```

The following table breaks this file down into each of its components, and describes the values it contains.

Hex Values	Description	Value
4E 41 54 49 56 45 0A FF 0D 0A 00	Signature	NATIVE\n\317\r\n\000
3D 00 00 00	Header area length	61 bytes
01 00	Native file format version	Version 1
00	Filler value	0
0E 00	Number of columns	14 columns
08 00 00 00	Width of column 1 (INTEGER)	8 bytes
08 00 00 00	Width of column 2 (FLOAT)	8 bytes
0A 00 00 00	Width of column 3 (CHAR(10))	10 bytes
FF FF FF FF	Width of column 4 (VARCHAR)	-1 (variable width column)
01 00 00 00	Width of column 5 (BOOLEAN)	1 bytes
08 00 00 00	Width of column 6 (DATE)	8 bytes
08 00 00 00	Width of column 7 (TIMESTAMP)	8 bytes

Hex Values	Description	Value
08 00 00 00	Width of column 8 (TIMESTAMPTZ)	8 bytes
08 00 00 00	Width of column 9 (TIME)	8 bytes
08 00 00 00	Width of column 10 (TIMETZ)	8 bytes
FF FF FF FF	Width of column 11 (VARBINARY)	-1 (variable width column)
03 00 00 00	Width of column 12 (BINARY)	3 bytes
18 00 00 00	Width of column 13 (NUMERIC)	24 bytes. The size is calculated by dividing 38 (the precision specified for the numeric column) by 19 (the number of digits each 64-bit chunk can represent) and adding 1. $38 \div 19 + 1 = 3$. then multiply by eight to get the number of bytes needed. $3 \times 8 = 24$ bytes.
08 00 00 00	Width of column 14 (INTERVAL). last portion of the header section.	8 bytes
73 00 00 00	Number of bytes of data for the first row. this is the start of the first row of data.	115 bytes
00 00	Bit field for the null values contained in the first row of data	The row contains no null values.
01 00 00 00 00 00 00 00	Value for 64-bit INTEGER column	1
C3 F5 28 5C	Value for the	-1.11

Hex Values	Description	Value
8F C2 F1 BF	FLOAT column	
6F 6E 65 20 20 20 20 20 20 20	Value for the CHAR(10) column	"one " (padded With 7 spaces to fill the full 10 characters for the column)
03 00 00 00	The number of bytes in the following VARCHAR value.	3 bytes
4F 4E 45	The value for the VARCHAR column	"ONE"
01	The value for the BOOLEAN column	True
9A FE FF FF FF FF FF FF	The value for the DATE column	1999-01-08
30 85 B3 4F 7E E7 FF FF	The value for the TIMESTAMP column	1999-02-23 03:11:52.35
40 1F 3E 64 E8 E3 FF FF	The value for the TIMESTAMPTZ column	1999-01-08 07:04:37-05
C0 2E 98 FF 05 00 00 00	The value for the TIME column	07:09:23
D0 97 01 80 F0 79 F0 10	The value for the TIMETZ column	15:12:34-05
02 00 00 00	The number of bytes in the following VARBINARY value	2 bytes
AB CD	The value for the VARBINARY column	Binary data (\253\315 as octal values)

Hex Values	Description	Value
AB CD	The value for the BINARY column	Binary data (\253\315 as octal values)
00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 64 D6 12 00 00 00 00 00	The value for the NUMERIC column	1234532
C0 47 A3 8E 02 00 00 00	The value for the INTERVAL column	03:03:03

Analyzing Data

Welcome to the Analyzing Data Guide! This guide explains how to query and analyze data in your Vertica database.

Queries

Queries are database operations that retrieve data from one or more tables or views. In Vertica, the top-level SELECT statement is the query, and a query nested within another SQL statement is called a subquery.

Vertica is designed to run the same SQL standard queries that run on other databases. However, there are some differences between Vertica queries and queries used in other relational database management systems.

The Vertica [transaction model](#) is different from the SQL standard in a way that has a profound effect on query performance. You can:

- Run a query on a static backup of the database from any specific date and time. Doing so avoids holding locks or blocking other database operations.
- Use a subset of the standard SQL isolation levels and access modes (read/write or read-only) for a user session.

In Vertica, the primary structure of a SQL query is its statement. Each statement ends with a semicolon, and you can write multiple queries separated by semicolons; for example:

```
=> CREATE TABLE t1( ..., date_col date NOT NULL, ...);  
=> CREATE TABLE t2(..., state VARCHAR NOT NULL, ...);
```

Multiple Instances of Dimension Tables in the FROM Clause

The same dimension table can appear multiple times in a query's FROM clause, using different aliases. For example:

```
=> SELECT * FROM fact, dimension d1, dimension d2  
WHERE fact.fk = d1.pk  
AND  
fact.name = d2.name;
```

Historical Queries

Vertica supports querying historical data for individual SELECT statements.

Syntax

Vertica can run a query from a backup of the database taken at a specific date and time or at a specific epoch. The syntax is:

```
AT TIME 'timestamp' select...  
AT EPOCH epoch_number select...  
AT EPOCH LATEST select...
```

The command queries all data in the database up to and including the specified epoch or the epoch representing the specified date and time, without holding a lock or blocking write operations. The specified `TIMESTAMP` and `epoch_number` values must be greater than or equal to the Ancient History Mark epoch.

Parameters

AT EPOCH LATEST	Queries all committed data in the database up to, but not including, the current epoch.
AT EPOCH <i>epoch_number</i>	Queries all data in the database up to and including the specified epoch without holding a lock or blocking write operations.
AT TIME ' <i>timestamp</i> '	Queries all committed data in the database up to the time stamp specified. <code>AT TIME 'timestamp'</code> queries are resolved to the next epoch boundary before being evaluated.

Historical queries are useful because they access data in past epochs only. Historical queries do not need to hold table locks or block write operations because they do not return the absolute latest data. Their content is private to the transaction and valid only for the length of the transaction.

Historical queries behave in the same manner regardless of transaction isolation level. Historical queries observe only committed data, even excluding updates made by the current transaction, unless those updates are to a temporary table.

Be aware that there is only one backup of the logical schema. This means that any changes you make to the schema are reflected across all epochs. If, for example, you add a new column to a table and you specify a default value for the column, all historical epochs display the new column and its default value.

- [Transactions](#)
- [AboutQueryExecution](#)

Temporary Tables

You can use the `CREATE TEMPORARY TABLE` statement to implement certain queries using multiple steps:

1. Create one or more temporary tables.
2. Execute queries and store the result sets in the temporary tables.
3. Execute the main query using the temporary tables as if they were a normal part of the logical schema.

See [CREATE TEMPORARY TABLE](#) in the SQL Reference Manual for details.

SQL Queries

All DML (Data Manipulation Language) statements can contain queries. This section introduces some of the query types in Vertica, with additional details in later sections.

Note: Many of the examples in this chapter use the [VMart schema](#). For information about other Vertica-supplied queries, see the [Getting Started](#).

Simple Queries

Simple queries contain a query against one table. Minimal effort is required to process the following query, which looks for product keys and SKU numbers in the product table:

```
=> SELECT product_key, sku_number FROM public.product_dimension;
product_key | sku_number
-----+-----
```

```
43      | SKU-#129
87      | SKU-#250
42      | SKU-#125
49      | SKU-#154
37      | SKU-#107
36      | SKU-#106
86      | SKU-#248
41      | SKU-#121
88      | SKU-#257
40      | SKU-#120
(10 rows)
```

Joins

Joins use a relational operator that combines information from two or more tables. The query's `ON` clause specifies how tables are combined, such as by matching foreign keys to primary keys. In the following example, the query requests the names of stores with transactions greater than 70 by joining the store key ID from the store schema's sales fact and sales tables:

```
=> SELECT store_name, COUNT(*) FROM store.store_sales_fact
      JOIN store.store_dimension ON store.store_sales_fact.store_key = store.store_dimension.store_key
      GROUP BY store_name HAVING COUNT(*) > 70 ORDER BY store_name;

store_name | count
-----+-----
Store49    |    72
Store83    |    78
(2 rows)
```

For more detailed information, see [Joins](#). See also the Multicolumn subqueries section in [Subquery Examples](#).

Cross Joins

Also known as the Cartesian product, a cross join is the result of joining every record in one table with every record in another table. A cross join occurs when there is no join key between tables to restrict records. The following query, for example, returns all instances of vendor and store names in the vendor and store tables:

```
=> SELECT vendor_name, store_name FROM public.vendor_dimension
      CROSS JOIN store.store_dimension;

vendor_name | store_name
-----+-----
Deal Warehouse | Store41
Deal Warehouse | Store12
Deal Warehouse | Store46
Deal Warehouse | Store50
```

```
Deal Warehouse | Store15
Deal Warehouse | Store48
Deal Warehouse | Store39
Sundry Wholesale | Store41
Sundry Wholesale | Store12
Sundry Wholesale | Store46
Sundry Wholesale | Store50
Sundry Wholesale | Store15
Sundry Wholesale | Store48
Sundry Wholesale | Store39
Market Discounters | Store41
Market Discounters | Store12
Market Discounters | Store46
Market Discounters | Store50
Market Discounters | Store15
Market Discounters | Store48
Market Discounters | Store39
Market Suppliers | Store41
Market Suppliers | Store12
Market Suppliers | Store46
Market Suppliers | Store50
Market Suppliers | Store15
Market Suppliers | Store48
Market Suppliers | Store39
... | ...
(4000 rows)
```

This example's output is truncated because this particular cross join returned several thousand rows. See also [Cross Joins](#).

Subqueries

A subquery is a query nested within another query. In the following example, we want a list of all products containing the highest fat content. The inner query (subquery) returns the product containing the highest fat content among all food products to the outer query block (containing query). The outer query then uses that information to return the names of the products containing the highest fat content.

```
=> SELECT product_description, fat_content FROM public.product_dimension
      WHERE fat_content IN
          (SELECT MAX(fat_content) FROM public.product_dimension
           WHERE category_description = 'Food' AND department_description = 'Bakery')
      LIMIT 10;
      product_description | fat_content
-----|-----
Brand #59110 hotdog buns |          90
Brand #58107 english muffins |          90
Brand #57135 english muffins |          90
Brand #54870 cinnamon buns |          90
Brand #53690 english muffins |          90
Brand #53096 bagels |          90
Brand #50678 chocolate chip cookies |          90
```

```
Brand #49269 wheat bread      |      90  
Brand #47156 coffee cake    |      90  
Brand #43844 corn muffins   |      90  
(10 rows)
```

For more information, see [Subqueries](#).

Sorting Queries

Use the `ORDER BY` clause to order the rows that a query returns.

Special Note About Query Results

You could get different results running certain queries on one machine or another for the following reasons:

- [Partitioning](#) on a `FLOAT` type could return nondeterministic results because of the precision, especially when the numbers are close to one another, such as results from the `RADIANS()` function, which has a very small range of output.

To get deterministic results, use `NUMERIC` if you must partition by data that is not an `INTEGER` type.

- Most analytics (with analytic aggregations, such as `MIN()`/`MAX()`/`SUM()`/`COUNT()`/`AVG()` as exceptions) rely on a unique order of input data to get deterministic result. If the analytic [window-order](#) clause cannot resolve ties in the data, results could be different each time you run the query.

For example, in the following query, the analytic `ORDER BY` does not include the first column in the query, `promotion_key`. So for a tie of `AVG(RADIANS(cost_dollar_amount))`, `product_version`, the same `promotion_key` could have different positions within the analytic partition, resulting in a different `NTILE()` number. Thus, `DISTINCT` could also have a different result:

```
=> SELECT COUNT(*) FROM  
      (SELECT DISTINCT SIN(FLOOR(MAX(store.store_sales_fact.promotion_key))),  
       NTILE(79) OVER(PARTITION BY AVG (RADIANS  
         (store.store_sales_fact.cost_dollar_amount ))  
       ORDER BY store.store_sales_fact.product_version)  
       FROM store.store_sales_fact  
       GROUP BY store.store_sales_fact.product_version,  
                store.store_sales_fact.sales_dollar_amount ) AS store;  
count
```

```
-----  
1425  
(1 row)
```

If you add `MAX(promotion_key)` to analytic `ORDER BY`, the results are the same on any machine:

```
=> SELECT COUNT(*) FROM (SELECT DISTINCT MAX(store.store_sales_fact.promotion_key),  
    NTILE(79) OVER(PARTITION BY MAX(store.store_sales_fact.cost_dollar_amount)  
    ORDER BY store.store_sales_fact.product_version,  
    MAX(store.store_sales_fact.promotion_key))  
    FROM store.store_sales_fact  
    GROUP BY store.store_sales_fact.product_version,  
    store.store_sales_fact.sales_dollar_amount) AS store;
```

Subqueries

A subquery is a `SELECT` statement embedded within another `SELECT` statement. The embedded subquery is often referenced as the query's inner statement, while the containing query is typically referenced as the query's statement, or outer query block. A subquery returns data that the outer query uses as a condition to determine what data to retrieve.

Like any query, a subquery returns records from a table that might consist of a single column and record, a single column with multiple records, or multiple columns and records. Queries can be [noncorrelated](#) or [correlated](#). You can even use them to [update](#) or [delete](#) records in a table based on values that are stored in other database tables.

Note: Many examples in this section use the [VMart database](#).

Subqueries Used in Search Conditions

Subqueries are used as search conditions in order to filter results. They specify the conditions for the rows returned from the containing query's select-list, a query expression, or the subquery itself. The operation evaluates to TRUE, FALSE, or UNKNOWN (NULL).

Syntax

```
search-condition {
  [ { AND | OR [ NOT ] } { predicate | ( search-condition ) } ]
  } [ ,... ]
predicate
  { expression comparison-operator expression
  ... | string-expression [ NOT ] { LIKE | ILIKE | LIKEB | ILIKEB } string-expression
  ... | expression IS [ NOT ] NULL
  ... | expression [ NOT ] IN ( subquery | expression [ ,...n ] )
  ... | expression comparison-operator [ ANY | SOME ] ( subquery )
  ... | expression comparison-operator ALL ( subquery )
  ... | expression OR ( subquery )
  ... | [ NOT ] EXISTS ( subquery )
  ... | [ NOT ] IN ( subquery )
  }
```

Parameters

<p><i>search-condition</i></p>	<p>Specifies the search conditions for the rows returned from one of the following:</p> <ul style="list-style-type: none"> • Containing query's select-list • Query expression • Subquery <p>If the subquery is used with an UPDATE or DELETE statement, UPDATE specifies the rows to update and DELETE specifies the rows to delete.</p>
<p>{ AND OR NOT }</p>	<p>Keywords that specify the logical operators that combine conditions, or in the case of NOT, negate conditions.</p> <ul style="list-style-type: none"> • AND — Combines two conditions and evaluates

	<p>to TRUE when both of the conditions are TRUE.</p> <ul style="list-style-type: none"> • OR — Combines two conditions and evaluates to TRUE when either condition is TRUE. • NOT — Negates the Boolean expression specified by the predicate.
<i>predicate</i>	An expression that returns TRUE, FALSE, or UNKNOWN (NULL).
<i>expression</i>	A column name, constant, functiona scalar subquery, or combination of column names, constants, and functions connected by operators or subqueries.
<i>comparison-operator</i>	<p>Test conditions between expressions, one of the following operators:</p> <ul style="list-style-type: none"> • < tests the condition of one expression being less than the other. • > tests the condition of one expression being greater than the other. • <= tests the condition of one expression being less than or equal to the other expression. • >= tests the condition of one expression being greater than or equal to the other expression. • = tests the equality between two expressions. • <=> tests equality like the = operator, but it returns TRUE instead of UNKNOWN if both operands are UNKNOWN and FALSE instead of UNKNOWN if one operand is UNKNOWN. • <> and != test the condition of two expressions not equal to one another.
<i>string-expression</i>	A character string with optional wildcard (*) characters.
[NOT] { LIKE ILIKE LIKEB ILIKEB }	Indicates that the character string following the

	predicate is to be used (or not used) for pattern matching.
IS [NOT] NULL	Searches for values that are null or are not null.
ALL	Used with a comparison operator and a subquery. Returns TRUE for the lefthand predicate if all values returned by the subquery satisfy the comparison operation, or FALSE if not all values satisfy the comparison or if the subquery returns no rows to the outer query block.
ANY SOME	ANY and SOME are synonyms and are used with a comparison operator and a subquery. Either returns TRUE for the lefthand predicate if any value returned by the subquery satisfies the comparison operation, or FALSE if no values in the subquery satisfy the comparison or if the subquery returns no rows to the outer query block. Otherwise, the expression is UNKNOWN.
[NOT] EXISTS	Used with a subquery to test for the existence of records that the subquery returns.
[NOT] IN	Searches for an expression on the basis of an expression's exclusion or inclusion from a list. The list of values is enclosed in parentheses and can be a subquery or a set of constants.

Logical Operators AND and OR

The AND and OR logical operators combine two conditions. AND evaluates to TRUE when both of the conditions joined by the AND keyword are matched, and OR evaluates to TRUE when either condition joined by OR is matched.

OR Subqueries (complex expressions)

Vertica supports subqueries in more complex expressions using OR; for example:

- More than one subquery in the conjunct expression:

```
(SELECT MAX(b) FROM t1) + SELECT (MAX FROM t2) a IN (SELECT a FROM t1) OR b IN (SELECT x FROM t2)
```

- An OR clause in the conjunct expression involves at least one subquery:

```
a IN (SELECT a FROM t1) OR b IN (SELECT x FROM t2) a IN (SELECT a from t1) OR b = 5  
a = (SELECT MAX FROM t2) OR b = 5
```

- One subquery is present but it is part of a another expression:

```
x IN (SELECT a FROM t1) = (x = (SELECT MAX FROM t2) (x IN (SELECT a FROM t1) IS NULL
```

How AND Queries Are Evaluated

Vertica treats expressions separated by AND (conjunctive) operators individually. For example if the WHERE clause were:

```
WHERE (a IN (SELECT a FROM t1) OR b IN (SELECT x FROM t2)) AND (c IN (SELECT a FROM t1))
```

the query would be interpreted as two conjunct expressions:

1. (a IN (SELECT a FROM t1) OR b IN (SELECT x FROM t2))
2. (c IN (SELECT a FROM t1))

The first expression is considered a complex subquery, whereas the second expression is not.

Examples

The following list shows some of the ways you can filter complex conditions in the WHERE clause:

- OR expression between a subquery and a non-subquery condition:

```
=> SELECT x FROM t WHERE x > (SELECT SUM(DISTINCT x) FROM t GROUP BY y) OR x < 9;
```

- OR expression between two subqueries:

```
=> SELECT * FROM t WHERE x=(SELECT x FROM t) OR EXISTS(SELECT x FROM tt);
```

- Subquery expression:

```
=> SELECT * FROM t WHERE x=(SELECT x FROM t)+1 OR x<>(SELECT x FROM t)+1;
```

- OR expression with [NOT] IN subqueries:

```
=> SELECT * FROM t WHERE NOT (EXISTS (SELECT x FROM t)) OR x >9;
```

- OR expression with IS [NOT] NULL subqueries:

```
=> SELECT * FROM t WHERE (SELECT * FROM t)IS NULL OR (SELECT * FROM tt)IS NULL;
```

- OR expression with boolean column and subquery that returns Boolean data type:

```
=> SELECT * FROM t2 WHERE x = (SELECT x FROM t2) OR x;
```

Note: To return TRUE, the argument of OR must be a Boolean data type.

- OR expression in the CASE statement:

```
=> SELECT * FROM t WHERE CASE WHEN x=1 THEN x > (SELECT * FROM t)
      OR x < (SELECT * FROM t2) END ;
```

- Analytic function, NULL-handling function, string function, math function, and so on:

```
=> SELECT x FROM t WHERE x > (SELECT COALESCE (x,y) FROM t GROUP BY x,y) OR
      x < 9;
```

- In user-defined functions (assuming f() is one):

```
=> SELECT * FROM t WHERE x > 5 OR x = (SELECT f(x) FROM t);
```

- Use of parentheses at different places to restructure the queries:

```
=> SELECT x FROM t WHERE (x = (SELECT x FROM t) AND y = (SELECT y FROM t))
      OR (SELECT x FROM t) =1;
```

- Multicolumn subqueries:

```
=> SELECT * FROM t WHERE (x,y) = (SELECT x,y FROM t) OR x > 5;
```

- Constant/NULL on lefthand side of subquery:

```
=> SELECT * FROM t WHERE x > 5 OR 5 = (SELECT x FROM t);
```

See Also

- [Subquery Restrictions](#)

In Place of an Expression

Subqueries that return a single value (unlike a list of values returned by IN subqueries) can be used just about anywhere an expression is allowed in SQL. It can be a column name, a constant, a function, a scalar subquery, or a combination of column names, constants, and functions connected by operators or subqueries.

For example:

```
=> SELECT c1 FROM t1 WHERE c1 = ANY (SELECT c1 FROM t2) ORDER BY c1;
=> SELECT c1 FROM t1 WHERE COALESCE((t1.c1 > ANY (SELECT c1 FROM t2)), TRUE);
=> SELECT c1 FROM t1 GROUP BY c1 HAVING
    COALESCE((t1.c1 <> ALL (SELECT c1 FROM t2)), TRUE);
```

Multi-column expressions are also supported:

```
=> SELECT c1 FROM t1 WHERE (t1.c1, t1.c2) = ALL (SELECT c1, c2 FROM t2);
=> SELECT c1 FROM t1 WHERE (t1.c1, t1.c2) <> ANY (SELECT c1, c2 FROM t2);
```

Vertica returns an error on queries where more than one row would be returned by any subquery used as an expression:

```
=> SELECT c1 FROM t1 WHERE c1 = (SELECT c1 FROM t2) ORDER BY c1;
ERROR: more than one row returned by a subquery used as an expression
```

See Also

- [Subquery Restrictions](#)

Comparison Operators

Vertica supports Boolean subquery expressions in the WHERE clause with any of the following operators:

>
<
>=
<=
=
<>
<=>

WHERE clause subqueries filter results and take the following form:

```
SELECT <column, ...> FROM <table>  
WHERE <condition> (SELECT <column, ...> FROM <table> WHERE <condition>);
```

These conditions are available for all data types where comparison makes sense. All [Comparison Operators](#) are binary operators that return values of TRUE, FALSE, or UNKNOWN (NULL).

Expressions that correlate to just one outer table in the outer query block are supported, and these correlated expressions can be comparison operators.

The following subquery scenarios are supported:

```
SELECT * FROM T1 WHERE T1.x = (SELECT MAX(c1) FROM T2);  
SELECT * FROM T1 WHERE T1.x >= (SELECT MAX(c1) FROM T2 WHERE T1.y = T2.c2);  
SELECT * FROM T1 WHERE T1.x <= (SELECT MAX(c1) FROM T2 WHERE T1.y = T2.c2);
```

See Also

[Subquery Restrictions](#)

LIKE Pattern Matching

Vertica supports LIKE pattern-matching conditions in subqueries and take the following form:

string-expression [NOT] { LIKE | ILIKE | LIKEB | ILIKEB } *string-expression*

The following command searches for customers whose company name starts with "Ev" and returns the total count:

```
=> SELECT COUNT(*) FROM customer_dimension WHERE customer_name LIKE  
      (SELECT 'Ev%' FROM customer_dimension LIMIT 1);  
count  
-----  
      153  
(1 row)
```

Vertica also supports single-row subqueries as the pattern argument for LIKEB and ILIKEB predicates; for example:

```
=> SELECT * FROM t1 WHERE t1.x LIKEB (SELECT t2.x FROM t2);
```

The following symbols are substitutes for the LIKE keywords:

```
~~      LIKE  
~#      LIKEB  
~~*     ILIKE  
~#*     ILIKEB  
!~~     NOT LIKE  
!~#     NOT LIKEB  
!~~*    NOT ILIKE  
!~#*    NOT IILIKEB
```

Note: The ESCAPE keyword is not valid for the above symbols.

See [LIKE-predicate](#) in the SQL Reference Manual for additional examples.

ANY and ALL

You typically use comparison operators (=, >, <, etc.) only on subqueries that return one row. With ANY and ALL operators, you can make comparisons on subqueries that return multiple rows.

These subqueries take the following form:

```
expression comparison-operator { ANY | ALL } (subquery)
```

ANY and ALL evaluate whether any or all of the values returned by a subquery match the left-hand expression.

Equivalent Operators

You can use following operators instead of ANY or ALL:

This operator...	Is equivalent to:
SOME	ANY
IN	= ANY
NOT IN	<> ALL

Example Data

Examples below use the following tables and data:

<pre>CREATE TABLE t1 (c1 int, c2 VARCHAR(8));</pre> <pre>=> SELECT * FROM t1 ORDER BY c1; c1 c2 -----+----- 1 cab 1 abc 2 fed 2 def 3 ihg 3 ghi 4 jkl 5 mno (8 rows)</pre>	<pre>CREATE TABLE t1 (c1 int, c2 VARCHAR(8));</pre> <pre>=> SELECT * FROM t2 ORDER BY c1; c1 c2 -----+----- 1 abc 2 fed 3 jkl 3 stu 3 zzz (5 rows)</pre>
---	--

ANY Subqueries

Subqueries that use the ANY keyword return true when any value retrieved in the subquery matches the value of the left-hand expression.

Examples

An ANY subquery within an expression:

```
=> SELECT c1, c2 FROM t1 WHERE COALESCE((t1.c1 > ANY (SELECT c1 FROM t2)));
c1 | c2
-----+-----
 2 | fed
 2 | def
 3 | ihg
 3 | ghi
 4 | jkl
 5 | mno
(6 rows)
```

ANY noncorrelated subqueries without aggregates:

```
=> SELECT c1 FROM t1 WHERE c1 = ANY (SELECT c1 FROM t2) ORDER BY c1;
c1
----
 1
 1
 2
 2
 3
 3
(6 rows)
```

ANY noncorrelated subqueries with aggregates:

```
=> SELECT c1, c2 FROM t1 WHERE c1 <> ANY (SELECT MAX(c1) FROM t2) ORDER BY c1;
c1 | c2
-----+-----
```

```
1 | cab
1 | abc
2 | fed
2 | def
4 | jkl
5 | mno
(6 rows)

=> SELECT c1 FROM t1 GROUP BY c1 HAVING c1 <> ANY (SELECT MAX(c1) FROM t2) ORDER BY c1;
c1
----
1
2
4
5
(4 rows)
```

ANY noncorrelated subqueries with aggregates and a GROUP BY clause:

```
=> SELECT c1, c2 FROM t1 WHERE c1 <> ANY (SELECT MAX(c1) FROM t2 GROUP BY c2) ORDER BY c1;
c1 | c2
----+-----
1 | cab
1 | abc
2 | fed
2 | def
3 | ihg
3 | ghi
4 | jkl
5 | mno
(8 rows)
```

ANY noncorrelated subqueries with a GROUP BY clause:

```
=> SELECT c1, c2 FROM t1 WHERE c1 <=> ANY (SELECT c1 FROM t2 GROUP BY c1) ORDER BY c1;
c1 | c2
----+-----
1 | cab
1 | abc
2 | fed
2 | def
3 | ihg
3 | ghi
(6 rows)
```

ANY correlated subqueries with no aggregates or GROUP BY clause:

```
=> SELECT c1, c2 FROM t1 WHERE c1 >= ANY (SELECT c1 FROM t2 WHERE t2.c2 = t1.c2) ORDER BY c1;
c1 | c2
----+-----
1 | abc
2 | fed
4 | jkl
(3 rows)
```

ALL Subqueries

A subquery that uses the ALL keyword returns true when all values retrieved by the subquery match the left-hand expression, otherwise it returns false.

Examples

ALL noncorrelated subqueries without aggregates:

```
=> SELECT c1, c2 FROM t1 WHERE c1 >= ALL (SELECT c1 FROM t2) ORDER BY c1;
c1 | c2
----+-----
 3 | ihg
 3 | ghi
 4 | jkl
 5 | mno
(4 rows)
```

ALL noncorrelated subqueries with aggregates:

```
=> SELECT c1, c2 FROM t1 WHERE c1 = ALL (SELECT MAX(c1) FROM t2) ORDER BY c1;
c1 | c2
----+-----
 3 | ihg
 3 | ghi
(2 rows)

=> SELECT c1 FROM t1 GROUP BY c1 HAVING c1 <> ALL (SELECT MAX(c1) FROM t2) ORDER BY c1;
c1
----
 1
 2
 4
 5
(4 rows)
```

ALL noncorrelated subqueries with aggregates and a GROUP BY clause:

```
=> SELECT c1, c2 FROM t1 WHERE c1 <= ALL (SELECT MAX(c1) FROM t2 GROUP BY c2) ORDER BY c1;
c1 | c2
----+-----
 1 | cab
 1 | abc
(2 rows)
```

ALL noncorrelated subqueries with a GROUP BY clause:

```
=> SELECT c1, c2 FROM t1 WHERE c1 <> ALL (SELECT c1 FROM t2 GROUP BY c1) ORDER BY c1;
c1 | c2
----+-----
 4 | jkl
 5 | mno
(2 rows)
```

NULL Handling

Vertica supports multicolumn `<>` ALL subqueries where the columns are not marked NOT NULL. If any column contains a NULL value, Vertica returns a run-time error.

Vertica does not support `=` ANY subqueries that are nested within another expression if any column values are NULL.

See Also

[Subquery Restrictions](#)

EXISTS and NOT EXISTS

The EXISTS predicate is one of the most common predicates used to build conditions that use noncorrelated and correlated subqueries. Use EXISTS to identify the existence of a relationship without regard for the quantity. For example, EXISTS returns true if the subquery returns any rows, and [NOT] EXISTS returns true if the subquery returns no rows.

[NOT] EXISTS subqueries take the following form:

```
expression [ NOT ] EXISTS ( subquery )
```

The EXISTS condition is considered to be met if the subquery returns at least one row. Since the result depends only on whether any records are returned, and not on the contents of those records, the output list of the subquery is normally uninteresting. A common coding convention is to write all EXISTS tests as follows:

```
EXISTS (SELECT 1 WHERE ...)
```

In the above fragment, SELECT 1 returns the value 1 for every record in the query. If the query returns, for example, five records, it returns 5 ones. The system doesn't care about the real values in those records; it just wants to know if a row is returned.

Alternatively, a subquery's select list that uses EXISTS might consist of the asterisk (*). You do not need to specify column names, because the query tests for the existence or nonexistence of records that meet the conditions specified in the subquery.

