backups subdirectory as a peer of the data directory you just created, such as in this example:

```
/home/dbadmin/data/backups  
/home/dbadmin/data/dbdata
```

Hard-Link Local Backups in Disaster Recovery

Hard-link local backups are only as reliable as the disk on which they are stored. If the local disk becomes corrupt, so does the hard link local backup. In this case, you are unable to restore the database from the hard-link local backup because it is also corrupt.

All sites should maintain full backups externally for disaster recovery because hard-link local backups do not actually copy any database files.

Related Tasks

- [Creating Hard-Link Local Backups](#)

Configuring Hard-Link Local Backup Hosts

When specifying the `backupHost` parameter for your hard link local configuration files, use the database host names (or IP addresses) as known to `admintools`. Do not use the node names. Host names (or IP addresses) are what you used when setting up the cluster. Do not use `localhost` for the `backupHost` parameter.

Listing Host Names

To query node names and host names:

```
VMart=> select node_name, host_name from node_resources;  
node_name      | host_name
```

```
-----+-----  
v_vmart_node0001 | 192.168.223.11  
v_vmart_node0002 | 192.168.223.22  
v_vmart_node0003 | 192.168.223.33  
(3 rows)
```

Because you are creating a local backup, use square brackets [] to map the host to the local host. For more information, refer to [\[Mapping\]](#).

```
[Mapping]  
v_vmart_node0001 = [ ]:/home/dbadmin/data/backups  
v_vmart_node0002 = [ ]:/home/dbadmin/data/backups  
v_vmart_node0003 = [ ]:/home/dbadmin/data/backups
```

Restoring Object-Level Backups

To restore an object-level backup to the database from which it was taken, the database must be UP. The vbr configuration file you use for the restore task specifies the backup to restore.

You can specify how Vertica reacts to duplicate objects by configuring the `objectRestoreMode` setting in your vbr configuration file.

Restoring Objects to a Changed Cluster

Unlike restoring from a full database backup, vbr supports restoring object-level backups after adding nodes to the cluster. Any nodes that were not in the cluster when you created the object-level backup do not participate in the restore. You can rebalance your cluster after the restore to distribute data among the new nodes.

You cannot restore an object-level backup after removing nodes, altering node names, or changing IP addresses. Trying to restore an object-level backup after such changes causes vbr to fail and display this message:

```
Preparing...  
Topology changed after backup; cannot restore.  
restore failed!
```

Projection Epoch After Restore

All object-level backup and restore events are treated as DDL events. If a table does not participate in an object-level backup, possibly because a node being down, restoring the

backup affects the projection in the following ways:

- Its epoch is reset to 0.
- It must recover any data that it does not have by comparing epochs and other recovery procedures.

Catalog Locks During Backup Restore

As with other databases, Vertica transactions follow strict locking protocols to maintain data integrity.

When restoring an object-level backup into a cluster that is UP `vbr` begins by copying data and managing storage containers. If necessary, `vbr` splits the containers. This process does not require any database locks.

After completing data copying tasks, `vbr` first requires a table object lock (O-lock) and then a global catalog lock (GCLX).

Sometimes, other database operations, such as DML statements, are in progress when the process attempts to get an O-lock on the table. In such cases, `vbr` is blocked from progress until the DML statement completes and releases the lock. After securing an O-lock first, and then a GCLX lock, `vbr` blocks other operations that require a lock on the same table.

To guarantee catalog consistency, processes can hold a GCLX for a minimal duration. When the restore locks are in effect, any concurrent table modifications are blocked until both locks are released. Database system operations, such as the Tuple Mover (TM) transferring data from memory to disk, are canceled to permit the object-level restore to complete.

Catalog Restore Events

Each object-level backup includes a section of the database catalog, called a *snippet*. A snippet contains the selected objects, their dependent objects, and principal objects. A catalog snippet is similar in structure to the database catalog but consists of a subset representing the object information. Objects being restored can be read from the catalog snippet and used to update both global and local catalogs.

Each object from a restored backup is updated in the catalog. If the object no longer exists, `vbr` drops the object from the catalog. Any dependent objects that are not in the backup are also dropped from the catalog.

The `vbr` utility uses existing dependency verification methods to check the catalog and adds a restore event to the catalog for each restored table. That event also includes the epoch at

which the event occurred. If a node misses the restore table event, it recovers projections anchored on the given table.

Catalog Size Limitations

Object level restores can fail if your catalog size is greater than five percent of the total memory available in the node performing the restore. In this situation, Micro Focus recommends restoring individual objects from the backup. For more information, refer to [Restoring Individual Objects from a Full or Object-Level Backup](#).

Related Tasks

- [Creating Object-Level Backups](#)
- [Restoring Full Database Backups](#)
- [Ownership of Restored Objects](#)

Restoring Full Database Backups

To restore a full database backup, you must verify that:

- The database is DOWN. You cannot restore a full backup when the database is running.
- All of the backup hosts are UP and available.
- The backup directory exists and contains the backups from which to restore the data.

- The cluster to which you are restoring the backup has:
 - The same number of hosts as the one used to create the backup
 - Identical node names
- The target database must already exist on the cluster to which you are restoring data.
 - Database can be completely empty, without any data or schema.
 - The database name must match the name in the backup
 - All of the node names in the database must match the names of the nodes in the configuration file.
- The user performing the restore is the database administrator.

You can use only a full database backup to restore a complete database. If you have saved multiple backup archives, you can restore from either the last backup or a specific archive.

Restoring from a full database backup injects the OIDs from each backup into the restored catalog of the full database backup. The catalog also receives all archives. Additionally, the OID generator and current epoch are set to the current epoch.

Restoring the Most-Recent Backup

To perform a full database restore, the cluster must be DOWN. Usually, when a node or cluster is DOWN, you want to return the cluster to its most-recent state. Doing so requires restoring a full database backup. You can restore any full database backup from the archive by identifying the name in the configuration file.

To restore from the most recent backup, use the configuration file used to create the backup, specifying `vbr` with the `--task restore`. If your [password configuration file](#) does not contain the database superuser password, the utility prompts you to enter it at run time.

The following example shows how you can use the `db.ini` configuration file for restoration:

```
> vbr --task restore --config-file db.ini
Copying...
1871652633 out of 1871652633, 100%
All child processes terminated successfully.
restore done!
```

You can restore a backup only to the database from which it was taken.

Restoring an Archive

If you saved multiple backups, you can specify a specific archive to restore. To list the archives that exist to choose one to restore, use the `vbr --listbackup` task, with a specific configuration file.

To restore from one of several archives:

Log in using the database administrator's account.

Invoke the utility with the `--task restore` command:

- Include the configuration file with which you created the backup.
- Next, add the file name with the `--archive` parameter with the *date_timestamp* suffix of the directory name, which identifies the archive to restore.

For example:

```
> vbr --task restore --config-file fullbak.ini --archive=20121111_205841
```

The `vbr` utility restores the backup.

The `--archive` parameter identifies the archive created on 11-11-2012 (`_archive20121111`), at time 205841 (20:58:41). You need specify only the `_archive` suffix, because the configuration file identifies the backup name of the subdirectory, and the OID identifier indicates the backup is an archive.

Full Backup Restore to an Alternate Cluster

Vertica supports restoring a full backup to an alternate cluster.

Requirements for Restoring to an Alternate Cluster

The process is similar to the process for [Restoring Full Database Backups](#), with the following additional requirements.

The destination database must:

- Be DOWN.
- Share the same name as the source database.
- Have the same number of nodes as the source database.
- Have the same names as the source nodes.
- Use the same catalog directory location as the source database.
- Use the same port numbers as the source database.
- Contain the same standby nodes as the backup.

Restore a Full Backup to an Alternate Cluster

1. Copy the [vbr configuration file](#) that you used to create the backup to any node on the destination cluster.
2. If you are using a [stored password](#), copy the password configuration file to the same location as the vbr configuration file.
3. From the destination node, issue a vbr restore command, such as:

```
vbr -t restore -c full.ini
```
4. After the restore has completed, [start the restored database](#).

Restoring Individual Objects from a Full or Object-Level Backup

You can copy individual tables or schemas from any backup that contains those objects without restoring the entire backup. This option is useful if you only need to restore a few objects and want to avoid the overhead of a larger scale restore. Your database must be running, and your nodes must be UP to restore individual objects.

To restore individual objects, the source backup must be from the same version of Vertica as the destination database. Vertica does not support individual object restore across different versions.

When you restore an object, Vertica does not automatically restore any dependent objects. For example, if you restore a schema containing views, Vertica does not automatically restore the tables corresponding to those views.

You can specify how Vertica reacts to duplicate objects by configuring the `objectRestoreMode` setting in your `vbr` configuration file.

Restoring an Object from the Most-Recent Backup

To restore individual objects from the most recent backup, you use the `vbr` utility, just as you did to create the backup. Execute the command using the following form:

```
vbr --task=restore --config-file=filename --restore-objects=objectname,objectname
```

To restore an object, log in using the database administrator's account. You cannot run the utility as root.

To restore from the most recent backup, use the configuration file used to create the backup, specifying the restore `vbr` task. Be sure to include the `--restore-objects` parameter and the names of the objects that you want to restore. Identify tables by fully qualified `schema.name`. To restore multiple objects, use a comma as a delimiter.

If your configuration file does not contain the database superuser password, the `vbr` utility prompts you to enter it at run time.

The following example uses the `db.ini` configuration file, which includes the database administrator's password:

```
> vbr --task restore --config-file=db.ini --restore-objects=saleschema,public.sales_
table,public.customer_info
Preparing...
Found Database port: 5433
Copying...
[=====] 100%
All child processes terminated successfully.
All extract object child processes terminated successfully.
Copying...
[=====] 100%
All child processes terminated successfully.
restore done!
```

Restoring an Object from an Archive

To restore individual objects from a specific archive, you use the same `vbr` utility that you used to create the backup. The command takes the following form:

```
> vbr --task=restore --config-file=filename --archive=date_time --restore-
objects=objectname,objectname
```

Invoke the utility with the `--task restore` command, the configuration file with which you created the backup. Next, add the `--archive` parameter with the *date_timestamp* suffix of the directory name to identify which archive to restore.

The `--archive` parameter identifies the archive subdirectory, including date and time. For example, `_archive20121111_205841` was created on date 11-11-2012 at time 20:58:41. You need specify only the `date_time` suffix because the configuration `.ini` file identifies the backup name of the subdirectory. Additionally, the OID identifier indicates the backup is an archive.

For example:

```
> vbr --task restore --config-file fullbak.ini --archive=20121111_205841 --restore-
objects=salesdb.contacts
```

The `vbr` utility restores the backup.

Restoring Hard-Link Local Backups

Before attempting a hard-link local backup, you must be aware of issues around restoring from this type of backup, whether full or object level.

Process for Restoring Full and Object-Level Hard Link Local Backups

If you have created both full and object-level backups and the database fails, restore the backups in this order:

1. Restore the full database backup.
2. Restore from any object-level backups.

Transferring Backups to and from Remote Storage

When a full hard-link local backup exists, you can use a utility (other than `vbr`) to transfer the backup to another storage media, such as tape. Transferring hard-link local backups to another storage media may copy the data files associated with the hard file links.

You can use a different directory when you return the backup files to the hard-link local backup host. However, you must also change the `backupDir` parameter value in the configuration file before restoring the backup.

Complete the following steps to restore hard link local backups from external media:

1. If the original backup directory no longer exists on one or more local backup host nodes, re-create the directory.

The directory structure into which you restore hard link backup files must be identical to

what existed when the backup was created. For example, if you created hard-link local backups at the following backup directory, you can then re-create that directory structure:

```
/home/dbadmin/backups/localbak
```

2. Copy the backup files to their original backup directory, as specified for each node in the configuration file. For more information, refer to [\[Mapping\]](#).
3. Restore the backup, using one of three options:

- a. To restore the latest version of the backup, move the backup files to the following directory:

```
/home/dbadmin/backups/localbak/node_name/snapshotname
```

- b. To restore a different backup version, move the backup files to this directory:

```
/home/dbadmin/backups/localbak/node_name/snapshotname_archivedate_timestamp
```

4. When the backup files are returned to their original backup directory, use the original configuration file to invoke vbr as follows:

```
>/opt/vertica/bin/vbr --task restore --config-file localbak.ini
```

5. Confirm that the backup has succeeded. Verify that:
 - The physical files are restored from tape into the correct directories.
 - You are using the configuration file that specifies `hardLinkLocal = true`.

Note: You can use a different directory when you return the backup files to the hard-link local backup host. However, you must also change the `backupDir` parameter value in the configuration file before restoring the backup.

Ownership of Restored Objects

When performing a restore, Vertica inserts data into existing database objects. By default, the restore does not affect the ownership, storage policies, or permissions of the restored objects. If, however, the restored object does not currently exist, Vertica re-creates it. In this situation,

the restored object is owned by the user (DBADMIN) performing the restore. Vertica does not restore dependent grants, roles, or client authentications with restored objects.

If the storage policies of a restored object are not valid, vbr applies the default storage policy. Restored storage policies can become invalid due to HDFS storage locations, table incompatibility, and unavailable min-max values at restore time.

Sometimes, Vertica encounters a catalog object that it does not need to restore. When this situation occurs Vertica generates a warning message for that object and the restore continues.

Examples

Suppose you have a full backup, including Schema1, owned by the user, Alice. Schema1 contains Table1, owned by Bob, who eventually passes ownership to Chris. The user dbadmin performs the restore. The following scenarios might occur that affect ownership of the schema:

Scenario 1:

Schema1.Table1 has been dropped at some point since the backup was created. When dbadmin performs the restore, Vertica re-creates Schema1.Table1. As the user performing the restore, dbadmin takes ownership of Schema1.Table1. Because Schema1 still exists, Alice retains ownership of the schema.

Scenario 2:

Schema1 is dropped, along with all contained objects. When dbadmin performs the restore, Vertica re-creates the schema and all contained objects. Dbadmin takes ownership of Schema1 and Schema1.Table1.

Scenario 3:

Schema1 and Schema1.Table1 both exist in the current database. When the user, dbadmin, rolls back to an earlier backup, the ownership of the objects remains unchanged. Alice owns Schema1 and Bob owns Schema1.Table1.

Scenario 4:

Schema1.Table1 exists and dbadmin wants to roll back to an earlier version. In the time since the backup was made, ownership of Schema1.Table1 has changed to Chris. When dbadmin restores Schema1.Table1, Alice remains owner of Schema1 and Chris remains owner of Schema1.Table1. The restore does not revert ownership of Schema1.Table1 from Chris to Bob.

Restoring Data When Node Type Is Not Permanent

The only node type on which Vertica supports data restoration is Permanent. You cannot restore data on the remaining node types:

- Ephemeral
- Execute
- Standby

To restore or replicate to these nodes, you must first change the [destination node type](#) to PERMANENT.

For more information, refer to [Setting Node Type](#).

Copying the Database to Another Cluster

You can use the `vbr` utility to copy the entire database to another Vertica cluster. This feature helps you perform tasks such as copying a database between a development and a production environment. Copying your database to another cluster is essentially a simultaneous backup and restore operation. The data is backed up from the source database cluster and restored to the destination cluster in a single operation.

Note: The `copycluster` task is not compatible with HDFS Storage Locations. `Copycluster` uses the Linux `rsync` command to copy files from the source cluster to the target cluster. HDFS storage backup and restore is based on use of snapshots. Data in an HDFS storage location is backed up to HDFS itself. Vertica cannot transfer data to a remote HDFS cluster the same way that it can for a Linux cluster.

The directory locations for the Vertica catalog, data, and temp directories must be identical on the source and target database. Use the following `vsql` query to view the source database directory locations. This example sets expanded display, for illustrative purposes, and lists the columns of most interest, `node_name`, `storage_path`, and `storage_usage`.

```
VMart=> \x  
Expanded display is on.
```

```
VMart=> select node_name,storage_path, storage_usage from disk_storage;
-[ RECORD 1 ]-+-----
node_name      | v_vmart_node0001
storage_path   | /home/dbadmin/VMart/v_vmart_node0001_catalog/Catalog
storage_usage  | CATALOG
-[ RECORD 2 ]-+-----
node_name      | v_vmart_node0001
storage_path   | /home/dbadmin/VMart/v_vmart_node0001_data
storage_usage  | DATA,TEMP
-[ RECORD 3 ]-+-----
node_name      | v_vmart_node0001
storage_path   | home/dbadmin/SSD/schemas
storage_usage  | DATA
-[ RECORD 4 ]-+-----
node_name      | v_vmart_node0001
storage_path   | /home/dbadmin/SSD/tables
storage_usage  | DATA
-[ RECORD 5 ]-+-----
node_name      | v_vmart_node0001
storage_path   | /home/dbadmin/SSD/schemas
storage_usage  | DATA
-[ RECORD 6 ]-+-----
node_name      | v_vmart_node0002
storage_path   | /home/dbadmin/VMart/v_vmart_node0002_catalog/Catalog
storage_usage  | CATALOG
-[ RECORD 7 ]-+-----
node_name      | v_vmart_node0002
storage_path   | /home/dbadmin/VMart/v_vmart_node0002_data
storage_usage  | DATA,TEMP
-[ RECORD 8 ]-+-----
node_name      | v_vmart_node0002
storage_path   | /home/dbadmin/SSD/tables
storage_usage  | DATA
.
.
.
```

Notice the directory paths for the Catalog, Data, and Tempstorage. These paths are the same on all nodes in the source database and must be the same in the target database.

Note: When copying a database to another cluster, if the target data is different, `vbr` overwrites all existing data. To retain existing data on the target cluster, create a full database backup of the target before invoking the `copycluster vbr` task.

Identifying Node Names for Target Cluster

Before you can configure the target cluster, you need to know the exact names that `adminTools` supplied to all nodes in the source database.

To see the node names, run a query such as:

```
VMart=> select node_name from nodes;
  node_name
-----
v_vmart_node0001
v_vmart_node0002
v_vmart_node0003
(3 rows)
```

You can also find the node names by running `Admintools` from the command line. For example, for the VMart database, you can enter a command such as:

```
$ /opt/vertica/bin/admintools -t node_map -d VMART
DATABASE | NODENAME          | HOSTNAME
-----
VMART    | v_vmart_node0001 | 192.168.223.xx
VMART    | v_vmart_node0002 | 192.168.223.yy
VMART    | v_vmart_node0003 | 192.168.223.zz
```

Configuring the Target Cluster

Configure the target to allow the source database to connect to it and restore the database. The target cluster must:

- Have the same number of nodes the source cluster.
- Have a database with the same name as the source database. The target database can be completely empty.
- Have the same node names as the source cluster. The nodes names listed in the `NODES` system tables on both clusters must match.
- Be accessible from the source cluster.
- Have the same database administrator account, and all nodes must allow a database administrator of the source cluster to login through SSH without a password.

Note: Passwordless access *within* the cluster is not the same as passwordless access *between* clusters. The SSH ID of the administrator account on the source cluster and the target cluster are likely not the same. You must configure each host in the target cluster to accept the SSH authentication of the source cluster.

- Have adequate disk space for the `vbr --task copycluster` command to complete.

Creating a Configuration File for CopyCluster

You must create a configuration file specifically for copying your database to another cluster. In the configuration file, specify the host names of nodes in the target cluster as the backup hosts. When you use the `copycluster` command, the `vbr` requires that you define the `backupHost`. However, the `vbr` ignores the `backupDir` option, and always stores the data in the catalog and data directories of the target database.

You cannot use an object-level backup with the `copycluster` command. Instead, you must perform a full database backup.

The following example shows how you can set up the `vbr` to copy a database on a 3-node cluster, `v_vmart`, to another cluster, `test-host`.

```
[Misc]
snapshotName = CopyVmart
restorePointLimit = 5
tempDir = /tmp/vbr
retryCount = 5
retryDelay = 1

[Database]
dbName = vmart
dbUser = dbadmin
dbPassword = password
dbPromptForPassword = False

[Transmission]
encrypt = False
checksum = False
port_rsync = 50000

[Mapping]
; backupDir is not used for cluster copy
v_vmart_node0001= test-host01
v_vmart_node0002= test-host02
v_vmart_node0003= test-host03
```

Copying the Database

You must stop the target cluster before you invoke `copycluster`.

To copy the cluster, run `vbr` from a node in the source database using the database administrator account. The following example demonstrates how you can copy a cluster using a configuration file located in the current directory.

```
$ vbr -t copycluster -c copycluster.ini
Starting copy of database VMART.
Participating nodes: vmart_node0001, vmart_node0002, vmart_node0003, vmart_node0004.
Enter vertica password:
Snapshotting database.
Snapshot complete.
Determining what data to copy.

Replicating Tables and Schemas to an Alternate Database

You can replicate Vertica tables and schemas from one database to alternate databases in your organization. Using this strategy helps you:

- Replicate objects to a secondary site.
- Copy tables and schemas between test, staging, and production clusters that have the same number of database nodes.

Important: The `vbr replicate` task does not support copying an entire database; use the `copycluster` task to replicate an entire database.

Advantages of Alternate Database Replication

Replicating objects is generally faster than exporting and importing objects. As with Vertica backup and restore, object replication is incremental. The first replication of an object

replicates the entire object. Subsequent replications copy only data that has changed since the last replication. Vertica replicates data as of the current epoch on the target database. Used with a cron job, you can replicate key objects to create a backup database.

In situations where the target database is down, or you plan to replicate the entire database, Micro Focus recommends that you try [Copying the Database to Another Cluster](#)

Catalog Size Limitations

Object level restores can fail if your catalog size is greater than five percent of the total memory available in the node performing the restore. In this situation, Micro Focus recommends restoring individual objects from the backup. For more information, refer to [Restoring Individual Objects from a Full or Object-Level Backup](#).

How DOWN Nodes Affect Replication

The effect of DOWN nodes on a replication task depends on whether they are present in the source or destination database.

Location	Effect on Replication
DOWN source nodes	Vertica can replicate objects from a source database containing DOWN nodes. If nodes in the source database are DOWN, set the corresponding nodes in the target database to DOWN as well.
DOWN destination nodes	Vertica can replicate objects when the destination database has DOWN nodes. If nodes in the destination database are DOWN, you must exclude the corresponding source database nodes using the <code>vbr --nodes</code> parameter.

Replication to Alternate Database Process Flow

To replicate objects to an alternate database, begin in the SOURCE database and complete the following process:

1. Verify Replication Requirements
2. Edit Your vbr Configuration File

3. Replicate Objects
4. Monitor Object Replication

Verify Replication Requirements

To replicate objects to an alternate database, verify that your source and target databases meet the following requirements.

Both the source and target databases must:

- Have the same Linux user associated with the dbadmin account on both the source and target databases.
- Be UP.
- Have the same number of nodes.
- Have the same exact version of Vertica.
- All nodes allowing a database administrator of the source cluster to login through SSH without a password.

Note: Passwordless access *within* the cluster is not the same as passwordless access *between* clusters. The SSH ID of the administrator account on the source cluster and the target cluster are likely not the same. You must configure each host in the target cluster to accept the SSH authentication of the source cluster.

Edit Your vbr Configuration File for Replication

The default configuration file that vbr creates does not contain all of the settings necessary to replicate objects to an alternate cluster.

Add the following parameters to the configuration file that you are using to replicate objects:

1. In the [\[Misc\] section](#) of your vbr configuration file, add the following parameter:

```
; Identify the objects that you want to replicate  
objects = schema.objectName
```

2. In the [\[Database\] section](#) of your vbr configuration file, add the following parameters:

```
; parameters used to replicate objects between databases
dest_dbName =
dest_dbUser =
dest_dbPromptForPassword =
```

If you are using a stored password, be sure to configure the `dest_dbPassword` parameter in your [Password Configuration File Reference](#).

3. In the [\[Mapping\] section](#), map your source nodes to your target hosts:

```
[Mapping]
v_source_node0001 = targethost01
v_source_node0002 = targethost02
v_source_node0003 = targethost03
```

Replicate Objects

To replicate objects, use the vbr task `replicate`. Specify this task in the following form:

```
vbr -t replicate -c configfile.ini
```

Monitor Object Replication

You can monitor object replication the following ways:

- Viewing vbr logs on the source database
- Checking database logs on the source and destination databases
- Querying [V_MONITOR.REMOTE_REPLICATION_STATUS](#) on the source database

Troubleshooting Backup and Restore

These tips can help you avoid issues related to backup and restore with Vertica and to troubleshoot any problems that occur.

Object Replication Fails

Confirm that you have excluded all DOWN nodes from your object replication.

If you do not exclude the DOWN node, replication fails with the following error:

```
Error connecting to a destination database node on the host <hostname>  
: <error> ...
```

Recovering the Database

Recovering a database can consist of any of the following:

- [Restarting Vertica on a host](#)
- [Restarting the Database](#)
- [Recovering the Cluster From a Backup](#)
- [Replacing Failed Disks](#)
- [Copying the Database to Another Cluster](#)
- [Exporting a Catalog](#) for support purposes
- [Recovering a node on a per-table basis](#)

You can [monitor a recovery](#) in progress by viewing log messages posted to the `vertica.log` file on each host.

See Also

- [Failure Recovery](#)

Failure Recovery

Vertica can restore the database to a fully functional state after one or more nodes in the system experiences a software- or hardware-related failure. Vertica recovers nodes by querying replicas of the data stored on other nodes. For example, a hardware failure can cause a node to lose database objects or to miss changes made to the database (INSERTs, UPDATEs, and so on) while offline. When the node comes back online, queries other nodes in the cluster to recover lost objects and catch up with database changes.

K-safety sets fault tolerance for the database cluster, where K can be set to 0, 1, or 2. The value of K specifies how many copies Vertica creates of [segmented projection](#) data. If K-safety for a database is set to 1 or 2, Vertica creates K+1 instances, or *buddies*, of each projection segment. Vertica distributes these buddies across the database cluster, such that projection data is protected in the event of node failure. If any node fails, the database can continue to process

queries so long as buddies of data on the failed node remain available elsewhere on the cluster.

Note: You can monitor the cluster state through the **View Database Cluster** state menu option.

Recovery Scenarios

Vertica begins the database recovery process when you restart failed nodes or the database. The mode of recovery for a K-safe database depends on the type of failure:

- One or more nodes in the database failed, but the database continued to operate.
- The database shut down cleanly.
- The database shut down uncleanly.

In the first two cases, node recovery is automatic; in the third case (unclean shutdown), recovery requires manual intervention by the database administrator. The following sections discuss these cases in greater detail.

Recovery of failed nodes

One or more nodes failed but the remaining nodes in the database filled in for them, so database operations continued without interruption. Use [Administration Tools](#) to restart failed nodes through the [Restart Vertica on Host](#) option. While restarted nodes recover their data from other nodes, their status is set to RECOVERING. Except for a short period at the end, the recovery phase has no effect on database transaction processing. After recovery is complete, the restarted nodes status changes to UP.

Recovery after clean shutdown

The database was shut down cleanly through Administration Tools. To restart the database, use the [Start Database](#) option. On restart, all nodes whose status was UP before the shutdown resume a status of UP. If the database contained one or more failed nodes on shutdown and they are now available, they begin the recovery process as described above.

Recovery after unclean shutdown

Reasons for unclean shutdown include:

- A critical node failed, leaving part of the database's data unavailable.
- A site-wide event such as a power failure causes all nodes to reboot.
- Vertica processes on the nodes exited due to a software or hardware failure.

Unclean shutdown can put the database in an inconsistent state—for example, Vertica might have been in the middle of writing data from WOS to disk at the time of failure, and this process was left incomplete. When you restart the database through the Administration Tools, Vertica determines that normal startup is not possible and uses the Last Good Epoch to determine when data was last consistent on all nodes. When you restart the database, Vertica prompts you to accept recovery with the suggested epoch. If accepted, the database recovers and all data changes after the Last Good Epoch are lost. If not accepted, startup is aborted.

Instead of accepting the recommended epoch, you can [recover from a backup](#). You can also choose an epoch that precedes the Last Good Epoch, through the Administration Tools Advanced Menu option Roll Back Database to Last Good Epoch. This is useful in special situations—for example the failure occurs during a batch of loads, where it is easier to restart the entire batch, even though some of the work must be repeated. In most cases, you should accept the recommended epoch.

Epochs and Node Recovery

The checkpoint epoch (CPE) for both the source and target projections are updated as ROS containers are moved. The start and end epochs of all storage containers, such as ROS containers, are modified to the commit epoch. When this occurs, the epochs of all columns without an actual data file rewrite advance the CPE to the commit epoch of `move_partitions_to_table`. If any nodes are down during the TM moveout and/or during the move partition, they will detect that there is storage to recover, and will recover from other nodes with the correct epoch upon rejoining the cluster.

Manual Recovery Notes

- You can manually recover a database where up to K nodes are offline—for example, they were physically removed for repair or not reachable at the time of recovery. When the missing nodes are restored, they recover and rejoin the cluster as described earlier in [Recovery Scenarios](#).
- You can manually recover a database if the nodes to be restarted can supply all partition segments, even if more than K nodes remain down at startup. In this case, all data is available from the remaining cluster nodes, so the database can successfully start.

- The default setting for the `HistoryRetentionTime` configuration parameter is 0, so Vertica only keeps historical data when nodes are down. This setting prevents use of the Administration Tools Roll Back Database to Last Good Epoch option because the AHM remains close to the current epoch and a rollback is not permitted to an epoch that precedes the AHM. If you rely on the Roll Back option to remove recently loaded data, consider setting a day-wide window to remove loaded data—for example:

```
=> ALTER DATABASE mydb SET HistoryRetentionTime = 86400;
```

See [Epoch Management Parameters](#) in the Administrator's Guide.

- When a node is down and manual recovery is required, it can take a full minute or longer for Vertica processes to time out while the system tries to form a cluster. Wait approximately one minute until the system returns the manual recovery prompt. Do not press CTRL-C during database startup.

[High Availability](#)

Restarting Vertica on a Host

When one node in a running database cluster fails, or if any files from the catalog or data directories are lost from any one of the nodes, you can check the status of failed nodes using either the Administration Tools or the Management Console.

Restarting Vertica on a Host Using the Administration Tools

1. Run Administration Tools.
2. From the Main Menu, select **Restart Vertica on Host** and click **OK**.
3. Select the database host you want to recover and click **OK**.

Note: You might see additional nodes in the list, which are used internally by the Administration Tools. You can safely ignore these nodes.

4. Verify recovery state by selecting **View Database Cluster State** from the **Main Menu**.

After the database is fully recovered, you can check the status at any time by selecting **View Database Cluster State** from the Administration Tools **Main Menu**.

Restarting Vertica on a Host Using the Management Console

1. Connect to a cluster node (or the host on which MC is installed).
2. Open a browser and [connect to MC](#) as an MC administrator.
3. On the MC **Home** page, double-click the running database under the **Recent Databases** section.
4. Within the **Overview** page, look at the node status under the Database sub-section and see if all nodes are up. The status will indicate how many nodes are up, critical, down, recovering, or other.
5. If a node is down, click **Manage** at the bottom of the page and inspect the graph. A failed node will appear in red.
6. Click the failed node to select it and in the Node List, click the **Start node** button.

Restarting the Database

If you lose the Vertica process on more than one node (for example, due to power loss), or if the servers are shut down without properly shutting down the Vertica database first, the database cluster indicates that it did not shut down gracefully the next time you start it.

The database automatically detects when the cluster was last in a consistent state and then shuts down, at which point an administrator can restart it.

From the Main Menu in the Administration Tools:

```
Database startup failed. Good epoch logs are available on all nodes.  
WARNING: if you say 'yes', changes made to database after  
'2008-01-28 16:49:31-05' (epoch 4203) will be permanently lost.  
  
Do you really want to restart the database from '2008-01-28 16:49:31-05' (epoch 4203)?  
  
< Yes > < No >
```

Caution: If you do not want to start from the last good epoch, you may instead restore the data from a backup and attempt to restart the database. For this to be useful, the backup must be more current than the last good epoch.

Vertica continues to initialize and recover all data prior to the last good epoch.