```
EXISTS (SELECT * WHERE ...)
```

Notes

- If EXISTS (*subquery*) returns at least 1 row, the result is TRUE.
- If EXISTS (*subquery*) returns no rows, the result is FALSE.

- If NOT EXISTS (subquery) returns at least 1 row, the result is FALSE.
- If NOT EXISTS (subquery) returns no rows, the result is TRUE.

Examples

The following query retrieves the list of all the customers who purchased anything from any of the stores amounting to more than 550 dollars:

```
=> SELECT customer_key, customer_name, customer_state
FROM public.customer_dimension WHERE EXISTS
(SELECT 1 FROM store.store_sales_fact
WHERE customer_key = public.customer_dimension.customer_key
AND sales_dollar_amount > 550)
AND customer_state = 'MA' ORDER BY customer_key;
customer_key | customer_name | customer_state
-----+-----+-----
14818 | William X. Nielson | MA
18705 | James J. Goldberg | MA
30231 | Sarah N. McCabe | MA
48353 | Mark L. Brown | MA
(4 rows)
```

Whether you use EXISTS or IN subqueries depends on which predicates you select in outer and inner query blocks. For example, to get a list of all the orders placed by all stores on January 2, 2003 for vendors with records in the vendor table:

```
=> SELECT store_key, order_number, date_ordered
FROM store.store_orders_fact WHERE EXISTS
(SELECT 1 FROM public.vendor_dimension
WHERE public.vendor_dimension.vendor_key = store.store_orders_fact.vendor_key)
AND date_ordered = '2012-01-02';
store_key | order_number | date_ordered
-----+-----+-----
37 | 2559 | 2012-01-02
16 | 552 | 2012-01-02
35 | 1156 | 2012-01-02
13 | 3885 | 2012-01-02
25 | 554 | 2012-01-02
21 | 2687 | 2012-01-02
49 | 3251 | 2012-01-02
19 | 2922 | 2012-01-02
26 | 1329 | 2012-01-02
40 | 1183 | 2012-01-02
(10 rows)
```

The above query looks for existence of the vendor and date ordered. To return a particular value, rather than simple existence, the query looks for orders placed by the vendor who got the best deal on January 4, 2004:

```
=> SELECT store_key, order_number, date_ordered
FROM store.store_orders_fact ord, public.vendor_dimension vd
```

```
WHERE ord.vendor_key = vd.vendor_key AND vd.deal_size IN
      (SELECT MAX(deal_size) FROM public.vendor_dimension)
AND date_ordered = '2013-01-04';
store_key | order_number | date_ordered
-----+-----+-----
      166 |         36008 | 2013-01-04
      113 |         66017 | 2013-01-04
      198 |         75716 | 2013-01-04
       27 |        150241 | 2013-01-04
      148 |        182207 | 2013-01-04
        9 |       188567 | 2013-01-04
       45 |       202416 | 2013-01-04
       24 |       250295 | 2013-01-04
      121 |       251417 | 2013-01-04
(9 rows)
```

- [Subquery Restrictions](#)

IN and NOT IN

While you cannot equate a single value to a set of values, you can check to see if a single value is found within that set of values. Use the IN clause for multiple-record, single-column subqueries. After the subquery returns results introduced by IN or NOT IN, the outer query uses them to return the final result.

[NOT] IN subqueries take the following form:

```
{ expression [ NOT ] IN ( subquery ) | expression [ NOT ] IN ( expression ) }
```

There is no limit to the number of parameters passed to the IN clause of the SELECT statement; for example:

```
=> SELECT * FROM tablename WHERE column IN (a, b, c, d, e, ...);
```

Vertica also supports queries where two or more outer expressions refer to different inner expressions:

```
=> SELECT * FROM A WHERE (A.x,A.x) IN (SELECT B.x, B.y FROM B);
```

Examples

The following query uses the [VMart](#) schema to illustrate the use of outer expressions referring to different inner expressions:

```
=> SELECT product_description, product_price FROM product_dimension
      WHERE (product_dimension.product_key, product_dimension.product_key) IN
            (SELECT store.store_orders_fact.order_number,
                 store.store_orders_fact.quantity_ordered
              FROM store.store_orders_fact);
product_description | product_price
-----+-----
Brand #72 box of candy |          326
Brand #71 vanilla ice cream |          270
(2 rows)
```

To find all products supplied by stores in MA, first create the inner query and run it to ensure that it works as desired. The following query returns all stores located in MA:

```
=> SELECT store_key FROM store.store_dimension WHERE store_state = 'MA';
store_key
-----
      13
      31
(2 rows)
```

Then create the outer or main query that specifies all distinct products that were sold in stores located in MA. This statement combines the inner and outer queries using the IN predicate:

```
=> SELECT DISTINCT s.product_key, p.product_description
      FROM store.store_sales_fact s, public.product_dimension p
      WHERE s.product_key = p.product_key
            AND s.product_version = p.product_version
            AND s.store_key IN
                  (SELECT store_key
                   FROM store.store_dimension
                   WHERE store_state = 'MA')
      ORDER BY s.product_key;
product_key | product_description
-----+-----
      1 | Brand #1 white bread
      1 | Brand #4 vegetable soup
      3 | Brand #9 wheelchair
      5 | Brand #15 cheddar cheese
      5 | Brand #19 bleach
      7 | Brand #22 canned green beans
      7 | Brand #23 canned tomatoes
      8 | Brand #24 champagne
      8 | Brand #25 chicken nuggets
     11 | Brand #32 sausage
      ... | ...
(281 rows)
```

When using `NOT IN`, the subquery returns a list of zero or more values in the outer query where the comparison column does not match any of the values returned from the subquery. Using the previous example, `NOT IN` returns all the products that are not supplied from MA.

Notes

Vertica supports multicolumn NOT IN subqueries in which the columns are not marked NOT NULL. If one of the columns is found to contain a NULL value during query execution, Vertica returns a run-time error.

Similarly, IN subqueries nested within another expression are not supported if any of the column values are NULL. For example, if in the following statement column x from either table contained a NULL value, Vertica returns a run-time error:

```
=> SELECT * FROM t1 WHERE (x IN (SELECT x FROM t2)) IS FALSE;  
ERROR: NULL value found in a column used by a subquery
```

- [Subquery Restrictions](#)
- [IN-predicate](#)

Subqueries in the SELECT List

Subqueries can occur in the select list of the containing query. The results from the following statement are ordered by the first column (customer_name). You could also write ORDER BY 2 and specify that the results be ordered by the select-list subquery.

```
=> SELECT c.customer_name, (SELECT AVG(annual_income) FROM customer_dimension  
WHERE deal_size = c.deal_size) AVG_SAL_DEAL FROM customer_dimension c  
ORDER BY 1;  
customer_name | AVG_SAL_DEAL  
-----+-----  
Goldstar      | 603429  
Metatech      | 628086  
Metadata      | 666728  
Foodstar      | 695962  
Verihope      | 715683  
Veridata      | 868252  
Bettercare    | 879156  
Foodgen       | 958954  
Virtacom      | 991551  
Inicorp       | 1098835  
...
```

Notes

- Scalar subqueries in the select-list return a single row/column value. These subqueries use Boolean comparison operators: =, >, <, <>, <=, >=.

If the query is correlated, it returns NULL if the correlation results in 0 rows. If the query returns more than one row, the query errors out at run time and Vertica displays an error message that the scalar subquery must only return 1 row.

- Subquery expressions such as [NOT] IN, [NOT] EXISTS, ANY/SOME, or ALL always return a single Boolean value that evaluates to TRUE, FALSE, or UNKNOWN; the subquery itself can have many rows. Most of these queries can be correlated or noncorrelated.

Note: ALL subqueries cannot be correlated.

- Subqueries in the ORDER BY and GROUP BY clauses are supported; for example, the following statement says to order by the first column, which is the select-list subquery:

```
=> SELECT (SELECT MAX(x) FROM t2 WHERE y=t1.b) FROM t1 ORDER BY 1;
```

WITH Clauses in SELECT

WITH clauses are concomitant queries within a larger, primary query. Vertica can evaluate WITH clauses in two ways:

- [Inline expansion](#) (default): Vertica evaluates each WITH clause every time it is referenced by the primary query.
- [Materialization](#): Vertica evaluates each WITH clause once, stores results in a temporary table, and references this table as often as the query requires.

For details on WITH clause syntax and requirements, see [WITH Clause](#) in the SQL Reference Manual.

Inline Expansion of WITH Clause

By default, Vertica uses inline expansion to evaluate WITH clauses. Vertica evaluates each WITH clause every time it is referenced by the primary query. Inline expansion often works best if the query does not reference the same WITH clause multiple times, or if some local optimizations are possible after inline expansion.

Example

The following example shows a WITH clause that is a good candidate for inline expansion. The WITH clause is used in a query that obtains order information for all orders shipped in 2007, between December 15-31.

```
-- Disable the materialization method if previously enabled
ALTER SESSION SET PARAMETER EnableWithClauseMaterialization=1;

-- Begin WITH clause

WITH
  store_orders_fact_new AS(
    SELECT * FROM store.store_orders_fact WHERE date_shipped between '2016-12-15' and '2016-12-31')
-- End WITH clause
-- Begin main primary query

SELECT store_key, product_key, product_version, SUM(quantity_ordered*unit_price) AS total_price
FROM store_orders_fact_new
GROUP BY store_key, product_key, product_version
ORDER BY total_price;
```

Vertica processes the query as follows:

1. Expands the WITH clause reference to `store_orders_fact_new` within the primary query.
2. After expanding the WITH clause, evaluates the primary query.

Materialization of WITH Clause

When materialization is enabled, Vertica evaluates each WITH clause once, stores results in a temporary table, and references this table as often as the query requires. Vertica drops the temporary table after primary query execution completes.

Note: If the primary query returns with an error, temporary tables might be dropped only after the client's session ends.

Materialization can facilitate better performance when `WITH` clauses are complex—for example, when the `WITH` clauses contain `JOIN` and `GROUP BY` clauses, and are referenced multiple times in the primary query.

If materialization is enabled, `WITH` statements perform an auto-commit of the user transaction. This occurs even when using `EXPLAIN` with the `WITH` statement.

Enabling Materialization

By default, materialization is disabled. You can enable and disable materialization by setting the configuration parameter `ENABLE_WITH_CLAUSE_MATERIALIZATION` at the following scopes:

- **Session:** Parameter setting remains in effect until you explicitly set or clear it, or the session ends.

```
ALTER SESSION SET PARAMETER EnableWithClauseMaterialization={ 0 | 1 };  
ALTER SESSION CLEAR PARAMETER EnableWithClauseMaterialization;
```

- **Query:** `WITH` clause includes `ENABLE_WITH_CLAUSE_MATERIALIZATION` hint. Materialization is automatically cleared when the query returns.

```
WITH /*+ENABLE_WITH_CLAUSE_MATERIALIZATION*/ with-query...
```

Example

The following example shows a `WITH` clause that is a good candidate for materialization. The query obtains data for the vendor who has the highest combined order cost for all orders:

```
-- Enable materialization  
ALTER SESSION SET PARAMETER EnableWithClauseMaterialization=1;  
  
-- Begin WITH clause, revenue  
  
WITH  
  revenue AS (  
    SELECT vendor_key, SUM(total_order_cost) AS total_revenue  
    FROM store.store_orders_fact  
    GROUP BY vendor_key ORDER BY 1)  
  
-- End defining WITH clause statement  
-- Begin main primary query  
SELECT vendor_name, vendor_address, vendor_city, total_revenue  
FROM vendor_dimension v, revenue r  
WHERE v.vendor_key = r.vendor_key AND total_revenue = (SELECT MAX(total_revenue) FROM revenue)  
ORDER BY vendor_name;
```

Vertica processes this query as follows:

1. The WITH clause revenue evaluates its SELECT statement from table store.store_orders_fact.
2. The results of the revenue clause are stored in a local temporary table.
3. Whenever the revenue clause statement is referenced, the results stored in the table are used.
4. The temporary table is dropped when query execution is complete.

Noncorrelated and Correlated Subqueries

Subqueries can be categorized into two types:

- A *noncorrelated* (simple) subquery obtains its results independently of its containing (outer) statement.
- A *correlated* subquery requires values from its outer query in order to execute.

Noncorrelated Subqueries

A noncorrelated subquery executes independently of the outer query. The subquery executes first, and then passes its results to the outer query, For example:

```
=> SELECT name, street, city, state FROM addresses WHERE state IN (SELECT state FROM states);
```

Vertica executes this query as follows:

1. Executes the subquery `SELECT state FROM states` (in bold).
2. Passes the subquery results to the outer query.

A query's WHERE and HAVING clauses can specify noncorrelated subqueries if the subquery resolves to a single row, as shown below:

In WHERE clause

```
=> SELECT COUNT(*) FROM SubQ1 WHERE SubQ1.a = (SELECT y from SubQ2);
```

In HAVING clause

```
=> SELECT COUNT(*) FROM SubQ1 GROUP BY SubQ1.a HAVING SubQ1.a = (SubQ1.a & (SELECT y from SubQ2))
```

Correlated Subqueries

A correlated subquery typically obtains values from its outer query before it executes. When the subquery returns, it passes its results to the outer query.

Note: You can use an outer join to obtain the same effect as a correlated subquery.

In the following example, the subquery needs values from the `addresses.state` column in the outer query:

```
=> SELECT name, street, city, state FROM addresses
      WHERE EXISTS (SELECT * FROM states WHERE states.state = addresses.state);
```

Vertica executes this query as follows:

1. The subquery evaluates each `addresses.state` value in the outer block records.
2. It then passes its results to the outer query block.

Flattening FROM Clause Subqueries

FROM [clause](#) subqueries are always evaluated before their containing query. In some cases, the optimizer *flattens* FROM clause subqueries so the query can execute more efficiently.

For example, in order to create a query plan for the following statement, the Vertica query optimizer evaluates all records in table `t1` before it evaluates the records in table `t0`:

```
=> SELECT * FROM (SELECT a, MAX(a) AS max FROM (SELECT * FROM t1) AS t0 GROUP BY a);
```

Given the previous query, the optimizer can internally flatten it as follows:

```
=> SELECT * FROM (SELECT a, MAX(a) FROM t1 GROUP BY a) AS t0;
```

Both queries return the same results, but the flattened query runs more quickly.

Flattening Views

When a query's FROM clause specifies a [view](#), the optimizer expands the view by replacing it with the query that the view encapsulates. If the view contains subqueries that are eligible for flattening, the optimizer produces a query plan that flattens those subqueries.

Flattening Restrictions

The optimizer cannot create a flattened query plan if a subquery or view contains one of the following elements:

- Aggregate function
- Analytic function
- Outer join (left, right or full)
- GROUP BY, ORDER BY, or HAVING clause
- DISTINCT keyword
- LIMIT or OFFSET clause
- UNION, EXCEPT, or INTERSECT clause
- EXISTS subquery

Examples

If a predicate applies to a view or subquery, the flattening operation can allow for optimizations by evaluating the predicates before the flattening takes place. Two examples follow.

View flattening

In this example, view v1 is defined as follows:

```
=> CREATE VIEW v1 AS SELECT * FROM a;
```

The following query specifies this view:

```
=> SELECT * FROM v1 JOIN b ON x=y WHERE x > 10;
```

Without flattening, the optimizer evaluates the query as follows:

1. Evaluates the subquery.
2. Applies the predicate WHERE $x > 10$.

In contrast, the optimizer can create a flattened query plan by applying the predicate before evaluating the subquery. This reduces the optimizer's work because it returns only the records WHERE $x > 10$ to the containing query.

Vertica internally transforms the previous query as follows:

```
=> SELECT * FROM (SELECT * FROM a) AS t1 JOIN b ON x=y WHERE x > 10;
```

The optimizer then flattens the query:

```
=> SELECT * FROM a JOIN b ON x=y WHERE x > 10;
```

Subquery flattening

The following example shows how Vertica transforms FROM clause subqueries within a WHERE clause IN subquery. Given the following query:

```
=> SELECT * FROM a  
WHERE b IN (SELECT b FROM (SELECT * FROM t2)) AS D WHERE x=1;
```

The optimizer flattens it as follows:

```
=> SELECT * FROM a  
WHERE b IN (SELECT b FROM t2) AS D WHERE x=1;
```

[Subquery Restrictions](#)

Subqueries in UPDATE and DELETE Statements

You can nest subqueries within [UPDATE](#) and [DELETE](#) statements.

UPDATE Subqueries

You can update records in one table according to values in others, by nesting a subquery within an UPDATE statement. The example below illustrates this through a couple of [noncorrelated subqueries](#). You can reproduce this example with the following tables:

```
CREATE TABLE addresses(cust_id INTEGER, address VARCHAR(2000));  
INSERT INTO addresses VALUES(20,'Lincoln Street');  
INSERT INTO addresses VALUES(30,'Booth Hill Road');  
INSERT INTO addresses VALUES(30,'Beach Avenue');  
INSERT INTO addresses VALUES(40,'Mt. Vernon Street');
```

```
INSERT INTO addresses VALUES(50,'Hillside Avenue');

CREATE TABLE new_addresses(new_cust_id integer, new_address Boolean DEFAULT 'T');
INSERT INTO new_addresses VALUES(20);
INSERT INTO new_addresses VALUES(30);
INSERT INTO new_addresses VALUES(60,'F');
INSERT INTO new_addresses VALUES(80,'T');
COMMIT;
```

Queries on these tables return the following results:

```
=> SELECT * FROM addresses;
cust_id |      address
-----+-----
      50 | Hillside Avenue
      30 | Booth Hill Road
      40 | Mt. Vernon Street
      20 | Lincoln Street
      30 | Beach Avenue
(5 rows)

=> SELECT * FROM new_addresses;
new_cust_id | new_address
-----+-----
          30 | t
          20 | t
          80 | t
          60 | f
(4 rows)
```

1. The following UPDATE statement uses a [noncorrelated subquery](#) to join `new_addresses` and `addresses` records on customer IDs. UPDATE sets the value 'New Address' in the joined `addresses` records. The statement output indicates that three rows were updated:

```
=> UPDATE addresses SET address='New Address'
   WHERE cust_id IN (SELECT new_cust_id FROM new_addresses WHERE new_address='T');
OUTPUT
-----
3
(1 row)
```

2. Query the `addresses` table to see the changes for matching customer ID 20 and 30. Addresses for customer ID 40 and 50 are not updated:

```
=> SELECT * FROM addresses;
cust_id |      address
-----+-----
      20 | New Address
      30 | New Address
      30 | New Address
      40 | Mt. Vernon Street
      50 | Hillside Avenue
(5 rows)
```

```
=>COMMIT;  
COMMIT
```

DELETE Subqueries

You can delete records in one table based according to values in others by nesting a subquery within a **DELETE** statement.

For example, you want to remove records from `new_addresses` that were used earlier to update records in `addresses`. The following **DELETE** statement uses a **noncorrelated subquery** to join `new_addresses` and `addresses` records on customer IDs. It then deletes the joined records from table `new_addresses`:

```
=> DELETE FROM new_addresses  
      WHERE new_cust_id IN (SELECT cust_id FROM addresses WHERE address='New Address');  
OUTPUT  
-----  
      2  
(1 row)  
  
=> COMMIT;  
COMMIT
```

Querying `new_addresses` confirms that the records were deleted:

```
=> SELECT * FROM new_addresses;  
new_cust_id | new_address  
-----+-----  
          60 | f  
          80 | t  
(2 rows)
```

Subquery Examples

This topic illustrates some of the subqueries you can write. The examples use the **VMart** example database.

Single-Row Subqueries

Single-row subqueries are used with single-row comparison operators (`=`, `>=`, `<=`, `<>`, and `<=>`) and return exactly one row.

For example, the following query retrieves the name and hire date of the oldest employee in the Vmart database:

```
=> SELECT employee_key, employee_first_name, employee_last_name, hire_date
      FROM employee_dimension
      WHERE hire_date = (SELECT MIN(hire_date) FROM employee_dimension);
employee_key | employee_first_name | employee_last_name | hire_date
-----+-----+-----+-----
          2292 | Mary                | Bauer              | 1956-01-11
(1 row)
```

Multiple-Row Subqueries

Multiple-row subqueries return multiple records.

For example, the following IN clause subquery returns the names of the employees making the highest salary in each of the six regions:

```
=> SELECT employee_first_name, employee_last_name, annual_salary, employee_region
      FROM employee_dimension WHERE annual_salary IN
      (SELECT MAX(annual_salary) FROM employee_dimension GROUP BY employee_region)
      ORDER BY annual_salary DESC;
employee_first_name | employee_last_name | annual_salary | employee_region
-----+-----+-----+-----
Alexandra           | Sanchez            | 992363        | West
Mark                 | Vogel              | 983634        | South
Tiffany             | Vu                 | 977716        | SouthWest
Barbara             | Lewis              | 957949        | MidWest
Sally               | Gauthier           | 927335        | East
Wendy               | Nielson            | 777037        | NorthWest
(6 rows)
```

Multicolumn Subqueries

Multicolumn subqueries return one or more columns. Sometimes a subquery's result set is evaluated in the containing query in column-to-column and row-to-row comparisons.

Note: Multicolumn subqueries can use the <>, !=, and = operators but not the <, >, <=, >= operators.

You can substitute some multicolumn subqueries with a join, with the reverse being true as well. For example, the following two queries ask for the sales transactions of all products sold online to customers located in Massachusetts and return the same result set. The only difference is the first query is written as a join and the second is written as a subquery.

Join query:	Subquery:
<pre>=> SELECT * FROM online_sales.online_sales_fact INNER JOIN public.customer_dimension USING (customer_key)</pre>	<pre>=> SELECT * FROM online_sales.online_sales_fact WHERE customer_key IN (SELECT customer_key</pre>

WHERE customer_state = 'MA';	FROM public.customer_dimension WHERE customer_state = 'MA');
------------------------------	---

The following query returns all employees in each region whose salary is above the average:

```
=> SELECT e.employee_first_name, e.employee_last_name, e.annual_salary,
       e.employee_region, s.average
FROM employee_dimension e,
     (SELECT employee_region, AVG(annual_salary) AS average
      FROM employee_dimension GROUP BY employee_region) AS s
WHERE e.employee_region = s.employee_region AND e.annual_salary > s.average
ORDER BY annual_salary DESC;
```

employee_first_name	employee_last_name	annual_salary	employee_region	average
Doug	Overstreet	995533	East	61192.786013986
Matt	Gauthier	988807	South	57337.8638902996
Lauren	Nguyen	968625	West	56848.4274914089
Jack	Campbell	963914	West	56848.4274914089
William	Martin	943477	NorthWest	58928.2276119403
Luigi	Campbell	939255	MidWest	59614.9170454545
Sarah	Brown	901619	South	57337.8638902996
Craig	Goldberg	895836	East	61192.786013986
Sam	Vu	889841	MidWest	59614.9170454545
Luigi	Sanchez	885078	MidWest	59614.9170454545
Michael	Weaver	882685	South	57337.8638902996
Doug	Pavlov	881443	SouthWest	57187.2510548523
Ruth	McNulty	874897	East	61192.786013986
Luigi	Dobisz	868213	West	56848.4274914089
Laura	Lang	865829	East	61192.786013986
...				

You can also use the **EXCEPT**, **INTERSECT**, and **UNION [ALL]** keywords in FROM, WHERE, and HAVING clauses.

The following subquery returns information about all Connecticut-based customers who bought items through either stores or online sales channel and whose purchases amounted to more than 500 dollars:

```
=> SELECT DISTINCT customer_key, customer_name FROM public.customer_dimension
       WHERE customer_key IN (SELECT customer_key FROM store.store_sales_fact
                             WHERE sales_dollar_amount > 500
                             UNION ALL
                             SELECT customer_key FROM online_sales.online_sales_fact
                             WHERE sales_dollar_amount > 500)
       AND customer_state = 'CT';
```

customer_key	customer_name
200	Carla Y. Kramer
733	Mary Z. Vogel
931	Lauren X. Roy
1533	James C. Vu
2948	Infocare
4909	Matt Z. Winkler
5311	John Z. Goldberg
5520	Laura M. Martin
5623	Daniel R. Kramer

HAVING Clause Subqueries

A HAVING clause is used in conjunction with the GROUP BY clause to filter the select-list records that a GROUP BY returns. HAVING clause subqueries must use Boolean comparison operators: =, >, <, <>, <=, >= and take the following form:

```
SELECT <column, ...>
FROM <table>
GROUP BY <expression>
HAVING <expression>
  (SELECT <column, ...>
   FROM <table>
   HAVING <expression>);
```

For example, the following statement uses the [VMart](#) database and returns the number of customers who purchased lowfat products. Note that the GROUP BY clause is required because the query uses an aggregate (COUNT).

```
=> SELECT s.product_key, COUNT(s.customer_key) FROM store.store_sales_fact s
   GROUP BY s.product_key HAVING s.product_key IN
   (SELECT product_key FROM product_dimension WHERE diet_type = 'Low Fat');
```

The subquery first returns the product keys for all low-fat products, and the outer query then counts the total number of customers who purchased those products.

```
product_key | count
-----+-----
         15 |      2
         41 |      1
         66 |      1
        106 |      1
        118 |      1
        169 |      1
        181 |      2
        184 |      2
        186 |      2
        211 |      1
        229 |      1
        267 |      1
        289 |      1
        334 |      2
        336 |      1
(15 rows)
```

Subquery Restrictions

The following list summarizes subquery restrictions in Vertica.

- Subqueries are not allowed in the defining query of a **CREATE PROJECTION** statement.
- Subqueries can be used in the **SELECT** list, but **GROUP BY** or aggregate functions are not allowed in the query if the subquery is not part of the **GROUP BY** clause in the containing query. For example, the following two statements return an error message:

```
=> SELECT y, (SELECT MAX(a) FROM t1) FROM t2 GROUP BY y;  
ERROR: subqueries in the SELECT or ORDER BY are not supported if the  
subquery is not part of the GROUP BY  
=> SELECT MAX(y), (SELECT MAX(a) FROM t1) FROM t2;  
ERROR: subqueries in the SELECT or ORDER BY are not supported if the  
query has aggregates and the subquery is not part of the GROUP BY
```

- Subqueries are supported within **UPDATE** statements with the following exceptions:
 - You cannot use **SET column = {expression}** to specify a subquery.
 - The table specified in the **UPDATE** list cannot also appear in the **FROM** list (no self joins).
- **FROM** clause subqueries require an alias but tables do not. If the table has no alias, the query must refer to columns inside it as *table-name.column-name*. However, if column names are uniquely identified among all tables used by the query, then column names do not need to include their table name.
- If the **ORDER BY** clause is inside a **FROM** clause subquery, rather than in the containing query, the query could return unexpected sort results. This is because Vertica data comes from multiple nodes, so sort order cannot be guaranteed unless an **ORDER BY** clause is specified in the outer query block. This behavior is compliant with the SQL standard but it might differ from other databases.
- Multicolumn subqueries cannot use the **<**, **>**, **<=**, **>=** comparison operators. They can use **<>**, **!=**, and **=** operators.
- **WHERE** and **HAVING** clause subqueries must use Boolean comparison operators: **=**, **>**, **<**, **<>**, **<=**, **>=**. Those subqueries can be noncorrelated and correlated.
- **[NOT] IN** and **ANY** subqueries nested within another expression are not supported if any of the column values are **NULL**. In the following statement, for example, if column **x** from either table **t1** or **t2** contains a **NULL** value, Vertica returns a run-time error:

```
=> SELECT * FROM t1 WHERE (x IN (SELECT x FROM t2)) IS FALSE;  
ERROR: NULL value found in a column used by a subquery
```

- Vertica returns an error message during subquery run time on scalar subqueries that return more than one row.
- Aggregates and GROUP BY clauses are allowed in subqueries, as long as those subqueries are not correlated.
- Correlated expressions under ALL and [NOT] IN are not supported.
- Correlated expressions under OR are not supported.
- Multiple correlations are allowed only for subqueries that are joined with an equality predicate (<, >, <=, >=, =, <>, <=>) but IN/NOT IN, EXISTS/NOT EXISTS predicates within correlated subqueries are not allowed:

```
=> SELECT t2.x, t2.y, t2.z FROM t2 WHERE t2.z NOT IN  
      (SELECT t1.z FROM t1 WHERE t1.x = t2.x);  
ERROR: Correlated subquery with NOT IN is not supported
```

- Up to one level of correlated subqueries is allowed in the WHERE clause if the subquery references columns in the immediate outer query block. For example, the following query is not supported because the `t2.x = t3.x` subquery can only refer to table `t1` in the outer query, making it a correlated expression because `t3.x` is two levels out:

```
=> SELECT t3.x, t3.y, t3.z FROM t3 WHERE t3.z IN (  
      SELECT t1.z FROM t1 WHERE EXISTS (  
        SELECT 'x' FROM t2 WHERE t2.x = t3.x) AND t1.x = t3.x);  
ERROR: More than one level correlated subqueries are not supported
```

The query is supported if it is rewritten as follows:

```
=> SELECT t3.x, t3.y, t3.z FROM t3 WHERE t3.z IN  
      (SELECT t1.z FROM t1 WHERE EXISTS  
        (SELECT 'x' FROM t2 WHERE t2.x = t1.x)  
        AND t1.x = t3.x);
```

Joins

Queries can combine records from multiple tables, or multiple instances of the same table. A query that combines records from one or more tables is called a join. Joins are allowed in SELECT statements and subqueries.

Supported Join Types

Vertica supports the following join types:

- Inner (including natural, cross) joins
- Left, right, and full outer joins
- Optimizations for equality and range joins predicates

Vertica does not support nested loop joins.

Join Algorithms

Vertica's query optimizer implements joins with either the hash join or merge join algorithm. For details, see [Hash Joins Versus Merge Joins](#).

Join Syntax

Vertica supports the ANSI SQL-92 standard for joining tables, as follows:

```
table-reference [join-type] JOIN table-reference [ ON join-predicate ]
```

where *join-type* can be one of the following:

- **INNER** (default)
- **LEFT [OUTER]**
- **RIGHT [OUTER]**
- **FULL [OUTER]**

- [NATURAL](#)
- [CROSS](#)

For example:

```
=> SELECT * FROM T1 INNER JOIN T2 ON T1.id = T2.id;
```

Note: The ON *join-predicate* clause is invalid for NATURAL and CROSS joins, required for all other join types.

Alternative Syntax Options

Vertica also supports two older join syntax conventions:

Join specified by WHERE clause join predicate

INNER JOIN is equivalent to a query that specifies its join predicate in a WHERE clause. For example, this example and the previous one return equivalent results. They both specify an inner join between tables T1 and T2 on columns T1.id and T2.id, respectively.