```
*** Restarting database QATESTDB at epoch 4203 ***  
Participating hosts:

Node Status: site01: (UP) site02: (UP) site03: (UP) site04: (UP)
```

If recovery takes more than a minute, you are prompted to answer <Yes> or <No> to "Do you want to continue waiting?"

When all the nodes' status have changed to RECOVERING or UP, selecting <No> lets you exit this screen and monitor progress via the Administration Tools Main Menu. Selecting <Yes> continues to display the database recovery window.

Note: Be sure to reload any data that was added after the last good epoch date to which you have recovered.

Recovering the Cluster From a Backup

To recover a cluster from a backup, refer to the following topics:

- [Backing Up and Restoring the Database](#)
- [Restoring Full Database Backups](#)

Phases of a Recovery

The phases of a Vertica recovery are the same regardless of whether you are recovering by table or node. In the case of a [recovery by table](#), tables become individually available as they complete the final phase. In the case of a recovery by node, the database objects only become available after the entire node completes recovery.

When you perform a recovery in Vertica, each recovered table goes through the following phases:

Order	Phase	Description	Lock Type
1	Historical	Vertica copies any historical data it may have missed while in a state of DOWN or INITIALIZING.	none
2	Historical Dirty	Vertica recovers any DML transactions that committed after the node or table began recovery.	none
3	Current Replay Delete	Vertica replays any delete transactions that took place during the recovery.	T-lock
4	Aggregate Projections	Vertica recovers any aggregate projections.	T-lock

After a table completes the last phase, Vertica considers it fully recovered. At this point, the table can participate in DDL and DML operations.

Monitoring Recovery

There are several ways to monitor database recovery:

- [Log files on each host](#)
- [Admintools \(View Database Cluster State\)](#)
- [System tables](#)
- [Cluster Status after recovery](#)

Exporting a Catalog

When you export a catalog you can quickly move a catalog to another cluster. Exporting a catalog transfers schemas, tables, constraints, projections, and views. System tables are not exported.

Exporting catalogs can also be useful for support purposes.

See the [EXPORT_CATALOG](#) function in the SQL Reference Manual for details.

Best Practices for Disaster Recovery

To protect your database from site failures caused by catastrophic disasters, maintain an off-site replica of your database to provide a standby. In case of disaster, you can switch database users over to the standby database. The amount of data loss between a disaster and fail over to the offsite replica depends on how frequently you save a full database backup.

The solution to employ for disaster recover depends upon two factors that you must determine for your application:

- **Recovery point objective (RPO):** How much data loss can your organization tolerate upon a disaster recovery?

- **Recovery time objective (RTO):** How quickly do you need to recover the database following a disaster?

Depending on your RPO and RTO, Vertica recommends choosing from the following solutions:

1. **Dual-load:** During each load process for the database, simultaneously load a second database. You can achieve this easily with off-the-shelf ETL software.
2. **Periodic Incremental Backups:** Use the procedure described in [Copying the Database to Another Cluster](#) to periodically copy the data to the target database. Remember that the script copies only files that have changed.
3. **Replication solutions provided by Storage Vendors:** Although some users have had success with SAN storage, the number of vendors and possible configurations prevent Micro Focus from providing support for SANs.

The following table summarizes the RPO, RTO, and the pros and cons of each approach:

	Dual Load	Periodic Incremental	Storage Replication
RPO	Up to the minute data	Up to the last backup	Recover to the minute
RTO	Available at all times	Available except when backup in progress	Available at all times
Pros	<ul style="list-style-type: none"> • Standby database can have different configuration • Can use the standby database for queries 	<ul style="list-style-type: none"> • Built-in scripts • High performance due to compressed file transfers 	Transparent to the database
Cons	<ul style="list-style-type: none"> • Possibly incur additional ETL licenses • Requires application logic to handle errors 	Need identical standby system	<ul style="list-style-type: none"> • More expensive • Media corruptions are also replicated

Query Performance with Failed Nodes

When a node fails within a Vertica cluster, the cluster detects the failure within milliseconds. The impact of a node failure on currently running queries depends on the [K-safety](#) level of your cluster and the location of your data within the cluster.

K-Safety 0 Cluster

If a node fails in a cluster with a K-safety of 0, any currently running queries roll back and the cluster shuts down. You cannot run further queries until you restore the failed node.

K-Safety 1 or Greater Cluster

The failure of a node can invalidate the query plan for a currently running query. If the running query does not require the failed node, the query continues to run. If a currently running query does require the failed node, the query rolls back. Vertica then automatically reconfigures the query plan to use alternate nodes and automatically retries the query. By default, Vertica makes three attempts to rerun the query before canceling it.

In clusters with a failed node, the database optimizer chooses different segmentations of buddy projections to distribute the workload throughout the cluster. Query performance within a cluster containing a failed node can, however, deteriorate, as one node must now do the work of two nodes. The extent of the performance impact varies depending on the queries that you run and the location of the data that you are querying. Query performance remains affected until the failed node has been completely restored.

Recovery By Table

Vertica supports node recovery on a per-table basis. Unlike a node-based recovery, recovering by table makes tables available as they recover, before the node itself is completely restored. You can [prioritize your most important tables](#) to ensure that they become available as soon as possible. Recovered tables support all DDL and DML operations.

To enhance recovery speed, Vertica recovers multiple tables in parallel. The maximum number of tables recoverable at one time is governed by the MAXCONCURRENCY parameter in the RECOVERY resource pool.

Once a node has fully recovered, it enables full Vertica functionality.

Recovery by table is enabled by default.

Note: Vertica does not support recovery by table for tables with pre-join projections.

Enabling Recovery by Table

With all the nodes in your cluster up, enable recovery by table with the following query:

```
SELECT SET_RECOVER_BY_TABLE('true');
```

Important: Do *not* disable recovery by table. SET_RECOVER_BY_TABLE has been deprecated and will be removed in a future release

Prioritizing Table Recovery

You can specify the order in which Vertica recovers tables. This feature ensures that your most critical tables become available as soon as possible. To specify the recovery order of your tables, assign an integer priority value. Tables with higher priority values recover first. For example, a table with a priority of 1000 is recovered before a table with a value of 500. Table priorities have the maximum value of a 64-bit integer.

If you do not assign a priority, or if multiple tables have the same priority, Vertica restores tables by [OID](#) order. Assign a priority with a query such as this:

```
=> SELECT set_table_recover_priority('avro_basic', '1000');
      set_table_recover_priority
-----
Table recovery priority has been set.
(1 row)
```

View assigned priorities with a query using this form:

```
SELECT table_name, recover_priority FROM v_catalog.tables;
```

The next example shows prioritized tables from the VMart sample database. In this case, the table with the highest recovery priorities are listed first (DESC). The shipping_dimension table has the highest priority and will be recovered first. (Example has hard Returns for display purposes.)

```
=> SELECT table_name AS Name, recover_priority from v_catalog.tables WHERE recover_priority > 1
      ORDER BY recover_priority DESC;
      Name          | recover_priority
-----+-----
shipping_dimension |          60000
```

```
warehouse_dimension |          50000  
employee_dimension  |          40000  
vendor_dimension    |          30000  
date_dimension      |          20000  
promotion_dimension |          10000  
iris2               |           9999  
product_dimension   |             10  
customer_dimension  |             10  
(9 rows)
```

Viewing Table Recovery Status

View general information about a recovery querying the `V_MONITOR.TABLE_RECOVERY_STATUS` table. You can also view detailed information about the status of the recovery the table being restored by querying the `V_MONITOR.TABLE_RECOVERIES` table.

Collecting Database Statistics

The Vertica cost-based query optimizer relies on data statistics to produce query plans. If statistics are incomplete or out-of-date, the optimizer is liable to use a sub-optimal plan to execute a query.

For example, you load timestamp data into a large table at regular intervals and query the table for the mostly recently loaded rows. The following scenarios influence how optimizer chooses a plan:

- You load days 1 through 15 into the table and run [ANALYZE_STATISTICS](#). When you next run a query that requests yesterday's data by filtering on the timestamp column, the optimizer chooses an optimized query plan.
- The next day, you load day 16 data and run the same query. If you do not run [ANALYZE_STATISTICS](#) again, the optimizer might conclude that the predicate results in only one row being returned because the date range falls outside the histogram range and the data becomes stale. When the optimizer detects that statistics are not current for a particular predicate—in this case, because a timestamp predicate is outside a histogram's boundary)—Vertica uses other considerations to plan the query, such as FK-PK constraints.

In this case, you can run [ANALYZE_STATISTICS](#) after loading new data on day 16. You can also look for statistics in the [EXPLAIN](#)-generated query plan. For example, when statistics are outside a histogram's boundaries, the query plan is annotated with a status.

Vertica provides a number of tools like [ANALYZE_STATISTICS](#) for analyzing and updating database statistics. For an overview, see [Database Statistics Tools](#).

Database Statistics Tools

Statistics collection is a cluster-wide operation that accesses data using a historical query (at epoch latest) without any locks. After statistics are computed, they are stored in the catalog and replicated on all nodes. The storage operation requires a brief, exclusive lock on the catalog, similar to when a DDL operation occurs. In fact, these operations require a COMMIT for the current transaction.

Vertica provides a number of tools for analyzing and updating database statistics:

Tool	Description
ANALYZE_	Collects a statistical data sampling.

Tool	Description
STATISTICS	
ANALYZE_ROW_COUNT	Invoked through the Vertica function DO_TM_TASK , collects projection row counts.
ANALYZE_EXTERNAL_ROW_COUNT	Collects row count data for external tables.
EXPORT_STATISTICS	Generates database statistics in XML format from data previously collected by ANALYZE_STATISTICS .
PROJECTION_COLUMNS	Monitors information about projection columns, such as encoding type, sort order, type of statistics, and the time at which columns statistics were last updated.

For more information about these analysis tools, see [Analyzing Row Counts](#) and [Getting Statistics](#).

See also

For information about tools to monitor and analyze query performance, see [Analyzing Workloads](#).

For information about managing statistics, see descriptions of the following Vertica functions in the SQL Reference Manual:

- [EXPORT_STATISTICS](#)
- [IMPORT_STATISTICS](#)
- [DROP_STATISTICS](#)
- [DROP_EXTERNAL_ROW_COUNT](#)

Analyzing Row Counts

Vertica lets you obtain row counts for projections and for external tables, through [ANALYZE_ROW_COUNT](#) and [ANALYZE_EXTERNAL_ROW_COUNT](#), respectively.

Projection Row Count

`ANALYZE_ROW_COUNT` is a lightweight operation that automatically collects the number of rows in a projection every 60 seconds to collect a minimal set of statistics and aggregate row counts calculated during loads. You can invoke this function through the function `DO_TM_TASK`. For example:

```
=> SELECT DO_TM_TASK ('analyze_row_count', 'public.Emp_Dimension_b0');
```

To change the collection interval, set the configuration parameter `AnalyzeRowCountInterval` (see [Configuration Parameters](#)). For example, you can change the collection interval to 1 hour (3600 seconds) as follows:

```
=> ALTER DATABASE mydb SET AnalyzeRowCountInterval = 3600;
```

External Table Row Count

`ANALYZE_EXTERNAL_ROW_COUNT` calculates the exact number of rows in an external table. The optimizer uses this count to optimize for queries that access external tables. This is especially useful when an external table participates in a join. This function enables the optimizer to identify the smaller table to use as the inner input to the join, and facilitate better query performance.

The following query calculates the exact number of rows in the external table `loader_rejects`:

```
=> SELECT ANALYZE_EXTERNAL_ROW_COUNT('loader_rejects');
ANALYZE_EXTERNAL_ROW_COUNT
-----
0
```

Getting Statistics

`ANALYZE_STATISTICS` collects and aggregates data samples and storage information from all nodes that store projections associated with the specified table. You call this function as follows:

```
ANALYZE_STATISTICS ('[schema.]table'
                    [, 'column[,...]']
                    [, percent ] )
```

If you call this function with a single empty string argument, Vertica collects statistics for all database tables and their projections:

```
=> SELECT ANALYZE_STATISTICS ('');
```

Operations

ANALYZE_STATISTICS performs the following operations:

- Performs fast data sampling, which expedites analysis of relatively small tables with a large number of columns.
- Includes data from WOS.
- Recognizes deleted data instead of ignoring delete markers.
- Records in system table [PROJECTION_COLUMNS](#) the last time statistics were run for a table.
- Enables table analysis tables on a per-column basis for improved performance.

Sampling Size

ANALYZE_STATISTICS constructs a column histogram from a set of rows that it randomly selects from all collected data. Regardless of the percentage setting, the function always creates a statistical sample that contains up to (approximately) the smaller of:

- 2^{17} (131,072) rows
- Number of rows that fit in 1 GB of memory

If a column has fewer rows than the maximum sample size, ANALYZE_STATISTICS reads all rows from disk and analyzes the entire column.

Note: The data collected in a sample range does not indicate how data should be distributed.

The following table shows how ANALYZE_STATISTICS, when set to different percentages, obtains a statistical sample from a given column:

Number of column rows	%	Number of rows read	Number of sampled rows
$\leq \text{max-sample-size}$	20	All	All

Number of column rows	%	Number of rows read	Number of sampled rows
400K	10	<i>max-sample-size</i>	<i>max-sample-size</i>
4000K	10	400K	<i>max-sample-size</i>

Note: When a column specified for `ANALYZE_STATISTICS` is first in a projection's sort order, the function reads all data from disk to avoid a biased sample.

Data Collection Percentage

If `ANALYZE_STATISTICS` omits specifying a percentage, Vertica collects a fixed 10-percent sample of statistical data from disk. Specifying a percentage of data to read from disk gives you more control over deciding between sample accuracy and speed.

The percentage of data you collect affects collection time and accuracy:

- A smaller percentage is faster but returns a smaller data sample, which might compromise histogram accuracy.
- A larger percentage reads more data off disk. Data collection is slower, but a larger data sample enables greater histogram accuracy.

Evaluating Results

After you collect the desired statistics, run the Workload Analyzer to retrieve hints about under-performing queries and their root causes, and obtain tuning recommendations. For more information, see [Analyzing Workloads](#).

Examples

Compute statistics on all projections in the `VMart` database:

```
=> SELECT ANALYZE_STATISTICS ('');
ANALYZE_STATISTICS
-----
0
(1 row)
```

Compute statistics on a single table:

```
=> SELECT ANALYZE_STATISTICS ('shipping_dimension');
ANALYZE_STATISTICS
-----
                0
(1 row)
```

Compute statistics on a single column across all projections for a table:

```
=> SELECT ANALYZE_STATISTICS('shipping_dimension','shipping_key');
ANALYZE_STATISTICS
-----
                0
(1 row)
```

Collect data from the entire disk by setting the percent parameter to 100:

```
=> SELECT ANALYZE_STATISTICS ('shipping_dimension', 'shipping_key', 100);
ANALYZE_STATISTICS
-----
                0
(1 row)
```

Collect data on all projections for `shipping_dimension` from 20 percent of the disk:

```
=> SELECT ANALYZE_STATISTICS ('shipping_dimension', 20);
ANALYZE_STATISTICS
-----
                0
(1 row)
```

Reporting Statistics

Vertica supplies hints about statistics two ways:

- The [EXPLAIN](#)-generated query plan is annotated with a status. See [Reacting to Stale Statistics](#).
- The last time [ANALYZE_STATISTICS](#) was run for a table is recorded, so that subsequent calls to the function are optimized. This is useful during the database design process because if Database Designer does not collect statistics when adding design tables, it generates a warning indicating that statistics are old. You can then decide whether to run [ANALYZE_STATISTICS](#) before you proceed with the design.

Two columns in the [V_CATALOG.PROJECTION_COLUMNS](#) system table capture statistical information, as follows:

- `STATISTICS_TYPE` returns the type of statistics the column contains, one of the following: `NONE`, `ROWCOUNT`, or `FULL`.
- `STATISTICS_UPDATED_TIMESTAMP` returns the last time statistics were collected in this table.

Determining When Statistics Were Last Updated

System table `PROJECTION_COLUMNS` returns statistics about projection columns, including the type of statistics and when they were last updated.

For example, the following sample schema defines a table named `trades`, which groups the highly-correlated columns `bid` and `ask` and stores the `stock` column separately:

```
=> CREATE TABLE trades (stock CHAR(5), bid INT, ask INT);
=> CREATE PROJECTION trades_p (
    stock ENCODING RLE, GROUPED(bid ENCODING DELTAVAL, ask))
    AS (SELECT * FROM trades) ORDER BY stock, bid;
=> INSERT INTO trades VALUES('acme', 10, 20);
=> COMMIT;
```

Query the `PROJECTION_COLUMNS` table for table `trades`:

```
=> \x
Expanded display is on.
=> SELECT * FROM PROJECTION_COLUMNS WHERE table_name = 'trades';
```

The `statistics_type` column returns `NONE` for all three columns in the `trades` table. The `statistics_updated_timestamp` field is empty because statistics have not yet been run on this table.