```
=> SELECT * FROM T1, T2 WHERE T1.id = T2.id;
```

Join specified by USING clause

You can join two tables on identically named columns in a USING clause. For example:

```
=> SELECT * FROM T1 INNER JOIN T2 USING(id);
```

The INNER keyword is optional; a join that is specified by a USING clause is always an inner join. Thus, this example and the previous ones return equivalent results.

Benefits of SQL-92 Join Syntax

Vertica recommends that you use SQL-92 join syntax for several reasons:

- SQL-92 outer join syntax is portable across databases; the older syntax was not consistent between databases.
- SQL-92 syntax provides greater control over whether predicates are evaluated during or after outer joins. This was also not consistent between databases when using the older syntax.

- SQL-92 syntax eliminates ambiguity in the order of evaluating the joins, in cases where more than two tables are joined with outer joins.

Join Conditions vs. Filter Conditions

If you do not use the SQL-92 syntax, join conditions (predicates that are evaluated during the join) are difficult to distinguish from filter conditions (predicates that are evaluated after the join), and in some cases cannot be expressed at all. With SQL-92, join conditions and filter conditions are separated into two different clauses, the `ON` clause and the `WHERE` clause, respectively, making queries easier to understand.

- **The `ON` clause** contains relational operators (for example, `<`, `<=`, `>`, `>=`, `<>`, `=`, `<=>`) or other predicates that specify which records from the left and right input relations to combine, such as by matching foreign keys to primary keys. `ON` can be used with inner, left outer, right outer, and full outer joins. Cross joins and union joins do not use an `ON` clause.

Inner joins return all pairings of rows from the left and right relations for which the `ON` clause evaluates to `TRUE`. In a left join, all rows from the left relation in the join are present in the result; any row of the left relation that does not match any rows in the right relation is still present in the result but with nulls in any columns taken from the right relation. Similarly, a right join preserves all rows from the right relation, and a full join retains all rows from both relations.

- **The `WHERE` clause** is evaluated after the join is performed. It filters records returned by the `FROM` clause, eliminating any records that do not satisfy the `WHERE` clause condition.

Vertica automatically converts outer joins to inner joins in cases where it is correct to do so, allowing the optimizer to choose among a wider set of query plans and leading to better performance.

Inner Joins

An inner join combines records from two tables based on a join predicate and requires that each record in the first table has a matching record in the second table. Thus, inner joins return only records from both joined tables that satisfy the join condition. Records that contain no matches are excluded from the result set.

Inner joins take the following form:

```
SELECT column-list FROM left-join-table  
[INNER] JOIN right-join-table ON join-predicate
```

If you omit the INNER keyword, Vertica assumes an inner join. Inner joins are commutative and associative. You can specify tables in any order without changing the results.

Example

The following example specifies an inner join between tables `store.store_dimension` and `public.employee_dimension` whose records have matching values in columns `store_region` and `employee_region`, respectively:

```
=> SELECT s.store_region, SUM(e.vacation_days) TotalVacationDays  
FROM public.employee_dimension e  
JOIN store.store_dimension s ON s.store_region=e.employee_region  
GROUP BY s.store_region ORDER BY TotalVacationDays;
```

This join can also be expressed as follows:

```
=> SELECT s.store_region, SUM(e.vacation_days) TotalVacationDays  
FROM public.employee_dimension e, store.store_dimension s  
WHERE s.store_region=e.employee_region  
GROUP BY s.store_region ORDER BY TotalVacationDays;
```

Both queries return the same result set:

```
store_region | TotalVacationDays  
-----+-----  
NorthWest   |          23280  
SouthWest   |          367250  
MidWest     |          925938  
South       |         1280468  
East        |         1952854  
West        |         2849976  
(6 rows)
```

If the join's inner table `store.store_dimension` has any rows with `store_region` values that do not match `employee_region` values in table `public.employee_dimension`, those rows are excluded from the result set. To include that row, you can specify an [outer join](#).

Equi-Joins and Non Equi-Joins

Vertica supports any arbitrary join expression with both matching and non-matching column values. For example:

```
SELECT * FROM fact JOIN dim ON fact.x = dim.x;
SELECT * FROM fact JOIN dim ON fact.x > dim.y;
SELECT * FROM fact JOIN dim ON fact.x <= dim.y;
SELECT * FROM fact JOIN dim ON fact.x <> dim.y;
SELECT * FROM fact JOIN dim ON fact.x <=> dim.y;
```

Note: Operators `=` and `<=>` generally run the fastest.

Equi-joins are based on equality (matching column values). This equality is indicated with an equal sign (`=`), which functions as the comparison operator in the `ON` clause using SQL-92 syntax or the `WHERE` clause using older join syntax.

The first example below uses SQL-92 syntax and the `ON` clause to join the online sales table with the call center table using the call center key; the query then returns the sale date key that equals the value 156:

```
=> SELECT sale_date_key, cc_open_date FROM online_sales.online_sales_fact
      INNER JOIN   online_sales.call_center_dimension
      ON (online_sales.online_sales_fact.call_center_key =
          online_sales.call_center_dimension.call_center_key
          AND sale_date_key = 156);
sale_date_key | cc_open_date
-----+-----
          156 | 2005-08-12
(1 row)
```

The second example uses older join syntax and the `WHERE` clause to join the same tables to get the same results:

```
=> SELECT sale_date_key, cc_open_date
      FROM online_sales.online_sales_fact, online_sales.call_center_dimension
      WHERE online_sales.online_sales_fact.call_center_key =
            online_sales.call_center_dimension.call_center_key
            AND sale_date_key = 156;
sale_date_key | cc_open_date
-----+-----
          156 | 2005-08-12
(1 row)
```

Vertica also permits tables with compound (multiple-column) primary and foreign keys. For example, to create a pair of tables with multi-column keys:

```
=> CREATE TABLE dimension(pk1 INTEGER NOT NULL, pk2 INTEGER NOT NULL);=> ALTER TABLE dimension ADD  
PRIMARY KEY (pk1, pk2);  
=> CREATE TABLE fact (fk1 INTEGER NOT NULL, fk2 INTEGER NOT NULL);  
=> ALTER TABLE fact ADD FOREIGN KEY (fk1, fk2) REFERENCES dimension (pk1, pk2);
```

To join tables using compound keys, you must connect two [join predicates](#) with a Boolean AND operator. For example:

```
=> SELECT * FROM fact f JOIN dimension d ON f.fk1 = d.pk1 AND f.fk2 = d.pk2;
```

You can write queries with expressions that contain the `<=>` operator for NULL=NULL joins.

```
=> SELECT * FROM fact JOIN dim ON fact.x <=> dim.y;
```

The `<=>` operator performs an equality comparison like the `=` operator, but it returns true, instead of NULL, if both operands are NULL, and false, instead of NULL, if one operand is NULL.

```
=> SELECT 1 <=> 1, NULL <=> NULL, 1 <=> NULL;  
?column? | ?column? | ?column?  
-----+-----+-----  
t        | t        | f  
(1 row)
```

Compare the `<=>` operator to the `=` operator:

```
=> SELECT 1 = 1, NULL = NULL, 1 = NULL;  
?column? | ?column? | ?column?  
-----+-----+-----  
t        |          |  
(1 row)
```

Note: Writing NULL=NULL joins on primary key/foreign key combinations is not an optimal choice because PK/FK columns are usually defined as NOT NULL.

When composing joins, it helps to know in advance which columns contain null values. An employee's hire date, for example, would not be a good choice because it is unlikely hire date would be omitted. An hourly rate column, however, might work if some employees are paid hourly and some are salaried. If you are unsure about the value of columns in a given table and want to check, type the command:

```
=> SELECT COUNT(*) FROM tablename WHERE columnname IS NULL;
```

Natural Joins

A natural join is just a join with an implicit join predicate. Natural joins can be inner, left outer, right outer, or full outer joins and take the following form:

```
SELECT column-list FROM left-join-table  
NATURAL [ INNER | LEFT OUTER | RIGHT OUTER | FULL OUTER ] JOIN right-join-table ON join-predicate
```

Natural joins are, by default, natural *inner* joins; however, there can also be natural (left/right) outer joins. The primary difference between an inner and natural join is that inner joins have an explicit join condition, whereas the natural join's conditions are formed by matching all pairs of columns in the tables that have the same name and compatible data types, making natural joins equi-joins because join condition are equal between common columns. (If the data types are incompatible, Vertica returns an error.)

Note: The [Data Type Coercion Chart](#) lists the data types that can be cast to other data types. If one data type can be cast to the other, those two data types are compatible.

The following query is a simple natural join between tables T1 and T2 when the T2 column val is greater than 5:

```
=> SELECT * FROM T1 NATURAL JOIN T2 WHERE T2.val > 5;
```

The following example shows a natural join between the `store_sales_fact` table and the `product_dimension` table with columns of the same name, `product_key` and `product_version`:

```
=> SELECT product_description, store.store_sales_fact.*  
FROM store.store_sales_fact, public.product_dimension  
WHERE store.store_sales_fact.product_key = public.product_dimension.product_key  
AND store.store_sales_fact.product_version = public.product_dimension.product_version;
```

The following three queries return the same result expressed as a basic query, an inner join, and a natural join. at the table expressions are equivalent only if the common attribute in the `store_sales_fact` table and the `store_dimension` table is `store_key`. If both tables have a column named `store_key`, then the natural join would also have a `store_sales_fact.store_key = store_dimension.store_key` join condition. Since the results are the same in all three instances, they are shown in the first (basic) query only:

```
=> SELECT store_name FROM store.store_sales_fact, store.store_dimension  
WHERE store.store_sales_fact.store_key = store.store_dimension.store_key  
AND store.store_dimension.store_state = 'MA' ORDER BY store_name;  
store_name  
-----  
Store11  
Store128  
Store178  
Store66  
Store8  
Store90  
(6 rows)
```

The query written as an inner join:

```
=> SELECT store_name FROM store.store_sales_fact
      INNER JOIN store.store_dimension
      ON (store.store_sales_fact.store_key = store.store_dimension.store_key)
      WHERE store.store_dimension.store_state = 'MA' ORDER BY store_name;
```

In the case of the natural join, the join predicate appears implicitly by comparing all of the columns in both tables that are joined by the same column name. The result set contains only one column representing the pair of equally-named columns.

```
=> SELECT store_name FROM store.store_sales_fact
      NATURAL JOIN store.store_dimension
      WHERE store.store_dimension.store_state = 'MA' ORDER BY store_name;
```

Cross Joins

Cross joins are the simplest joins to write, but they are not usually the fastest to run because they consist of all possible combinations of two tables' records. Cross joins contain no join condition and return what is known as a Cartesian product, where the number of rows in the result set is equal to the number of rows in the first table multiplied by the number of rows in the second table.

The following query returns all possible combinations from the promotion table and the store sales table:

```
=> SELECT * FROM promotion_dimension CROSS JOIN store.store_sales_fact;
```

Because this example returns over 600 million records, many cross join results can be extremely large and difficult to manage. Cross joins can be useful, however, such as when you want to return a single-row result set.

Tip: Filter out unwanted records in a cross with `WHERE` clause join predicates:

```
=> SELECT * FROM promotion_dimension p CROSS JOIN store.store_sales_fact f
      WHERE p.promotion_key LIKE f.promotion_key;
```

Implicit versus Explicit Joins

Vertica recommends that you do not write implicit cross joins (comma-separated tables in the `FROM` clause). These queries can imply accidental omission of a join predicate.

The following query implicitly cross joins tables `promotion_dimension` and `store.store_sales_fact`:

```
=> SELECT * FROM promotion_dimension, store.store_sales_fact;
```

It is better practice to express this cross join explicitly, as follows:

```
=> SELECT * FROM promotion_dimension CROSS JOIN store.store_sales_fact;
```

Examples

The following example creates two small tables and their superprojections and then runs a cross join on the tables:

```
=> CREATE TABLE employee(employee_id INT, employee_fname VARCHAR(50));
=> CREATE TABLE department(dept_id INT, dept_name VARCHAR(50));
=> INSERT INTO employee VALUES (1, 'Andrew');
=> INSERT INTO employee VALUES (2, 'Priya');
=> INSERT INTO employee VALUES (3, 'Michelle');
=> INSERT INTO department VALUES (1, 'Engineering');
=> INSERT INTO department VALUES (2, 'QA');
=> SELECT * FROM employee CROSS JOIN department;
```

In the result set, the cross join retrieves records from the first table and then creates a new row for every row in the 2nd table. It then does the same for the next record in the first table, and so on.

```
employee_id | employee_name | dept_id | dept_name
-----+-----+-----+-----
          1 | Andrew       |        1 | Engineering
          2 | Priya        |        1 | Engineering
          3 | Michelle     |        1 | Engineering
          1 | Andrew       |        2 | QA
          2 | Priya        |        2 | QA
          3 | Michelle     |        2 | QA
(6 rows)
```

Outer Joins

Outer joins extend the functionality of inner joins by letting you preserve rows of one or both tables that do not have matching rows in the non-preserved table. Outer joins take the following form:

```
SELECT column-list FROM left-join-table
[ LEFT | RIGHT | FULL ] OUTER JOIN right-join-table ON join-predicate
```

Note: Omitting the keyword OUTER from your statements does not affect results of left and right joins. LEFT OUTER JOIN and LEFT JOIN perform the same operation and return the same results.

Left Outer Joins

A left outer join returns a complete set of records from the left-joined (preserved) table T1, with matched records, where available, in the right-joined (non-preserved) table T2. Where Vertica finds no match, it extends the right side column (T2) with null values.

```
=> SELECT * FROM T1 LEFT OUTER JOIN T2 ON T1.x = T2.x;
```

To exclude the non-matched values from T2, write the same left outer join, but filter out the records you don't want from the right side by using a `WHERE` clause:

```
=> SELECT * FROM T1 LEFT OUTER JOIN T2  
ON T1.x = T2.x WHERE T2.x IS NOT NULL;
```

The following example uses a left outer join to enrich telephone call detail records with an incomplete numbers dimension. It then filters out results that are known not to be from Massachusetts:

```
=> SELECT COUNT(*) FROM calls LEFT OUTER JOIN numbers  
ON calls.to_phone = numbers.phone WHERE NVL(numbers.state, '') <> 'MA';
```

Right Outer Joins

A right outer join returns a complete set of records from the right-joined (preserved) table, as well as matched values from the left-joined (non-preserved) table. If Vertica finds no matching records from the left-joined table (T1), `NULL` values appears in the T1 column for any records with no matching values in T1. A right join is, therefore, similar to a left join, except that the treatment of the tables is reversed.

```
=> SELECT * FROM T1 RIGHT OUTER JOIN T2 ON T1.x = T2.x;
```

The above query is equivalent to the following query, where `T1 RIGHT OUTER JOIN T2 = T2 LEFT OUTER JOIN T1`.

```
=> SELECT * FROM T2 LEFT OUTER JOIN T1 ON T2.x = T1.x;
```

The following example identifies customers who have *not* placed an order:

```
=> SELECT customers.customer_id FROM orders RIGHT OUTER JOIN customers  
ON orders.customer_id = customers.customer_id  
GROUP BY customers.customer_id HAVING COUNT(orders.customer_id) = 0;
```

Full Outer Joins

A full outer join returns results for both left and right outer joins. The joined table contains all records from both tables, including nulls (missing matches) from either side of the join. This is useful if you want to see, for example, each employee who is assigned to a particular department and each department that has an employee, but you also want to see all the employees who are not assigned to a particular department, as well as any department that has no employees:

```
=> SELECT employee_last_name, hire_date FROM employee_dimension emp  
FULL OUTER JOIN department dept ON emp.employee_key = dept.department_key;
```

Notes

Vertica also supports joins where the outer (preserved) table or subquery is replicated on more than one node and the inner (non-preserved) table or subquery is segmented across more than one node. For example, in the following query, the fact table, which is almost always segmented, appears on the non-preserved side of the join, and it is allowed:

```
=> SELECT sales_dollar_amount, transaction_type, customer_name  
FROM store.store_sales_fact f RIGHT JOIN customer_dimension d  
ON f.customer_key = d.customer_key;
```

sales_dollar_amount	transaction_type	customer_name
252	purchase	Inistar
363	purchase	Inistar
510	purchase	Inistar
-276	return	Foodcorp
252	purchase	Foodcorp
195	purchase	Foodcorp
290	purchase	Foodcorp
222	purchase	Foodcorp
		Foodgen
		Goldcare

(10 rows)

Controlling Join Inputs

By default, the optimizer uses its own internal logic to determine whether to join one table to another as an inner or outer input. Occasionally, the optimizer might choose the larger table as the inner input to a join. Doing so can incur performance and concurrency issues.

If the configuration parameter `EnableForceOuter` is set to 1, you can control join inputs for specific tables through `ALTER TABLE . . FORCE OUTER`. The

`FORCE OUTER` option modifies a table's `force_outer` setting in the system table [TABLES](#). When implementing a join, Vertica compares the `force_outer` settings of the participating tables:

- If table settings are unequal, Vertica uses them to set the join inputs:
 - A table with a low `force_outer` setting relative to other tables is joined to them as an inner input.
 - A table with a high `force_outer` setting relative to other tables is joined to them as an outer input.
- If all table settings are equal, Vertica ignores them and assembles the join on its own.

The `force_outer` column is initially set to 5 for all newly-defined tables. You can use [ALTER TABLE . . FORCE OUTER](#) to reset `force_outer` to a value equal to or greater than 0. For example, you might change the `force_outer` settings of tables `abc` and `xyz` to 3 and 8, respectively:

```
=> ALTER TABLE abc FORCE OUTER 3;  
=> ALTER TABLE xyz FORCE OUTER 8;
```

Given these settings, the optimizer joins `abc` as the inner input to any table with a `force_outer` value greater than 3. The optimizer joins `xyz` as the outer input to any table with a `force_outer` value less than 8.

Projection Inheritance

When you query a projection directly, it inherits the `force_outer` setting of its anchor table. The query then uses this setting when joined to another projection.

Enabling Forced Join Inputs

The configuration parameter `EnableForceOuter` determines whether Vertica uses a table's `force_outer` value to implement a join. By default, this parameter is set to 0, and forced join inputs are disabled. You can enable forced join inputs at session and database scopes, through [ALTER SESSION](#) and [ALTER DATABASE](#), respectively:

```
=> ALTER SESSION SET EnableForceOuter = { 0 | 1 };  
=> ALTER DATABASE db-name SET EnableForceOuter = { 0 | 1 };
```

If `EnableForceOuter` is set to 0, `ALTER TABLE . . FORCE OUTER` statements return with this warning:

```
WARNING 0: Set configuration parameter EnableForceOuter for the current session or the database in order to use force_outer value
```

Viewing Forced Join Inputs

EXPLAIN-generated query plans indicate whether the configuration parameter `EnableForceOuter` is on. A join query might include tables whose `force_outer` settings are less or greater than the default value of 5. In this case, the query plan includes a `Force outer level` field for the relevant join inputs.

For example, the following query joins tables `store.store_sales` and `public.products`, where both tables have the same `force_outer` setting (5). `EnableForceOuter` is on, as indicated in the generated query plan:

```
=> EXPLAIN SELECT s.store_key, p.product_description, s.sales_quantity, s.sale_date
FROM store.store_sales s JOIN public.products p ON s.product_key=p.product_key
WHERE s.sale_date='2014-12-01' ORDER BY s.store_key, s.sale_date;

EnableForceOuter is on
Access Path:
+-SORT [Cost: 7K, Rows: 100K (NO STATISTICS)] (PATH ID: 1)
| Order: sales.store_key ASC, sales.sale_date ASC
| Execute on: All Nodes
| +---> JOIN HASH [Cost: 5K, Rows: 100K (NO STATISTICS)] (PATH ID: 2) Outer (BROADCAST)(LOCAL ROUND ROBIN)
| | Join Cond: (sales.product_key = products.product_key)
| | Execute on: All Nodes
| | +-- Outer -> STORAGE ACCESS for sales [Cost: 2K, Rows: 100K (NO STATISTICS)] (PATH ID: 3)
| | | Projection: store.store_sales_b0
| | | Materialize: sales.sale_date, sales.store_key, sales.product_key, sales.sales_quantity
| | | Filter: (sales.sale_date = '2014-12-01'::date)
| | | Execute on: All Nodes
| | +-- Inner -> STORAGE ACCESS for products [Cost: 177, Rows: 60K (NO STATISTICS)] (PATH ID: 4)
| | | Projection: public.products_b0
| | | Materialize: products.product_key, products.product_description
| | | Execute on: All Nodes
```

The following `ALTER TABLE` statement resets the `force_outer` setting of `public.products` to 1:

```
=> ALTER TABLE public.products FORCE OUTER 1;
ALTER TABLE
```

The regenerated query plan for the same join now includes a `Force outer level` field and specifies `public.products` as the inner input:

```
=> EXPLAIN SELECT s.store_key, p.product_description, s.sales_quantity, s.sale_date
FROM store.store_sales s JOIN public.products p ON s.product_key=p.product_key
WHERE s.sale_date='2014-12-01' ORDER BY s.store_key, s.sale_date;
```

```
EnableForceOuter is on
Access Path:
+-SORT [Cost: 7K, Rows: 100K (NO STATISTICS)] (PATH ID: 1)
| Order: sales.store_key ASC, sales.sale_date ASC
| Execute on: All Nodes
| +--> JOIN HASH [Cost: 5K, Rows: 100K (NO STATISTICS)] (PATH ID: 2) Outer (BROADCAST)(LOCAL ROUND
ROBIN)
| | Join Cond: (sales.product_key = products.product_key)
| | Execute on: All Nodes
| | +-- Outer -> STORAGE ACCESS for sales [Cost: 2K, Rows: 100K (NO STATISTICS)] (PATH ID: 3)
| | | Projection: store.store_sales_b0
| | | Materialize: sales.sale_date, sales.store_key, sales.product_key, sales.sales_quantity
| | | Filter: (sales.sale_date = '2014-12-01'::date)
| | | Execute on: All Nodes
| | +-- Inner -> STORAGE ACCESS for products [Cost: 177, Rows: 60K (NO STATISTICS)] (PATH ID: 4)
| | | Projection: public.products_b0
| | | Force outer level: 1
| | | Materialize: products.product_key, products.product_description
| | | Execute on: All Nodes
```

If you change the `force_outer` setting of `public.products` to 8, Vertica creates a different query plan that specifies `public.products` as the outer input:

```
=> ALTER TABLE public.products FORCE OUTER 8;
ALTER TABLE

=> EXPLAIN SELECT s.store_key, p.product_description, s.sales_quantity, s.sale_date
FROM store.store_sales s JOIN public.products p ON s.product_key=p.product_key
WHERE s.sale_date='2014-12-01' ORDER BY s.store_key, s.sale_date;

EnableForceOuter is on
Access Path:
+-SORT [Cost: 7K, Rows: 100K (NO STATISTICS)] (PATH ID: 1)
| Order: sales.store_key ASC, sales.sale_date ASC
| Execute on: All Nodes
| +--> JOIN HASH [Cost: 5K, Rows: 100K (NO STATISTICS)] (PATH ID: 2) Inner (BROADCAST)
| | Join Cond: (sales.product_key = products.product_key)
| | Materialize at Output: products.product_description
| | Execute on: All Nodes
| | +-- Outer -> STORAGE ACCESS for products [Cost: 20, Rows: 60K (NO STATISTICS)] (PATH ID: 3)
| | | Projection: public.products_b0
| | | Force outer level: 8
| | | Materialize: products.product_key
| | | Execute on: All Nodes
| | | Runtime Filter: (SIP1(HashJoin): products.product_key)
| | +-- Inner -> STORAGE ACCESS for sales [Cost: 2K, Rows: 100K (NO STATISTICS)] (PATH ID: 4)
| | | Projection: store.store_sales_b0
| | | Materialize: sales.sale_date, sales.store_key, sales.product_key, sales.sales_quantity
| | | Filter: (sales.sale_date = '2014-12-01'::date)
| | | Execute on: All Nodes
```

Restrictions

Vertica ignores `force_outer` settings when it performs the following operations:

- Outer joins: Vertica generally respects OUTER JOIN clauses regardless of the force_outer settings of the joined tables.
- MERGE statement joins.
- Queries that include the SYNTACTIC_JOIN hint.
- Half-join queries such as SEMI JOIN.
- Joins to subqueries, where the subquery is always processed as having a force_outer setting of 5 regardless of the force_outer settings of the tables that are joined in the subquery. This setting determines a subquery's designation as inner or outer input relative to other join inputs. If two subqueries are joined, the optimizer determines which one is the inner input, and which one the outer.

Range Joins

Vertica provides performance optimizations for <, <=, >, >=, and BETWEEN predicates in join ON clauses. These optimizations are particularly useful when a column from one table is restricted to be in a range specified by two columns of another table.

Key Ranges

Multiple, consecutive key values can map to the same dimension values. Consider, for example, a table of IPv4 addresses and their owners. Because large subnets (ranges) of IP addresses could belong to the same owner, this dimension can be represented as:

```
=> CREATE TABLE ip_owners(  
    ip_start INTEGER,  
    ip_end INTEGER,  
    owner_id INTEGER);  
=> CREATE TABLE clicks(  
    ip_owners INTEGER,  
    dest_ip INTEGER);
```

A query that associates a click stream with its destination can use a join similar to the following, which takes advantage of the range optimization:

```
=> SELECT owner_id, COUNT(*) FROM clicks JOIN ip_owners  
    ON clicks.dest_ip BETWEEN ip_start AND ip_end  
    GROUP BY owner_id;
```

Requirements

Operators `<`, `<=`, `>`, `>=`, or `BETWEEN` must appear as top-level conjunctive predicates for range join optimization to be effective, as shown in the following examples:

`BETWEEN` as the only predicate:

```
=> SELECT COUNT(*) FROM fact JOIN dim
     ON fact.point BETWEEN dim.start AND dim.end;
```

Comparison operators as top-level predicates (within `AND`):

```
=> SELECT COUNT(*) FROM fact JOIN dim
     ON fact.point > dim.start AND fact.point < dim.end;
```

`BETWEEN` as a top-level predicate (within `AND`):

```
=> SELECT COUNT(*) FROM fact JOIN dim
     ON (fact.point BETWEEN dim.start AND dim.end) AND fact.c <> dim.c;
```

Query not optimized because `OR` is top-level predicate (disjunctive):

```
=> SELECT COUNT(*) FROM fact JOIN dim
     ON (fact.point BETWEEN dim.start AND dim.end) OR dim.end IS NULL;
```

Notes

- Expressions are optimized in range join queries in many cases.
- If range columns can have `NULL` values indicating that they are open-ended, it is possible to use range join optimizations by replacing nulls with very large or very small values:

```
=> SELECT COUNT(*) FROM fact JOIN dim
     ON fact.point BETWEEN NVL(dim.start, -1) AND NVL(dim.end, 100000000000);
```

- If there is more than one set of ranging predicates in the same `ON` clause, the order in which the predicates are specified might impact the effectiveness of the optimization:

```
=> SELECT COUNT(*) FROM fact JOIN dim
     ON fact.point1 BETWEEN dim.start1 AND dim.end1
     AND fact.point2 BETWEEN dim.start2 AND dim.end2;
```

The optimizer chooses the first range to optimize, so write your queries so that the range you most want optimized appears first in the statement.

- The use of the range join optimization is not directly affected by any characteristics of the physical schema; no schema tuning is required to benefit from the optimization.
- The range join optimization can be applied to joins without any other predicates, and to HASH or MERGE joins.
- To determine if an optimization is in use, search for RANGE in the EXPLAIN plan.

Query Optimization

When you submit a query to Vertica for processing, the Vertica query optimizer automatically chooses a set of operations to compute the requested result. These operations together are called a *query plan*. The choice of operations can significantly affect how many resources are needed to compute query results, and overall run-time performance. Optimal performance depends in great part on the projections that are available for a given query.

This section describes the different operations that the optimizer uses and how you can facilitate optimizer performance.

Note: Database response time depends on many factors. These include type and size of the application query, database design, data size and data types stored, available computational power, and network bandwidth. Adding nodes to a database cluster does not necessarily improve the system response time for every query, especially if response times are already short, or are not hardware bound.

Initial Process for Improving Query Performance

To optimize query performance, begin by performing the following tasks:

1. [Run Database Designer.](#)
2. [Check query events proactively.](#)
3. [Review the query plan.](#)

Run Database Designer

Database Designer creates a physical schema for your database that provides optimal query performance. The first time you run Database Designer, you should create a comprehensive design that includes relevant sample queries and data on which to base the design. If you develop performance issues later, consider loading additional queries that you run frequently and then rerunning Database Designer to create an incremental design.

When you run Database Designer, choose the option, Update Statistics. The Vertica query optimizer uses statistics about the data to create a query plan. Statistics help the optimizer determine:

- Multiple eligible projections to answer the query
- The best order in which to perform joins
- Data distribution algorithms, such as broadcast and resegmentation

If your statistics become out of date, run the Vertica function [ANALYZE_STATISTICS](#) function to update statistics for a schema, table, or columns. For more information, see [Collecting Database Statistics](#).

Check Query Events Proactively

The [QUERY_EVENTS](#) system table returns information on query planning, optimization, and execution events.

The `EVENT_TYPE` column provides various event types:

- Some event types are [informational](#).
- Others you should [review for possible corrective action](#).
- Several are [most important to address](#).

The following table lists informational event types.

Event Type	Description
SIP_FALLBACK	This optimization did not apply to this query type.
SMALL_MERGE_REPLACED	Vertica has chosen a more efficient way to access the data by replacing a merge.
STORAGE_CONTAINERS_ELIMINATED	Vertica has performed partition pruning for the purpose of optimization.
GROUPBY PUSHDOWN	(Message is Internal to Vertica.)
NO GROUPBY PUSHDOWN	(Message is Internal to Vertica.)
VALUE_TRUNCATED	A character value is too long.
GROUP_BY_PREPASS_FALLBACK	Vertica could not run an optimization. In-memory prepass is disabled. The projection may not be optimal.
MERGE_CONVERTED_TO_UNION	Vertica has converted a merge operator to a union operator due to the sort order of the multi-threaded storage access stream.
TRANSITIVE PREDICATE	<p>Vertica has optimized by adding predicates to joins where it makes logical sense to do so.</p> <p>For example, for the statement, <code>SELECT * FROM A, B WHERE A.a = B.a AND A.a = 1;</code> Vertica may add a predicate <code>B a = 1</code> as a filter for better storage access of table B.</p>
NODE PRUNING	Vertica has performed node pruning, which is similar to partition pruning, but at the

Event Type	Description
	node level.
SEQUENCE CACHE REFILLED	Vertica has refilled sequence cache.
OUTER OVERRIDE USED	For efficiency and optimization, Vertica has swapped the inner/outer tables in a join. Vertica used the smaller table as the inner table.
OUTER OVERRIDE NOT USED	Vertica found swapping inner/outer tables in a join unnecessary because the inner/outer tables were in good order. (For example, a smaller table was used in an inner join.)
EXTERNAL_PREDICATE_PUSHDOWN_NOT_SUPPORTED	Predicate pushdown for older Hive versions may not be supported. For more information, see Improving Query Performance for Data Stored in HDFS .
LibHDFS++ UNSUPPORTED OPERATION	Vertica accessed HDFS using the hdfs URL scheme, but the HDFS cluster uses an unsupported feature such as wire encryption or HTTPS_ONLY. Vertica fell back to WebHDFS.
LibHDFS++ FAILOVER RETRY	Vertica attempted to contact a Name Node on an HDFS cluster that uses High Availability Name Node and did not receive a response. Vertica retried with a different Name Node.

The following table lists event types that you should review for possible corrective action.

Event Type	Description	Action
GROUP_BY_SPILLED	This event type is typically related to a specific type of query, which you may need to adjust.	Identify the type of query and make adjustments accordingly. You may need to adjust resource pools, projections, or the amount of RAM available. Try

Event Type	Description	Action
		running the query on a cluster with no additional workload.
RESEGMENTED_MANY_ROWS	This event type is typically related to a specific type of query, which you may need to adjust.	Do projections need to be segmented in a different way to allow for join locality? Can you rewrite the query to filter out more rows at storage access time? (Typically, Vertica does so automatically through predicate pushdown.) Review your explain plan.
RLE_OVERRIDDEN	The average run counts are not large enough for Run Length Encoding (RLE). This event occurs with queries where the filtered results for certain columns do not work with RLE because cardinality is less than 10.	Review and rewrite your query, if necessary.
PREDICATE_OUTSIDE_HISTOGRAM	A predicate value you are trying to match does not exist in a set of possible values for a specific column. For example, you try to match a VARCHAR value WHERE mystring = "ABC<newline>". In this case, the newline character throws off the predicate matching optimizations.	Review and rewrite your query, if necessary.

The following table lists more critical event types, and recommends actions you can take to resolve issues.

Event Type	Description	Action
WOS_SPILL	WOS ran out of memory, and began spilling to ROS.	Try one or more of the following: <ul style="list-style-type: none"> • Adjust the load process to run bigger batches less frequently. • Give the WOS resource pool more memory. • Increase how often the Tuple Mover moveout and mergeout processes run for high ingest rates. (Adjustment of the moveout process helps avoid ROS issues.)
NO HISTOGRAM	Indicates a table does not have an updated column histogram.	Running the function ANALYZE_STATISTICS most often corrects this issue.
MEMORY LIMIT HIT	Indicates query complexity or, possibly, lack of available system memory.	Consider adjusting the <code>MAXMEMORYSIZE</code> and <code>PLANNEDCONCURRENCY</code> resource pools so that the optimizer has sufficient memory. On a heavily used system, this event may occur more frequently.
DELETE WITH NON OPTIMIZED PROJECTION	One or more projections do not have your delete filter column in their sort order, causing Vertica difficulty identifying rows to mark as deleted.	Add the delete filter column to the end of every projection sort order for your target delete table.

Event Type	Description	Action
JOIN_SPILLED	Vertica has spilled a join to disk. A join spill event slows down the subject query and all other queries as it consumes resources while using disk as virtual memory.	Try the following (in sequence): <ul style="list-style-type: none">• Review the explain plan. The query could be too ambitious, for example, cross joining two large tables.• Consider adding the query to a lower priority pool to reduce impact on other queries.• Create projections that allow for a merge join instead of a hash join.• Adjust the <code>PLANNEDCONCURRENCY</code> resource pool so that queries have more memory to execute.

Review the Query Plan

A *query plan* is a sequence of step-like paths that the Vertica query optimizer selects to access or alter information in your Vertica database. There are two ways to get information about the query plan:

- Run the [EXPLAIN](#) command. Each step (path) represents a single operation that the optimizer uses for its execution strategy.
- Query the [QUERY_PLAN_PROFILES](#) system table. This table provides detailed execution status for currently running queries. Output from the `QUERY_PLAN_PROFILES` table shows the real-time flow of data and the time and resources consumed for each path in each query plan.

Column Encoding

You can potentially make queries faster by changing column encoding. Encoding reduces the on-disk size of your data so the amount of I/O required for queries is reduced, resulting in faster execution times. Make sure all columns and projections included in the query use the correct data encoding. To do this, take the following steps:

1. Run Database Designer to create an incremental design. Database Designer implements the optimum encoding and projection design.
2. After creating the incremental design, update statistics using the [ANALYZE_STATISTICS](#) function.
3. Run [EXPLAIN](#) with one or more of the queries you submitted to the design to make sure it is using the new projections.

Alternatively, run [DESIGNER_DESIGN_PROJECTION_ENCODINGS](#) to re-evaluate the current encoding and update it if necessary.

Improving Column Compression

If you see slow performance or a large storage footprint with your [FLOAT](#) data, evaluate the data and your business needs to see if it can be contained in a [NUMERIC](#) column with a precision of 18 digits or less. Converting a [FLOAT](#) column to a [NUMERIC](#) column can improve data compression, reduce the on-disk size of your database, and improve performance of queries on that column.

When you define a [NUMERIC](#) data type, you specify the precision and the scale; [NUMERIC](#) data are exact representations of data. [FLOAT](#) data types represent variable precision and approximate values; they take up more space in the database.

Converting [FLOAT](#) columns to [NUMERIC](#) columns is most effective when:

- [NUMERIC](#) precision is 18 digits or less. Performance of [NUMERIC](#) data is fine-tuned for the common case of 18 digits of precision. Vertica recommends converting [FLOAT](#) columns to [NUMERIC](#) columns only if they require precision of 18 digits or less.
- [FLOAT](#) precision is bounded, and the values will all fall within a specified precision for a [NUMERIC](#) column. One example is monetary values like product prices or financial transaction amounts. For example, a column defined as [NUMERIC\(11,2\)](#) can accommodate

prices from 0 to a few million dollars and can store cents, and compresses more efficiently than a FLOAT column.

If you try to load a value into a NUMERIC column that exceeds the specified precision, Vertica returns an error and does not load the data. If you assign a value with more decimal digits than the specified scale, the value is rounded to match the specified scale and stored in that column.

[Numeric Data Types](#)

Using Run Length Encoding

When you run Database Designer, you can choose to optimize for loads, which minimizes database footprint. In this case, Database Designer applies encodings to columns to maximize query performance. [Encoding options](#) include run length encoding (RLE), which replaces sequences (runs) of identical values in a column with a set of pairs, where each pair represents the number of contiguous occurrences for a given value: (*occurrences*, *value*).

RLE is generally applicable to a column with low-cardinality, and where identical values are contiguous—typically, because table data is sorted on that column. For example, a customer profile table typically includes a gender column that contains values of F and M only. Sorting on gender ensures runs of F or M values that can be expressed as a set of two pairs: (*occurrences*, F) and (*occurrences*, M). So, given 8,147 occurrences of F and 7,956 occurrences of M, and a projection that is sorted primarily on gender, Vertica can apply RLE and store these values as a single set of two pairs: (8147, F) and (7956, M). Doing so reduces this projection's footprint and improves query performance.

Projections for Queries with Predicates

If your query contains one or more predicates, you can modify the projections to improve the query's performance, as described in the following two examples.

Queries That Use Date Ranges

This example shows how to encode data using RLE and change the projection sort order to improve the performance of a query that retrieves all data within a given date range.

Suppose you have a query that looks like this:

```
=> SELECT * FROM trades
    WHERE trade_date BETWEEN '2016-11-01' AND '2016-12-01';
```

To optimize this query, determine whether all of the projections can perform the SELECT operation in a timely manner. Run SELECT COUNT(*) statement for each projection, specifying the date range, and note the response time. For example:

```
=> SELECT COUNT(*) FROM [ projection_name ]
    WHERE trade_date BETWEEN '2016-11-01' AND '2016-12-01';
```

If one or more of the queries is slow, check the uniqueness of the trade_date column and determine if it needs to be in the projection's ORDER BY clause and/or can be encoded using RLE. RLE replaces sequences of the same data values within a column by a pair that represents the value and a count. For best results, order the columns in the projection from lowest cardinality to highest cardinality, and use RLE to encode the data in low-cardinality columns.

Note: For an example of using sorting and RLE, see [Combine RLE and Sort Order](#).

If the number of unique columns is unsorted, or if the average number of repeated rows is less than 10, trade_date is too close to being unique and cannot be encoded using RLE. In this case, add a new column to minimize the search scope.

The following example adds a new column trade_year:

1. Determine if the new column trade_year returns a manageable result set. The following query returns the data grouped by trade_year:

```
=> SELECT DATE_TRUNC('trade_year', trade_date), COUNT(*)
    FROM trades
    GROUP BY DATE_TRUNC('trade_year', trade_date);
```

2. Assuming that trade_year = 2007 is near 8k, add a column for trade_year to the trades table. The SELECT statement then becomes:

```
=> SELECT * FROM trades
    WHERE trade_year = 2007
```

```
AND trade_date BETWEEN '2016-11-01' AND '2016-12-01';
```

As a result, you have a projection that is sorted on `trade_year`, which can be encoded using RLE.

Queries for Tables with a High-Cardinality Primary Key

This example demonstrates how you can modify the projection to improve the performance of queries that select data from a table with a high-cardinality primary key.

Suppose you have the following query:

```
=> SELECT FROM [table]
WHERE pk IN (12345, 12346, 12347,...);
```

Because the primary key is a high-cardinality column, Vertica has to search a large amount of data.

To optimize the schema for this query, create a new column named `buckets` and assign it the value of the primary key divided by 10000. In this example, `buckets=(int) pk/10000`. Use the `buckets` column to limit the search scope as follows:

```
=> SELECT FROM [table]
WHERE buckets IN (1,...)
AND pk IN (12345, 12346, 12347,...);
```

Creating a lower cardinality column and adding it to the query limits the search scope and improves the query performance. In addition, if you create a projection where `buckets` is first in the sort order, the query may run even faster.

GROUP BY Queries

The following sections include several examples that show how you can design your projections to optimize the performance of your GROUP BY queries.

GROUP BY Implementation Options

Vertica implements a query GROUP BY clause with one of these algorithms: GROUPBY PIPELINED or GROUPBY HASH. Both algorithms return the same results. Performance of both is generally similar for queries that return a small number of distinct groups—typically a thousand per node .

You can use [EXPLAIN](#) to determine which algorithm the query optimizer chooses for a given query. The following conditions generally determine which algorithm is chosen:

- GROUPBY PIPELINED requires all GROUP BY data to be specified in the projection's ORDER BY clause. For details, see [GROUPBY PIPELINED Requirements](#) below.

Because GROUPBY PIPELINED only needs to retain in memory the current group data, this algorithm generally requires less memory and executes faster than GROUPBY HASH. Performance improvements are especially notable for queries that aggregate large numbers of distinct groups.

- GROUPBY HASH is used for any query that does not comply with GROUP BY PIPELINED sort order requirements. In this case, Vertica must build a hash table on GROUP BY columns before it can start grouping the data.

GROUPBY PIPELINED Requirements

You can enable use of the GROUP BY PIPELINED algorithm by ensuring that the query and one of its projections comply with GROUP BY PIPELINED requirements. The following conditions apply to GROUPBY PIPELINED. If none of them is true for the query, then Vertica uses GROUPBY HASH.

All examples that follow assume this schema:

```
CREATE TABLE sortopt (  
  a INT NOT NULL,  
  b INT NOT NULL,
```

```

        c INT,
        d INT
    );
CREATE PROJECTION sortopt_p (
    a_proj,
    b_proj,
    c_proj,
    d_proj )
AS SELECT * FROM sortopt
ORDER BY a,b,c
UNSEGMENTED ALL NODES;
INSERT INTO sortopt VALUES(5,2,13,84);
INSERT INTO sortopt VALUES(14,22,8,115);
INSERT INTO sortopt VALUES(79,9,401,33);

```

Condition 1

All GROUP BY columns are also included in the projection ORDER BY clause.

For example:

GROUP BY columns	GROUPBY algorithm	Reason chosen
a a, b b, a a, b, c c, a, b	GROUPBY PIPELINED	Columns a, b, and c are included in the projection sort columns.
a, b, c, d	GROUPBY HASH	Column d is not part of the projection sort columns.

Condition 2

If the query's GROUP BY clause has fewer columns than the projection's ORDER BY clause, the GROUP BY columns must:

- Be a subset of ORDER BY columns that are contiguous.
- Include the first ORDER BY column.

For example:

GROUP BY columns	GROUPBY algorithm	Reason chosen
a a, b b, a	GROUPBY PIPELINED	All GROUP BY columns are a subset of contiguous columns in the projection's ORDER BY clause {a, b, c}, and include column a.

GROUP BY columns	GROUPBY algorithm	Reason chosen
a, c	GROUPBY HASH	GROUP BY columns {a, c} are not contiguous in the projection ORDER BY clause {a, b, c}.
b, c	GROUPBY HASH	GROUP BY columns {b, c} do not include the projection's first ORDER BY column a.

Condition 3

If a query's GROUP BY columns do not appear first in the projection's ORDER BY clause, then any early-appearing projection sort columns that are missing in the query's GROUP BY clause must be present as single-column constant equality predicates in the query's WHERE clause.

For example:

Query	GROUPBY algorithm	Reason chosen
SELECT SUM(a) FROM sortopt WHERE a = 10 GROUP BY b	GROUPBY PIPELINED	All columns preceding b in the projection sort order appear as constant equality predicates.
SELECT SUM(a) FROM sortopt WHERE a = 10 GROUP BY a, b	GROUPBY PIPELINED	Grouping column a is redundant but has no effect on algorithm selection.
SELECT SUM(a) FROM sortopt WHERE a = 10 GROUP BY b, c	GROUPBY PIPELINED	All columns preceding b and c in the projection sort order appear as constant equality predicates.
SELECT SUM(a) FROM sortopt WHERE a = 10 GROUP BY c, b	GROUPBY PIPELINED	All columns preceding b and c in the projection sort order appear as constant equality predicates.
SELECT SUM(a) FROM sortopt WHERE a = 10 GROUP BY c	GROUPBY HASH	All columns preceding c in the projection sort order do not appear as constant equality predicates.

Controlling GROUPBY Algorithm Choice

It is generally best to allow Vertica to determine which GROUP BY algorithm is best suited for a given query. Occasionally, you might want to use one algorithm over another. In such cases,

you can qualify the GROUP BY clause with a [GBYTYPE](#) hint:

```
GROUP BY /*+ GBYTYPE( HASH | PIPE ) */
```

For example, given the following query, the query optimizer uses the GROUPBY PIPELINED algorithm:

```
=> EXPLAIN SELECT SUM(a) FROM sortopt GROUP BY a,b;
-----
QUERY PLAN DESCRIPTION:
-----

EXPLAIN SELECT SUM(a) FROM sortopt GROUP BY a,b;

Access Path:
+-GROUPBY PIPELINED [Cost: 11, Rows: 3 (NO STATISTICS)] (PATH ID: 1)
| Aggregates: sum(sortopt.a)
| Group By: sortopt.a, sortopt.b

...
```

You can use the GBYTYPE hint to force the query optimizer to use the GROUPBY HASH algorithm instead:

```
=> EXPLAIN SELECT SUM(a) FROM sortopt GROUP BY /*+GBYTYPE(HASH) */ a,b;
-----
QUERY PLAN DESCRIPTION:
-----

EXPLAIN SELECT SUM(a) FROM sortopt GROUP BY /*+GBYTYPE(HASH) */ a,b;

Access Path:
+-GROUPBY HASH (LOCAL RESEGMENT GROUPS) [Cost: 11, Rows: 3 (NO STATISTICS)] (PATH ID: 1)
| Aggregates: sum(sortopt.a)
| Group By: sortopt.a, sortopt.b

...
```

The GBYTYPE hint can specify a PIPE (GROUPBY PIPELINED algorithm) argument only if the query and one of its projections comply with GROUP BY PIPELINED [requirements](#). Otherwise, Vertica issues a warning and uses GROUPBY HASH.

For example, the following query cannot use the GROUPBY PIPELINED algorithm, as the GROUP BY columns {b, c} do not include the projection's first ORDER BY column a:

```
=> SELECT SUM(a) FROM sortopt GROUP BY /*+GBYTYPE(PIPE) */ b,c;
WARNING 7765: Cannot apply Group By Pipe algorithm. Proceeding with Group By Hash and hint will be ignored
SUM
-----
 79
 14
  5
(3 rows)
```

Avoiding Resegmentation During GROUP BY Optimization with Projection Design

To compute the correct result of a query that contains a GROUP BY clause, Vertica must ensure that all rows with the same value in the GROUP BY expressions end up at the same node for final computation. If the projection design already guarantees the data is segmented by the GROUP BY columns, no resegmentation is required at run time.

To avoid resegmentation, the GROUP BY clause must contain all the segmentation columns of the projection, but it can also contain other columns.

When your query includes a GROUP BY clause and joins, if the join depends on the results of the GROUP BY, as in the following example, Vertica performs the GROUP BY first:

```
=> EXPLAIN SELECT * FROM (SELECT b from foo GROUP BY b) AS F, foo WHERE foo.a = F.b;

Access Path:
+-JOIN MERGEJOIN(inputs presorted) [Cost: 649, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
|   Join Cond: (foo.a = F.b)
|   Materialize at Output: foo.b
|   Execute on: All Nodes
|   +- Outer -> STORAGE ACCESS for foo [Cost: 202, Rows: 10K (NO STATISTICS)] (PATH ID: 2)
|   |   Projection: public.foo_super
|   |   Materialize: foo.a
|   |   Execute on: All Nodes
|   |   Runtime Filter: (SIP1(MergeJoin): foo.a)
|   +- Inner -> SELECT [Cost: 245, Rows: 10K (NO STATISTICS)] (PATH ID: 3)
|   |   Execute on: All Nodes
|   |   +---> GROUPBY HASH (SORT OUTPUT) (GLOBAL RESEGMENT GROUPS) (LOCAL RESEGMENT GROUPS) [Cost: 245,
Rows: 10K (NO STATISTICS)] (PATH ID:
4)
|   |   |   Group By: foo.b
|   |   |   Execute on: All Nodes
|   |   +---> STORAGE ACCESS for foo [Cost: 202, Rows: 10K (NO STATISTICS)] (PATH ID: 5)
|   |   |   Projection: public.foo_super
|   |   |   Materialize: foo.b
|   |   |   Execute on: All Nodes
```

If the result of the join operation is the input to the GROUP BY clause, Vertica performs the join first, as in the following example. The segmentation of those intermediate results may not be consistent with the GROUP BY clause in your query, resulted in resegmentation at run time.

```
=> EXPLAIN SELECT * FROM foo AS F, foo WHERE foo.a = F.b GROUP BY 1,2,3,4;

Access Path:
+-GROUPBY HASH (LOCAL RESEGMENT GROUPS) [Cost: 869, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
|   Group By: F.a, F.b, foo.a, foo.b
|   Execute on: All Nodes
|   +---> JOIN HASH [Cost: 853, Rows: 10K (NO STATISTICS)] (PATH ID: 2) Outer (RESEGMENT)(LOCAL ROUND
ROBIN)
|   |   Join Cond: (foo.a = F.b)
```

```

| |      Execute on: All Nodes
| | +-- Outer -> STORAGE ACCESS for F [Cost: 403, Rows: 10K (NO STATISTICS)] (PUSHED GROUPING) (PATH
ID: 3)
| | |      Projection: public.foo_super
| | |      Materialize: F.a, F.b
| | |      Execute on: All Nodes
| | +-- Inner -> STORAGE ACCESS for foo [Cost: 403, Rows: 10K (NO STATISTICS)] (PATH ID: 4)
| | |      Projection: public.foo_super
| | |      Materialize: foo.a, foo.b
| | |      Execute on: All Nodes

```

If your query does not include joins, the GROUP BY clauses are processed using the existing database projections.

Examples

Assume the following projection:

```
CREATE PROJECTION ... SEGMENTED BY HASH(a,b) ALL NODES
```

The following table explains whether or not resegmentation occurs at run time and why.

GROUP BY a	Requires resegmentation at run time. The query does not contain all the projection segmentation columns.
GROUP BY a, b	Does not require resegmentation at run time. The GROUP BY clause contains all the projection segmentation columns.
GROUP BY a, b, c	Does not require resegmentation at run time. The GROUP BY clause contains all the projection segmentation columns.
GROUP BY a+1, b	Requires resegmentation at run time because of the expression on column a.

To determine if resegmentation will occur during your GROUP BY query, look at the [EXPLAIN](#)-generated query plan.

For example, the following plan uses GROUPBY PIPELINED sort optimization and requires resegmentation to perform the GROUP BY calculation:

```
+--GROUPBY PIPELINED (RESEGMENT GROUPS) [Cost: 194, Rows: 10K (NO
STATISTICS)] (PATH ID: 1)
```

The following plan uses GROUPBY PIPELINED sort optimization, but does not require resegmentation:

```
+--GROUPBY PIPELINED [Cost: 459, Rows: 10K (NO STATISTICS)] (PATH ID:
1)
```

DISTINCT in a SELECT Query List

This section describes how to optimize queries that have the `DISTINCT` keyword in their `SELECT` list. The techniques for optimizing `DISTINCT` queries are similar to the techniques for optimizing `GROUP BY` queries because when processing queries that use `DISTINCT`, the Vertica optimizer rewrites the query as a `GROUP BY` query.

The following sections below this page describe specific situations:

- [Query Has No Aggregates in SELECT List](#)
- [COUNT \(DISTINCT\) and Other DISTINCT Aggregates](#)
- [Approximate Count Distinct Functions](#)
- [Single DISTINCT Aggregates](#)
- [Multiple DISTINCT Aggregates](#)

Examples in these sections use the following table:

```
=> CREATE TABLE table1 (  
    a INT,  
    b INT,  
    c INT  
);
```

Query Has No Aggregates in SELECT List

If your query has no aggregates in the `SELECT` list, internally, Vertica treats the query as if it uses `GROUP BY` instead.

For example, you can rewrite the following query:

```
SELECT DISTINCT a, b, c FROM table1;
```

as:

```
SELECT a, b, c FROM table1 GROUP BY a, b, c;
```

For fastest execution, apply the optimization techniques for `GROUP BY` queries described in [GROUP BY Queries](#).

COUNT (DISTINCT) and Other DISTINCT Aggregates

Computing a DISTINCT aggregate generally requires more work than other aggregates. Also, a query that uses a single DISTINCT aggregate consumes fewer resources than a query with multiple DISTINCT aggregates.

Tip: Vertica executes queries with multiple distinct aggregates more efficiently when all distinct aggregate columns have a similar number of distinct values.

Approximate Count Distinct Functions

Vertica provides the COUNT(DISTINCT) function to compute the exact number of distinct values in a data set. If projections are available that allow COUNT(DISTINCT) to execute using the GROUPBY PIPELINED algorithm, COUNT(DISTINCT) performs well. In some situations, however, using APPROXIMATE_COUNT_DISTINCT performs better than COUNT(DISTINCT).

A [COUNT \[Aggregate\]](#) operation performs well when:

- One of the sorted projections delivers an order that enables sorted aggregation to be performed.
- The number of distinct values is fairly small.
- Hashed aggregation is required to execute the query.

When an approximate value will suffice or the values need to be rolled up, consider using the APPROXIMATE_COUNT_DISTINCT* functions.

Note: The APPROXIMATE_COUNT_DISTINCT* functions cannot appear in the same query block as DISTINCT aggregates.

Use Cases

Use [APPROXIMATE_COUNT_DISTINCT](#) as a direct replacement for COUNT (DISTINCT) when:

- You have a large data set and you do not require an exact count of distinct values.
- The performance of COUNT(DISTINCT) on a given data set is insufficient.

- You calculate several distinct counts in the same query.
- The plan for COUNT(DISTINCT) uses hashed aggregation.

Most of the time, APPROXIMATE_COUNT_DISTINCT executes faster than a comparable COUNT (DISTINCT) operation when hashed.

The expected value that APPROXIMATE_COUNT_DISTINCT returns is equal to COUNT (DISTINCT), with an error that is lognormally distributed with standard deviation s . You can control the standard deviation directly by setting the *error_tolerance*.

Use [APPROXIMATE_COUNT_DISTINCT_SYNOPSIS](#) and [APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS](#) together when:

- You have a large data set and you don't require an exact count of distinct values.
- The performance of COUNT(DISTINCT) on a given data set is insufficient.

and

- You want to pre-compute the distinct counts and later combine them in different ways.

Pass APPROXIMATE_COUNT_DISTINCT_SYNOPSIS the data set and a normally distributed confidence interval. The function returns a subset of the data, called a *synopsis*.

Pass the synopsis to the APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS function, which then performs an approximate count distinct on the synopsis.

Single DISTINCT Aggregates

Vertica computes a DISTINCT aggregate by first removing all duplicate values of the aggregate's argument to find the distinct values. Then it computes the aggregate.

For example, you can rewrite the following query:

```
SELECT a, b, COUNT(DISTINCT c) AS dcnt FROM table1 GROUP BY a, b;
```

as:

```
SELECT a, b, COUNT(dcnt) FROM  
(SELECT a, b, c AS dcnt FROM table1 GROUP BY a, b, c)  
GROUP BY a, b;
```

For fastest execution, apply the optimization techniques for GROUP BY queries.

Multiple DISTINCT Aggregates

If your query has multiple `DISTINCT` aggregates, there is no straightforward SQL rewrite that can compute them. The following query cannot easily be rewritten for improved performance:

```
SELECT a, COUNT(DISTINCT b), COUNT(DISTINCT c) AS dcnt FROM table1 GROUP BY a;
```

For a query with multiple `DISTINCT` aggregates, there is no projection design that can avoid using `GROUPBY HASH` and resegmenting the data. To improve performance of this query, make sure that it has large amounts of memory available. For more information about memory allocation for queries, see [Resource Manager](#).

JOIN Queries

In general, you can optimize execution of queries that join multiple tables in several ways:

- [Create projections for the joined tables that are sorted on join predicate columns.](#) This facilitates use of the merge join algorithm, which generally joins tables more efficiently than the merge join algorithm.
- [Create projections that are identically segmented on the join keys.](#)

Other Best Practices

Vertica also executes joins more efficiently if the following conditions are true:

- Query construction enables the query optimizer to create a plan where the larger table is defined as the outer input.
- The columns on each side of the equality predicate are from the same table. For example in the following query, the left and right sides of the equality predicate include only columns from tables T and X, respectively:

```
=> SELECT * FROM T JOIN X ON T.a + T.b = X.x1 - X.x2;
```

Conversely, the following query incurs more work to process, because the right side of the predicate includes columns from both tables T and X:

```
=> SELECT * FROM T JOIN X WHERE T.a = X.x1 + T.b
```

Hash Joins Versus Merge Joins

The Vertica optimizer implements a join with one of the following algorithms:

- **Merge join** is used when projections of the joined tables are sorted on the join columns. Merge joins are faster and uses less memory than hash joins.
- **Hash join** is used when projections of the joined tables are not already sorted on the join columns. In this case, the optimizer builds an in-memory hash table on the inner table's join column. The optimizer then scans the outer table for matches to the hash table, and joins

data from the two tables accordingly. The cost of performing a hash join is low if the entire hash table can fit in memory. Cost rises significantly if the hash table must be written to disk.

The optimizer automatically chooses the most appropriate algorithm to execute a query, given the projections that are available.

Facilitating Merge Joins

To facilitate a merge join, create projections for the joined tables that are sorted on the join predicate columns. The join predicate columns should be the first columns in the `ORDER BY` clause.

For example, tables `first` and `second` are defined as follows, with projections `first_p1` and `second_p1`, respectively. The projections are sorted on `data_first` and `data_second`:

```
CREATE TABLE first ( id INT, data_first INT );
CREATE PROJECTION first_p1 AS SELECT * FROM first ORDER BY data_first;

CREATE TABLE second ( id INT, data_second INT );
CREATE PROJECTION second_p1 AS SELECT * FROM first ORDER BY data_second;
```

When you join these tables on unsorted columns `first.id` and `second.id`, Vertica uses the hash join algorithm:

```
EXPLAIN SELECT first.data_first, second.data_second FROM first JOIN second ON first.id = second.id;

Access Path:
+-JOIN HASH [Cost: 752, Rows: 300K] (PATH ID: 1) Inner (BROADCAST)
```

You can facilitate execution of this query with the merge join algorithm by creating projections `first_p2` and `second_p2`, which are sorted on join columns `first_p2.id` and `second_p2.id`, respectively:

```
CREATE PROJECTION first_p2 AS SELECT id, data_first FROM first ORDER BY id SEGMENTED BY hash(id,
data_first) ALL NODES;
CREATE PROJECTION second_p2 AS SELECT id, data_second FROM second ORDER BY id SEGMENTED BY hash(id,
data_second) ALL NODES;
```

If the query joins significant amounts of data, the query optimizer uses the merge algorithm:

```
EXPLAIN SELECT first.data_first, second.data_second FROM first JOIN second ON first.id = second.id;

Access Path:
+-JOIN MERGEJOIN(inputs presorted) [Cost: 731, Rows: 300K] (PATH ID: 1) Inner (BROADCAST)
```

You can also facilitate a merge join by using subqueries to pre-sort the join predicate columns. For example:

```
SELECT first.id, first.data_first, second.data_second FROM  
  (SELECT * FROM first ORDER BY id ) first JOIN (SELECT * FROM second ORDER BY id) second ON first.id  
  = second.id;
```

Identical Segmentation

To improve query performance when you join multiple tables, create projections that are identically segmented on the join keys. Identically-segmented projections allow the joins to occur locally on each node, thereby helping to reduce data movement across the network during query processing.

To determine if projections are identically-segmented on the query join keys, create a query plan with EXPLAIN. If the query plan contains RESEGMENT or BROADCAST, the projections are not identically segmented.

The Vertica optimizer chooses a projection to supply rows for each table in a query. If the projections to be joined are segmented, the optimizer evaluates their segmentation against the query join expressions. It thereby determines whether the rows are placed on each node so it can join them without fetching data from another node.

Join Conditions for Identically Segmented Projections

A projection *p* is segmented on join columns if all column references in *p*'s segmentation expression are a subset of the columns in the join expression.

The following conditions must be true for two segmented projections *p1* of table *t1* and *p2* of table *t2* to participate in a join of *t1* to *t2*:

- The join condition must have the following form:

```
t1.j1 = t2.j1 AND t1.j2 = t2.j2 AND ... t1.jN = t2.jN
```

- The join columns must share the same base data type. For example:
 - If *t1.j1* is an INTEGER, *t2.j1* can be an INTEGER but it cannot be a FLOAT.
 - If *t1.j1* is a CHAR(10), *t2.j1* can be any CHAR or VARCHAR (for example, CHAR(10), VARCHAR(10), VARCHAR(20)), but *t2.j1* cannot be an INTEGER.
- If *p1* is segmented by an expression on columns {*t1.s1*, *t1.s2*, ... *t1.sN*}, each segmentation column *t1.sX* must be in the join column set {*t1.jX*}.

- If p2 is segmented by an expression on columns {t2.s1, t2.s2, ... t2.sN}, each segmentation column t2.sX must be in the join column set {t2.jX}.
- The segmentation expressions of p1 and p2 must be structurally equivalent. For example:
 - If p1 is SEGMENTED BY hash(t1.x) and p2 is SEGMENTED BY hash(t2.x), p1 and p2 are identically segmented.
 - If p1 is SEGMENTED BY hash(t1.x) and p2 is SEGMENTED BY hash(t2.x + 1), p1 and p2 are not identically segmented.
- p1 and p2 must have the same segment count.
- The assignment of segments to nodes must match. For example, if p1 and p2 use an OFFSET clause, their offsets must match.
- If Vertica finds projections for t1 and t2 that are not identically segmented, the data is redistributed across the network during query run time, as necessary.

Tip: If you create custom designs, try to use segmented projections for joins whenever possible.

Examples

The following statements create two tables and specify to create identical segments:

```
=> CREATE TABLE t1 (id INT, x1 INT, y1 INT) SEGMENTED BY HASH(id, x1) ALL NODES;  
=> CREATE TABLE t2 (id INT, x1 INT, y1 INT) SEGMENTED BY HASH(id, x1) ALL NODES;
```

Given this design, the join conditions in the following queries can leverage identical segmentation:

```
=> SELECT * FROM t1 JOIN t2 ON t1.id = t2.id;  
=> SELECT * FROM t1 JOIN t2 ON t1.id = t2.id AND t1.x1 = t2.x1;
```

Conversely, the join conditions in the following queries require resegmentation:

```
=> SELECT * FROM t1 JOIN t2 ON t1.x1 = t2.x1;  
=> SELECT * FROM t1 JOIN t2 ON t1.id = t2.x1;
```

ORDER BY Queries

You can improve the performance of queries that contain only `ORDER BY` clauses if the columns in a projection's `ORDER BY` clause are the same as the columns in the query.

If you define the projection sort order in the `CREATE PROJECTION` statement, the Vertica query optimizer does not have to sort projection data before performing certain `ORDER BY` queries.

The following table, `sortopt`, contains the columns `a`, `b`, `c`, and `d`. Projection `sortopt_p` specifies to order on columns `a`, `b`, and `c`.

```
CREATE TABLE sortopt (  
  a INT NOT NULL,  
  b INT NOT NULL,  
  c INT,  
  d INT  
);  
CREATE PROJECTION sortopt_p (  
  a_proj,  
  b_proj,  
  c_proj,  
  d_proj )  
AS SELECT * FROM sortopt  
ORDER BY a,b,c  
UNSEGMENTED ALL NODES;  
INSERT INTO sortopt VALUES(5,2,13,84);  
INSERT INTO sortopt VALUES(14,22,8,115);  
INSERT INTO sortopt VALUES(79,9,401,33);
```

Based on this sort order, if a `SELECT * FROM sortopt` query contains one of the following `ORDER BY` clauses, the query does not have to resort the projection:

- `ORDER BY a`
- `ORDER BY a, b`
- `ORDER BY a, b, c`

For example, Vertica does not have to resort the projection in the following query because the sort order includes columns specified in the `CREATE PROJECTION .ORDER BY a, b, c` clause, which mirrors the query's `ORDER BY a, b, c` clause:

```
=> SELECT * FROM sortopt ORDER BY a, b, c;  
 a | b | c | d  
----+-----+-----+-----  
 5 | 2 | 13 | 84  
14 | 22 | 8 | 115
```

```
79 | 9 | 401 | 33  
(3 rows)
```

If you include column `d` in the query, Vertica must re-sort the projection data because column `d` was not defined in the `CREATE PROJECTION . .ORDER BY` clause. Therefore, the `ORDER BY d` query won't benefit from any sort optimization.

You cannot specify an `ASC` or `DESC` clause in the `CREATE PROJECTION` statement's `ORDER BY` clause. Vertica always uses an ascending sort order in physical storage, so if your query specifies descending order for any of its columns, the query still causes Vertica to re-sort the projection data. For example, the following query requires Vertica to sort the results:

```
=> SELECT * FROM sortopt ORDER BY a DESC, b, c;  
a | b | c | d  
-----  
79 | 9 | 401 | 33  
14 | 22 | 8 | 115  
5 | 2 | 13 | 84  
(3 rows)
```

[CREATE PROJECTION](#)

Analytic Functions

The following sections describe how to optimize SQL-99 analytic functions that Vertica supports.

Empty OVER Clauses

The `OVER()` clause does not require a windowing clause. If your query uses an analytic function like `SUM(x)` and you specify an empty `OVER()` clause, the analytic function is used as a reporting function, where the entire input is treated as a single partition; the aggregate returns the same aggregated value for each row of the result set. The query executes on a single node, potentially resulting in poor performance.

If you add a `PARTITION BY` clause to the `OVER()` clause, the query executes on multiple nodes, improving its performance.

NULL Sort Order

By default, projection column values are stored in ascending order, but placement of NULL values depends on a column's data type.

NULL Placement Differences With ORDER BY Clauses

The analytic `OVER(window-order-clause)` and the SQL `ORDER BY` clause have slightly different semantics:

OVER(ORDER BY ...)

The analytic window order clause uses the `ASC` or `DESC` sort order to determine `NULLS FIRST` or `NULLS LAST` placement for analytic function results. NULL values are placed as follows:

- `ASC, NULLS LAST` — NULL values appear at the end of the sorted result.
- `DESC, NULLS FIRST` — NULL values appear at the beginning of the sorted result.

(SQL) ORDER BY

The SQL and VERTICA ORDER BY clauses produce different results. The SQL ORDER BY clause specifies only ascending or descending sort order. The VERTICA ORDER BY clause determines NULL placement based on the column data type:

- NUMERIC, INTEGER, DATE, TIME, TIMESTAMP, and INTERVAL columns: NULLS FIRST (NULL values appear at the beginning of a sorted projection.)
- FLOAT, STRING, and BOOLEAN columns: NULLS LAST (NULL values appear at the end of a sorted projection.)

NULL Sort Options

If you do not care about NULL placement in queries that involve analytic computations, or if you know that columns do not contain any NULL values, specify NULLS AUTO—irrespective of data type. Vertica chooses the placement that gives the fastest performance, as in the following query. Otherwise, specify NULLS FIRST or NULLS LAST.