```

table_name            | trades
table_column_id       | 45035996273718836-3
table_column_name     | ask
statistics_type        | NONE
statistics_updated_timestamp |

```

Now, run statistics on the stock column:

```
=> SELECT ANALYZE_STATISTICS('trades.stock');
```

The system returns 0 for success:

```
-[ RECORD 1 ]-----+--
ANALYZE_STATISTICS | 0
```

Now query PROJECTION_COLUMNS again:

```
=> SELECT * FROM PROJECTION_COLUMNS where table_name = 'trades';
```

This time, `statistics_type` changes to FULL for the `trades.stock` column (representing full statistics were run). The `statistics_updated_timestamp` column returns the time the stock columns statistics were updated. The timestamp for the `bid` and `ask` columns have not changed because statistics were not run on those columns. Also, the `bid` and `ask` columns changed from NONE to ROWCOUNT because Vertica automatically updates ROWCOUNT statistics from time to time. The statistics are created by looking at existing catalog metadata.

ask                    | FULL           | 2012-12-08 13:54:27.428639-05
(3 rows)
```

Reacting to Stale Statistics

During predicate selectivity estimation, the query optimizer can identify when histograms are not available or are out of date. If the value in the predicate is outside the histogram's maximum range, the statistics are stale. If no histograms are available, then no statistics are available to the plan.

When the optimizer detects stale or no statistics, such as when it encounters a column predicate for which it has no histogram, the optimizer performs the following actions:

- Displays and logs a message that you should run [ANALYZE_STATISTICS](#).
- Annotates [EXPLAIN](#)-generated query plans with a statistics entry.
- Ignores stale statistics when it generates a query plan. The optimizer uses other considerations to create a query plan, such as FK-PK constraints.

For example, the following query plan fragment shows no statistics (histograms unavailable):

```
| | +-- Outer -> STORAGE ACCESS for fact [Cost: 604, Rows: 10K (NO STATISTICS)]
```

The following query plan fragment shows that the predicate falls outside the histogram range:

```
| | +-- Outer -> STORAGE ACCESS for fact [Cost: 35, Rows: 1 (PREDICATE VALUE OUT-OF-RANGE)]
```

You can get information about which table column has no statistics by querying a system table; for example, view the timestamp for when statistics were last run by querying system table [PROJECTION_COLUMNS](#).

Example

1. Run full statistics on table trades:

```
=> SELECT ANALYZE_STATISTICS('trades'); ANALYZE_STATISTICS
-----
                                0
(1 row)
```

2. Query columns `column_name`, `statistics_type`, and `statistics_updated_timestamp` from projection `PROJECTION_COLUMNS`.

```
=> SELECT projection_column_name, statistics_type, statistics_updated_timestamp
FROM PROJECTION_COLUMNS where table_name = 'trades';
projection_column_name | statistics_type | STATISTICS_UPDATED_TIMESTAMP
-----+-----+-----
stock                  | FULL           | 2011-03-31 13:39:16.968177-04
bid                    | FULL           | 2011-03-31 13:39:16.96885-04
ask                    | FULL           | 2011-03-31 13:39:16.968883-04
(3 rows)
```

You can also query the `PROJECTIONS` column `HAS_STATISTICS`, which returns true only when all non-epoch columns for a table have full statistics. Otherwise, the column returns false.

See Also

[Analyzing Workloads](#)

Canceling Statistics Collection

To cancel statistics collection mid analysis, execute CTRL-C on vsql or call the `INTERRUPT_STATEMENT()` function.

If you want to remove statistics for the specified table or type, call the `DROP_STATISTICS()` function.

Caution: After you drop statistics, it can be time consuming to regenerate them.

Best Practices for Statistics Collection

When you query a table, the query optimizer requires representative statistics on its data in order to choose the best query plan. For many applications, statistics do not need to be accurate to the latest minute. Vertica regularly calls `ANALYZE ROW COUNT`, which collects partial statistics and supplies enough data to satisfy many optimizer requirements.

Requesting Statistics

You can explicitly request Vertica to gather detailed information on the data of individual tables and their columns, by calling `ANALYZE_STATISTICS`. This function analyzes distribution of column data and storage usage across all projections. Without this data, the query optimizer assumes uniform distribution of data values and equal storage usage for all projections, and creates query plans accordingly.

You can specify the size of the data sample—by default, 10 percent. You can also narrow the scope of the collection by specifying individual columns.

You should call `ANALYZE_STATISTICS` on a table or individual columns when one or more of following conditions are true:

- Data is bulk loaded for the first time.
- A new projection is refreshed.
- The number of rows changes significantly.
- A new column is added to the table.
- Column minimum/maximum values change significantly.
- New primary key values with referential integrity constraints are added . The primary key and foreign key tables should be re-analyzed.
- Table size notably changes relative to other tables it is joined to—for example, a table that was 50 times larger than another table is now only five times larger.
- A notable deviation in data distribution necessitates recalculating histograms—for example, an event causes abnormally high levels of trading for a particular stock.
- The database is inactive for an extended period of time.

Overhead Considerations

Running `ANALYZE_STATISTICS` is an efficient but potentially long-running operation. You can run it concurrently with queries and loads in a production environment. However, the function can incur considerable overhead on system resources (CPU and memory), at the expense of queries and load operations. To minimize overhead, run `ANALYZE_STATISTICS` on individual tables rather than the entire database, or on individual table columns.

Related Tools

You can diagnose and resolve many statistics-related issues by calling [ANALYZE_WORKLOAD](#), which returns tuning recommendations.

If you update statistics and find that the query still performs poorly, run your query through the Database Designer and choose incremental as the design type. See [Incremental Design](#).

Using Diagnostic Tools

Micro Focus provides several diagnostic tools. This section includes the following.

- [Determining Your Version of Vertica](#)
- [Collecting Diagnostics \(scrutinize Command\)](#)
- [Exporting a Catalog](#)
- [Exporting Profiling Data](#)

Determining Your Version of Vertica

To determine which version of Vertica is installed on a host, log in to that host and type:

```
$ rpm -qa | grep vertica
```

The command returns the name of the installed package, which contains the version and build numbers. The following example indicates that both Vertica 7.0.x and Management Console 7.0.x are running on the targeted host:

```
[dbadmin@myhost01 ~]$ rpm -qa | grep vertica  
vertica-7.0.0-0  
vertica-console-7.0.0-0.x86_64
```

When you are logged in to your Vertica Analytics Platform database, you can also run a query for the version only, by running the following command:

```
dbadmin=> SELECT version();  
          version  
-----  
Vertica Analytic Database v7.0.0-0  
(1 row)
```

Collecting Diagnostics (scrutinize Command)

The diagnostics tool `scrutinize` collects a broad range of information from a Vertica cluster. It also supports a range of options that let you control the amount and type of data that is collected. Collected data can include but is not limited to:

- Host diagnostics and configuration data
- Run-time state (number of nodes up or down)
- Log files from the installation process, the database, and the administration tools (such as, `vertica.log`, `dbLog`, `/opt/vertica/log/adminTools.log`)
- Error messages
- Database design
- System table information, such as system, resources, workload, and performance
- Catalog metadata, such as system configuration parameters
- Backup information

Requirements

`scrutinize` requires that a cluster be configured to support the Administration Tools utility. If Administration Tools cannot run on the initiating host, then `scrutinize` cannot run on that host.

Further Information

- [Running scrutinize](#)
- [Limiting the Scope of scrutinize Data Collection](#)
- [Troubleshooting scrutinize](#)
- [Uploading scrutinize Results to Support](#)

Running scrutinize

You can run `scrutinize` unqualified by any options:

```
$ /opt/vertica/bin/scrutinize
```

When run without options, `scrutinize` collects a wide range of information from all cluster nodes. It stores the results in a `.tar` file (`VerticaScrutinizeNumericID.tar`), with

minimal effect on database performance. `scrutinize` output can help diagnose most issues and yet reduces upload size by omitting fine-grained profiling data.

`scrutinize` requires temporary disk space where it can collect data before posting the final compressed (`.tar`) output. How much space depends on variables such as the size of the Vertica log and extracted system tables, as well as user-specified options that limit the scope of information collected. Before `scrutinize` runs, it verifies that the temporary directory contains at least 1 GB of space; however, the amount that it actually needs can be much higher. By default, `scrutinize` uses `/opt/vertica/tmp` as the temporary directory. To avoid problems, you can create a temporary directory with as much space as you think `scrutinize` is likely to need. Then, specify that `scrutinize` use this temporary directory through its `--tmpdir` option.

You can run `scrutinize` with one or more options that limit the scope of information that it collects. For example, you can limit the time span of collected data, or collect data only from specific cluster nodes. These options can help you narrow the focus of a collection to information that pertains to a specific issue; they can also reduce output size and improve performance. For more information on these options, see [Limiting the Scope of scrutinize Data Collection](#).

Privileges

You must have database administrator (`dbadmin`) privileges to run `scrutinize`. If you run `scrutinize` as `root` when the `dbadmin` user exists, Vertica returns the following error:

```
[root@host01 ~]# /opt/vertica/bin/scrutinize
Root user is not allowed to use this tool.
Try again as the DB administrative user.
```

Command Options

Option	Description
<code>--auth-upload=<i>url</i></code> <code>-A <i>url</i></code> <code>--url=<i>url</i></code> <code>-u <i>url</i></code>	<p>The <code>--auth-upload</code> and <code>--url</code> options both post <code>scrutinize</code> output to a Vertica support-provided URL, where <i>url</i> specifies the URL or FTP address supplied by Vertica Customer Support for file upload:</p> <ul style="list-style-type: none">• <code>--auth-upload</code> uses your Vertica license to authenticate with the Vertica server.

Option	Description
	<ul style="list-style-type: none"> • <code>--url</code> requires <i>url</i> to include a user name and password that is supplied by Vertica Customer Support. <p>For more information, see Uploading scrutinize Results to Support.</p>
<p><code>--begin=timestamp</code> <code>--end=timestamp</code></p>	<p>Used together or separately, the <code>--begin</code> and <code>--end</code> options narrow the time frame of diagnostic data that is collected from <code>vertica.log</code> and <code>editor.log</code>:</p> <ul style="list-style-type: none"> • <code>--begin</code> specifies to collect log data from the specified begin time to the specified end time or log end. • <code>--end</code> specifies to collect data from the specified begin time or log start to the specified end time. <p>Note: These options cannot be combined with the <code>--include_gzlogs</code> option.</p> <p>You can specify <i>timestamp</i> arguments as offsets from the current time or as absolute times:</p> <ul style="list-style-type: none"> • Offset time format: '<i>DdHhMmSs</i>' For example: '3d2h1m' • Absolute time format: '<i>YYYY-MM-DD HH:MM:SS</i>' For example: '2014-01-02 13:29:59' <p>Examples</p> <pre>\$ scrutinize --begin='2014-01-01 00:00:00' --end='2014-01-07 23:59:59' \$ scrutinize --begin='2014-01-01 00:00:00' \$ scrutinize --end='2014-01-07 23:59:59' \$ scrutinize --begin='2014-09-23 00:00:00' --end='1d'</pre>
<p><code>--by-second</code> <code>--by-minute=boolean-value</code></p>	<p>Specifies the granularity of information that is collected from Data Collector tables with one of the following options:</p> <ul style="list-style-type: none"> • <code>--by-second</code>: Highest level of granularity, specifies to collect data down to the second.

Option	Description
	<ul style="list-style-type: none"> • <code>--by-minute=<i>boolean-value</i></code> where <i>boolean-value</i> is set to one of the following: <ul style="list-style-type: none"> ■ <code>{yes on}</code>: The default setting, specifies to collect data down to the minute. ■ <code>{no off}</code>: The lowest level of granularity, specifies to collect data down to the hour. <p>For example, the following command collects the last five days of data down to the hour:</p> <pre style="background-color: #f0f0f0; padding: 5px;">\$ scrutinize --begin=5d --by-minute=no</pre> <p>This command collects the last hour's data down to the second:</p> <pre style="background-color: #f0f0f0; padding: 5px;">\$ scrutinize --begin=1h --by-second</pre>
<pre>--database=DB -d DB</pre>	<p>Gathers diagnostics for the specified database.</p> <p>This option is required only if the following conditions are true:</p> <ul style="list-style-type: none"> • Multiple databases are defined on the cluster. • More than one database is active, or no database is active. <p>If you omit this option when these conditions are true, <code>scrutinize</code> returns a message that asks you to specify a database.</p> <p>Example</p> <pre style="background-color: #f0f0f0; padding: 5px;">\$ scrutinize -d VMart</pre>
<pre>--debug</pre>	<p>Increases the amount of information written to the log.</p>
<pre>--diag-dump</pre>	<p>Limits the collection to database design, system tables, and Data Collector tables. Use this option to collect data to analyze system performance.</p>
<pre>--diagnostics</pre>	<p>Limits the collection to log file data and output from commands that are run against Vertica and its host system. Use this option to collect data to evaluate unexpected behavior in your Vertica system.</p>

Option	Description
<pre>--exclude-tasks=<i>tasks</i> -X <i>tasks</i></pre>	<p>Excludes one or more of the specified types of tasks from the diagnostics collection, where <i>tasks</i> is a comma-separated list of the task types to exclude. To exclude all default tasks, supply the argument <code>all</code>.</p> <p>Important: Use <code>--exclude-tasks</code> only in consultation with your Vertica Customer Support contact.</p> <p>For detailed information, see Limiting the Scope of scrutinize Data Collection.</p>
<pre>--get-files <i>file-list</i></pre>	<p>Specifies extra files to collect, including globs, where <i>file-list</i> is a semicolon-delimited list of files.</p>
<pre>--help -h</pre>	<p>Outputs all <code>scrutinize</code> options to the console.</p>
<pre>--hosts=<i>host-list</i> -n <i>host-list</i></pre>	<p>Collects diagnostics for the specified hosts, where <i>host-list</i> is a comma-separated list of IP addresses or host names. By default, <code>scrutinize</code> collects diagnostics on all cluster hosts.</p> <p>To collect data only from the node on which <code>scrutinize</code> was invoked, use the <code>--local_diags (-s)</code> option.</p> <p>Example</p> <pre>scrutinize -n host1,host2,host3 scrutinize --hosts=127.0.0.1,host_3,host_1</pre>
<pre>--include_gzlogs=<i>num-files</i> -z <i>num-files</i></pre>	<p>Specifies to include <i>num-files</i> rotated log files (<code>vertica.log*.gz</code>) in the <code>scrutinize</code> output, where <i>num-files</i> can be one of the following:</p> <ul style="list-style-type: none"> • An integer specifies how many of the most recent rotated log files to collect. • <code>all</code> specifies to collect all rotated log files. <p>By default, <code>scrutinize</code> includes one rotated log file.</p> <p>Note: This option cannot be combined with the <code>--begin</code> and <code>--end</code> options.</p> <p>Example</p>

Option	Description
	<p><code>scrutinize</code> includes the four most recent rotated log files:</p> <pre data-bbox="553 338 1403 401">\$ scrutinize --include_gzlogs 4</pre>
<p><code>--include-ros-info</code></p>	<p>Includes ROS related information from system tables.</p>
<p><code>--local_diags</code> <code>-s</code></p>	<p>Gathers diagnostics from the host where <code>scrutinize</code> was invoked. By default, <code>scrutinize</code> collects data from all nodes in the cluster.</p> <p>Tip: To collect data from multiple nodes in the cluster, use the <code>--hosts (-n)</code> option.</p>
<p><code>--log-limit <i>Limit</i></code></p>	<p>Limits how much data is collected from Vertica logs, where <i>Limit</i> specifies, in gigabytes, how much log data to collect, starting from the most recent log entry. By default, 1 GB of log data is collected.</p>
<p><code>--message= <i>message</i></code> <code>-m <i>message</i></code></p>	<p>Includes a message in the <code>scrutinize</code> output, in the file <code>reason.txt</code>. Messages are typically included when you upload <code>scrutinize</code> to Vertica Customer Support.</p> <p>You can set a message several ways:</p> <ul style="list-style-type: none"> • Supply a message string enclosed by double quotation marks ("). • Supply the path to a file enclosed by double quotation marks. <code>scrutinize</code> includes the file contents in its output file. • Use the PROMPT keyword to open an input stream. <code>scrutinize</code> reads input until you type a period (.) on a new line. This closes the input stream, and <code>scrutinize</code> writes the message to the collected output. <p>For detailed information and examples, see Uploading scrutinize Results to Support.</p>
<p><code>--no-active-queries</code> <code>--with-active-queries</code></p>	<p>Specifies whether to collect diagnostic information from system tables and Data Collector tables about currently running queries. By default, <code>scrutinize</code> always collects active query information</p>

Option	Description
	<p>(<code>--with-active-queries</code>).</p>
<p><code>--no-containers</code></p>	<p>Omits running system table queries from the <code>scrutinize</code> collection. Omitting these queries can help reduce <code>scrutinize</code> run time.</p>
<p><code>--no-package-info</code></p>	<p>Excludes information collected about Vertica add-on packages like Vertica Kafka.</p>
<p><code>--output_dir=path</code> <code>-o path</code></p>	<p>Redirects output to a location that is not the current directory. By default, <code>scrutinize</code> places its output in the current directory.</p> <p>Example</p> <pre data-bbox="553 768 1401 831">\$ scrutinize --output_dir="/my_diagnostics/"</pre>
<p><code>--password='password'</code> <code>-P 'password'</code></p>	<p>Specifies the database password. <code>scrutinize</code> supports <code>VSQL_PASSWORD</code>.</p> <p>Omitting this argument on a password-protected database returns a warning. Enclose the password with single quotation marks (<code>'</code>) to protect passwords with special characters.</p> <p>Use this option if the Vertica administrator account (default <code>dbadmin</code>) has password authentication.</p> <p>Example</p> <pre data-bbox="553 1262 1401 1373">\$ scrutinize -P '@password**' \$ scrutinize --password='\$password1*'</pre>
<p><code>--tasks=tasks</code> <code>-T tasks</code></p>	<p>Specifies that <code>scrutinize</code> gather diagnostics on one or more specified tasks, as specified in a file or JSON list.</p> <p>Note: Use this option only in consultation with Vertica Customer Support.</p>
<p><code>--type=type</code> <code>-t type</code></p>	<p>Specifies the type of diagnostics collection to perform, where <code>type</code> can be set to one of the following arguments:</p> <ul data-bbox="553 1759 1122 1835" style="list-style-type: none"> • <code>profiling</code>: Gather profiling data. • <code>context</code>: Gather summary information.

Option	Description
<code>--tmpdir=path</code>	<p>Specifies the temporary directory to use on all nodes. By default, the temporary directory is in the Administration Tools directory <code>/tmp</code>. Use this option to ensure that the temporary directory has enough free space so <code>scrutinize</code> can complete execution.</p> <p>The following requirements apply:</p> <ul style="list-style-type: none">• The temporary directory must have at least 1 GB of free space.• You must have write permission to the directory.
<code>--user=username</code> <code>-U username</code>	<p>Specifies the dbadmin user name. By default, <code>scrutinize</code> uses the user name of the invoking user.</p>
<code>--version</code>	<p>Displays the version number of the Vertica server and the <code>scrutinize</code> version number.</p>
<code>--vsq1-off</code> <code>-v</code>	<p>Excludes Query and SystemTable tasks, which are used to connect to the database. This option can help you deal with problems that occur during an upgrade, and is typically used in the following cases:</p> <ul style="list-style-type: none">• Vertica is running but is slow to respond.• You haven't created a database but need help troubleshooting other cluster issues.
<code>-w</code> <code>--prompt-password</code>	<p><code>scrutinize</code> displays a DB Password prompt at the command line, where users must enter their database passwords.</p>

Limiting the Scope of `scrutinize` Data Collection

`scrutinize` provides several options that let you narrow scope of the data collection, to reduce output size and improve performance:

- [Limit the time span of collected data.](#)
- [Limit the amount of collected data.](#)
- [Limit collection to specific cluster nodes.](#)

- [Specify the type of content to collect.](#)
- [Exclude types of content.](#)

You can use these options singly or in combination, to achieve the desired level of granularity.

Limiting the Time Span of Collected Data

You can use `scrutinize --begin` and `--end` options together or separately to limit the time frame of diagnostic data that is collected from `vertica.log` and `editor.log`:

- `--begin` specifies to collect log data from the specified begin time to the specified end time or log end.
- `--end` specifies to collect data from the specified begin time or log start to the specified end time.

You can specify begin and end *time* arguments as offsets from the current time or as absolute times:

Offset time format:	'DdHhMmSs' For example: '3d2h1m'
Absolute time format:	'YYYY-MM-DD HH:MM:SS' For example: '2014-01-02 13:29:59'

For example:

```
$ scrutinize --begin='2014-01-01 00:00:00' --end='2014-01-07 23:59:59'  
$ scrutinize --begin='2014-01-01 00:00:00'  
$ scrutinize --end='2014-01-07 23:59:59'  
$ scrutinize --begin='2014-09-23 00:00:00' --end='1d''
```

Limiting the Amount of Collected Data

Two options let you limit how much data `scrutinize` collects:

<code>--log-limit=<i>limit</i></code> <code>-l <i>limit</i></code>	Limits how much data is collected from Vertica logs, where <i>limit</i> specifies, in gigabytes, how much log data to collect,
---	--

	<p>starting from the most recent log entry. By default, 1 GB of log data is collected.</p> <p>For example, the following command specifies to collect 4 GB of log data:</p> <pre>\$ scrutinize --log-limit=4</pre>
<pre>--include_gzlogs=num-files -z num-files</pre>	<p>Specifies to include <i>num-files</i> rotated log files (<i>vertica.log*.gz</i>) in the <i>scrutinize</i> output, where <i>num-files</i> can be one of the following:</p> <ul style="list-style-type: none"> • An integer specifies the number of rotated log files to collect. • <i>all</i> specifies to collect all rotated log files. <p>By default, <i>scrutinize</i> includes three rotated log files.</p> <p>For example the following command specifies to collect two rotated log files:</p> <pre>\$ scrutinize --include_gzlogs=2</pre>

Limiting Collection to Specific Cluster Nodes

By default, *scrutinize* collects data from all cluster nodes. You can specify that *scrutinize* collect from individual nodes in two ways:

<pre>--local_diags -s</pre>	<p>Specifies to collect diagnostics only from the host on which <i>scrutinize</i> was invoked.</p>
<pre>--hosts=host-List -n host-List</pre>	<p>Specifies to collect diagnostics only from the hosts specified in <i>host-List</i>, where <i>host-List</i> is a comma-separated list of IP addresses or host names.</p> <p>Example:</p> <pre>\$ scrutinize -n host_1,host_2,host_3</pre> <pre>\$ scrutinize --hosts=127.0.0.1,host_3,host_1</pre>

Specifying the Type of Content to Collect

`scrutinize` provides several options that let you specify the type of data to collect:

<code>--diag-dump</code>	Limits the collection to database design, system tables, and Data Collector tables. Use this option to collect data to analyze system performance.
<code>--diagnostics</code>	Limits the collection to log file data and output from commands that are run against Vertica and its host system. Use this option to collect data to evaluate unexpected behavior in your Vertica system.
<code>--type=<i>type</i></code> <code>-t <i>type</i></code>	Specifies the type of diagnostics collection to perform, where <i>type</i> can be one of the following arguments: <ul style="list-style-type: none">• <code>profiling</code>: Gather profiling data.• <code>context</code>: Gather summary information.
<code>--tasks=<i>tasks</i></code> <code>-T <i>tasks</i></code>	Specifies that <code>scrutinize</code> gather diagnostics on one or more tasks, as specified in a file or JSON list. This option is typically used together with the <code>--exclude</code> option. Note: Use this option only in consultation with Vertica Customer Support

Excluding Types of Content

`scrutinize` provides two options that let you specify types of data to exclude from its collection:

<code>--vsq1-off</code> <code>-v</code>	Excludes Query and SystemTable tasks, which are used to connect to the database. This option can help you deal with problems that occur during an upgrade, and is typically used in the following cases: <ul style="list-style-type: none">• Vertica is running but is slow to respond.• You haven't yet created a database but need help troubleshooting other cluster issues.
<code>--exclude=<i>tasks</i></code> <code>-X <i>tasks</i></code>	Excludes one or more types of tasks from the diagnostics collection, where <i>tasks</i> is a comma-separated list of the tasks to exclude.

Note: This option is typically used only in consultation with your Vertica Customer Support contact.

Specify the tasks to exclude with the following case-insensitive arguments :

- `all`: All default tasks
- `DC`: Data Collector tables
- `File`: Log files from the installation process, the database, and Administration Tools, such as `vertica.log`, `dbLog`, and `adminTools.log`
- `VerticaLog`: Vertica logs
- `CatalogObject`: Vertica catalog metadata, such as system configuration parameters
- `SystemTable`: Vertica system tables that contain information about system, resources, workload, and performance
- `Query`: Vertica metafunctions that use `vsql` to connect to the database, such as `EXPORT_CATALOG()`
- `Command`: Operating system information, such as the length of time that a node has been up

scrutinize Security

`scrutinize` supports password handling in the following ways:

- The `--password (-P)` option sets the database password as an argument to the `scrutinize` command.

Omitting this argument on a password-protected database returns a warning. Enclose the password with single quotes to protect passwords with special characters.

For example:

```
$ scrutinize -P '@passWord**'  
$ scrutinize --password='$password1*'
```

Use this option if the administrator account (default dbadmin) has password authentication.

- The `--prompt-password (-W)` option invokes a DB Password prompt at the command line, where users must enter their database password.
- Support for [VSQL_PASSWORD](#)

Troubleshooting scrutinize

The troubleshooting advice in this section can help you resolve common issues that you might encounter when using `scrutinize`.

Collection Time Is Too Slow

To speed up collection time, omit system tables when running an instance of `scrutinize`. Be aware that collecting from fewer nodes does not necessarily speed up the collection process.

Output Size Is Too Large

Output size depends on system table size and vertica log size.

To create a smaller `scrutinize` output, omit some system tables or truncate the vertica log. For more information, see [Narrowing the Scope of scrutinize Data Collection](#).

System Tables Not Collected on Databases with Password

Running `scrutinize` on a password-protected database might require you to supply a user name and password:

```
$ scrutinize -U username -P 'password'
```

Uploading scrutinize Results to Support

In most cases, your Customer Support contact provides arguments for you to run with the `scrutinize` script. These arguments include the URL that you supply with the `--url` or `--auth-upload` options.

Before you run `scrutinize` with an upload option:

- Install the `cURL` program installed in the path for the database administrator user who is running `scrutinize`.
- Verify each node in the cluster can make an HTTP or FTP connection directly to the Internet.

When you use the upload options:

- `scrutinize` does not collect results into a single `VerticaScrutinizetimestamp.zip` file.
- Each node posts the files directly to the specified URL:
 - A smaller, context file is posted first, which lets Customer Support review high-level information.
 - The larger, more complete diagnostics collection downloads at the end of the run.

Authenticated Upload

You can use the `--url` or the `--auth-upload` option to upload `scrutinize` output to Vertica Customer Support. Each option authenticates the upload in a different way:

- The `--url` upload method requires the URL to include a user name and password.
- When you use the `--auth-upload` option, `scrutinize` uploads your customer name from your Vertica Premium Edition license. Customer Support uses this information to verify your identity on receiving your uploaded file.

The `--auth-upload` argument requires a valid Vertica Premium Edition license. In both cases, the upload uses a URL or FTP address supplied by Vertica Customer Support.

Upload Examples

The following example shows a generic upload that invokes the `--url` option to gather all diagnostics on the cluster and posts the collected output to a support-provided URL:

```
$ scrutinize -U username -P 'password' -u 'ftp://username/password@customers.vertica.com/'
```

You can also use the authenticated upload method to gather the same information and your customer name:

```
$ scrutinize -U username -P 'password' --auth-upload "url"
```

Including Messages in scrutinize Output

The `scrutinize` option `--message (-m)` includes a message in the `scrutinize` output, in `reason.txt`. Messages are typically included in order to provide the following information:

- Reason for gathering/submitting diagnostics.
- Support-supplied case number and other issue-specific information, in order to help Vertica Customer Support identify your case and analyze the problem.

If no message is specified, `scrutinize` generates the default message 'Unknown reason for collection.'

You can set a message several ways:

- Supply a message string enclosed by double-quotation marks (`"`). For example:

```
$ scrutinize --message="re: case number #ABC-12345"
```

- Supply the path to a file enclosed by double quotation marks. `scrutinize` includes the file contents in its output file. For example:

```
$ scrutinize --message="/path/to/file"
```

- The `PROMPT` keyword opens an input stream. `scrutinize` reads input until you type a period (`.`) on a new line. This closes the input stream, and `scrutinize` writes the message to the collected output. For example:

```
$ scrutinize --message=PROMPT
Enter reason for collecting diagnostics; end with '.' on a line by itself:
Query performance degradation noticed around 9AM EST on Saturday
.
Vertica Scrutinize Report
-----
Result Dir:                /home/dbadmin/VerticaScrutinize.20131126083311
...
```

Database Identifiers

`scrutinize` generates a unique identifier for the database that it analyzes. This identifier is based on your Vertica license and the database creation time. `scrutinize` generates the same name for a given database each time it collects data on that database. It displays this name near the end of its standard output—in the following example, **PURPLE LEAD**:

```
Vertica Scrutinize Report
-----
Result Dir:                /home/dbadmin/VerticaScrutinize.20140206144429
...
Gathered diagnostics for
Customer: Vertica Systems, Inc.
Database designation: PURPLE LEAD
Timestamp: 20140206144429
...
```

You can use this identifier when you interact with Customer Support. It is particularly useful in the following cases:

- A cluster hosts multiple databases.
- Different clusters host databases with the same name.

Exporting a Catalog

When you export a catalog you can quickly move a catalog to another cluster. Exporting a catalog transfers schemas, tables, constraints, projections, and views. System tables are not exported.

Exporting catalogs can also be useful for support purposes.

See the [EXPORT_CATALOG](#) function in the SQL Reference Manual for details.

Exporting Profiling Data

The diagnostics audit script gathers system table contents, design, and planning objects from a running database and exports the data into a file named `./diag_dump_<timestamp>.tar.gz`, where `<timestamp>` denotes when you ran the script.

If you run the script without parameters, you will be prompted for a database password.

Syntax

```
/opt/vertica/scripts/collect_diag_dump.sh [ command... ]
```

Parameters

<i>command</i>	-U	User name, typically the database administrator account, dbadmin.
	-w	Database password.
	-c	Includes a compression analysis, resulting in a longer script execution time.

Example

The following command runs the audit script with all arguments:

```
$ /opt/vertica/scripts/collect_diag_dump.sh -U dbadmin -w password -c
```

Profiling Database Performance

You can profile database performance to evaluate how efficiently queries execute. For example, profiles can provide the following information:

- How much memory and how many threads each operator is allocated.
- How data flows through each operator at different points in time during query execution.
- Whether a query is network bound.

Profiling information can help you evaluate query performance and determine whether to rewrite the query. You can use profiling when considering projection design issues, such as segmentation and sort order.