```
=> SELECT x, RANK() OVER (ORDER BY x NULLS AUTO) FROM t;
```

You can carefully formulate queries so Vertica can avoid sorting the data and increase query performance, as illustrated by the following example. Vertica sorts inputs from table `t` on column `x`, as specified in the `OVER(ORDER BY)` clause, and then evaluates `RANK()`:

```
=> CREATE TABLE t (  
  x FLOAT,  
  y FLOAT );  
=> CREATE PROJECTION t_p (x, y) AS SELECT * FROM t  
  ORDER BY x, y UNSEGMENTED ALL NODES;  
=> SELECT x, RANK() OVER (ORDER BY x) FROM t;
```

In the preceding `SELECT` statement, Vertica eliminates the `ORDER BY` clause and executes the query quickly because column `x` is a `FLOAT` data type. As a result, the projection sort order matches the analytic default ordering (`ASC + NULLS LAST`). Vertica can also avoid having to sort the data when the underlying projection is already sorted.

However, if column `x` is an `INTEGER` data type, Vertica must sort the data because the projection sort order for `INTEGER` data types (`ASC + NULLS FIRST`) does not match the default analytic ordering (`ASC + NULLS LAST`). To help Vertica eliminate the sort, specify the placement of `NULLS` to match the default ordering:

```
=> SELECT x, RANK() OVER (ORDER BY x NULLS FIRST) FROM t;
```

If column `x` is a `STRING`, the following query eliminates the sort:

```
=> SELECT x, RANK() OVER (ORDER BY x NULLS LAST) FROM t;
```

If you omit `NULLS LAST` in the preceding query, VERTICA eliminates the sort because `ASC + NULLS LAST` is the default sort specification for both the analytic `ORDER BY` clause and for string-related columns in Vertica.

Runtime Sorting of NULL Values in Analytic Functions

By carefully writing queries or creating your design (or both), you can help the Vertica query optimizer skip sorting all columns in a table when performing an analytic function, which can improve query performance.

To minimize Vertica's need to sort projections during query execution, redefine the `employee` table and specify that `NULL` values are not allowed in the sort fields:

```
=> DROP TABLE employee CASCADE;
=> CREATE TABLE employee
  (empno INT,
   deptno INT NOT NULL,
   sal INT NOT NULL);
CREATE TABLE
=> CREATE PROJECTION employee_p AS
  SELECT * FROM employee
  ORDER BY deptno, sal;
CREATE PROJECTION
=> INSERT INTO employee VALUES(101,10,50000);
=> INSERT INTO employee VALUES(103,10,43000);
=> INSERT INTO employee VALUES(104,10,45000);
=> INSERT INTO employee VALUES(105,20,97000);
=> INSERT INTO employee VALUES(108,20,33000);
=> INSERT INTO employee VALUES(109,20,51000);
=> COMMIT;
COMMIT
```

```
=> SELECT * FROM employee;
 empno | deptno | sal
-----+-----+-----
   101 |      10 | 50000
   103 |      10 | 43000
   104 |      10 | 45000
   105 |      20 | 97000
   108 |      20 | 33000
   109 |      20 | 51000
(6 rows)
=> SELECT deptno, sal, empno, RANK() OVER
```

```
(PARTITION BY deptno ORDER BY sal)
FROM employee;
deptno | sal | empno | ?column?
-----+-----+-----+-----
 10 | 43000 | 103 | 1
 10 | 45000 | 104 | 2
 10 | 50000 | 101 | 3
 20 | 33000 | 108 | 1
 20 | 51000 | 109 | 2
 20 | 97000 | 105 | 3
(6 rows)
```

Tip: If you do not care about NULL placement in queries that involve analytic computations, or if you know that columns contain no NULL values, specify `NULLS AUTO` in your queries. Vertica attempts to choose the placement that gives the fastest performance. Otherwise, specify `NULLS FIRST` or `NULLS LAST`.

LIMIT Queries with ROW_NUMBER Predicates

Queries that use the [LIMIT clause](#) with `ORDER BY` or analytic function `ROW_NUMBER()` return a specific subset of rows in the query result. Vertica processes these queries efficiently using *Top-K Optimization*, which is a database query ranking process. Top-K optimization avoids sorting (and potentially writing to disk) an entire data set to find a small number of rows. This can significantly improve query performance.

For example, in the following query, Vertica extracts only the three smallest rows from column `x`:

```
=> SELECT * FROM t1 ORDER BY x LIMIT 3;
```

If table `t1` contains millions of rows, it is time consuming to sort all the `x` values. Instead, Vertica keeps track of the smallest three values in `x`.

Note: If you omit the `ORDER BY` clause, when using the `LIMIT` clause, the results can be nondeterministic.

Sort operations that precede a [SQL analytics](#) computation benefit from Top-K optimization if the query contains an `OVER(ORDER BY)` clause and a predicate on the `ROW_NUMBER` function, as in the following example:

```
=> SELECT x FROM
  (SELECT *, ROW_NUMBER() OVER (ORDER BY x) AS row
   FROM t1) t2 WHERE row <= 3;
```

The preceding query has the same behavior as the following query, which uses a `LIMIT` clause:

```
=> SELECT ROW_NUMBER() OVER (ORDER BY x) AS RANK FROM t1 LIMIT 3;
```

You can use `ROW_NUMBER()` with the analytic [window partition clause](#), something you cannot do if you use `LIMIT`:

```
=> SELECT x, y FROM  
      (SELECT *, ROW_NUMBER() OVER (PARTITION BY x ORDER BY y)  
       AS row FROM t1) t2 WHERE row <= 3;
```

Note: When the `OVER()` clause includes the *window-partition-clause*, Top-K optimization occurs only when the analytic sort matches the input's sort, for example, if the projection is sorted on columns `x` and `y` in table `t1`.

If you still want to improve the performance of your query, consider using the optimization techniques described in [ORDER BY Queries](#).

INSERT-SELECT Operations

There are several ways to optimize an INSERT-SELECT query that has the following format:

```
INSERT /*+direct*/ INTO destination SELECT * FROM source;
```

Matching Sort Orders

When performing INSERT-SELECT operations, to avoid the sort phase of the INSERT, make sure that the sort order for the SELECT query matches the projection sort order of the target table.

For example, on a single-node database:

```
=> CREATE TABLE source (col1 INT, col2 INT, col3 INT);
=> CREATE PROJECTION source_p (col1, col2, col3)
  AS SELECT col1, col2, col3 FROM source
  ORDER BY col1, col2, col3
  SEGMENTED BY HASH(col3)
  ALL NODES;
=> CREATE TABLE destination (col1 INT, col2 INT, col3 INT);
=> CREATE PROJECTION destination_p (col1, col2, col3)
  AS SELECT col1, col2, col3 FROM destination
  ORDER BY col1, col2, col3
  SEGMENTED BY HASH(col3)
  ALL NODES;
```

The following INSERT does not require a sort because the query result has the column order of the projection:

```
=> INSERT /*+direct*/ INTO destination SELECT * FROM source;
```

The following INSERT requires a sort because the order of the columns in the SELECT statement does not match the projection order:

```
=> INSERT /*+direct*/ INTO destination SELECT col1, col3, col2 FROM source;
```

The following INSERT does not require a sort. The order of the columns doesn't match, but the explicit ORDER BY causes the output to be sorted by c1, c3, c2 in Vertica:

```
=> INSERT /*+direct*/ INTO destination SELECT col1, col3, col2 FROM source
  GROUP BY col1, col3, col2
  ORDER BY col1, col2, col3 ;
```

Identical Segmentation

When performing an INSERT-SELECT operation from a segmented source table to a segmented destination table, segment both projections on the same column to avoid resegmenting the data, as in the following example:

```
CREATE TABLE source (col1 INT, col2 INT, col3 INT);
CREATE PROJECTION source_p (col1, col2, col3) AS
  SELECT col1, col2, col3 FROM source
  SEGMENTED BY HASH(col3) ALL NODES;
CREATE TABLE destination (col1 INT, col2 INT, col3 INT);
CREATE PROJECTION destination_p (col1, col2, col3) AS
  SELECT col1, col2, col3 FROM destination
  SEGMENTED BY HASH(col3) ALL NODES;
INSERT /*+direct*/ INTO destination SELECT * FROM source;
```

DELETE and UPDATE Queries

Vertica is optimized for query-intensive workloads, so DELETE and UPDATE queries might not achieve the same level of performance as other queries. A DELETE and UPDATE operation has to update all projections, so the operation is as slow as the slowest projection. For additional information, see [Using INSERT, UPDATE, and DELETE](#).

The topics that follow discuss best practices for optimizing DELETE and UPDATE queries in Vertica.

DELETE and UPDATE Performance Considerations

To improve the performance of your DELETE and UPDATE queries, consider the following issues:

- **Query performance after large deletes**—A large number of (unpurged) deleted rows can negatively affect query performance.

To eliminate rows that have been deleted from the result, a query must do extra processing. If 10% or more of the total rows in a table have been deleted, the performance of a query on the table degrades. However, your experience may vary depending on the size of the table, the table definition, and the query. If a table has a large number of deleted rows, consider purging those rows to improve performance. For more information on purging, see [Purging Deleted Data](#).

- **Recovery performance**—Recovery is the action required for a cluster to restore K-safety after a crash. Large numbers of deleted records can degrade the performance of a recovery. To improve recovery performance, purge the deleted rows. For more information on purging, see [Purging Deleted Data](#).
- **Concurrency**—DELETE and UPDATE take exclusive locks on the table. Only one DELETE or UPDATE transaction on a table can be in progress at a time and only when no loads (or INSERTs) are in progress. DELETES and UPDATES on different tables can be run concurrently.

For detailed tips about improving DELETE and UPDATE performance, see [DELETE and UPDATE Optimization](#).

Caution: Vertica does not remove deleted data immediately but keeps it as history for the purposes of historical query. A large amount of history can result in slower query performance. For information about how to configure the appropriate amount of history to retain, see [Purging Deleted Data](#).

DELETE and UPDATE Optimization

The process of optimizing DELETE and UPDATE queries is the same for both operations. Some simple steps can increase the query performance by tens to hundreds of times. The following sections describe several ways to improve projection design and improve DELETE and UPDATE queries to significantly increase DELETE and UPDATE performance.

Note: For large bulk deletion, Vertica recommends using [Partitioned Tables](#) where possible because they provide the best DELETE performance and improve query performance.

Projection Column Requirements for Optimized Deletes

When all columns required by the DELETE or UPDATE predicate are present in a projection, the projection is optimized for DELETES and UPDATES. DELETE and UPDATE operations on such projections are significantly faster than on non-optimized projections.

For example, consider the following table and projections:

```
CREATE TABLE t (a INTEGER, b INTEGER, c INTEGER);  
CREATE PROJECTION p1 (a, b, c) AS SELECT * FROM t ORDER BY a;  
CREATE PROJECTION p2 (a, c) AS SELECT a, c FROM t ORDER BY c, a;
```

In the following query, both p1 and p2 are eligible for DELETE and UPDATE optimization because column a is available:

```
DELETE from t WHERE a = 1;
```

In the following example, only projection p1 is eligible for DELETE and UPDATE optimization because the b column is not available in p2:

```
DELETE from t WHERE b = 1;
```

Optimized Deletes in Subqueries

To be eligible for DELETE optimization, all target table columns referenced in a DELETE or UPDATE statement's WHERE clause must be in the projection definition.

For example, the following simple schema has two tables and three projections:

```
CREATE TABLE tb1 (a INT, b INT, c INT, d INT);  
CREATE TABLE tb2 (g INT, h INT, i INT, j INT);
```

The first projection references all columns in `tb1` and sorts on column `a`:

```
CREATE PROJECTION tb1_p AS SELECT a, b, c, d FROM tb1 ORDER BY a;
```

The buddy projection references and sorts on column `a` in `tb1`:

```
CREATE PROJECTION tb1_p_2 AS SELECT a FROM tb1 ORDER BY a;
```

This projection references all columns in `tb2` and sorts on column `i`:

```
CREATE PROJECTION tb2_p AS SELECT g, h, i, j FROM tb2 ORDER BY i;
```

Consider the following DML statement, which references `tb1.a` in its `WHERE` clause. Since both projections on `tb1` contain column `a`, both are eligible for the optimized DELETE:

```
DELETE FROM tb1 WHERE tb1.a IN (SELECT tb2.i FROM tb2);
```

Restrictions

Optimized DELETES are not supported under the following conditions:

- With replicated projections if subqueries reference the target table. For example, the following syntax is not supported:

```
DELETE FROM tb1 WHERE tb1.a IN (SELECT e FROM tb2, tb2 WHERE tb2.e = tb1.e);
```

- With subqueries that do not return multiple rows. For example, the following syntax is not supported:

```
DELETE FROM tb1 WHERE tb1.a = (SELECT k from tb2);
```

Projection Sort Order for Optimizing Deletes

Design your projections so that frequently-used DELETE or UPDATE predicate columns appear in the sort order of all projections for large DELETES and UPDATES.

For example, suppose most of the DELETE queries you perform on a projection look like the following:

```
DELETE from t where time_key < '1-1-2007'
```

To optimize the DELETES, make `time_key` appear in the ORDER BY clause of all your projections. This schema design results in better performance of the DELETE operation.

In addition, add additional sort columns to the sort order such that each combination of the sort key values uniquely identifies a row or a small set of rows. For more information, see [Combine RLE and Sort Order](#). To analyze projections for sort order issues, use the [EVALUATE_DELETE_PERFORMANCE](#) function.

Data Collector Table Queries

The Vertica Data Collector extends system table functionality by gathering and retaining information about your database cluster. The Data Collector makes this information available in system tables.

Vertica Analytics Platform stores Data Collection data in the Data Collector directory under the Vertica or catalog path. Use Data Collector information to query the past state of system tables and extract aggregate information.

In general, queries on Data Collector tables are more efficient when they include only the columns that contain the desired data. Queries are also more efficient when they:

- [Avoid resegmentation](#)
- [Use time predicates](#)

Avoiding Resegmentation

You can avoid resegmentation when you join the following DC tables on `session_id` or `transaction_id`, because all data is local:

- `dc_session_starts`
- `dc_session_ends`
- `dc_requests_issued`
- `dc_requests_completed`

Resegmentation is not required when a query includes the `node_name` column. For example:

```
=> SELECT dri.transaction_id, dri.request, drc.processed_row_count
      FROM dc_requests_issued dri
      JOIN dc_requests_completed drc
      USING (node_name, session_id, request_id)
      WHERE dri.time between 'April 7,2015'::timestamptz and 'April 8,2015'::timestamptz
      AND drc.time between 'April 7,2015'::timestamptz and 'April 8,2015'::timestamptz;
```

This query runs efficiently because:

- The [initiator node](#) writes only to `dc_requests_issued` and `dc_requests_completed`.
- Columns `session_id` and `node_name` are correlated.

Using Time Predicates

Use non-volatile functions and [TIMESTAMP](#) for the time range predicates. Vertica Analytics Platform optimizes SQL performance for DC tables that use the time predicate.

Each DC table has a `time` column. Use this column to enter the time range as the query predicate.

For example, this query returns data for dates between September 1 and September 10:

```
select * from dc_foo where time > 'Sept 1, 2015::timestamptz and time < 'Sept 10
2015':: timestamptz;
```

You can change the minimum and maximum time values to adjust the time for which you want to retrieve data.

You must use non-volatile functions as time predicates. [Volatile functions](#) cause queries to run inefficiently. This example returns all queries that started and ended on April 7, 2015.

However, the query runs at less than optimal performance because `trunc` and `timestamp` are volatile:

```
=> SELECT dri.transaction_id, dri.request, drc.processed_row_count
      FROM dc_requests_issued dri
      LEFT JOIN dc_requests_completed drc
      USING (session_id, request_id)
      WHERE trunc(dri.time, 'DDD') > 'April 7,2015'::timestamp
      AND trunc(drc.time, 'DDD') < 'April 8,2015'::timestamp;
```

Views

A view is a stored query that encapsulates one or more `SELECT` statements. Views dynamically access and compute data from the database at execution time. A view is read-only, and can reference any combination of tables, temporary tables, and other views.

You can use views to achieve the following goals:

- Hide the complexity of `SELECT` statements from users for support or security purposes. For example, you can create a view that exposes only the data users need from various tables, while withholding sensitive data from the same tables.
- Encapsulate details about table structures, which might change over time, behind a consistent user interface.

Unlike projections, views are not materialized—that is, they do not store data on disk. Thus, the following restrictions apply:

- Vertica does not need to refresh view data when the underlying table data changes. However, a view does incur overhead to access and compute data.
- Views do not support inserts, deletes, or updates.

Creating Views

You can create two types of views:

- `CREATE VIEW` creates a view that persists across all sessions until it is explicitly dropped with `DROP VIEW`
- `CREATE LOCAL TEMPORARY VIEW` creates a view that is accessible only during the current Vertica session, and only to its creator. The view is automatically dropped when the current session ends.

After you create a view, you cannot change its definition. You can replace it with another view of the same name; or you can delete and redefine it.

Create Permissions

To create a view, you must be a superuser or have the following privileges:

Privilege	Objects
CREATE	Schema where the view is created.
SELECT	Tables and views referenced by the view query.
USAGE	All schemas that contain tables and views referenced by the view query.

For information about enabling users to access views, see [Enabling View Access](#).

Using Views

Views can be used in the FROM clause of any SQL query or subquery. At execution, Vertica internally substitutes the name of the view used in the query with the actual query used in the view definition.

CREATE VIEW Example

The following [CREATE VIEW](#) statement creates the view `myview`, which sums all individual incomes of customers listed in the `store.store_sales_fact` table, and groups results by state:

```
=> CREATE VIEW myview AS
  SELECT SUM(annual_income), customer_state FROM public.customer_dimension
  WHERE customer_key IN (SELECT customer_key FROM store.store_sales_fact)
  GROUP BY customer_state
  ORDER BY customer_state ASC;
```

You can use this view to find all combined salaries greater than \$2 billion:

```
=> SELECT * FROM myview where sum > 2000000000 ORDER BY sum DESC;
  SUM      | customer_state
-----+-----
29253817091 | CA
14215397659 | TX
5225333668  | MI
4907216137  | CO
4581840709  | IL
3769455689  | CT
3330524215  | FL
3310667307  | IN
2832710696  | TN
2806150503  | PA
2793284639  | MA
27234441590 | AZ
2642551509  | UT
```

```
2128169759 | NV  
(14 rows)
```

Enabling View Access

You can query any view that you create. To enable other non-superusers to access a view, you must grant them USAGE privileges to the view schema, and SELECT privileges to the view itself. The following example grants user2 access to view `schema1.view1`:

```
=> GRANT USAGE ON schema schema1 TO user2;  
=> GRANT SELECT ON schema1.view1 TO user2;
```

Important: If the view references an external table, you must also grant USAGE privileges to the external table's schema. So, if `schema1.view1` references external table `schema2.extTable1`, you must also grant user2 USAGE privileges to `schema2`:

```
=> GRANT USAGE on schema schema2 to user2;
```

For more information see [GRANT \(View\)](#).

View Execution

When Vertica processes a query that contains a view, it treats the view as a subquery. Vertica executes the query by expanding it to include the query in the view definition. For example, Vertica expands the query on the view `myview` shown in [CREATE VIEW Example](#), to include the query that the view encapsulates, as follows:

```
=> SELECT * FROM  
  (SELECT SUM(annual_income), customer_state FROM public.customer_dimension  
   WHERE customer_key IN  
     (SELECT customer_key FROM store.store_sales_fact)  
   GROUP BY customer_state  
   ORDER BY customer_state ASC)  
 AS ship where sum > 2000000000;
```

View Optimization

If you query a view and your query only includes columns from a subset of the tables that are joined in that view, Vertica executes that query by expanding it to include only those tables. This optimization requires one of the following conditions to be true:

- Join columns are foreign and primary keys.
- The join is a left or right outer join on columns with unique values.

View Sort Order

When processing a query on a view, Vertica considers the `ORDER BY` clause only in the outermost query. If the view definition includes an `ORDER BY` clause, Vertica ignores it. Thus, in order to sort the results returned by a view, you must specify the `ORDER BY` clause in the outermost query:

```
=> SELECT * FROM view-name ORDER BY view-column;
```

Note: One exception applies: Vertica sorts view data when the view includes a `LIMIT` clause. In this case, Vertica must sort the data before it can process the `LIMIT` clause.

For example, the following view definition contains an `ORDER BY` clause inside a `FROM` subquery:

```
=> CREATE VIEW myview AS SELECT SUM(annual_income), customer_state FROM public.customer_dimension
WHERE customer_key IN
  (SELECT customer_key FROM store.store_sales_fact)
GROUP BY customer_state
ORDER BY customer_state ASC;
```

When you query the view, Vertica does not sort the data:

```
=> SELECT * FROM myview WHERE SUM > 200000000;
  SUM      | customer_state
-----+-----
 5225333668 | MI
 2832710696 | TN
14215397659 | TX
 4907216137 | CO
 2793284639 | MA
 3769455689 | CT
 3310667307 | IN
 2723441590 | AZ
 2642551509 | UT
 3330524215 | FL
 2128169759 | NV
29253817091 | CA
 4581840709 | IL
 2806150503 | PA
(14 rows)
```

To return sorted results, the outer query must include an `ORDER BY` clause:

```
=> SELECT * FROM myview WHERE SUM > 200000000 ORDER BY customer_state ASC;
      SUM      | customer_state
-----+-----
  2723441590 | AZ
  29253817091 | CA
  4907216137 | CO
  3769455689 | CT
  3330524215 | FL
  4581840709 | IL
  3310667307 | IN
  2793284639 | MA
  5225333668 | MI
  2128169759 | NV
  2806150503 | PA
  2832710696 | TN
  14215397659 | TX
  2642551509 | UT
(14 rows)
```

Run-Time Errors

If Vertica does not have to evaluate an expression that would generate a run-time error in order to answer a query, the run-time error might not occur.

For example, the following query returns an error, because `TO_DATE` cannot convert the string `F` to the specified date format:

```
=> SELECT TO_DATE('F','dd mm yyyy') FROM customer_dimension;
ERROR: Invalid input for DD: "F"
```

Now create a view using the same query:

```
=> CREATE VIEW temp AS SELECT TO_DATE('F','dd mm yyyy')
      FROM customer_dimension;
CREATE VIEW
```

In many cases, this view generates the same error message. For example:

```
=> SELECT * FROM temp;
ERROR: Invalid input for DD: "F"
```

However, if you query that view with the `COUNT` function, Vertica returns with the desired results:

```
=> SELECT COUNT(*) FROM temp;
COUNT
-----
    100
(1 row)
```

This behavior works as intended. You can create views that contain subqueries, where not every row is intended to pass the predicate.

Managing Views

Obtaining View Information

You can query system tables [VIEWS](#) and [VIEW_COLUMNS](#) to obtain information about existing views—for example, a view's definition and the attributes of columns that comprise that view.

Renaming a View

Use [ALTER VIEW](#) to rename a view.

Dropping a View

Use [DROP VIEW](#) to drop a view. Only the specified view is dropped. Vertica does not support CASCADE functionality for views, and does not check for dependencies. Dropping a view causes any view that references it to fail.

Disabling and Re-enabling Views

If you drop a table that is referenced by a view, Vertica does not drop the view. However, attempts to use that view or access information about it from system table [VIEW_COLUMNS](#) return an error that the referenced table does not exist. If you restore that table, Vertica also re-enables usage of the view.

Flattened Tables

Highly normalized database design often uses a star or snowflake schema model, comprising multiple large fact tables and many smaller dimension tables. Queries typically involve joins between a large fact table and multiple dimension tables. Depending on the number of tables and quantity of data that are joined, these queries can incur significant overhead.

To avoid this problem, some users create wide tables that combine all fact and dimension table columns that their queries require. These tables can dramatically speed up query execution. However, maintaining redundant sets of normalized and denormalized data has its own administrative costs.

Denormalized, or *flattened*, tables, can minimize these problems. Flattened tables can include columns that get their values by querying other tables. Operations on the source tables and flattened table are decoupled; changes in one are not automatically propagated to the other. This minimizes the overhead that is otherwise typical of denormalized tables.

A flattened table defines derived columns with one of the following [column constraint](#) clauses:

- `DEFAULT query-expression` sets the column value on two events:
 - When the column is created with `CREATE TABLE` or `ALTER TABLE . . . ADD COLUMN`.
 - Any table load operation such as `INSERT`.
- `SET USING query-expression` sets the column value only when the function `REFRESH_COLUMNS` is invoked.

In both cases, *query-expression* must return only one row and column value, or none. If the query returns no rows, the column value is set to `NULL`.

Like other tables defined in Vertica, you can add and remove `DEFAULT` and `SET USING` columns from a flattened table at any time. Vertica enforces dependencies between a flattened table and the tables that it queries. For details, see [Modifying SET USING and DEFAULT Columns](#).

Flattened Table Example

In the following example, columns `orderFact.cust_name` and `orderFact.cust_gender` are defined as `SET USING` and `DEFAULT` columns, respectively. Both columns obtain their values by querying table `custDim`:

```
=> CREATE TABLE public.custDim(  
    cid int PRIMARY KEY NOT NULL,  
    name varchar(20),  
    age int,  
    gender varchar(1)  
);  
  
=> CREATE TABLE public.orderFact(  
    order_id int PRIMARY KEY NOT NULL,  
    cid int REFERENCES public.custDim(cid),  
    cust_name varchar(20) SET USING (SELECT name FROM public.custDim WHERE (custDim.cid =  
orderFact.cid)),  
    cust_gender varchar(1) DEFAULT (SELECT gender FROM public.custDim WHERE (custDim.cid =  
orderFact.cid)),  
    amount numeric(12,2)  
);
```

The following INSERT commands load data into both tables:

```
=> INSERT INTO custDim VALUES(1, 'Alice', 25, 'F');  
=> INSERT INTO custDim VALUES(2, 'Boz', 30, 'M');  
=> INSERT INTO custDim VALUES(3, 'Eva', 32, 'F');  
=>  
=> INSERT INTO orderFact (order_id, cid, amount) VALUES(100, 1, 15);  
=> INSERT INTO orderFact (order_id, cid, amount) VALUES(200, 1, 1000);  
=> INSERT INTO orderFact (order_id, cid, amount) VALUES(300, 2, -50);  
=> INSERT INTO orderFact (order_id, cid, amount) VALUES(400, 3, 100);  
=> INSERT INTO orderFact (order_id, cid, amount) VALUES(500, 2, 200);  
=> COMMIT;
```

When you query the tables, Vertica returns the following result sets:

```
=> SELECT * FROM custDim;  
cid | name | age | gender  
-----+-----+-----+-----  
  1 | Alice |  25 | F  
  2 | Boz  |  30 | M  
  3 | Eva  |  32 | F  
(3 rows)  
  
=> SELECT * FROM orderFact ORDER BY cid;  
order_id | cid | cust_name | cust_gender | amount  
-----+-----+-----+-----+-----  
   100 |  1 |           | F           |  15.00  
   200 |  1 |           | F           | 1000.00  
   300 |  2 |           | M           |  -50.00  
   500 |  2 |           | M           |  200.00  
   400 |  3 |           | F           |  100.00  
(5 rows)
```

Vertica automatically populates the DEFAULT column `orderFact.cust_gender`, but the SET USING column `orderFact.cust_name` remains NULL. To populate this column, you must call the function [REFRESH_COLUMNS](#) on flattened table `orderFact`. This function invokes the SET USING query for column `orderFact.cust_name` and populates the column from the result set:

```
=> SELECT REFRESH_COLUMNS('orderFact', 'cust_name', 'REBUILD');

      REFRESH_COLUMNS
-----
refresh_columns completed
(1 row)

=> COMMIT;
COMMIT
=> SELECT * FROM orderFact ORDER BY cid;
 order_id | cid | cust_name | cust_gender | amount
-----+-----+-----+-----+-----
      100 |   1 | Alice     | F           |  15.00
      200 |   1 | Alice     | F           | 1000.00
      300 |   2 | Boz       | M           |  -50.00
      500 |   2 | Boz       | M           |  200.00
      400 |   3 | Eva      | F           |  100.00
(5 rows)
```

Creating Flattened Tables

A flattened table is typically a fact table where one or more columns query other tables for their values, through `DEFAULT` or `SET USING` constraints. Like other columns, you can set these constraints when you create the flattened table, or any time thereafter by modifying the table schema:

```
CREATE TABLE...(..., column-name data-type { DEFAULT | SET USING } expression,...)
```

```
ALTER TABLE...ADD COLUMN column-name { DEFAULT | SET USING } expression
```

```
ALTER TABLE...ALTER COLUMN column-name { SET DEFAULT | SET USING } expression
```

`DEFAULT` and `SET USING` constraints can be used for columns of all data types. The expressions that you set for these constraints are stored in the system table [COLUMNS](#), in columns `COLUMN_DEFAULT` and `COLUMN_SET_USING`. Both constraints support the same expressions. For detailed information, including restrictions, see [Defining Column Values](#) in the Administrator's Guide.

Supported Expressions

`DEFAULT` and `SET USING` generally support the same expressions. These include:

- Queries (see [Flattened Tables](#))
- Other columns in the same table
- [Literals](#) (constants)

- All [operators](#) supported by Vertica
- The following categories of functions:
 - [Null-handling](#)
 - [User-defined scalar](#)
 - [System information](#)
 - [String](#)
 - [Mathematical](#)
 - [Formatting](#)

Disambiguating Predicate Columns

If a `SET USING` or `DEFAULT` query expression joins two columns with the same name, the column names must include their table names. Otherwise, Vertica assumes that both columns reference the dimension table, and the predicate always evaluates to true.

For example, tables `orderFact` and `custDim` both include column `cid`. Flattened table `orderFact` defines column `cust_name` with a `SET USING` query expression. Because the query predicate references columns `cid` from both tables, the column names are fully qualified:

```
CREATE TABLE public.orderFact
(
  ...
  cid int REFERENCES public.custDim(cid),
  cust_name varchar(20) SET USING (
    SELECT name FROM public.custDim WHERE (custDIM.cid = orderFact.cid)),
  ...
)
```

Required Privileges

Flattened tables require the following privileges:

- To view flattened table data: `READ` privileges. No privileges are required on queried tables.
- To add `SET USING` or `DEFAULT` columns that query other tables: `SELECT` privileges on the queried tables, `CREATE` privileges on the flattened table.
- To load data: `SELECT` privileges on queried tables.

Running `REFRESH_COLUMNS` requires the following privileges on the flattened table:

- MODIFY privilege on the table, USAGE privilege on its schema
- For each SET USING column that queries another table or view: SELECT privilege on the queried table, USAGE privilege on its schema.

SET USING versus DEFAULT

Columns in a flattened table can query other tables with constraints SET USING and DEFAULT. In both cases, changes in the queried tables are not automatically propagated to the flattened table. The two constraints differ as described below.

DEFAULT Columns

Vertica executes DEFAULT queries only on new rows when they are added to the flattened table, through load operations such as INSERT and COPY. Thereafter, changes in the original data sources have no effect on the flattened table.

SET USING Columns

Vertica executes SET USING queries only when you invoke the function [REFRESH_COLUMNS](#). Load operations set SET USING columns in new rows to NULL. After the load, you must call REFRESH_COLUMNS to populate these columns from the queried tables. This can be useful in two ways: you can defer the overhead of updating the flattened table to any time that is convenient; and you can repeatedly query source tables for new data.

One exception applies: when you use [ALTER TABLE . . . ALTER COLUMN](#) to apply SET USING to an existing column, or modify an existing SET USING expression. In this case, the DDL operation automatically invokes REFRESH_COLUMNS on the column, using UPDATE mode. After the refresh operation is complete, the DDL operation auto-commits the updates and returns. If the refresh operation fails, Vertica rolls back the entire DDL operation. Execution time can be significant if the refresh operation involves a large data set.

Tip: It might be more efficient to drop the column and add a new one.

[ALTER TABLE . . . ADD COLUMN](#) does not call REFRESH_COLUMNS when you add a SET USING column to a table.

SET USING is especially useful for large flattened tables that reference data from multiple dimension tables. Often, only a small subset of SET USING columns are subject to change, and

queries on the flattened table do not always require up-to-the-minute data. Given this scenario, you can refresh table content at regular intervals, or only during off-peak hours. One or both of these strategies can minimize maintenance costs, and facilitate performance when querying large data sets.

Combining DEFAULT and SET USING Constraints

A column can specify both DEFAULT and SET USING constraints, as follows:

```
column-name data-type DEFAULT default-expr SET USING using-expr
```

Typically, both constraints specify the same expression. In this case, you can define the column as follows:

```
column-name data-type DEFAULT USING expression
```

DEFAULT USING columns support the same expressions as SET USING columns, and are subject to the same [restrictions](#).

Example

The following SQL illustrates differences between SET USING and DEFAULT constraints. The examples use the custDim and orderFact tables described in [Flattened Table Example](#).

The following [UPDATE](#) statement updates the custDim table:

```
=> UPDATE custDim SET name='Roz', gender='F' WHERE cid=2;
OUTPUT
-----
      1
(1 row)

=> COMMIT;
COMMIT
```

Changes are not propagated to flattened table orderFact, which includes SET USING and DEFAULT columns cust_name and cust_gender, respectively:

```
=> SELECT * FROM custDim ORDER BY cid;
cid | name | age | gender
-----+-----+-----+-----
  1 | Alice | 25 | F
  2 | Roz  | 30 | F
  3 | Eva  | 32 | F
(3 rows)

=> SELECT * FROM orderFact ORDER BY cid;
order_id | cid | cust_name | cust_gender | amount
-----+-----+-----+-----+-----
```

```
100 | 1 | Alice | F | 15.00
200 | 1 | Alice | F | 1000.00
300 | 2 | Boz | M | -50.00
500 | 2 | Boz | M | 200.00
400 | 3 | Eva | F | 100.00
(5 rows)
```

The following INSERT statement invokes the cust_gender column's DEFAULT query and sets that column to F. The load operation does not invoke the cust_name column's SET USING query, so cust_name is set to null:

```
=> INSERT INTO orderFact(order_id, cid, amount) VALUES(500, 3, 750);
OUTPUT
-----
1
(1 row)

=> COMMIT;
COMMIT
=> SELECT * FROM orderFact ORDER BY cid;
 order_id | cid | cust_name | cust_gender | amount
-----+-----+-----+-----+-----
100 | 1 | Alice | F | 15.00
200 | 1 | Alice | F | 1000.00
300 | 2 | Boz | M | -50.00
500 | 2 | Boz | M | 200.00
400 | 3 | Eva | F | 100.00
500 | 3 | | F | 750.00
(6 rows)
```

To set a value in cust_name, invoke its SET USING query by calling REFRESH_COLUMNS:

```
=> SELECT REFRESH_COLUMNS ('orderFact','');
REFRESH_COLUMNS
-----
refresh_columns completed
(1 row)

=> COMMIT;
COMMIT
=> SELECT * from orderFact ORDER BY cid;
 order_id | cid | cust_name | cust_gender | amount
-----+-----+-----+-----+-----
100 | 1 | Alice | F | 150.00
200 | 1 | Alice | F | 1000.00
300 | 2 | Roz | M | -50.00
500 | 2 | Roz | M | 200.00
400 | 3 | Eva | F | 100.00
500 | 3 | Eva | F | 750.00
(6 rows)
```

REFRESH_COLUMNS executes cust_name's SET USING query: it queries the name column in table custDim and updates cust_name with the following values:

- Sets `cust_name` in the new row to Eva.
- Returns updated values for `cid=2`, and changes Boz to Roz.

`REFRESH_COLUMNS` only affects the values in column `cust_name`. Values in column `gender` are unchanged, so settings for rows where `cid=2` (Roz) remain set to M. To repopulate `orderFact.cust_gender` with default values from `custDim.gender`, call `UPDATE` on `orderFact`:

```
=> UPDATE orderFact SET cust_gender=DEFAULT WHERE cust_name='Roz';
OUTPUT
-----
      2
(1 row)

=> COMMIT;
COMMIT
=> SELECT * FROM orderFact ORDER BY cid;
 order_id | cid | cust_name | cust_gender | amount
-----+-----+-----+-----+-----
    100 |  1 | Alice     | F           |  15.00
    200 |  1 | Alice     | F           | 1000.00
    300 |  2 | Roz       | F           |  -50.00
    500 |  2 | Roz       | F           |  200.00
    400 |  3 | Eva       | F           |  100.00
    500 |  3 | Eva       | F           |  750.00
(6 rows)
```

Modifying SET USING and DEFAULT Columns

You can drop `SET USING` and `DEFAULT` columns from a flattened table at any time. Doing so has no effect on the tables that these columns query.

Removing SET USING and DEFAULT Constraints

You remove a column's `SET USING` or `DEFAULT` constraint with `ALTER TABLE...ALTER COLUMN`, as follows:

```
ALTER TABLE table-name ALTER COLUMN column-name DROP { SET USING | DEFAULT };
```

Vertica removes the constraint from the specified column, but the column and its data are otherwise unaffected.

Modifying a SET USING and DEFAULT Expression

You can change the query expression of an existing SET USING or DEFAULT column by calling `ALTER TABLE...ALTER COLUMN`. When you modify a SET USING column expression, Vertica automatically invokes `REFRESH_COLUMNS` using UPDATE mode, and repopulates that column. If a large number of rows must be refreshed, the following approach might be preferable:

1. Drop the column with `ALTER TABLE...DROP COLUMN`.
2. Call `ALTER TABLE...ADD COLUMN` to add a new one with the desired SET USING expression.

This approach has two benefits:

- Avoids the immediate call to `REFRESH_COLUMNS`, and defers the overhead that is otherwise incurred.
- Lets you specify `REBUILD` mode when you call `REFRESH_COLUMNS`, which in many cases repopulates the column more efficiently.

Dropping Columns Queried by SET USING or DEFAULT

Vertica enforces dependencies between a flattened table and the tables that it queries. Attempts to drop a queried column or its table return an error unless the drop operation, such as `DROP TABLE`, also includes `CASCADE`. Vertica implements `CASCADE` by removing the SET USING or DEFAULT constraint from the flattened table. The table column and its data are otherwise unaffected.

For example, attempts to drop column `name` in table `custDim` returns a rollback error, as this column is referenced by SET USING column `cust_name` in `orderFact`:

```
=> ALTER TABLE custDim DROP COLUMN name;  
ROLLBACK 7302: Cannot drop column "name" since it is referenced in the set using expression of table  
"public.orderFact", column "cust_name"
```

To drop this column, use the `CASCADE` option:

```
=> ALTER TABLE custDim DROP COLUMN name CASCADE;  
ALTER TABLE
```

Vertica removes the `SET USING` constraint from `orderFact.cust_name` as part of the drop operation. However, `cust_name` retains the data that it derived from dropped column `custDim.name`:

```
=> SELECT EXPORT_TABLES('', 'orderFact');
                                EXPORT_TABLES
-----
CREATE TABLE public.orderFact
(
  order_id int NOT NULL,
  cid int,
  cust_name varchar(20)
  cust_gender varchar(1) DEFAULT ( SELECT custDim.gender
FROM public.custDim
WHERE (custDim.cid = orderFact.cid)),
  amount numeric(12,2)
);
ALTER TABLE public.orderFact ADD CONSTRAINT C_PRIMARY PRIMARY KEY (order_id) ENABLED;
ALTER TABLE public.orderFact ADD CONSTRAINT C_FOREIGN FOREIGN KEY (cid) references public.custDim
(cid);
(1 row)

=> SELECT * FROM orderFact;
order_id | cid | cust_name | cust_gender | amount
-----+-----+-----+-----+-----
    300 |  2 | Roz       | F           | -50.00
    400 |  3 | Eva       | F           | 100.00
    100 |  1 | Alice     | F           |  15.00
    500 |  2 | Roz       | F           | 200.00
    200 |  1 | Alice     | F           | 1000.00
(5 rows)
```

Impact of SET USING Columns on License Limits

Vertica does not count the data in denormalized columns towards your raw data license limit. `SET USING` columns obtain their data by querying columns in other tables. You cannot modify `SET USING` data directly—for example, through DML operations such as `INSERT` and `COPY`. Thus, only the source data counts against your raw data license limit.

For a list of `SET USING` restrictions, see [Defining Column Values](#).

SQL Analytics

Vertica analytics are SQL functions based on the ANSI 99 standard. These functions handle complex analysis and reporting tasks—for example:

- Rank the longest-standing customers in a particular state.
- Calculate the moving average of retail volume over a specified time.
- Find the highest score among all students in the same grade.
- Compare the current sales bonus that salespersons received against their previous bonus.

Analytic functions return aggregate results but they do not group the result set. They return the group value multiple times, once per record. You can sort group values, or partitions, using a window `ORDER BY` clause, but the order affects only the function result set, not the entire query result set.

For details about supported functions, see [Analytic Functions](#) in the SQL Reference Manual.

Invoking Analytic Functions

You invoke analytic functions as follows:

```
analytic-function (arguments) OVER(  
    [ window-partition-clause ]  
    [ window-order-clause [ window-frame-clause ] ]  
)
```

An analytic function's `OVER` clause can contain up to three sub-clauses, which specify how to partition and sort function input, and how to frame input with respect to the current row. Function input is the result set that the query returns after it evaluates `FROM`, `WHERE`, `GROUP BY`, and `HAVING` clauses.

Each function has its own `OVER` clause requirements. For example, some analytic functions do not support window order and window frame clauses.

Function Execution

An analytic function executes as follows:

1. Takes the input rows that the query returns after it performs all joins, and evaluates FROM, WHERE, GROUP BY, and HAVING clauses.
2. Groups input rows according to the window partition (PARTITION BY) clause. If this clause is omitted, all input rows are treated as a single partition.
3. Sorts rows within each partition according to window order (ORDER BY) clause.
4. If the OVER clause includes a window order clause, the function checks for a window frame clause and executes it as it processes each input row. If the OVER clause omits a window frame clause, the function treats the entire partition as a window frame.

Restrictions

- Analytic functions are allowed only in a query's SELECT and ORDER BY clauses.
- Analytic functions cannot be nested. For example, the following query throws an error:

```
=> SELECT MEDIAN(RANK() OVER(ORDER BY sal) OVER()).
```

Analytic Functions Versus Aggregate Functions

Like aggregate functions, analytic functions return aggregate results, but analytics do not group the result set. Instead, they return the group value multiple times with each record, allowing further analysis.

Analytic queries generally run faster and use fewer resources than aggregate queries.

Aggregate functions	Analytic functions
Return a single summary value.	Return the same number of rows as the input.
Define the groups of rows on which they operate through the SQL GROUP BY clause.	Define the groups of rows on which they operate through window partition and window frame clauses.

Examples

The examples below contrast the aggregate function `COUNT` with its analytic counterpart `COUNT`. The examples use the `employees` table as defined below:

```
CREATE TABLE employees(emp_no INT, dept_no INT);
INSERT INTO employees VALUES(1, 10);
INSERT INTO employees VALUES(2, 30);
INSERT INTO employees VALUES(3, 30);
INSERT INTO employees VALUES(4, 10);
INSERT INTO employees VALUES(5, 30);
INSERT INTO employees VALUES(6, 20);
INSERT INTO employees VALUES(7, 20);
INSERT INTO employees VALUES(8, 20);
INSERT INTO employees VALUES(9, 20);
INSERT INTO employees VALUES(10, 20);
INSERT INTO employees VALUES(11, 20);
COMMIT;
```

When you query this table, the following result set returns:

```
=> SELECT * FROM employees ORDER BY emp_no;
 emp_no | dept_no
-----+-----
      1 |     10
      2 |     30
      3 |     30
      4 |     10
      5 |     30
      6 |     20
      7 |     20
      8 |     20
      9 |     20
     10 |     20
     11 |     20
(11 rows)
```

Below, two queries use the `COUNT` function to count the number of employees in each department. The query on the left uses aggregate function `COUNT`; the query on the right uses analytic function `COUNT`:

Aggregate COUNT	Analytics COUNT
<pre>=> SELECT dept_no, COUNT(*) AS emp_count FROM employees GROUP BY dept_no ORDER BY dept_no;</pre>	<pre>=> SELECT emp_no, dept_no, COUNT(*) OVER(PARTITION BY dept_no ORDER BY emp_no) AS emp_count FROM employees;</pre>
<pre>dept_no emp_count -----+-----</pre>	<pre>emp_no dept_no emp_count</pre>

<pre>10 2 20 6 30 3 (3 rows)</pre>	<pre>-----+-----+----- 1 10 1 4 10 2 -----+-----+----- 6 20 1 7 20 2 8 20 3 9 20 4 10 20 5 11 20 6 -----+-----+----- 2 30 1 3 30 2 5 30 3 (11 rows)</pre>
<p>Aggregate function COUNT returns one row per department for the number of employees in that department.</p>	<p>Within each dept_no partition analytic function COUNT returns a cumulative count of employees. The count is ordered by emp_no, as specified by the ORDER BY clause.</p>

- [Analytic Query Examples](#)

Window Partitioning

Optionally specified in an analytic function's OVER clause, a partition (PARTITION BY) clause groups input rows before the function processes them. Window partitioning is similar to an aggregate function's GROUP BY clause, except it returns exactly one result row per input row. If you omit the window partition clause, the function treats all input rows as a single partition.

Specifying Window Partitioning

You specify window partitioning in the analytic function's OVER clause, as shown below. The window partition clause is set off in bold:

```
OVER( { PARTITION BY expression | PARTITION BEST | PARTITION NODES }
      window-order-clause
      window-frame-clause )
```

For syntax details, see [Window Partition Clause](#) in the SQL Reference Manual.

Examples

The examples in this topic use the allsales schema defined in [Invoking Analytic Functions](#).

```
CREATE TABLE allsales(state VARCHAR(20), name VARCHAR(20), sales INT);
INSERT INTO allsales VALUES('MA', 'A', 60);
INSERT INTO allsales VALUES('NY', 'B', 20);
INSERT INTO allsales VALUES('NY', 'C', 15);
INSERT INTO allsales VALUES('MA', 'D', 20);
INSERT INTO allsales VALUES('MA', 'E', 50);
INSERT INTO allsales VALUES('NY', 'F', 40);
INSERT INTO allsales VALUES('MA', 'G', 10);
COMMIT;
```

Median of sales within each state

The following query uses the analytic *window-partition-clause* to calculate the median of sales within each state. The analytic function is computed per partition and starts over again at the beginning of the next partition.

```
=> SELECT state, name, sales, MEDIAN(sales)
      OVER (PARTITION BY state) AS median from allsales;
```

Results are grouped into partitions for MA (35) and NY (20) under the median column.

state	name	sales	median
NY	C	15	20
NY	B	20	20
NY	F	40	20
MA	G	10	35
MA	D	20	35
MA	E	50	35
MA	A	60	35

(7 rows)

Median of sales among all states

The following query calculates the median of total sales among states. When you use `OVER()` with no parameters, there is one partition—the entire input:

```
=> SELECT state, sum(sales), median(SUM(sales))
      OVER () AS median FROM allsales GROUP BY state;
```

state	sum	median
NY	75	107.5
MA	140	107.5

(2 rows)

Sales larger than median (evaluation order)

Analytic functions are evaluated after all other clauses except the query's final `SQL ORDER BY`

clause. So a query that asks for all rows with sales larger than the median returns an error because the WHERE clause is applied before the analytic function and column m does not yet exist:

```
=> SELECT name, sales, MEDIAN(sales) OVER () AS m
   FROM allsales WHERE sales > m;
ERROR 2624: Column "m" does not exist
```

You can work around this by placing in a subquery the predicate WHERE sales > m:

```
=> SELECT * FROM
   (SELECT name, sales, MEDIAN(sales) OVER () AS m FROM allsales) sq
  WHERE sales > m;
 name | sales | m
-----+-----+---
 F    |    40 | 20
 E    |    50 | 20
 A    |    60 | 20
(3 rows)
```

For more examples, see [Analytic Query Examples](#).

Window Ordering

Window ordering specifies how to sort rows that are supplied to the analytic function. You specify window ordering through an ORDER BY clause in the function's OVER clause, as shown below. If the OVER clause includes a [window partition clause](#), rows are sorted within each partition. An window order clause also creates a default [window frame](#) if none is explicitly specified.

The window order clause only specifies order within a window result set. The query can have its own [ORDER BY](#) clause outside the OVER clause. This has precedence over the window order clause and orders the final result set.

Specifying Window Order

You specify a window frame in the analytic function's OVER clause, as shown below. The window order clause is set off in bold:

```
OVER(
  [ window-partition-clause ]
  ORDER BY { expression [ sort-qualifiers ] } [,...]
  [ window-frame-clause ]
)
sort-qualifiers =
```

```
[ ASC | DESC ]  
[ NULLS { FIRST | LAST | AUTO} ]
```

For syntax details, see [Window Order Clause](#) in the SQL Reference Manual.

Analytic Function Usage

Analytic aggregation functions such as [SUM](#) support window order clauses.

Required Usage

The following functions require a window order clause:

- [RANK](#)
- [DENSE_RANK](#)
- [LEAD](#)
- [LAG](#)
- [PERCENT_RANK](#)
- [CUME_DIST](#)
- [NTILE](#)

Invalid Usage

You cannot use a window order clause with the following functions:

- [PERCENTILE_CONT](#)
- [PERCENTILE_DISC](#)
- [MEDIAN](#)

Examples

The examples below use the `allsales` table schema:

```
CREATE TABLE allsales(state VARCHAR(20), name VARCHAR(20), sales INT);  
INSERT INTO allsales VALUES('MA', 'A', 60);  
INSERT INTO allsales VALUES('NY', 'B', 20);  
INSERT INTO allsales VALUES('NY', 'C', 15);  
INSERT INTO allsales VALUES('MA', 'D', 20);  
INSERT INTO allsales VALUES('MA', 'E', 50);
```

```
INSERT INTO allsales VALUES('NY', 'F', 40);
INSERT INTO allsales VALUES('MA', 'G', 10);
COMMIT;
```

Example 1

The following query orders sales inside each state partition:

```
=> SELECT state, sales, name, RANK() OVER(
  PARTITION BY state
  ORDER BY sales) AS RANK
FROM allsales;
```

state	sales	name	RANK
MA	10	G	1
MA	20	D	2
MA	50	E	3
MA	60	A	4
NY	15	C	1
NY	20	B	2
NY	40	F	3

(7 rows)

Example 2

The following query's final ORDER BY clause sorts results by name:

```
=> SELECT state, sales, name, RANK() OVER(
  PARTITION by state
  ORDER BY sales) AS RANK
FROM allsales ORDER BY name;
```

state	sales	name	RANK
MA	60	A	4
NY	20	B	2
NY	15	C	1
MA	20	D	2
MA	50	E	3
NY	40	F	3
MA	10	G	1

(7 rows)

Window Framing

The window frame of an analytic function comprises a set of rows relative to the row that is currently being evaluated by the function. After the analytic function processes that row and its window frame, Vertica advances the current row and adjusts the frame boundaries accordingly. If the `OVER` clause also specifies a [partition](#), Vertica also checks that frame boundaries do not cross partition boundaries. This process repeats until the function evaluates the last row of the last partition.

Specifying a Window Frame

You specify a window frame in the analytic function's `OVER` clause, as shown below. The window frame clause is set off in bold:

```
OVER(  
  [ window-partition-clause ]  
  window-order-clause  
  { ROWS | RANGE } { BETWEEN start-point AND end-point } | start-point  
)
```

start-point and *end-point* specify the window frame's offset from the current row, as follows:

```
{ UNBOUNDED {PRECEDING | FOLLOWING}  
  | CURRENT ROW  
  | constant-value {PRECEDING | FOLLOWING}  
}
```

The keywords `ROWS` and `RANGE` specify whether the offset is physical or logical. If you specify only a start point, Vertica creates a window from that point to the current row.

For syntax details, see [window-frame-clause](#) in the SQL Reference Manual.

Requirements

In order to specify a window frame, the `OVER` must also specify a [window order](#) (`ORDER BY`) clause. If the `OVER` clause includes a window order clause but omits specifying a window frame, the function creates a default frame that extends from the first row in the current partition to the current row. This is equivalent to the following clause:

```
RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW
```

Window Aggregate Functions

Analytic functions that support window frames are called window aggregates. They return information such as moving averages and cumulative results. To use the following functions as window (analytic) aggregates, instead of basic aggregates, the `OVER` clause must specify a [window order](#) clause and, optionally, a window frame clause. If the `OVER` clause omits specifying a window frame, the function creates a default window frame as described earlier.

The following analytic functions support window frames:

- [AVG](#)
- [COUNT](#)
- [MAX](#) / [MIN](#)
- [SUM](#)
- [STDDEV](#) / [STDDEV_POP](#) / [STDDEV_SAMP](#)
- [VARIANCE](#) / [VAR_POP](#) / [VAR_SAMP](#)

Note: Functions [FIRST_VALUE](#) and [LAST_VALUE](#) also support window frames, but they are only analytic functions with no aggregate counterpart. [EXPONENTIAL_MOVING_AVERAGE](#), [LAG](#), and [LEAD](#) analytic functions do not support window frames.

A window aggregate with an empty `OVER` clause creates no window frame. The function is used as a reporting function, where all input is treated as a single partition.

Windows with a Physical Offset (ROWS)

The keyword `ROWS` in a window frame clause specifies window dimensions as the number of rows relative to the current row. The value can be `INTEGER` data type only.

Note: The value returned by an analytic function with a physical offset is liable to produce nondeterministic results unless the ordering expression results in a unique ordering. To achieve unique ordering, the [window order clause](#) might need to specify multiple columns.

Examples

The examples on this page use the emp table schema:

```
CREATE TABLE emp(deptno INT, sal INT, empno INT);
INSERT INTO emp VALUES(10,101,1);
INSERT INTO emp VALUES(10,104,4);
INSERT INTO emp VALUES(20,100,11);
INSERT INTO emp VALUES(20,109,7);
INSERT INTO emp VALUES(20,109,6);
INSERT INTO emp VALUES(20,109,8);
INSERT INTO emp VALUES(20,110,10);
INSERT INTO emp VALUES(20,110,9);
INSERT INTO emp VALUES(30,102,2);
INSERT INTO emp VALUES(30,103,3);
INSERT INTO emp VALUES(30,105,5);
COMMIT;
```

The following query invokes COUNT to count the current row and the rows preceding it, up to two rows:

```
SELECT deptno, sal, empno, COUNT(*) OVER
      (PARTITION BY deptno ORDER BY sal ROWS BETWEEN 2 PRECEDING AND CURRENT ROW)
      AS count FROM emp;
```

The OVER clause contains three components:

- Window partition clause PARTITION BY deptno
- Order by clause ORDER BY sal
- Window frame clause ROWS BETWEEN 2 PRECEDING AND CURRENT ROW. This clause defines window dimensions as extending from the current row through the two rows that precede it.

The query returns results that are divided into three partitions, indicated below as red lines. Within the second partition (deptno=20), COUNT processes the window frame clause as follows:

1. Creates the first window (green box). This window comprises a single row, as the current row (blue box) is also the the partition's first row. Thus, the value in the count column shows the number of rows in the current window, which is 1:

deptno	sal	empno	count
10	101	1	1
10	104	4	2
20	100	11	1
20	109	7	
20	109	6	
20	109	8	
20	110	10	
20	110	9	
30	102	2	1
30	103	3	2
30	105	5	3

- After COUNT processes the partition's first row, it resets the current row to the partition's second row. The window now spans the current row and the row above it, so COUNT returns a value of 2:

deptno	sal	empno	count
10	101	1	1
10	104	4	2
20	100	11	1
20	109	7	2
20	109	6	
20	109	8	
20	110	10	
20	110	9	
30	102	2	1
30	103	3	2
30	105	5	3

- After COUNT processes the partition's second row, it resets the current row to the partition's third row. The window now spans the current row and the two rows above it, so

COUNT returns a value of 3:

deptno	sal	empno	count
10	101	1	1
10	104	4	2
20	100	11	1
20	109	7	2
20	109	6	3
20	109	8	
20	110	10	
20	110	9	
30	102	2	1
30	103	3	2
30	105	5	3

- Thereafter, COUNT continues to process the remaining partition rows and moves the window accordingly, but the window dimensions (ROWS BETWEEN 2 PRECEDING AND CURRENT ROW) remain unchanged as three rows. Accordingly, the value in the count column also remains unchanged (3):

deptno	sal	empno	count
10	101	1	1
10	104	4	2
20	100	11	1
20	109	7	2
20	109	6	3
20	109	8	3
20	110	10	
20	110	9	
30	102	2	1
30	103	3	2
30	105	5	3

deptno	sal	empno	count
10	101	1	1
10	104	4	2
20	100	11	1
20	109	7	2
20	109	6	3
20	109	8	3
20	110	10	3
20	110	9	3
30	102	2	1
30	103	3	2
30	105	5	3

deptno	sal	empno	count
10	101	1	1
10	104	4	2
20	100	11	1
20	109	7	2
20	109	6	3
20	109	8	3
20	110	10	3
20	110	9	3
30	102	2	1
30	103	3	2
30	105	5	3

Windows with a Logical Offset (RANGE)

The RANGE keyword defines an analytic window frame as a logical offset from the current row.

Note: The value returned by an analytic function with a logical offset is always deterministic.

For each row, an analytic function uses the [window order clause](#) (ORDER_BY) column or expression to calculate window frame dimensions as follows:

1. Within the current partition, evaluates the ORDER_BY value of the current row against the ORDER_BY values of contiguous rows.
2. Determines which of these rows satisfy the specified range requirements relative to the current row.
3. Creates a window frame that includes only those rows.
4. Executes on the current window.

Example

This example uses the table `property_sales`, which contains data about neighborhood home sales:

```
=> SELECT property_key, neighborhood, sell_price FROM property_sales ORDER BY neighborhood, sell_price;
```

property_key	neighborhood	sell_price
10918	Jamaica Plain	353000
10921	Jamaica Plain	450000
10927	Jamaica Plain	450000
10922	Jamaica Plain	474000
10919	Jamaica Plain	515000
10917	Jamaica Plain	675000
10924	Jamaica Plain	675000
10920	Jamaica Plain	705000
10923	Jamaica Plain	710000
10926	Jamaica Plain	875000
10925	Jamaica Plain	900000
10930	Roslindale	300000
10928	Roslindale	422000
10932	Roslindale	450000
10929	Roslindale	485000
10931	Roslindale	519000
10938	West Roxbury	479000
10933	West Roxbury	550000
10937	West Roxbury	550000
10934	West Roxbury	574000
10935	West Roxbury	598000
10936	West Roxbury	615000
10939	West Roxbury	720000

(23 rows)

The analytic function `AVG` can obtain the average of proximate selling prices within each neighborhood. The following query calculates for each home the average sale for all other neighborhood homes whose selling price was \$50k higher or lower:

```
=> SELECT property_key, neighborhood, sell_price, AVG(sell_price) OVER(  
    PARTITION BY neighborhood ORDER BY sell_price  
    RANGE BETWEEN 50000 PRECEDING and 50000 FOLLOWING)::int AS comp_sales
```

```
FROM property_sales ORDER BY neighborhood;
property_key | neighborhood | sell_price | comp_sales
-----+-----+-----+-----
10918 | Jamaica Plain | 353000 | 353000
10927 | Jamaica Plain | 450000 | 458000
10921 | Jamaica Plain | 450000 | 458000
10922 | Jamaica Plain | 474000 | 472250
10919 | Jamaica Plain | 515000 | 494500
10917 | Jamaica Plain | 675000 | 691250
10924 | Jamaica Plain | 675000 | 691250
10920 | Jamaica Plain | 705000 | 691250
10923 | Jamaica Plain | 710000 | 691250
10926 | Jamaica Plain | 875000 | 887500
10925 | Jamaica Plain | 900000 | 887500
10930 | Roslindale | 300000 | 300000
10928 | Roslindale | 422000 | 436000
10932 | Roslindale | 450000 | 452333
10929 | Roslindale | 485000 | 484667
10931 | Roslindale | 519000 | 502000
10938 | West Roxbury | 479000 | 479000
10933 | West Roxbury | 550000 | 568000
10937 | West Roxbury | 550000 | 568000
10934 | West Roxbury | 574000 | 577400
10935 | West Roxbury | 598000 | 577400
10936 | West Roxbury | 615000 | 595667
10939 | West Roxbury | 720000 | 720000
(23 rows)
```

AVG processes this query as follows:

- 1. AVG evaluates row 1 of the first partition (Jamaica Plain), but finds no sales within \$50k of this row's sell_price, (\$353k). AVG creates a window that includes this row only, and returns an average of 353k for row 1:

property_key	neighborhood	sell_price	comp_sales
10918	Jamaica Plain	353000	353000
10927	Jamaica Plain	450000	458000
10921	Jamaica Plain	450000	458000
10922	Jamaica Plain	474000	472250

- 2. AVG evaluates row 2 and finds three sell_price values within \$50k of the current row. AVG creates a window that includes these three rows, and returns an average of 458k for

row 2:

property_key	neighborhood	sell_price	comp_sales
10918	Jamaica Plain	353000	353000
10927	Jamaica Plain	450000	458000
10921	Jamaica Plain	450000	458000
10922	Jamaica Plain	474000	472250

- 3. AVG evaluates row 3 and finds the same three sell_price values within \$50k of the current row. AVG creates a window identical to the one before, and returns the same average of 458k for row 3:

property_key	neighborhood	sell_price	comp_sales
10918	Jamaica Plain	353000	353000
10927	Jamaica Plain	450000	458000
10921	Jamaica Plain	450000	458000
10922	Jamaica Plain	474000	472250

- 4. AVG evaluates row 4 and finds four sell_price values within \$50k of the current row. AVG expands its window to include rows 2 through 5, and returns an average of \$472.25k for row 4:

property_key	neighborhood	sell_price	comp_sales
10918	Jamaica Plain	353000	353000
10927	Jamaica Plain	450000	458000
10921	Jamaica Plain	450000	458000
10922	Jamaica Plain	474000	472250
10919	Jamaica Plain	515000	494500
10917	Jamaica Plain	675000	691250

5. In similar fashion, AVG evaluates the remaining rows in this partition. When the function evaluates the first row of the second partition (Roslindale), it resets the window as follows:

property_key	neighborhood	sell_price	comp_sales
10918	Jamaica Plain	353000	353000
10927	Jamaica Plain	450000	458000
10921	Jamaica Plain	450000	458000
10922	Jamaica Plain	474000	472250
10919	Jamaica Plain	515000	494500
10917	Jamaica Plain	675000	691250
10924	Jamaica Plain	675000	691250
10920	Jamaica Plain	705000	691250
10923	Jamaica Plain	710000	691250
10926	Jamaica Plain	875000	887500
10925	Jamaica Plain	900000	887500
10930	Roslindale	300000	300000
10928	Roslindale	422000	436000

AVG () →

Restrictions

If RANGE specifies a constant value, that value's data type and the window's ORDER BY data type must be the same. The following exceptions apply:

- RANGE can specify INTERVAL Year to Month if the window order clause data type is one of following: TIMESTAMP, TIMESTAMP WITH TIMEZONE, or DATE. TIME and TIME WITH TIMEZONE are not supported.
- RANGE can specify INTERVAL Day to Second if the window order clause data is one of following: TIMESTAMP, TIMESTAMP WITH TIMEZONE, DATE, TIME, or TIME WITH TIMEZONE.

The window order clause must specify one of the following data types: NUMERIC, DATE/TIME, FLOAT or INTEGER. This requirement is ignored if the window specifies one of following frames:

- RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW
- RANGE BETWEEN CURRENT ROW AND UNBOUNDED FOLLOWING
- RANGE BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING

Reporting Aggregates

Some of the analytic functions that take the window-frame-clause are the reporting aggregates. These functions let you compare a partition's aggregate values with detail rows, taking the place of correlated subqueries or joins.

- [AVG\(\)](#)
- [COUNT\(\)](#)
- [MAX\(\)](#) and [MIN\(\)](#)
- [SUM\(\)](#)
- [STDDEV\(\)](#), [STDDEV_POP\(\)](#), and [STDDEV_SAMP\(\)](#)
- [VARIANCE\(\)](#), [VAR_POP\(\)](#), and [VAR_SAMP\(\)](#)

If you use a window aggregate with an empty `OVER()` clause, the analytic function is used as a reporting function, where the entire input is treated as a single partition.

About Standard Deviation and Variance Functions

With standard deviation functions, a low standard deviation indicates that the data points tend to be very close to the mean, whereas high standard deviation indicates that the data points are spread out over a large range of values.

Standard deviation is often graphed and a distributed standard deviation creates the classic bell curve.

Variance functions measure how far a set of numbers is spread out.

Examples

Think of the window for reporting aggregates as a window defined as `UNBOUNDED PRECEDING` and `UNBOUNDED FOLLOWING`. The omission of a window-order-clause makes all rows in the partition also the window (reporting aggregates).