The topics in this section focus on obtaining profile data via vsql statements. The Vertica Management Console also provides an easy-to-read [view of query profile data](#).

Profiling Categories

Vertica divides profiling data into three categories and captures this information in several system tables. You can query those tables for specific performance information, as shown in the following table:

Profiling Category	System Tables	Description of Profiled Data
Session	SESSION_PROFILES	General information about query execution on each node during the current session. For example, you can find out how many statements ran successfully and unsuccessfully, how many locks were granted and deadlocks encountered, and so on.
Queries	QUERY_PLAN_PROFILES QUERY_PROFILES	Query-specific information, such as query string and duration of execution, divided between two system tables: <ul style="list-style-type: none">• QUERY_PLAN_PROFILES: Real-time status for each query plan path.• QUERY_PROFILES: Query information.

Profiling Category	System Tables	Description of Profiled Data
Execution engine	EXECUTION_ENGINE_PROFILES	Information on execution engine performance.

Note: If execution engine profiling is disabled, Vertica saves no data in `EXECUTION_ENGINE_PROFILES`. However, if query and session profiling is disabled, Vertica saves some data in `QUERY_PROFILES`, `QUERY_PLAN_PROFILES`, and `SESSION_PROFILES`.

For each category, you can enable profiling globally, for the entire database, or only for the current session. For more information, see [Enabling and Disabling Profiling](#).

Enabling and Disabling Profiling

You can enable and disable profiling for a specific category globally (for the entire database) and the current session. Use [SHOW_PROFILING_CONFIG](#) to determine whether profiling is enabled. Output from this command shows:

- At what scope (global and session) profiling is enabled.
- For what [categories](#) profiling is enabled.

Note: If profiling is enabled globally for a given category, enabling or disabling session profiling has no effect on whether Vertica gathers profile data for that category. The session profiling setting enables profiling for a given category only when global profiling is disabled for the same category.

In the following example, [SHOW_PROFILING_CONFIG](#) shows that profiling is enabled globally (Global on) across all profiling categories—session, EE (execution engine), and query. For the current session, it is disabled (Session off) across all categories:

```
=> SELECT SHOW_PROFILING_CONFIG();
SHOW_PROFILING_CONFIG
-----
Session Profiling: Session off, Global on
EE Profiling:      Session off, Global on
Query Profiling:   Session off, Global on
(1 row)
```

Enable or Disable Global Profiling

```
ALTER DATABASE db-name SET profiling-category = {0 | 1}
```

where *profiling-category* is set to one of the following arguments:

Use this argument...	To specify...
GlobalSessionProfiling	Session profile data
GlobalQueryProfiling	Query data
GlobalEETProfiling	Execution engine data

For example, the following statement globally enables query profiling:

```
=> ALTER DATABASE mydb SET GlobalQueryProfiling = 1;
```

Enable or Disable Session Profiling

```
ENABLE_PROFILING( profiling-category )  
DISABLE_PROFILING( profiling-category )
```

where *profiling-category* is set to one of the following arguments:

Use this argument...	To specify...
session	Session profile data
query	Query data
ee	Execution engine data

For example, the following statement enables session-scoped profiling for the execution run of each query:

```
=> SELECT ENABLE_PROFILING('ee');  
   ENABLE_PROFILING  
-----  
   EE Profiling Enabled  
(1 row)
```

What to look for in query profiles

Profile data can show data skew, when some nodes are processing more data than others. The `rows_produced` counter in the system table `EXECUTION_ENGINE_PROFILES` shows how many rows have been processed by each operator. Comparing the `rows_produced` across all nodes for a given operator reveals if there is a data skew issue.

Note: Some profiling operators in `EXECUTION_ENGINE_PROFILES` are generic, such as `JOIN`. The `EXPLAIN`-generated query plan includes more details about the specific join that is executing.

Real-Time Profiling

With real-time profiling, you can monitor long-running queries while they execute.

Real-time profiling counters are available for all statements while they execute, including internal operations such as mergeout, recovery, and refresh. Unless you explicitly enable profiling using the keyword `PROFILE` on a specific SQL statement, or generally [enable profiling](#) for the database and/or the current session, profiling counters are unavailable after the statement completes.

Queries for real-time profiling data require a transaction ID. If the transaction executes multiple statements, the query also requires a statement ID to identify the desired statement. You obtain transaction and statement IDs the `SYSTEM_SESSIONS` system table from columns `transaction_id` and `statement_id`, respectively:

```
=> SELECT transaction_id, statement_id FROM SYSTEM_SESSIONS;
```

Profiling Counters

The `EXECUTION_ENGINE_PROFILES` system table contains available profiling counters for internal operations and user statements.

Useful counters include:

- Execution time (μ s)
- Rows produced

- Total merge phases
- Completed merge phases
- Current size of temp files (bytes)

You can view all available counters by querying [EXECUTION_ENGINE_PROFILES](#):

```
=> SELECT DISTINCT(counter_name) FROM EXECUTION_ENGINE_PROFILES;
```

To monitor the profiling counters, you can run a command like the following using a retrieved transaction ID (a000000000027):

```
=> SELECT * FROM execution_engine_profiles  
WHERE TO_HEX(transaction_id)='a000000000027'  
AND counter_name = 'execution time (us)'  
ORDER BY node_name, counter_value DESC;
```

The following example finds operators with the largest execution time on each node:

```
=> SELECT node_name, operator_name, counter_value execution_time_us FROM V_MONITOR.EXECUTION_ENGINE_  
PROFILES WHERE counter_name='execution time (us)' LIMIT 1 OVER(PARTITION BY node_name ORDER BY  
counter_value DESC);
```

node_name	operator_name	execution_time_us
v_vmart_node0001	Join	131906
v_vmart_node0002	Join	227778
v_vmart_node0003	NetworkSend	524080

(3 rows)

Query Plan Profiles

You can obtain query-specific data by profiling the query statement and evaluating the data that is captured in system tables [QUERY_PLAN_PROFILES](#) and [EXECUTION_ENGINE_PROFILES](#). For example, you can query [QUERY_PLAN_PROFILES](#) to determine how much time a query spends on each query plan operation. For details, see [Profiling Query Plans](#).

Linux watch Command

You can use the Linux `watch` command to monitor long-running queries at frequent intervals. Common use cases include:

- Observing executing operators within a query plan on each Vertica cluster node.
- Monitoring workloads that might be unbalanced among cluster nodes—for example, some nodes become idle while others are active. Such imbalances might be caused by data skews or by hardware issues.

In the following example, watch queries operators with the largest execution time on each node. The command specifies to re-execute the query each second:

```
watch -n 1 -d "vsq1 VMart -c\"SELECT node_name, operator_name, counter_value execution_time_us
FROM v_monitor.execution_engine_profiles WHERE counter_name='execution time (us)'
LIMIT 1 OVER(PARTITION BY node_name ORDER BY counter_value DESC);

Every 1.0s: vsq1 VMart -c"SELECT node_name, operator_name, counter_value execution_time_us FROM v_
monitor.execu... Thu Jan 21 15:00:44 2016

  node_name      | operator_name | execution_time_us
-----+-----+-----
v_vmart_node0001 | Root          |           110266
v_vmart_node0002 | UnionAll     |             38932
v_vmart_node0003 | Scan         |             22058
(3 rows)
```

Profiling Single Statements

To profile a single statement, prefix it with [PROFILE](#). You can profile a query (SELECT) statement, or any DML statement such as [INSERT](#), [UPDATE](#), [COPY](#), and [MERGE](#). The statement returns with a profile summary:

- Profile identifiers `transaction_id` and `statement_id`
- Initiator memory for the query
- Total memory required

For example:

```
=> PROFILE SELECT customer_name, annual_income FROM public.customer_dimension
  WHERE (customer_gender, annual_income) IN (SELECT customer_gender, MAX(annual_income)
  FROM public.customer_dimension GROUP BY customer_gender);
NOTICE 4788: Statement is being profiled
HINT: Select * from v_monitor.execution_engine_profiles where transaction_id=45035996278193955 and
statement_id=1;
NOTICE 3557: Initiator memory for query: [on pool pool1: 996147 KB, minimum: 746280 KB]
NOTICE 5077: Total memory required by query: [996147 KB]
  customer_name | annual_income
-----+-----
```

```
Emily G. Vogel | 999998
James M. McNulty | 999979
(2 rows)
```

You can use the profile identifiers `transaction_id` and `statement_id` to obtain detailed profile information for this query from system tables [EXECUTION_ENGINE_PROFILES](#) and [QUERY_PLAN_PROFILES](#). For example:

```
=> SELECT path_id, path_line::VARCHAR(68), running_time FROM v_monitor.query_plan_profiles
WHERE transaction_id=45035996278193955 AND statement_id=1 ORDER BY path_id, path_line_index;
path_id | path_line | running_time
-----+-----+-----
1 | +-JOIN HASH [Semi] [Cost: 644, Rows: 25K] (PATH ID: 1) | 00:00:00.009077
1 | | Join Cond: (customer_dimension.customer_gender = VAL(2)) AND (cus |
1 | | Materialize at Output: customer_dimension.customer_name |
1 | | Execute on: Query Initiator |
2 | | +- Outer -> STORAGE ACCESS for customer_dimension [Cost: 149, Row | 00:00:00.008763
2 | | | Projection: public.customer_dimension_DBD_1_rep_VMartDesign |
2 | | | Materialize: customer_dimension.customer_gender, customer_d |
2 | | | Execute on: Query Initiator |
2 | | | Runtime Filters: (SIP1(HashJoin): customer_dimension.custom |
4 | | | +---> GROUPBY HASH (LOCAL RESEGMENT GROUPS) [Cost: 159, Rows: 3] | 00:00:00.006566
4 | | | | Aggregates: max(customer_dimension.annual_income) |
4 | | | | Group By: customer_dimension.customer_gender |
4 | | | | Execute on: Query Initiator |
5 | | | | +---> STORAGE ACCESS for customer_dimension [Cost: 149, Rows: | 00:00:00.006943
5 | | | | | Projection: public.customer_dimension_DBD_1_rep_VMartDe |
5 | | | | | Materialize: customer_dimension.customer_gender, custom |
5 | | | | | Execute on: Query Initiator |
(17 rows)
```

Sample Views for Counter Information

The `EXECUTION_ENGINE_PROFILES` table contains the data for each profiling counter as a row within the table. For example, the execution time (us) counter is in one row, and the rows produced counter is in a second row. Since there are many different profiling counters, many rows of profiling data exist for each operator. Some sample views are installed by default to simplify the viewing of profiling counters.

Running scripts to create the sample views

The following script creates the `v_demo` schema and places the views in that schema.

```
/opt/vertica/scripts/demo_eeprofile_view.sql
```

Viewing counter values using the sample views

There is one view for each of the profiling counters to simplify viewing of a single counter value. For example, to view the execution time for all operators, issue the following command from the database:

```
=> SELECT * FROM v_demo.eeprof_execution_time_us;
```

To view all counter values available for all profiled queries:

```
=> SELECT * FROM v_demo.eeprof_counters;
```

To select all distinct operators available for all profiled queries:

```
=> SELECT * FROM v_demo.eeprof_operators;
```

Combining sample views

These views can be combined:

```
=> SELECT * FROM v_demo.eeprof_execution_time_us  
NATURAL LEFT OUTER JOIN v_demo.eeprof_rows_produced;
```

To view the execution time and rows produced for a specific transaction and `statement_id` ranked by execution time on each node:

```
=> SELECT * FROM v_demo.eeprof_execution_time_us_rank  
WHERE transaction_id=45035996273709699  
AND statement_id=1  
ORDER BY transaction_id, statement_id, node_name, rk;
```

To view the top five operators by execution time on each node:

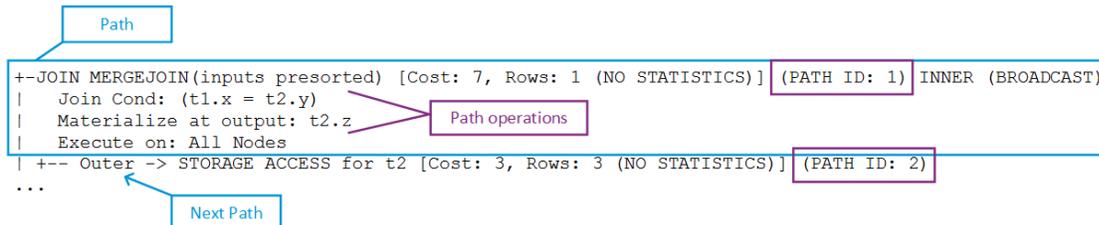

```
=> SELECT * FROM v_demo.eeprof_execution_time_us_rank  
WHERE transaction_id=45035996273709699  
AND statement_id=1 AND rk<=5  
ORDER BY transaction_id, statement_id, node_name, rk;
```

Profiling Query Plans

To monitor real-time flow of data through a query plan, query system tables [EXECUTION_ENGINE_PROFILES](#) and [QUERY_PLAN_PROFILES](#). These tables provides data on how Vertica executed a query plan and its individual paths:

- [EXECUTION_ENGINE_PROFILES](#) summarizes query execution runs.
- [QUERY_PLAN_PROFILES](#) shows the real-time flow of data, and the time and resources consumed for each query plan path

Each query plan path has a unique ID, as shown in the following [EXPLAIN](#) output fragment.

Both tables provide path-specific data. For example, [QUERY_PLAN_PROFILES](#) provides high-level data for each path, which includes:

- Length of a query operation execution
- How much memory that path's operation consumed
- Size of data sent/received over the network

For example, you might observe that a `GROUP BY HASH` operation executed in 0.2 seconds using 100MB of memory.

Requirements

Real-time profiling minimally requires the ID of the transaction to monitor. If the transaction includes multiple statements, you also need the statement ID. You can get statement and transaction IDs by issuing [PROFILE](#) on the query to profile. You can then use these identifiers to query system tables [EXECUTION_ENGINE_PROFILES](#) and [QUERY_PLAN_PROFILES](#).

For more information, see [Profiling Single Statements](#).

Getting Query Plan Status for Small Queries

Real-time profiling counters, stored in the `EXECUTION_ENGINE_PROFILES` system table, are available for all currently executing statements—including internal operations, such as a mergeout.

Profiling counters are available after query execution has completed if any of the following conditions are true:

- The query was run via the `PROFILE <query>` command
- Systemwide profiling has been enabled through the `ENABLE_PROFILING()` function
- The query took longer than two seconds to run

Profiling counters are saved in the `EXECUTION_ENGINE_PROFILES` system table until the storage quota has been exceeded.

Here's an example:

1. Profile the query to get the `transaction_id` and `statement_id` from from `EXECUTION_ENGINE_PROFILES`; for example:

```
=> PROFILE SELECT * FROM t1 JOIN t2 ON t1.x = t2.y;
NOTICE 4788: Statement is being profiled
HINT: Select * from v_monitor.execution_engine_profiles where transaction_id=45035996273955065
and statement_id=4;
NOTICE 3557: Initiator memory for query: [on pool general: 248544 KB, minimum: 248544 KB]
NOTICE 5077: Total memory required by query: [248544 KB]
 x | y | z
---+---+-----
 3 | 3 | three
(1 row)
```

2. Query the `QUERY_PLAN_PROFILES` system table.

Note: For best results, sort on the `transaction_id`, `statement_id`, `path_id`, and `path_line_index` columns.

```
=> SELECT ... FROM query_plan_profiles
WHERE transaction_id=45035996273955065 and statement_id=4;
ORDER BY transaction_id, statement_id, path_id, path_line_index;
```

Getting Query Plan Status for Large Queries

Real-time profiling is designed to monitor large (long-running) queries. Take the following steps to monitor plans for large queries:

1. Get the statement and transaction IDs for the query plan you want to profile by querying the `CURRENT_SESSION` system table:

```
=> SELECT transaction_id, statement_id from current_session;
transaction_id | statement_id
-----+-----
45035996273955001 | 4
(1 row)
```

2. Run the query:

```
=> SELECT * FROM t1 JOIN t2 ON x=y JOIN ext on y=z;
```

3. Query the `QUERY_PLAN_PROFILES` system table, and sort on the `transaction_id`, `statement_id`, `path_id`, and `path_line_index` columns.

```
=> SELECT ... FROM query_plan_profiles WHERE transaction_id=45035996273955001 and statement_id=4
ORDER BY transaction_id, statement_id, path_id, path_line_index;
```

You can also use the Linux `watch` command to monitor long-running queries (see [Real-Time Profiling](#)).

Example

The following series of commands creates a table for a long-running query and then runs the `QUERY_PLAN_PROFILES` system table:

```
=> CREATE TABLE longq(x int);
CREATE TABLE
=> COPY longq FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1
>> 2
>> 3
>> 4
>> 5
>> 6
>> 7
```

```
>> 8
>> 9
>> 10
>> \.
=> INSERT INTO longq SELECT f1.x+f2.x+f3.x+f4.x+f5.x+f6.x+f7.x
    FROM longq f1
    CROSS JOIN longq f2
    CROSS JOIN longq f3
    CROSS JOIN longq f4
    CROSS JOIN longq f5
    CROSS JOIN longq f6
    CROSS JOIN longq f7;
OUTPUT
-----
10000000
(1 row)
=> COMMIT;
COMMIT
```

Suppress query output on the terminal window by using the vsql `\o` command:

```
=> \o /home/dbadmin/longQprof
```

Query the new table:

```
=> SELECT * FROM longq;
```

Get the transaction and statement IDs:

```
=> SELECT transaction_id, statement_id from current_session;
transaction_id | statement_id
-----+-----
45035996273955021 |          4
(1 row)
```

Turn off the `\o` command so that Vertica continues to save query plan information to the file you specified. Alternatively, leave it on and examine the file after you query the `QUERY_PLAN_PROFILES` system table.

```
=> \o
```

Query the `QUERY_PLAN_PROFILES` system table;

```
=> SELECT
    transaction_id,
    statement_id,
    path_id,
    path_line_index,
    is_executing,
    running_time,
    path_line
FROM query_plan_profiles
WHERE transaction_id=45035996273955021 AND statement_id=4
```

```
ORDER BY transaction_id, statement_id, path_id, path_line_index;
```

Improving Readability of QUERY_PLAN_PROFILES Output

Output from the [QUERY_PLAN_PROFILES](#) table can be very wide because of the `path_line` column. To facilitate readability, query `QUERY_PLAN_PROFILES` using one or more of the following options:

- Sort output by `transaction_id`, `statement_id`, `path_id`, and `path_line_index`:

```
=> SELECT ... FROM query_plan_profiles  
      WHERE ...  
      ORDER BY transaction_id, statement_id, path_id, path_line_index;
```

- Use column aliases to decrease column width:

```
=> SELECT statement_id AS sid, path_id AS id, path_line_index AS order,  
       is_started AS start, is_completed AS end, is_executing AS exe,  
       running_time AS run, memory_allocated_bytes AS mem,  
       read_from_disk_bytes AS read, received_bytes AS rec,  
       sent_bytes AS sent, FROM query_plan_profiles  
      WHERE transaction_id=45035996273910558 AND statement_id=3  
      ORDER BY transaction_id, statement_id, path_id, path_line_index;
```

- Use the `vsql \o` command to redirect [EXPLAIN](#) output to a file:

```
=> \o /home/dbadmin/long-queries  
=> EXPLAIN SELECT * FROM customer_dimension;  
=> \o
```

Managing Query Profile Data

Vertica retains data for queries until the storage quota for the table is exceeded, when it automatically purges the oldest queries to make room for new ones. You can clear profiled data by manually calling one of the following functions:

- [CLEAR_PROFILING\(\)](#) clears profiled data from memory. For example, the following command clears profiling for general query-run information, such as the query strings used and the duration of queries.

```
=> SELECT CLEAR_PROFILING('query');
```

- [CLEAR_DATA_COLLECTOR\(\)](#) clears all memory and disk records on the Data Collector tables and functions and resets collection statistics in the [V_MONITOR.DATA_COLLECTOR](#) system table.
- [FLUSH_DATA_COLLECTOR\(\)](#) waits until memory logs are moved to disk and then flushes the Data Collector, synchronizing the DataCollector log with the disk storage.

Configuring data retention policies

Vertica retains the historical data it gathers based on retention policies, which a superuser can configure. See [Retaining Monitoring Information](#).

Analyzing Suboptimal Query Plans

If profiling uncovers a suboptimal query, invoking one of the following functions might help:

- [ANALYZE_WORKLOAD](#) analyzes system information held in system tables and provides tuning recommendations that are based on a combination of statistics, system and data collector events, and database-table-projection design.
- [ANALYZE_STATISTICS](#) collects and aggregates data samples and storage information from all nodes that store projections associated with the specified table or column.

You can also run your query through the Database Designer. See [Incremental Design](#).

Labeling Queries

To quickly identify queries for profiling and debugging purposes, include the [LABEL](#) hint.

LABEL hints are valid in the following statements:

- [DELETE](#)
- [INSERT](#)
- [MERGE](#)

- [SELECT](#)
- [UPDATE](#)
- [UNION](#): Valid in the UNION's first SELECT statement. Vertica ignores labels in subsequent SELECT statements.

For example:

```
SELECT /*+label(myselectquery)*/ COUNT(*) FROM t;  
INSERT /*+label(myinsertquery)*/ INTO t VALUES(1);
```

After you add a label to one or more queries, query the [QUERY_PROFILES](#) system table to see which queries ran with your supplied labels. The `QUERY_PROFILES` system table `IDENTIFIER` column returns the user-defined label that you previously assigned to a query. You can also obtain other query-specific data that can be useful for querying other system tables, such as transaction IDs.

For example:

```
=> SELECT identifier, query FROM query_profiles;  
  identifier | query  
-----+-----  
myselectquery | SELECT /*+label(myselectquery)*/ COUNT(*) FROM t;  
myinsertquery | INSERT /*+label(myinsertquery)*/ INTO t VALUES(1);  
myupdatequery | UPDATE /*+label(myupdatequery)*/ t SET a = 2 WHERE a = 1;  
mydeletequery | DELETE /*+label(mydeletequery)*/ FROM t WHERE a = 1;  
              | SELECT identifier, query from query_profiles;  
(5 rows)
```

About Locale

Locale specifies the user's language, country, and any special variant preferences, such as collation. Vertica uses locale to determine the behavior of certain string functions. Locale also determines the collation for various SQL commands that require ordering and comparison, such as aggregate `GROUP BY` and `ORDER BY` clauses, joins, and the analytic `ORDER BY` clause.

The default locale for a Vertica database is `en_US@collation=binary` (English US). You can define a new default locale that is used for all sessions on the database. You can also override the locale for individual sessions. However, projections are always collated using the default `en_US@collation=binary` collation, regardless of the session collation. Any locale-specific collation is applied at query time.

If you set the locale to null, Vertica sets the locale to `en_US_POSIX`. You can set the locale back to the default locale and collation by issuing the `vsq` meta-command `\locale`. For example:

```
=> set locale to '';
INFO 2567: Canonical locale: 'en_US_POSIX'
Standard collation: 'LEN'
English (United States, Computer)
SET
=> \locale en_US@collation=binary;
INFO 2567: Canonical locale: 'en_US'
Standard collation: 'LEN_KBINARY'
English (United States)
=> \locale
en_US@collation=binary;
```

You can set locale through [ODBC](#), [JDBC](#), and [ADO.net](#).

Vertica locale specifications follow a subset of the [Unicode LDML](#) standard as implemented by the [ICU library](#).

Locale Handling in Vertica

The following sections describes how Vertica handles locale.

Session Locale

Locale is session-scoped and applies only to queries executed in that session. You cannot specify locale for individual queries. When you start a session it obtains its locale from the

configuration parameter `DefaultSessionLocale`.

Query Restrictions

The following restrictions apply when queries are run with locale other than the default `en_US@collation=binary`:

- When one or more of the left-side `NOT IN` columns is `CHAR` or `VARCHAR`, multi-column `NOT IN` subqueries are not supported. For example:

```
=> CREATE TABLE test (x VARCHAR(10), y INT);
=> SELECT ... FROM test WHERE (x,y) NOT IN (SELECT ...);
ERROR: Multi-expression NOT IN subquery is not supported because a left
hand expression could be NULL
```

Note: Even if columns `test.x` and `test.y` have a `NOT NULL` constraint, an error occurs.

- If the outer query contains a `GROUP BY` clause on a `CHAR` or `VARCHAR` column, correlated `HAVING` clause subqueries are not supported. In the following example, the `GROUP BY x` in the outer query causes the error:

```
=> DROP TABLE test CASCADE;
=> CREATE TABLE test (x VARCHAR(10));
=> SELECT COUNT(*) FROM test t GROUP BY x HAVING x
    IN (SELECT x FROM test WHERE t.x||'a' = test.x||'a' );
ERROR: subquery uses ungrouped column "t.x" from outer query
```

- Subqueries that use analytic functions in the `HAVING` clause are not supported. For example:

```
=> DROP TABLE test CASCADE;
=> CREATE TABLE test (x VARCHAR(10));
=> SELECT MAX(x)OVER(PARTITION BY 1 ORDER BY 1) FROM test
    GROUP BY x HAVING x IN (SELECT MAX(x) FROM test);
ERROR: Analytics query with having clause expression that involves
aggregates and subquery is not supported
```

Collation and Projections

Projection data is sorted according to the default `en_US@collation=binary` collation. Thus, regardless of the session setting, issuing the following command creates a projection sorted by `col1` according to the binary collation:

```
=> CREATE PROJECTION p1 AS SELECT * FROM table1 ORDER BY col1;
```

In such cases, `straße` and `strasse` are not stored near each other on disk.

Sorting by binary collation also means that sort optimizations do not work in locales other than binary. Vertica returns the following warning if you create tables or projections in a non-binary locale:

```
WARNING: Projections are always created and persisted in the default  
Vertica locale. The current locale is de_DE
```

Non-Binary Locale Input Handling

When the locale is non-binary, Vertica uses the [COLLATION](#) function to transform input to a binary string that sorts in the proper order.

This transformation increases the number of bytes required for the input according to this formula:

```
result_column_width = input_octet_width * CollationExpansion + 4
```

The default value of configuration parameter `CollationExpansion` is 5.

Character Data Type Handling

- CHAR fields are displayed as fixed length, including any trailing spaces. When CHAR fields are processed internally, they are first stripped of trailing spaces. For VARCHAR fields, trailing spaces are usually treated as significant characters; however, trailing spaces are ignored when sorting or comparing either type of character string field using a non-binary locale.
- The maximum length parameter for VARCHAR and CHAR data type refers to the number of octets (bytes) that can be stored in that field and not number of characters. When using multi-byte UTF-8 characters, the fields must be sized to accommodate from 1 to 4 bytes per character, depending on the data.

Specifying Locale: Long Form

Vertica supports long forms that specify the `collation` keyword. Vertica extends long-form processing to accept collation arguments.

Syntax

[*Language*][*_script*][*_country*][*_variant*][*@collation-spec*]

Note: The following syntax options apply:

- Locale specification strings are case insensitive. For example, en_us and EN_US, are equivalent.
- You can substitute underscores with hyphens. For example: [-script]

Parameters

<i>Language</i>	A two- or three-letter lowercase code for a particular language. For example, Spanish is es English is en and French is fr. The two-letter language code uses the ISO-639 standard.
<i>_script</i>	An optional four-letter script code that follows the language code. If specified, it should be a valid script code as listed on the Unicode ISO 15924 Registry.
<i>_country</i>	A specific language convention within a generic language for a specific country or region. For example, French is spoken in many countries, but the currencies are different in each country. To allow for these differences among specific geographical, political, or cultural regions, locales are specified by two-letter, uppercase codes. For example, FR represents France and CA represents Canada. The two letter country code uses the ISO-3166 standard.
<i>_variant</i>	Differences may also appear in language conventions used within the same country. For example, the Euro currency is used in several European countries while the individual country's currency is still in circulation. To handle variations inside a language and country pair, add a third code, the variant code. The variant code is arbitrary and completely application-specific. ICU adds <code>_EURO</code> to its locale designations for locales that support the Euro currency. Variants can have any number of underscored key words. For example, <code>EURO_WIN</code> is a variant for the Euro currency on a Windows computer.

	<p>Another use of the variant code is to designate the Collation (sorting order) of a locale. For instance, the <code>es__TRADITIONAL</code> locale uses the traditional sorting order which is different from the default modern sorting of Spanish.</p>
<p><code>@collation-spec</code></p>	<p>Vertica only supports the keyword <code>collation</code>, as follows:</p> <pre>@collation=collation-type[;arg]...</pre> <p>Collation can specify one or more semicolon-delimited arguments, described below.</p> <p><i>collation-type</i> is set to one of the following values:</p> <ul style="list-style-type: none">• <code>big5han</code>: Pinyin ordering for Latin, big5 charset ordering for CJK characters (used in Chinese).• <code>dict</code>: For a dictionary-style ordering (such as in Sinhala).• <code>direct</code>: Hindi variant.• <code>gb2312/gb2312han</code>: Pinyin ordering for Latin, gb2312han charset ordering for CJK characters (used in Chinese).• <code>phonebook</code>: For a phonebook-style ordering (such as in German).• <code>pinyin</code>: Pinyin ordering for Latin and for CJK characters; that is, an ordering for CJK characters based on a character-by-character transliteration into a pinyin (used in Chinese).• <code>reformed</code>: Reformed collation (such as in Swedish).• <code>standard</code>: The default ordering for each language. For root it is [UCA] order; for each other locale it is the same as UCA (Unicode Collation Algorithm) ordering except for appropriate modifications to certain characters for that language. The following are additional choices for certain locales; they have effect only in certain locales.• <code>stroke</code>: Pinyin ordering for Latin, stroke order for CJK characters (used in Chinese) not supported.• <code>traditional</code>: For a traditional-style ordering (such as in Spanish).• <code>unihan</code>: Pinyin ordering for Latin, Unihan radical-stroke ordering

	<p>for CJK characters (used in Chinese) not supported.</p> <ul style="list-style-type: none"> • binary: Vertica default, providing UTF-8 octet ordering. <p>Notes:</p> <ul style="list-style-type: none"> • Collations might default to root, the ICU default collation. • Invalid values of the collation keyword and its synonyms do not cause an error. For example, the following does not generate an error. It simply ignores the invalid value: <pre>=> \locale en_GB@collation=xyz INFO 2567: Canonical locale: 'en_GB@collation=xyz' Standard collation: 'LEN' English (United Kingdom, collation=xyz)</pre> <p>For more about collation options, see Unicode Locale Data Markup Language (LDML).</p>
--	---

Collation Arguments

collation can specify one or more of the following arguments :

Parameter	Short form	Description
colstrength	S	<p>Sets the default strength for comparison. This feature is locale dependent.</p> <p>Set colstrength to one of the following:</p> <ul style="list-style-type: none"> • 1 primary: Ignores case and accents. Only primary differences are used during comparison—for example, a versus z. • 2 secondary: Ignores case. Only secondary and above differences are considered for comparison—for example, different accented forms of the same base letter such as a versus \u00E4. • 3 tertiary (default): Only tertiary differences and higher are considered for

Parameter	Short form	Description
		<p>comparison. Tertiary comparisons are typically used to evaluate case differences—for example, Z versus z.</p> <ul style="list-style-type: none"> • 4 quaternary: For example, used with Hiragana.
colAlternate	A	<p>Sets alternate handling for variable weights, as described in UCA, one of the following:</p> <ul style="list-style-type: none"> • non-ignorable N D • shifted S
colBackwards	F	<p>For Latin with accents, this parameter determines which accents are sorted. It sets the comparison for the second level to be backwards.</p> <p>Note: colBackwards is automatically set for French accents.</p> <p>Set colBackwards to one of the following:</p> <ul style="list-style-type: none"> • on 0: The normal UCA algorithm is used. • off X: All strings that are in Fast C or D normalization form (FCD) sort correctly, but others do not necessarily sort correctly. Set to off if the strings to be compared are in FCD.
colNormalization	N	<p>Set to one of the following:</p> <ul style="list-style-type: none"> • on 0: The normal UCA algorithm is used. • off X: All strings that are in Fast C or D normalization form (FCD) sort correctly, but others won't necessarily sort correctly. It should only be set off if the strings to be compared are in FCD.
colCaseLevel	E	<p>Set to one of the following:</p>

Parameter	Short form	Description
		<ul style="list-style-type: none"> • on 0: A level consisting only of case characteristics is inserted in front of tertiary level. To ignore accents but take cases into account, set strength to primary and case level to on. • off X: This level is omitted.
colCaseFirst	C	<p>Set to one of the following:</p> <ul style="list-style-type: none"> • upper U: Upper case sorts before lower case. • lower L: Lower case sorts before upper case. This is useful for locales that have already supported ordering but require different order of cases. It affects case and tertiary levels. • off short: Tertiary weights unaffected
colHiraganaQuaternary	H	<p>Controls special treatment of Hiragana code points on quaternary level, one of the following:</p> <ul style="list-style-type: none"> • on 0: Hiragana codepoints get lower values than all the other non-variable code points. The strength must be greater or equal than quaternary for this attribute to take effect. • off X: Hiragana letters are treated normally.
colNumeric	D	<p>If set to on, any sequence of Decimal Digits (General_Category = Nd in the [UCD]) is sorted at a primary level with its numeric value. For example, A-21 < A-123.</p>
variableTop	B	<p>Sets the default value for the variable top. All code points with primary weights less than or equal to the variable top will be considered variable, and are affected by the alternate</p>

Parameter	Short form	Description
		handling. For example, the following command sets variableTop to be HYPHEN (u2010) <pre>=> \locale en_US@colalternate=shifted;variabletop=u2010</pre>

Locale Processing Notes

- Incorrect locale strings are accepted if the prefix can be resolved to a known locale version.

For example, the following works because the language can be resolved:

```
=> \locale en_XX
INFO 2567: Canonical locale: 'en_XX'
Standard collation: 'LEN'
English (XX)
```

The following does not work because the language cannot be resolved:

```
=> \locale xx_XX
xx_XX: invalid locale identifier
```

- POSIX-type locales such as en_US.UTF-8 work to some extent in that the encoding part "UTF-8" is ignored.
- Vertica uses the icu4c-4_2_1 library to support basic locale/collation processing with some extensions. This does not currently meet [current standards for locale processing](https://tools.ietf.org/html/rfc5646) (<https://tools.ietf.org/html/rfc5646>).

Examples

Specify German locale as used in Germany (de), with phonebook-style collation:

```
=> \locale de_DE@collation=phonebook
INFO 2567: Canonical locale: 'de_DE@collation=phonebook'
Standard collation: 'KPHONEBOOK_LDE'
German (Germany, collation=Phonebook Sort Order)
Deutsch (Deutschland, Sortierung=Telefonbuch-Sortierregeln)
```

Specify German locale as used in Germany (de), with phonebook-style collation and strength set to secondary:

```
=> \locale de_DE@collation=phonebook;colStrength=secondary
INFO 2567: Canonical locale: 'de_DE@collation=phonebook'
Standard collation: 'KPHONEBOOK_LDE_S2'
German (Germany, collation=Phonebook Sort Order)
Deutsch (Deutschland, Sortierung=Telefonbuch-Sortierregeln)
```

Specifying Locale: Short Form

Vertica accepts locales in short form. You can use the short form to specify the locale and keyname pair/value names.

To determine the short form for a locale, type in the long form and view the last line of INFO, as follows:

```
\locale fr
INFO: Locale: 'fr'
INFO: French
INFO: français
INFO: Short form: 'LFR'
```

Examples

Specify en (English) locale:

```
\locale LEN
INFO: Locale: 'en'
INFO: English
INFO: Short form: 'LEN'
```

Specify German locale as used in Germany (de), with phonebook-style collation:

```
\locale LDE_KPHONEBOOK
INFO: Locale: 'de@collation=phonebook'
INFO: German (collation=Phonebook Sort Order)
INFO: Deutsch (Sortierung=Telefonbuch-Sortierregeln)
INFO: Short form: 'KPHONEBOOK_LDE'
```

Specify German locale as used in Germany (de), with phonebook-style collation:

```
\locale LDE_KPHONEBOOK_S2
INFO: Locale: 'de@collation=phonebook'
INFO: German (collation=Phonebook Sort Order)
INFO: Deutsch (Sortierung=Telefonbuch-Sortierregeln)
INFO: Short form: 'KPHONEBOOK_LDE_S2'
```

Supported Locales

The following are the supported locale strings for Vertica. Each locale can optionally have a list of key/value pairs (see [Specifying Locale: Long Form](#)).

Locale Name	Language or Variant	Region
af	Afrikaans	
af_NA	Afrikaans	Namibian Afrikaans
af_ZA	Afrikaans	South Africa
am	Ethiopic

Locale and UTF-8 Support

Vertica supports Unicode Transformation Format-8, or UTF8, where 8 equals 8-bit. UTF-8 is a variable-length character encoding for Unicode created by Ken Thompson and Rob Pike. UTF-8 can represent any universal character in the Unicode standard. Initial encoding of byte codes and character assignments for UTF-8 coincides with ASCII. Thus, UTF8 requires little or no change for software that handles ASCII but preserves other values.

Vertica database servers expect to receive all data in UTF-8, and Vertica outputs all data in UTF-8. The ODBC API operates on data in UCS-2 on Windows systems, and normally UTF-8 on Linux systems. JDBC and ADO.NET APIs operate on data in UTF-16. Client drivers automatically convert data to and from UTF-8 when sending to and receiving data from Vertica using API calls. The drivers do not transform data loaded by executing a [COPY](#) or [COPY LOCAL](#) statement.

UTF-8 String Functions

The following string functions treat VARCHAR arguments as UTF-8 strings (when USING OCTETS is not specified) regardless of locale setting.

String function	Description
LOWER	Returns a VARCHAR value containing the argument converted to lowercase letters.
UPPER	Returns a VARCHAR value containing the argument converted to uppercase letters.
INITCAP	Capitalizes first letter of each alphanumeric word and puts the rest in lowercase.
INSTR	Searches string for substring and returns an integer indicating the position of the character in string that is the first character of this occurrence.
SPLIT_PART	Splits string on the delimiter and returns the location of the beginning of the given field (counting from one).
POSITION	Returns an integer value representing the character location of a specified substring with a string (counting from one).

String function	Description
STRPOS	Returns an integer value representing the character location of a specified substring within a string (counting from one).

Locale-Aware String Functions

Vertica provides string functions to support internationalization. Unless otherwise specified, these string functions can optionally specify whether VARCHAR arguments should be interpreted as octet (byte) sequences, or as (locale-aware) sequences of characters. Specify this information by adding the parameter `USING OCTETS` and `USING CHARACTERS` (default) to the function.

The following table lists all string functions that are locale-aware:

String function	Description
BTRIM	Removes the longest string consisting only of specified characters from the start and end of a string.
CHARACTER_LENGTH	Returns an integer value representing the number of characters or octets in a string.
GREATEST	Returns the largest value in a list of expressions.
GREATESTB	Returns its greatest argument, using binary ordering, not UTF-8 character ordering.
INITCAP	Capitalizes first letter of each alphanumeric word and puts the rest in lowercase.
INSTR	Searches string for substring and returns an integer indicating the position of the character in string that is the first character of this occurrence.
LEAST	Returns the smallest value in a list of expressions.
LEASTB	Returns its least argument, using binary ordering, not UTF-8 character ordering.
LEFT	Returns the specified characters from the left side of a string.
LENGTH	Takes one argument as an input and returns returns an integer value

String function	Description
	representing the number of characters in a string.
LTRIM	Returns a VARCHAR value representing a string with leading blanks removed from the left side (beginning).
OVERLAY	Returns a VARCHAR value representing a string having had a substring replaced by another string.
OVERLAYB	Returns an octet value representing a string having had a substring replaced by another string.
REPLACE	replaces all occurrences of characters in a string with another set of characters.
RIGHT	Returns the <i>length</i> right-most characters of string.
SUBSTR	Returns a VARCHAR value representing a substring of a specified string.
SUBSTRB	Returns a byte value representing a substring of a specified string.
SUBSTRING	Given a value, a position, and an optional length, returns a value representing a substring of the specified string at the given position.
TRANSLATE	Replaces individual characters in <i>string_to_replace</i> with other characters.
UPPER	Returns a VARCHAR value containing the argument converted to uppercase letters.

Appendix: Binary File Formats

This appendix presents the binary file format details required to load files into the Vertica database with the COPY statement. Binary files must adhere to the required format.

Creating Native Binary Format Files

Using COPY to load data with the NATIVE parser requires that the input data files adhere to the format described below. All NATIVE files must contain:

- A file signature.
- A set of column size definitions.
- The rows of data.

Note: You cannot mix Binary and ASCII source files in the same COPY statement.

File Signature

The first part of a NATIVE binary file consists of a file signature. The contents of the signature are fixed, and listed in the following table.

Byte Offset	0	1	2	3	4	5	6	7	8	9	10
Hex Value	4E	41	54	49	56	45	0A	FF	0D	0A	00
Text Literals	N	A	T	I	V	E	E'\n'	E'\317'	E'\r'	E'\n'	E'\000'

The purpose of the required signature is to ensure that the file has neither been corrupted by a non-8-bit file transfer, nor stripped of carriage returns, linefeeds, or null values. If the signature is intact, Vertica determines that the file has not been corrupted.

Column Definitions

Following the file signature, the file must define the widths of each column in the file as follows.

Byte Offset	Length (bytes)	Description	Comments
11	4	Header area length	32-bit integer in little-endian format that contains the length in bytes of remaining in the header, not including itself. This is the number of bytes from the end of this value to the start of the row data.
15	2	NATIVE file version	16-bit integer in little-endian format containing the version number of the NATIVE file format. The only valid value is currently 1. Future changes to the format could be assigned different version numbers to maintain backward compatibility.
17	1	Filler	Always 0.
18	2	Number of columns	16-bit integer in little-endian format that contains the number of columns in each row in the file.
20+	4 bytes for each column of data in the table	Column widths	Array of 32-bit integers in little-endian format that define the width of each column in the row. Variable-width columns have a value of -1 (0xFF 0xFF 0xFF 0xFF).

Note: All integers in NATIVE files are in **little-endian format** (least significant byte first).

The width of each column is determined by the data type it contains. The following table explains the column width needed for each data type, along with the data encoding.

Data Type	Length (bytes)	Column Content
INTEGER	1, 2, 4, 8	8-, 16-, 32-, and 64-bit integers are supported. All multi-byte values are stored in little-endian format. Note: All values for a column must be the width you

Data Type	Length (bytes)	Column Content
		specify here. If you set the length of an INTEGER column to be 4 bytes, then all of the values you supply for that column must be 32-bit integers.
BOOLEAN	1	0 for false, 1 for true.
FLOAT	8	Encoded in IEEE-754 format.
CHAR	User-specified	<ul style="list-style-type: none"> • Strings shorter than the specified length must be right-padded with spaces (E'\040'). • Strings are not null-terminated. • Character encoding is UTF-8. • UTF-8 strings can contain multi-byte characters. Therefore, number of characters in the string may not equal the number of bytes.
VARCHAR	4-byte integer (length) + data	<p>The column width for a VARCHAR column is always -1 to signal that it contains variable-length data.</p> <ul style="list-style-type: none"> • Each VARCHAR column value starts with a 32-bit integer that contains the number of bytes in the string. • The string must not be null-terminated. • Character encoding must be UTF-8. • Remember that UTF-8 strings can contain multi-byte characters. Therefore, number of characters in the string may not equal the number of bytes.
DATE	8	64-bit integer in little-endian format containing the Julian day since Jan 01 2000 (J2451545)
TIME	8	64-bit integer in little-endian format containing the number of microseconds since midnight in the UTC time zone.
TIMETZ	8	64-bit value where

Data Type	Length (bytes)	Column Content
		<ul style="list-style-type: none"> Upper 40 bits contain the number of microseconds since midnight. Lower 24 bits contain time zone as the UTC offset in microseconds calculated as follows: Time zone is logically from -24hrs to +24hrs from UTC. Instead it is represented here as a number between 0hrs to 48hrs. Therefore, 24hrs should be added to the actual time zone to calculate it. <p>Each portion is stored in little-endian format (5 bytes followed by 3 bytes).</p>
TIMESTAMP	8	64-bit integer in little-endian format containing the number of microseconds since Julian day: Jan 01 2000 00:00:00.
TIMESTAMPPTZ	8	A 64-bit integer in little-endian format containing the number of microseconds since Julian day: Jan 01 2000 00:00:00 in the UTC timezone.
INTERVAL	8	64-bit integer in little-endian format containing the number of microseconds in the interval.
BINARY	User-specified	Similar to CHAR. The length should be specified in the file header in the <i>Field Lengths</i> entry for the field. The field in the record must contain <i>length</i> number of bytes. If the value is smaller than the specified length, the remainder should be filled with nulls (E'\000').
VARBINARY	4-byte integer + data	Stored just like VARCHAR but data is interpreted as bytes rather than UTF-8 characters.
NUMERIC	(precision, scale) (precision ÷ 19 + 1) × 8 rounded up	A constant-length data type. Length is determined by the precision, assuming that a 64-bit unsigned integer can store roughly 19 decimal digits. The data consists of a sequence of 64-bit integers, each stored in little-endian format, with the most significant integer first. Data in the integers is stored in base 2 ⁶⁴ . 2's complement is used for

Data Type	Length (bytes)	Column Content
		<p>negative numbers.</p> <p>If there is a scale, then the numeric is stored as $\text{numeric} \times 10^{\text{scale}}$; that is, all real numbers are stored as integers, ignoring the decimal point. It is required that the scale matches that of the target column in the dataanchor table. Another option is to use FILLER columns to coerce the numeric to the scale of the target column.</p>

Row Data

Following the file header is a sequence of records that contain the data for each row of data. Each record starts with a header:

Length (bytes)	Description	Comments
4	Row length	<p>A 32-bit integer in little-endian format containing the length of the row's data in bytes. It includes the size of data only, not the header.</p> <p>Note: The number of bytes in each row can vary not only because of variable-length data, but also because columns containing NULL values do not have any data in the row. If column 3 has a NULL value, then column 4's data immediately follows the end of column 2's data. See the next</p>
Number of columns ÷ 8 rounded up (<code>CEILING (NumFields / (sizeof (uint8) * 8));</code>)	Null value bit field	<p>A series of bytes whose bits indicate whether a column contains a NULL. The most significant bit of the first byte indicates whether the first column in this row contains a NULL, the next most significant bit indicates whether the next column contains a NULL, and so on. If a bit is 1 (true) then the column contains a NULL, and there is no value for the column in the data for the row.</p>

Following the record header is the column values for the row. There is no separator characters for these values. Their location in the row of data is calculated based on where the previous column's data ended. Most data types have a fixed width, so their location is easy to

determine. Variable-width values (such as VARCHAR and VARBINARY) start with a count of the number of bytes the value contains.

See the table in the previous section for details on how each data type's value is stored in the row's data.

Example

The example below demonstrates creating a table and loading a NATIVE file that contains a single row of data. The table contains all possible data types.

```
=> CREATE TABLE allTypes (INTCOL INTEGER,
                           FLOATCOL FLOAT,
                           CHARCOL CHAR(10),
                           VARCHARCOL VARCHAR,
                           BOOLCOL BOOLEAN,
                           DATECOL DATE,
                           TIMESTAMPCOL TIMESTAMP,
                           TIMESTAMPTZCOL TIMESTAMPTZ,
                           TIMECOL TIME,
                           TIMETZCOL TIMETZ,
                           VARBINCOL VARBINARY,
                           BINCOL BINARY,
                           NUMCOL NUMERIC(38,0),
                           INTERVALCOL INTERVAL
                           );
=> COPY allTypes FROM '/home/dbadmin/allTypes.bin' NATIVE DIRECT;
=> \pset expanded
Expanded display is on.