```
=> SELECT deptno, sal, empno, COUNT(sal)
   OVER (PARTITION BY deptno) AS COUNT FROM emp;
deptno | sal | empno | count
-----+-----+-----+-----
```

```
10 | 101 | 1 | 2
10 | 104 | 4 | 2
-----
20 | 110 | 10 | 6
20 | 110 | 9 | 6
20 | 109 | 7 | 6
20 | 109 | 6 | 6
20 | 109 | 8 | 6
20 | 100 | 11 | 6
-----
30 | 105 | 5 | 3
30 | 103 | 3 | 3
30 | 102 | 2 | 3
(11 rows)
```

If the `OVER()` clause in the above query contained a `window-order-clause` (for example, `ORDER BY sal`), it would become a moving window (window aggregate) query with a default window of `RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW`:

```
=> SELECT deptno, sal, empno, COUNT(sal) OVER (PARTITION BY deptno ORDER BY sal) AS COUNT FROM emp;
deptno | sal | empno | count
-----+-----+-----+-----
10 | 101 | 1 | 1
10 | 104 | 4 | 2
-----
20 | 100 | 11 | 1
20 | 109 | 7 | 4
20 | 109 | 6 | 4
20 | 109 | 8 | 4
20 | 110 | 10 | 6
20 | 110 | 9 | 6
-----
30 | 102 | 2 | 1
30 | 103 | 3 | 2
30 | 105 | 5 | 3
(11 rows)
```

What About `LAST_VALUE`?

You might wonder why you couldn't just use the `LAST_VALUE()` analytic function.

For example, for each employee, get the highest salary in the department:

```
=> SELECT deptno, sal, empno, LAST_VALUE(empno) OVER (PARTITION BY deptno ORDER BY sal) AS lv FROM emp;
```

deptno	sal	empno	lv
10	101	1	1
10	104	4	4
20	100	11	11
20	109	7	7
20	109	6	7
20	109	8	7
20	110	10	10
20	110	9	10
30	102	2	2
30	103	3	3
30	105	5	5

Due to default window semantics, `LAST_VALUE` does not always return the last value of a partition. If you omit the window-frame-clause from the analytic clause, `LAST_VALUE` operates on this default window. Results, therefore, can seem non-intuitive because the function does not return the bottom of the current partition. It returns the bottom of the window, which continues to change along with the current input row being processed.

Remember the default window:

```
OVER (PARTITION BY deptno ORDER BY sal)
```

is the same as:

```
OVER(PARTITION BY deptno ORDER BY sal ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW)
```

deptno	sal	empno	lv
10	101	1	1
10	104	4	4
20	100	11	11
20	109	7	
20	109	6	
20	109	8	
20	110	10	
20	110	9	
30	102	2	2
30	103	3	3

10	101	1	1
10	104	4	4
20	100	11	11
20	109	7	7
20	109	6	7
20	109	8	7
20	110	10	10
20	110	9	10
30	102	2	2
30	103	3	3
30	105	5	5

deptno	sal	empno	lv
10	101	1	1
10	104	4	4
20	100	11	11
20	109	7	7
20	109	6	7
20	109	8	7
20	110	10	10
20	110	9	10
30	102	2	2
30	103	3	3
30	105	5	5

deptno	sal	empno	lv
10	101	1	1
10	104	4	4
20	100	11	11
20	109	7	7
20	109	6	7
20	109	8	7
20	110	10	10
20	110	9	10
30	102	2	2
30	103	3	3
30	105	5	5

If you want to return the last value of a partition, use UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING.

```
=> SELECT deptno, sal, empno, LAST_VALUE(empno)
OVER (PARTITION BY deptno ORDER BY sal
ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING) AS lv
FROM emp;
```

deptno	sal	empno	lv
10	101	1	4
10	104	4	4
20	100	11	9
20	109	7	9
20	109	6	9
20	109	8	9
20	110	10	9
20	110	9	9
30	102	2	5
30	103	3	5
30	105	5	5

Vertica recommends that you use `LAST_VALUE` with the `window-order-clause` to produce deterministic results.

In the following example, `empno` 6, 7, and 8 have the same salary, so they are in adjacent rows. `empno` 8 appears first in this case but the order is not guaranteed.

deptno	sal	empno	lv
10	101	1	4
10	104	4	4
20	100	11	7
20	109	8	7
20	109	6	7
20	109	7	7
30	102	2	5
30	103	3	5
30	105	5	5

Notice in the output above, the last value is 7, which is the last row from the partition `deptno = 20`. If the rows have a different order, then the function returns a different value:

deptno	sal	empno	lv
10	101	1	4
10	104	4	4
20	100	11	6
20	109	8	6
20	109	7	6
20	109	6	6
30	102	2	5
30	103	3	5
30	105	5	5

Now the last value is 6, which is the last row from the partition deptno = 20. The solution is to add a unique key to the sort order. Even if the order of the query changes, the result will always be the same, and so deterministic.

```
=> SELECT deptno, sal, empno, LAST_VALUE(empno)
OVER (PARTITION BY deptno ORDER BY sal, empno
ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING) as lv
FROM emp;
```

deptno	sal	empno	lv
10	101	1	4
10	104	4	4
20	100	11	8
20	109	6	8
20	109	7	8
20	109	8	8
30	102	2	5
30	103	3	5
30	105	5	5

Notice how the rows are now ordered by empno, the last value stays at 8, and it does not matter the order of the query.

Named Windows

An analytic function's OVER clause can reference a named window, which encapsulates one or more window clauses: a window partition (PARTITION BY) clause and (optionally) a window order (ORDER BY) clause. Named windows can be useful when you write queries that invoke

multiple analytic functions with similar OVER clause syntax—for example, they use the same partition clauses.

A query names a window as follows:

```
WINDOW window-name AS ( window-partition-clause [window-order-clause] );
```

The same query can name and reference multiple windows. All window names must be unique within the same query.

Examples

The following query invokes two analytic functions, [RANK](#) and [DENSE_RANK](#). Because the two functions use the same partition and order clauses, the query names a window w that specifies both clauses. The two functions reference this window as follows:

```
=> SELECT employee_region region, employee_key, annual_salary,
        RANK() OVER w Rank,
        DENSE_RANK() OVER w "Dense Rank"
        FROM employee_dimension WINDOW w AS (PARTITION BY employee_region ORDER BY annual_salary);
```

region	employee_key	annual_salary	Rank	Dense Rank
West	5248	1200	1	1
West	6880	1204	2	2
West	5700	1214	3	3
West	9857	1218	4	4
West	6014	1218	4	4
West	9221	1220	6	5
West	7646	1222	7	6
West	6621	1222	7	6
West	6488	1224	9	7
West	7659	1226	10	8
West	7432	1226	10	8
West	9905	1226	10	8
West	9021	1228	13	9
West	7855	1228	13	9
West	7119	1230	15	10
...				

If the named window omits an order clause, the query's OVER clauses can specify their own order clauses. For example, you can modify the previous query so each function uses a different order clause. The named window is defined so it includes only a partition clause:

```
=> SELECT employee_region region, employee_key, annual_salary,
        RANK() OVER (w ORDER BY annual_salary DESC) Rank,
        DENSE_RANK() OVER (w ORDER BY annual_salary ASC) "Dense Rank"
        FROM employee_dimension WINDOW w AS (PARTITION BY employee_region);
```

region	employee_key	annual_salary	Rank	Dense Rank
West	5248	1200	2795	1
West	6880	1204	2794	2
West	5700	1214	2793	3
West	6014	1218	2791	4

West	9857	1218	2791	4
West	9221	1220	2790	5
West	6621	1222	2788	6
West	7646	1222	2788	6
West	6488	1224	2787	7
West	7432	1226	2784	8
West	9905	1226	2784	8
West	7659	1226	2784	8
West	7855	1228	2782	9
West	9021	1228	2782	9
West	7119	1230	2781	10
...				

Similarly, an `OVER` clause specifies a named window can also specify a [window frame clause](#), provided the named window includes an order clause. This can be useful inasmuch as you cannot define a named windows to include a window frame clause.

For example, the following query defines a window that encapsulates partitioning and order clauses. The `OVER` clause invokes this window and also includes a window frame clause:

```
=> SELECT deptno, sal, empno, COUNT(*) OVER (w ROWS BETWEEN 2 PRECEDING AND CURRENT ROW) AS count
FROM emp WINDOW w AS (PARTITION BY deptno ORDER BY sal);
deptno | sal | empno | count
-----+-----+-----+-----
 10 | 101 | 1 | 1
 10 | 104 | 4 | 2
 20 | 100 | 11 | 1
 20 | 109 | 8 | 2
 20 | 109 | 6 | 3
 20 | 109 | 7 | 3
 20 | 110 | 10 | 3
 20 | 110 | 9 | 3
 30 | 102 | 2 | 1
 30 | 103 | 3 | 2
 30 | 105 | 5 | 3
(11 rows)
```

Recursive Window References

A `WINDOW` clause can reference another window that is already named. For example, because named window `w1` is defined before `w2`, the `WINDOW` clause that defines `w2` can reference `w1`:

```
=> SELECT RANK() OVER(w1 ORDER BY sal DESC), RANK() OVER w2
FROM EMP WINDOW w1 AS (PARTITION BY deptno), w2 AS (w1 ORDER BY sal);
```

Restrictions

- An `OVER` clause can reference only one named window.
- Each `WINDOW` clause within the same query must have a unique name.

Analytic Query Examples

- [Calculating a Median Value](#)
- [Getting Price Differential for Two Stocks](#)
- [Calculating the Moving Average](#)
- [Getting Latest Bid and Ask Results](#)

Calculating a Median Value

A median is a numerical value that separates the higher half of a sample from the lower half. For example, you can retrieve the median of a finite list of numbers by arranging all observations from lowest value to highest value and then picking the middle one.

If the number of observations is even, then there is no single middle value; the median is the mean (average) of the two middle values.

The following example uses this table:

```
CREATE TABLE allsales(state VARCHAR(20), name VARCHAR(20), sales INT);
INSERT INTO allsales VALUES('MA', 'A', 60);
INSERT INTO allsales VALUES('NY', 'B', 20);
INSERT INTO allsales VALUES('NY', 'C', 15);
INSERT INTO allsales VALUES('MA', 'D', 20);
INSERT INTO allsales VALUES('MA', 'E', 50);
INSERT INTO allsales VALUES('NY', 'F', 40);
INSERT INTO allsales VALUES('MA', 'G', 10);
COMMIT;
```

You can use the analytic function **MEDIAN** to calculate the median of all sales in this table. In the following query, the function's **OVER** clause is empty, so the query returns the same aggregated value for each row of the result set:

```
=> SELECT name, sales, MEDIAN(sales) OVER() AS median FROM allsales;
 name | sales | median
-----+-----+-----
 G    |    10 |    20
 C    |    15 |    20
 D    |    20 |    20
 B    |    20 |    20
 F    |    40 |    20
 E    |    50 |    20
 A    |    60 |    20
(7 rows)
```

You can modify this query to group sales by state and obtain the median for each one. To do so, include a window partition clause in the OVER clause:

```
=> SELECT state, name, sales, MEDIAN(sales) OVER(partition by state) AS median FROM allsales;
```

state	name	sales	median
MA	G	10	35
MA	D	20	35
MA	E	50	35
MA	A	60	35
NY	C	15	20
NY	B	20	20
NY	F	40	20

(7 rows)

Getting Price Differential for Two Stocks

The following subquery selects out two stocks of interest. The outer query uses the LAST_VALUE() and OVER() components of analytics, with IGNORE NULLS.

Schema

```
DROP TABLE Ticks CASCADE;
```

```
CREATE TABLE Ticks (ts TIMESTAMP, Stock varchar(10), Bid float);
```

```
INSERT INTO Ticks VALUES('2011-07-12 10:23:54', 'abc', 10.12);
```

```
INSERT INTO Ticks VALUES('2011-07-12 10:23:58', 'abc', 10.34);
```

```
INSERT INTO Ticks VALUES('2011-07-12 10:23:59', 'abc', 10.75);
```

```
INSERT INTO Ticks VALUES('2011-07-12 10:25:15', 'abc', 11.98);
```

```
INSERT INTO Ticks VALUES('2011-07-12 10:25:16', 'abc');
```

```
INSERT INTO Ticks VALUES('2011-07-12 10:25:22', 'xyz', 45.16);
```

```
INSERT INTO Ticks VALUES('2011-07-12 10:25:27', 'xyz', 49.33);
```

```
INSERT INTO Ticks VALUES('2011-07-12 10:31:12', 'xyz', 65.25);
```

```
INSERT INTO Ticks VALUES('2011-07-12 10:31:15', 'xyz');
```

```
COMMIT;
```

ticks Table

```
=> SELECT * FROM ticks;
```

ts	stock	bid
2011-07-12 10:23:59	abc	10.75
2011-07-12 10:25:22	xyz	45.16
2011-07-12 10:23:58	abc	10.34
2011-07-12 10:25:27	xyz	49.33
2011-07-12 10:23:54	abc	10.12

```
2011-07-12 10:31:15 | xyz |  
2011-07-12 10:25:15 | abc | 11.98  
2011-07-12 10:25:16 | abc |  
2011-07-12 10:31:12 | xyz | 65.25  
(9 rows)
```

Query

```
=> SELECT ts, stock, bid, last_value(price1 IGNORE NULLS)  
      OVER(ORDER BY ts) - last_value(price2 IGNORE NULLS)  
      OVER(ORDER BY ts) as price_diff  
FROM  
(SELECT ts, stock, bid,  
  CASE WHEN stock = 'abc' THEN bid ELSE NULL END AS price1,  
  CASE WHEN stock = 'xyz' THEN bid ELSE NULL END AS price2  
  FROM ticks  
  WHERE stock IN ('abc','xyz')  
 ) v1  
ORDER BY ts;  
      ts          | stock | bid  | price_diff  
-----+-----+-----+-----  
2011-07-12 10:23:54 | abc  | 10.12 |  
2011-07-12 10:23:58 | abc  | 10.34 |  
2011-07-12 10:23:59 | abc  | 10.75 |  
2011-07-12 10:25:15 | abc  | 11.98 |  
2011-07-12 10:25:16 | abc  |      |  
2011-07-12 10:25:22 | xyz  | 45.16 | -33.18  
2011-07-12 10:25:27 | xyz  | 49.33 | -37.35  
2011-07-12 10:31:12 | xyz  | 65.25 | -53.27  
2011-07-12 10:31:15 | xyz  |      | -53.27  
(9 rows)
```

Calculating the Moving Average

Calculate a 40-second moving average of bids for one stock. This examples uses the [ticks](#) table schema.

Query

```
=> SELECT ts, bid, AVG(bid)  
      OVER(ORDER BY ts  
          RANGE BETWEEN INTERVAL '40 seconds'  
          PRECEDING AND CURRENT ROW)  
FROM ticks  
WHERE stock = 'abc'  
GROUP BY bid, ts  
ORDER BY ts;
```

```
      ts          | bid |      ?column?
-----+-----+-----
2011-07-12 10:23:54 | 10.12 |          10.12
2011-07-12 10:23:58 | 10.34 |          10.23
2011-07-12 10:23:59 | 10.75 | 10.40333333333333
2011-07-12 10:25:15 | 11.98 |          11.98
2011-07-12 10:25:16 |      |          11.98
(5 rows)
```

```
DROP TABLE Ticks CASCADE;
```

```
CREATE TABLE Ticks (ts TIMESTAMP, Stock varchar(10), Bid float);
INSERT INTO Ticks VALUES('2011-07-12 10:23:54', 'abc', 10.12);
INSERT INTO Ticks VALUES('2011-07-12 10:23:58', 'abc', 10.34);
INSERT INTO Ticks VALUES('2011-07-12 10:23:59', 'abc', 10.75);
INSERT INTO Ticks VALUES('2011-07-12 10:25:15', 'abc', 11.98);
INSERT INTO Ticks VALUES('2011-07-12 10:25:16', 'abc');
INSERT INTO Ticks VALUES('2011-07-12 10:25:22', 'xyz', 45.16);
INSERT INTO Ticks VALUES('2011-07-12 10:25:27', 'xyz', 49.33);
INSERT INTO Ticks VALUES('2011-07-12 10:31:12', 'xyz', 65.25);
INSERT INTO Ticks VALUES('2011-07-12 10:31:15', 'xyz');

COMMIT;
```

Getting Latest Bid and Ask Results

The following query fills in missing NULL values to create a full book order showing latest bid and ask price and size, by vendor id. Original rows have values for (typically) one price and one size, so use `last_value` with "ignore nulls" to find the most recent non-null value for the other pair each time there is an entry for the ID. `Sequenceno` provides a unique total ordering.

Schema:

```
=> CREATE TABLE bookorders(
  vendorid VARCHAR(100),
  date TIMESTAMP,
  sequenceno INT,
  askprice FLOAT,
  asksize INT,
  bidprice FLOAT,
  bidsize INT);
=> INSERT INTO bookorders VALUES('3325XPK','2011-07-12 10:23:54', 1, 10.12, 55, 10.23, 59);
=> INSERT INTO bookorders VALUES('3345XPZ','2011-07-12 10:23:55', 2, 10.55, 58, 10.75, 57);
=> INSERT INTO bookorders VALUES('445XPKF','2011-07-12 10:23:56', 3, 10.22, 43, 54);
=> INSERT INTO bookorders VALUES('445XPKF','2011-07-12 10:23:57', 3, 10.22, 59, 10.25, 61);
=> INSERT INTO bookorders VALUES('3425XPY','2011-07-12 10:23:58', 4, 11.87, 66, 11.90, 66);
=> INSERT INTO bookorders VALUES('3727XVK','2011-07-12 10:23:59', 5, 11.66, 51, 11.67, 62);
=> INSERT INTO bookorders VALUES('5325XYZ','2011-07-12 10:24:01', 6, 15.05, 44, 15.10, 59);
=> INSERT INTO bookorders VALUES('3675XVS','2011-07-12 10:24:05', 7, 15.43, 47, 58);
```

```
=> INSERT INTO bookorders VALUES('8972VUG','2011-07-12 10:25:15', 8, 14.95, 52, 15.11, 57);  
COMMIT;
```

Query:

```
=> SELECT  
  sequenceno Seq,  
  date "Time",  
  vendorid ID,  
  LAST_VALUE (bidprice IGNORE NULLS)  
    OVER (PARTITION BY vendorid ORDER BY sequenceno  
          ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW)  
  AS "Bid Price",  
  LAST_VALUE (bidsize IGNORE NULLS)  
    OVER (PARTITION BY vendorid ORDER BY sequenceno  
          ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW)  
  AS "Bid Size",  
  LAST_VALUE (askprice IGNORE NULLS)  
    OVER (PARTITION BY vendorid ORDER BY sequenceno  
          ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW)  
  AS "Ask Price",  
  LAST_VALUE (asksize IGNORE NULLS)  
    OVER (PARTITION BY vendorid order by sequenceno  
          ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW )  
  AS "Ask Size"  
FROM bookorders  
ORDER BY sequenceno;
```

Seq	Time	ID	Bid Price	Bid Size	Ask Price	Ask Size
1	2011-07-12 10:23:54	3325XPK	10.23	59	10.12	55
2	2011-07-12 10:23:55	3345XPZ	10.75	57	10.55	58
3	2011-07-12 10:23:57	445XPKF	10.25	61	10.22	59
3	2011-07-12 10:23:56	445XPKF	54		10.22	43

Event-Based Windows

Event-based windows let you break time series data into windows that border on significant events within the data. This is especially relevant in financial data where analysis often focuses on specific events as triggers to other activity.

Vertica provides two event-based window functions that are not part of the SQL-99 standard:

- [CONDITIONAL_CHANGE_EVENT](#) assigns an event window number to each row, starting from 0, and increments by 1 when the result of evaluating the argument expression on the current row differs from that on the previous row. This function is similar to the analytic function [ROW_NUMBER](#), which assigns a unique number, sequentially, starting from 1, to each row within a partition.
- [CONDITIONAL_TRUE_EVENT](#) assigns an event window number to each row, starting from 0, and increments the number by 1 when the result of the boolean argument expression evaluates true.

Both functions are described in greater detail below.

Note: [CONDITIONAL_CHANGE_EVENT](#) and [CONDITIONAL_TRUE_EVENT](#) do not support [window framing](#).

Example schema

The examples on this page use the following schema:

```
CREATE TABLE TickStore3 (ts TIMESTAMP, symbol VARCHAR(8), bid FLOAT);
CREATE PROJECTION TickStore3_p (ts, symbol, bid) AS SELECT * FROM TickStore3 ORDER BY ts, symbol, bid
UNSEGMENTED ALL NODES;
INSERT INTO TickStore3 VALUES ('2009-01-01 03:00:00', 'XYZ', 10.0);
INSERT INTO TickStore3 VALUES ('2009-01-01 03:00:03', 'XYZ', 11.0);
INSERT INTO TickStore3 VALUES ('2009-01-01 03:00:06', 'XYZ', 10.5);
INSERT INTO TickStore3 VALUES ('2009-01-01 03:00:09', 'XYZ', 11.0);
COMMIT;
```

Using [CONDITIONAL_CHANGE_EVENT](#)

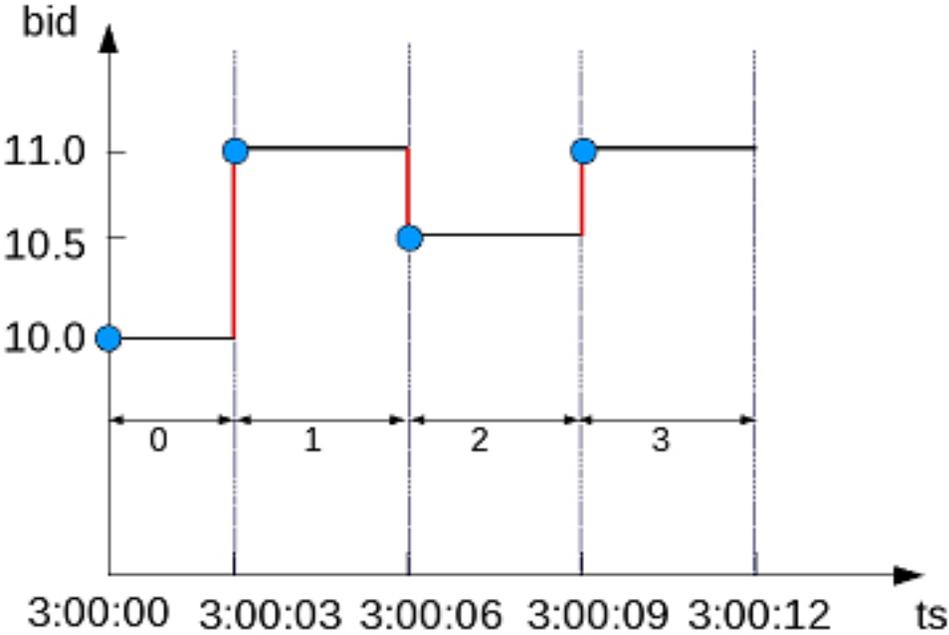

The analytical function [CONDITIONAL_CHANGE_EVENT](#) returns a sequence of integers indicating event window numbers, starting from 0. The function increments the event window number when the result of evaluating the function expression on the current row differs from the previous value.

In the following example, the first query returns all records from the TickStore3 table. The second query uses the [CONDITIONAL_CHANGE_EVENT](#) function on the bid column. Since each bid row value is different from the previous value, the function increments the window ID from 0 to 3:

<pre>SELECT ts, symbol, bid FROM Tickstore3 ORDER BY ts;</pre>	==>	<pre>SELECT CONDITIONAL_CHANGE_EVENT(bid) OVER(ORDER BY ts) FROM Tickstore3;</pre>														
<table style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: left; border-bottom: 1px dashed black;">ts</th> <th style="text-align: left; border-bottom: 1px dashed black;">symbol</th> <th style="text-align: left; border-bottom: 1px dashed black;">bid</th> </tr> </thead> <tbody> <tr> <td style="border-bottom: 1px dashed black;">2009-01-01 03:00:00</td> <td style="border-bottom: 1px dashed black;">XYZ</td> <td style="border-bottom: 1px dashed black;">10</td> </tr> </tbody> </table>	ts	symbol	bid	2009-01-01 03:00:00	XYZ	10		<table style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: left; border-bottom: 1px dashed black;">ts</th> <th style="text-align: left; border-bottom: 1px dashed black;">symbol</th> <th style="text-align: left; border-bottom: 1px dashed black;">bid</th> <th style="text-align: left; border-bottom: 1px dashed black;">cce</th> </tr> </thead> <tbody> <tr> <td style="border-bottom: 1px dashed black;">2009-01-01 03:00:00</td> <td style="border-bottom: 1px dashed black;">XYZ</td> <td style="border-bottom: 1px dashed black;">10</td> <td style="border-bottom: 1px dashed black;">0</td> </tr> </tbody> </table>	ts	symbol	bid	cce	2009-01-01 03:00:00	XYZ	10	0

2009-01-01 03:00:00	XYZ	10	0													

2009-01-01 03:00:03 XYZ 11	2009-01-01 03:00:03 XYZ 11 1
2009-01-01 03:00:06 XYZ 10.5	2009-01-01 03:00:06 XYZ 10.5 2
2009-01-01 03:00:09 XYZ 11	2009-01-01 03:00:09 XYZ 11 3
(4 rows)	(4 rows)

The following figure is a graphical illustration of the change in the bid price. Each value is different from its previous one, so the window ID increments for each time slice:

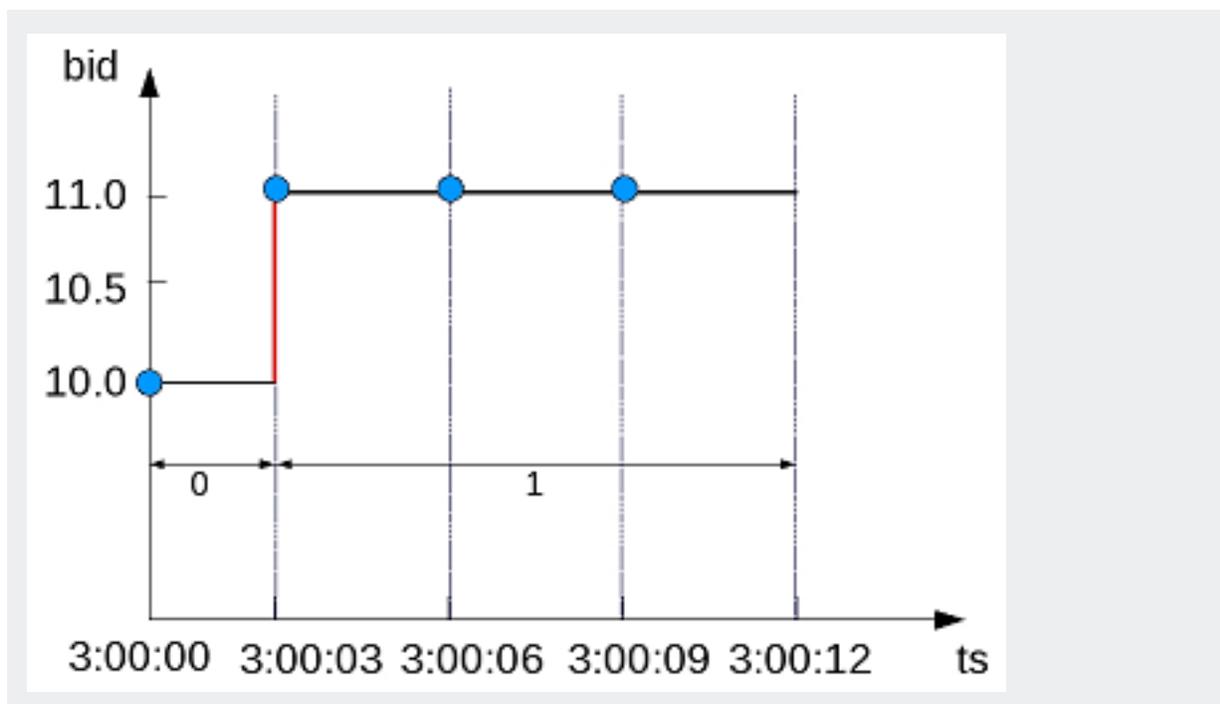

So the window ID starts at 0 and increments at every change in from the previous value.

In this example, the bid price changes from \$10 to \$11 in the second row, but then stays the same. `CONDITIONAL_CHANGE_EVENT` increments the event window ID in row 2, but not subsequently:

<code>SELECT ts, symbol, bid FROM Tickstore3 ORDER BY ts;</code>	<code>SELECT CONDITIONAL_CHANGE_EVENT(bid) OVER(ORDER BY ts) FROM Tickstore3;</code>																																			
<table border="1"> <thead> <tr> <th>ts</th> <th>symbol</th> <th>bid</th> </tr> </thead> <tbody> <tr><td>2009-01-01 03:00:00</td><td>XYZ</td><td>10</td></tr> <tr><td>2009-01-01 03:00:03</td><td>XYZ</td><td>11</td></tr> <tr><td>2009-01-01 03:00:06</td><td>XYZ</td><td>11</td></tr> <tr><td>2009-01-01 03:00:09</td><td>XYZ</td><td>11</td></tr> </tbody> </table>	ts	symbol	bid	2009-01-01 03:00:00	XYZ	10	2009-01-01 03:00:03	XYZ	11	2009-01-01 03:00:06	XYZ	11	2009-01-01 03:00:09	XYZ	11	<p>==></p> <table border="1"> <thead> <tr> <th>ts</th> <th>symbol</th> <th>bid</th> <th>cce</th> </tr> </thead> <tbody> <tr><td>2009-01-01 03:00:00</td><td>XYZ</td><td>10</td><td>0</td></tr> <tr><td>2009-01-01 03:00:03</td><td>XYZ</td><td>11</td><td>1</td></tr> <tr><td>2009-01-01 03:00:06</td><td>XYZ</td><td>11</td><td>1</td></tr> <tr><td>2009-01-01 03:00:09</td><td>XYZ</td><td>11</td><td>1</td></tr> </tbody> </table>	ts	symbol	bid	cce	2009-01-01 03:00:00	XYZ	10	0	2009-01-01 03:00:03	XYZ	11	1	2009-01-01 03:00:06	XYZ	11	1	2009-01-01 03:00:09	XYZ	11	1
ts	symbol	bid																																		
2009-01-01 03:00:00	XYZ	10																																		
2009-01-01 03:00:03	XYZ	11																																		
2009-01-01 03:00:06	XYZ	11																																		
2009-01-01 03:00:09	XYZ	11																																		
ts	symbol	bid	cce																																	
2009-01-01 03:00:00	XYZ	10	0																																	
2009-01-01 03:00:03	XYZ	11	1																																	
2009-01-01 03:00:06	XYZ	11	1																																	
2009-01-01 03:00:09	XYZ	11	1																																	

The following figure is a graphical illustration of the change in the bid price at 3:00:03 only. The price stays the same at 3:00:06 and 3:00:09, so the window ID remains at 1 for each time slice after the change:

Using CONDITIONAL_TRUE_EVENT

Like `CONDITIONAL_CHANGE_EVENT`, the analytic function `CONDITIONAL_TRUE_EVENT` also returns a sequence of integers indicating event window numbers, starting from 0. The two functions differ as follows:

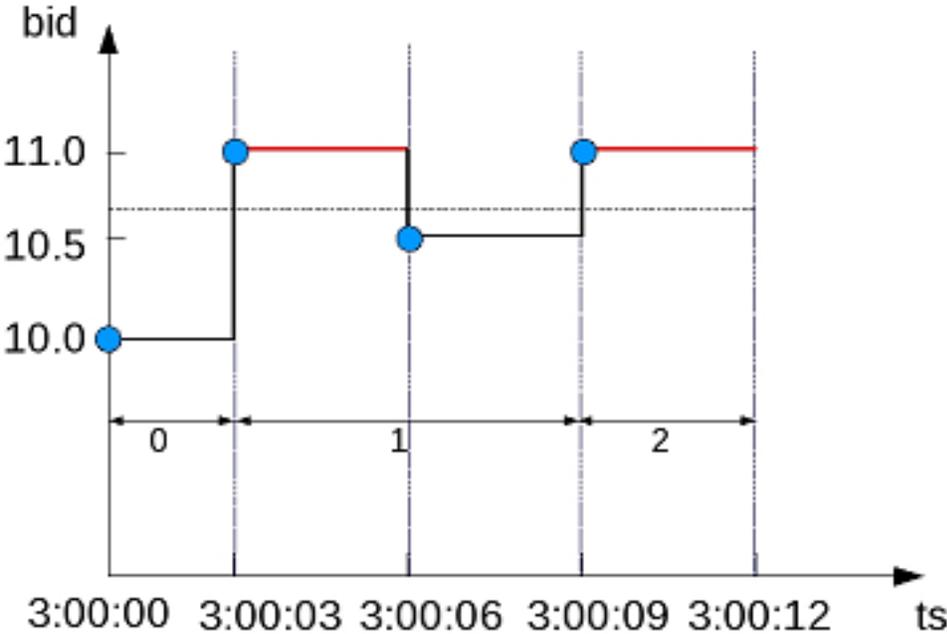

- `CONDITIONAL_TRUE_EVENT` increments the window ID each time its expression evaluates to true.
- `CONDITIONAL_CHANGE_EVENT` increments on a comparison expression with the previous value.

In the following example, the first query returns all records from the `TickStore3` table. The second query uses `CONDITIONAL_TRUE_EVENT` to test whether the current bid is greater than a given value (10.6). Each time the expression tests true, the function increments the window ID. The first time the function increments the window ID is on row 2, when the value is 11. The expression tests false for the next row (value is not greater than 10.6), so the function does not increment the event window ID. In the final row, the expression is true for the given condition, and the function increments the window:

<pre>SELECT ts, symbol, bid FROM Tickstore3 ORDER BY ts;</pre>		<pre>SELECT CONDITIONAL_TRUE_EVENT(bid > 10.6) OVER(ORDER BY ts) FROM Tickstore3;</pre>
ts symbol bid	==>	ts symbol bid cte-----

<pre>-- 2009-01-01 03:00:00 XYZ 10 2009-01-01 03:00:03 XYZ 11 2009-01-01 03:00:06 XYZ 10.5 2009-01-01 03:00:09 XYZ 11</pre>	<pre>2009-01-01 03:00:00 XYZ 10 0 2009-01-01 03:00:03 XYZ 11 1 2009-01-01 03:00:06 XYZ 10.5 1 2009-01-01 03:00:09 XYZ 11 2</pre>
---	--

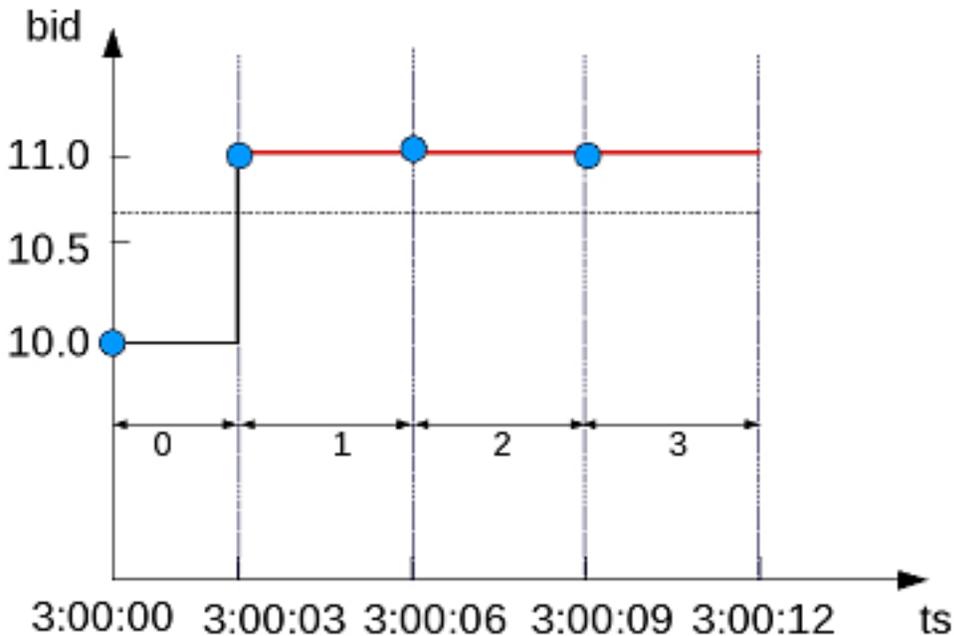

The following figure is a graphical illustration that shows the bid values and window ID changes. Because the bid value is greater than \$10.6 on only the second and fourth time slices (3:00:03 and 3:00:09), the window ID returns <0,1,1,2>:

In the following example, the first query returns all records from the TickStore3 table, ordered by the tickstore values (ts). The second query uses `CONDITIONAL_TRUE_EVENT` to increment the window ID each time the bid value is greater than 10.6. The first time the function increments the event window ID is on row 2, where the value is 11. The window ID then increments each time after that, because the expression `(bid > 10.6)` tests true for each time slice:

<pre>SELECT ts, symbol, bid FROM Tickstore3 ORDER BY ts;</pre>	<pre>SELECT CONDITIONAL_TRUE_EVENT(bid > 10.6) OVER(ORDER BY ts) FROM Tickstore3;</pre>
<pre>ts symbol bid -----+-----+----- 2009-01-01 03:00:00 XYZ 10 2009-01-01 03:00:03 XYZ 11 2009-01-01 03:00:06 XYZ 11 2009-01-01 03:00:09 XYZ 11</pre>	<pre>ts symbol bid cte -----+-----+-----+----- 2009-01-01 03:00:00 XYZ 10 0 2009-01-01 03:00:03 XYZ 11 1 2009-01-01 03:00:06 XYZ 11 2 2009-01-01 03:00:09 XYZ 11 3</pre>

The following figure is a graphical illustration that shows the bid values and window ID changes. The bid value is greater than 10.6 on the second time slice (3:00:03) and remains for the remaining two time slices. The function increments the event window ID each time because the expression tests true:

Advanced Use of Event-Based Windows

In event-based window functions, the condition expression accesses values from the current row only. To access a previous value, you can use a more powerful event-based window that allows the window event condition to include previous data points. For example, analytic function `LAG(x, n)` retrieves the value of column `x` in the `n`th to last input record. In this case, `LAG` shares the `OVER` specifications of the `CONDITIONAL_CHANGE_EVENT` or `CONDITIONAL_TRUE_EVENT` function expression.

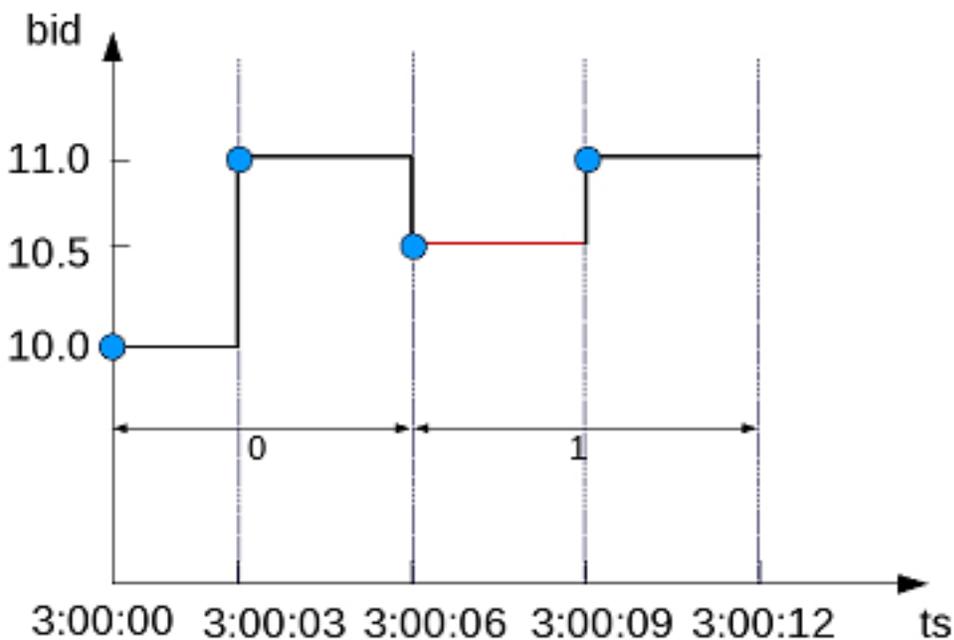

In the following example, the first query returns all records from the `TickStore3` table. The second query uses `CONDITIONAL_TRUE_EVENT` with the `LAG` function in its boolean expression. In this case, `CONDITIONAL_TRUE_EVENT` increments the event window ID each time the bid value on the current row is less than the previous value. The first time `CONDITIONAL_TRUE_EVENT` increments the window ID starts on the third time slice, when the expression tests true. The current value (10.5) is less than the previous value. The window ID is not incremented in the last row because the final value is greater than the previous row:

```
SELECT ts, symbol, bid FROM Tickstore3 ORDER BY ts;
```

```
SELECT CONDITIONAL_TRUE_EVENT(bid < LAG(bid))  
OVER(ORDER BY ts) FROM Tickstore3;
```

ts	symbol	bid	ts	symbol	bid	cte
2009-01-01 03:00:00	XYZ	10	2009-01-01 03:00:00	XYZ	10	0
2009-01-01 03:00:03	XYZ	11	2009-01-01 03:00:03	XYZ	11	0
2009-01-01 03:00:06	XYZ	10.5	2009-01-01 03:00:06	XYZ	10.5	1
2009-01-01 03:00:09	XYZ	11	2009-01-01 03:00:09	XYZ	11	1

The following figure illustrates the second query above. When the bid price is less than the previous value, the window ID gets incremented, which occurs only in the third time slice (3:00:06):

Sessionization with Event-Based Windows

Sessionization, a special case of event-based windows, is a feature often used to analyze click streams, such as identifying web browsing sessions from recorded web clicks.

In Vertica, given an input clickstream table, where each row records a Web page click made by a particular user (or IP address), the sessionization computation attempts to identify Web

browsing sessions from the recorded clicks by grouping the clicks from each user based on the time-intervals between the clicks. If two clicks from the same user are made too far apart in time, as defined by a time-out threshold, the clicks are treated as though they are from two different browsing sessions.

Example Schema

The examples in this topic use the following WebClicks schema to represent a simple clickstream table:

```
CREATE TABLE WebClicks(userId INT, timestamp TIMESTAMP);
INSERT INTO WebClicks VALUES (1, '2009-12-08 3:00:00 pm');
INSERT INTO WebClicks VALUES (1, '2009-12-08 3:00:25 pm');
INSERT INTO WebClicks VALUES (1, '2009-12-08 3:00:45 pm');
INSERT INTO WebClicks VALUES (1, '2009-12-08 3:01:45 pm');
INSERT INTO WebClicks VALUES (2, '2009-12-08 3:02:45 pm');
INSERT INTO WebClicks VALUES (2, '2009-12-08 3:02:55 pm');
INSERT INTO WebClicks VALUES (2, '2009-12-08 3:03:55 pm');
COMMIT;
```

The input table `WebClicks` contains the following rows:

```
=> SELECT * FROM WebClicks;
  userId |      timestamp
-----+-----
      1 | 2009-12-08 15:00:00
      1 | 2009-12-08 15:00:25
      1 | 2009-12-08 15:00:45
      1 | 2009-12-08 15:01:45
      2 | 2009-12-08 15:02:45
      2 | 2009-12-08 15:02:55
      2 | 2009-12-08 15:03:55
(7 rows)
```

In the following query, sessionization performs computation on the SELECT list columns, showing the difference between the current and previous timestamp value using `LAG()`. It evaluates to true and increments the window ID when the difference is greater than 30 seconds.

```
=> SELECT userId, timestamp,
  CONDITIONAL_TRUE_EVENT(timestamp - LAG(timestamp) > '30 seconds')
  OVER(PARTITION BY userId ORDER BY timestamp) AS session FROM WebClicks;
  userId |      timestamp | session
-----+-----+-----
      1 | 2009-12-08 15:00:00 |      0
      1 | 2009-12-08 15:00:25 |      0
      1 | 2009-12-08 15:00:45 |      0
      1 | 2009-12-08 15:01:45 |      1
      2 | 2009-12-08 15:02:45 |      0
      2 | 2009-12-08 15:02:55 |      0
      2 | 2009-12-08 15:03:55 |      1
(7 rows)
```

In the output, the session column contains the window ID from the `CONDITIONAL_TRUE_EVENT` function. The window ID evaluates to true on row 4 (timestamp 15:01:45), and the ID that follows row 4 is zero because it is the start of a new partition (for user ID 2), and that row does not evaluate to true until the last line in the output.

You might want to give users different time-out thresholds. For example, one user might have a slower network connection or be multi-tasking, while another user might have a faster connection and be focused on a single Web site, doing a single task.

To compute an adaptive time-out threshold based on the last 2 clicks, use `CONDITIONAL_TRUE_EVENT` with `LAG` to return the average time between the last 2 clicks with a grace period of 3 seconds:

```
=> SELECT userId, timestamp, CONDITIONAL_TRUE_EVENT(timestamp - LAG(timestamp) >
(LAG(timestamp, 1) - LAG(timestamp, 3)) / 2 + '3 seconds')
OVER(PARTITION BY userId ORDER BY timestamp) AS session
FROM WebClicks;
```

userId	timestamp	session
2	2009-12-08 15:02:45	0
2	2009-12-08 15:02:55	0
2	2009-12-08 15:03:55	0
1	2009-12-08 15:00:00	0
1	2009-12-08 15:00:25	0
1	2009-12-08 15:00:45	0
1	2009-12-08 15:01:45	1

(7 rows)

Note: You cannot define a moving window in time series data. For example, if the query is evaluating the first row and there's no data, it will be the current row. If you have a lag of 2, no results are returned until the third row.

Machine Learning for Predictive Analytics

Vertica provides a number of machine learning functions for performing in-database analysis. These functions can perform a number of data preparation and predictive tasks—for example:

- Balance an uneven distribution of classes — See [Balancing Imbalanced Data](#) for an example.
- Remove outliers from your data — See [Detecting Outliers](#) for an example.
- Impute missing values in a data set — See [Imputing Missing Values](#) for an example.
- Normalize data to organize different scales of numeric data to an equivalent scale — See [Normalizing Data](#) for an example.
- Create a sample of a larger data set — See [Sampling Data](#) for an example.
- Use regression algorithms to make predictions about features in your data set and an observed value response — See [Regression Algorithms](#) for more information.
- Use classification algorithms to assign items in a data set to different categories — See [Classification Algorithms](#) for more information.
- Use the clustering algorithm to partition data using k-means clustering — See [Clustering Algorithms](#) for more information.

For more information about specific machine learning functions see [Machine Learning Functions](#).

Downloading the Machine Learning Example Data

You need several data sets to run the machine learning examples. You can download these data sets from the Vertica Github repository. These examples introduce the machine learning functionality provide by Vertica.

You can download the example data in either of two ways:

- Download the ZIP file. Extract the contents of the file into a directory.
- Clone the Vertica Machine Learning Github repository. Using a terminal window, run the following command:

```
$ git clone https://github.com/vertica/Machine-Learning-Examples
```

Loading the Example Data

You can load the example data by either:

- Copying and pasting the DDL and DML operations in `load_ml_data.sql` in a vsql prompt or another Vertica client.
- Running the following command from a terminal window in the Machine-Learning-Examples directory:

```
$ /opt/vertica/bin/vsql -d <name of your database> -f load_ml_data.sql
```

Example Data Descriptions

The repository contains the following data sets.

Name	Description
agar_dish	Synthetic data set meant to represent clustering of bacteria on an agar dish. Contains the following columns: id, x-coordinate, and y-coordinate.
agar_dish_2	125 rows sampled randomly from the original 500 rows of the agar_dish data set.
agar_dish_1	375 rows sampled randomly from the original 500 rows of the agar_dish data set.
baseball	Contains statistics from a fictional baseball league. The statistics included are: first name, last name, date of birth, team name, homeruns, hits, batting average, and salary.
faithful	Wait times between eruptions and the duration of the eruption for the Old Faithful geyser in Yellowstone National Park, Wyoming, USA.

Name	Description
	<p>Reference</p> <p>Härdle, W. (1991) <i>Smoothing Techniques with Implementation in S</i>. New York: Springer.</p> <p>Azzalini, A. and Bowman, A. W. (1990). A look at some data on the Old Faithful geyser. <i>Applied Statistics</i> 39, 357–365.</p>
faithful_testing	Roughly 60% of the original 272 rows of the faithful data set.
faithful_training	Roughly 40% of the original 272 rows of the faithful data set.
house84	<p>The house84 data set includes votes for each of the U.S. House of Representatives Congress members on 16 votes. Contains the following columns: id, party, vote1, vote2, vote3, vote4, vote5, vote6, vote7, vote8, vote9, vote10, vote11, vote12, vote13, vote14, vote15, vote16.</p> <p>Reference</p> <p>Congressional Quarterly Almanac, 98th Congress, 2nd session 1984, Volume XL: Congressional Quarterly Inc. Washington, D.C., 1985.</p>
iris	<p>The iris data set gives the measurements in centimeters of the variables sepal length and width and petal length and width, respectively, for 50 flowers from each of 3 species of iris. The species are Iris setosa, versicolor, and virginica.</p> <p>Reference</p> <p>Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) <i>The New S Language</i>. Wadsworth & Brooks/Cole.</p>
iris1	90 rows sampled randomly from the original 150 rows in the iris data set.
iris2	60 rows sampled randomly from the original 150 rows in the iris data set.
mtcars	<p>The data was extracted from the 1974 Motor Trend US magazine, and comprises fuel consumption and 10 aspects of automobile design and performance for 32 automobiles (1973–74 models).</p> <p>Reference</p> <p>Henderson and Velleman (1981), Building multiple regression models interactively. <i>Biometrics</i>, 37, 391–411.</p>

Name	Description
salary_data	Contains fictional employee data. The data included are: employee id, first name, last name, years worked, and current salary.
transaction_data	Contains fictional credit card transactions with a BOOLEAN column indicating whether there was fraud associated with the transaction. The data included are: first name, last name, store, cost, and fraud.

Data Preparation

Before you can analyze your data, you must prepare it. You can do the following data preparation tasks in Vertica:

- [Balancing Imbalanced Data](#)
- [Detecting Outliers](#)
- [Imputing Missing Values](#)
- [Normalizing Data](#)
- [Sampling Data](#)

Balancing Imbalanced Data

Imbalanced data occurs when an uneven distribution of classes occurs in the data. You see imbalanced data a lot in financial transaction data where the majority of the transactions are not fraudulent and a small number of the transactions are fraudulent. Building a predictive model on the imbalanced data set would cause a model that appears to yield high accuracy but does not generalize well to the new data in the minority class. To prevent creating models with false levels of accuracy, you should rebalance your imbalanced data before creating a predictive model.

Before you begin the example, make sure that you have [loaded the Machine Learning sample data](#).

The following example shows you how to use the BALANCE function to create a more balanced data set.

1. View the distribution of the classes.

```
=> SELECT fraud, COUNT(fraud) FROM transaction_data GROUP BY fraud;
 fraud | COUNT
-----+-----
 TRUE  |    19
 FALSE |   981
(2 rows)
```

2. Use the BALANCE function to create a more balanced data set.

```
=> SELECT BALANCE('balance_fin_data', 'transaction_data', 'fraud', 'under_sampling'
                USING PARAMETERS sampling_ratio = 0.2);
      BALANCE
-----
Finished in 1 iteration

(1 row)
```

3. View the new distribution of the classifiers.

```
=> SELECT fraud, COUNT(fraud) FROM balance_fin_data GROUP BY fraud;
 fraud | COUNT
-----+-----
 t     |    19
 f     |   236
(2 rows)
```

See Also

- [BALANCE](#)

Detecting Outliers

Before you perform an in-depth analysis of your data, you should first remove the outliers from the data. Outliers are data points that greatly differ from other similar data points. If you leave outliers in your data, then you risk misclassifying data, introducing bias, or incorrect calculations.

For this example we will use the baseball data set found on the Vertica GitHub page.

1. Create a table.

```
=> CREATE TABLE baseball (id identity, first_name varchar(50), last_name varchar(50), dob DATE,
                          team varchar(20), hr int, hits int, avg float, salary float);
```

```
CREATE TABLE
```

2. Load the data.

```
=> COPY baseball FROM 'baseball.csv' DELIMITER ',';
Rows Loaded
-----
      1000
(1 row)
```

3. Detect the outliers based on the hr, hits, and salary columns. We will use the id and team columns as our key columns. The DETECT_OUTLIERS function will create a view containing the outliers with the input and key columns. Before you use the DETECT_OUTLIERS function, make sure that you are a superuser or have CREATE privileges for the schema and SELECT privileges for the table.

```
=> SELECT DETECT_OUTLIERS('baseball_hr_hits_salary_outliers', 'baseball', 'hr, hits, salary',
'robust_zscore'
                        USING PARAMETERS outlier_threshold=3.0, key_columns='id, team');
DETECT_OUTLIERS
-----
Detected 5 outliers
(1 row)
```

4. Query the output view containing the outliers.

```
=> SELECT * FROM baseball_hr_hits_salary_outliers;
id | team | hr | hits | salary
-----+-----+-----+-----+-----
 73 | Mauv | 8888 | 34 | 9.99999999341471e+16
 89 | Pink | 273333 | 4490260 | 4.44444444444828e+17
147 | Maroon | 1100037 | 230 | 9000101403
 87 | Green | 80 | 64253 | 16032567.12
222 | Goldenrod | 3200000 | 216 | 37008899.76
(5 rows)
```

5. Create a view omitting the outliers from the table.

```
=> CREATE VIEW clean_baseball AS
SELECT * FROM baseball WHERE id NOT IN (SELECT id FROM baseball_hr_hits_salary_outliers);
CREATE VIEW
```

6. Perform your analysis.

Imputing Missing Values

You can use the [IMPUTE](#) function to impute missing values in your data set. The function helps you impute missing values with plausible data values. This impute example uses the `small_input_impute` table. Using the function, you can specify either the mean or mode method.

These examples show how you can use the `IMPUTE` function on the `small_input_impute` table.

Create the Table

First, create the `small_input_impute` table:

```
=> CREATE TABLE small_input_impute(pid int, pclass int, gender int, x1 float, x2 float, x3 float, x4 INT, x5 char, x6 varchar);
```

Then insert the table values:

```
=> INSERT INTO small_input_impute VALUES( 1, 0, 0, -9.445818, -9.740541, -9.786974, 3, 't', 'A');
=> INSERT INTO small_input_impute VALUES( 2, 0, 0, -9.618292, -9.308881, -9.562255, 4, 't', 'A');
=> INSERT INTO small_input_impute VALUES( 3, 0, 0, -9.060605, -9.390844, -9.559848, 6, 't', 'B');
=> INSERT INTO small_input_impute VALUES( 4, 0, 0, -2.264599, -2.615146, -2.107290, 15, 't', 'B');
=> INSERT INTO small_input_impute VALUES( 5, 0, 1, -2.590837, -2.892819, -2.702960, 2, 't', 'C');
=> INSERT INTO small_input_impute VALUES( 6, 0, 1, -2.264599, -2.615146, -2.107290, 11, 't', 'C');
=> INSERT INTO small_input_impute VALUES( 7, 1, 1, 3.829239, 3.087650, 'INFINITY', NULL, 'f', 'C');
=> INSERT INTO small_input_impute VALUES( 8, 1, 1, 3.273592, NULL, 3.477332, 18, 'f', 'B');
=> INSERT INTO small_input_impute VALUES( 9, 1, 1, NULL, 3.841606, 3.754375, 20, 'f', 'B');
=> INSERT INTO small_input_impute VALUES( 10,1, 1, NULL, 3.841606, 3.754375, 20, 't', 'A');
=> INSERT INTO small_input_impute VALUES( 11, 0, 0, -9.445818, -9.740541, -9.786974, 3, 't', 'B');
=> INSERT INTO small_input_impute VALUES( 12, 0, 0, -9.618292, -9.308881, -9.562255, 4, 't', 'C');
=> INSERT INTO small_input_impute VALUES( 13, 0, 0, -9.060605, -9.390844, -9.559848, 6, 't', 'C');
=> INSERT INTO small_input_impute VALUES( 14, 0, 0, -2.264599, -2.615146, -2.107290, 15, 'f', 'A');
=> INSERT INTO small_input_impute VALUES( 15, 0, 1, -2.590837, -2.892819, -2.702960, 2, 'f', 'A');
=> INSERT INTO small_input_impute VALUES( 16, 0, 1, -2.264599, -2.615146, -2.107290, 11, 'f', 'A');

(20 rows)
```

Specify the Mean Method

Execute the IMPUTE function, specifying the mean method, without using the partition_ columns parameter:

```
=> SELECT IMPUTE('output_view','small_input_impute', 'pid, x1,x2,x3,x4','mean'
                USING PARAMETERS exclude_columns='pid');
impute
-----
Finished in 1 iteration
(1 row)
```

View output_view to see the imputed values:

```
=> SELECT * FROM output_view;
x1 | x2 | x3 | x4
-----+-----+-----+-----
-9.445818 | -9.740541 | -9.786974 | 3
```

```

-9.618292 | -9.308881 | -9.562255 | 4
-9.060605 | -9.390844 | -9.559848 | 6
-2.264599 | -2.615146 | -2.10729 | 15
-2.264599 | -2.615146 | -2.10729 | 11

-2.264599 | -2.615146 | -2.10729 | 11
(20 rows)

```

You can also execute the IMPUTE function, specifying the mean method and using the partition_columns parameter. This parameter uses the GROUP BY clause:

```

=> SELECT impute('output_view_group','small_input_impute', 'pid, x1,x2,x3,x4','mean'
USING PARAMETERS exclude_columns='pid', partition_columns='pclass,gender');
impute
-----
Finished in 1 iteration
(1 row)

```

View output_view_group to see the imputed values:

```

=> SELECT * FROM output_view_group;

pclass | gender | x1 | x2 | x3 | x4
-----+-----+-----+-----+-----+-----
0 | 0 | -9.445818 | -9.740541 | -9.786974 | 3
0 | 0 | -9.618292 | -9.308881 | -9.562255 | 4
0 | 0 | -9.060605 | -9.390844 | -9.559848 | 6
0 | 0 | -2.264599 | -2.615146 | -2.10729 | 15
0 | 1 | -2.264599 | -2.615146 | -2.10729 | 11
1 | 1 | 3.273592 | 3.590287333333333 | 3.477332 | 18
1 | 1 | 3.5514155 | 3.841606 | 3.754375 | 20
1 | 1 | 3.273592 | 3.590287333333333 | 3.477332 | 18

1 | 1 | 3.5514155 | 3.841606 | 3.754375 | 20
0 | 0 | -9.445818 | -9.740541 | -9.786974 | 3

```

```
0      |      0 | -9.618292 |      -9.308881 |      -9.562255 | 4
1      |      1 |  3.829239 |      3.08765  |  3.66202733333333 | 19
(20 rows)
```

Specify the Mode Method

Execute the IMPUTE function, specifying the mode method, without using the `partition_columns` parameter:

```
=> SELECT impute('output_view_mode','small_input_impute', 'pid, x5,x6','mode'
                USING PARAMETERS exclude_columns='pid');
impute
-----
Finished in 1 iteration
(1 row)
```

View `output_view_mode` to see the imputed values:

```
=> SELECT * FROM output_view_mode;

x5 | x6
---+---
t  | A
t  | A
t  | B
t  | B
t  | C
f  | B
t  | A
t  | B

Normalizing Data

The purpose of normalization is, primarily, to scale numeric data from different columns down to an equivalent scale. For example, suppose you execute the [LINEAR_REG](#) function on a data set with two feature columns, `current_salary` and `years_worked`. The output value you are trying to predict is a worker's future salary. The values in the `current_salary` column are likely to have a far wider range, and much larger values, than the values in the `years_worked` column. Therefore, the values in the `current_salary` column can overshadow the values in the `years_worked` column, thus skewing your model.

Vertica offers the following data preparation methods which use normalization. These methods are:

- **MinMax**
Using the MinMax normalization method, you can normalize the values in both of these columns to be within a distribution of values between 0 and 1. Doing so allows you to compare values on very different scales to one another by reducing the dominance of one column over the other.
- **Z-score**
Using the Z-score normalization method, you can normalize the values in both of these columns to be the number of standard deviations an observation is from the mean of each column. This allows you to compare your data to a normally distributed random variable.
- **Robust Z-score**
Using the Robust Z-score normalization method, you can lessen the influence of outliers on Z-score calculations. Robust Z-score normalization uses the median value as opposed to the mean value used in Z-score. By using the median instead of the mean, it helps remove some of the influence of outliers in the data.

Normalizing data results in the creation of a view where the normalized data is saved. The `output_view` option in the `NORMALIZE` function determines name of the view .

Normalizing Salary Data Using MinMax

The following example shows how you can normalize the `salary_data` table using the MinMax normalization method.

Before you begin the example, make sure that you have [loaded the Machine Learning sample data](#).

```
=> SELECT NORMALIZE('normalized_salary_data', 'salary_data', 'current_salary, years_worked',  
  'minmax');  
      NORMALIZE

Sampling Data

The goal of data sampling is to take a smaller, more manageable sample of a much larger data set. With a sample data set, you can produce predictive models or use it to help you tune your

database. The following example shows how you can use the TABLESAMPLE clause to create a sample of your data.

Sampling Data from a Table

Before you begin the example, make sure that you have [loaded the Machine Learning sample data](#).

Using the `baseball` table, create a new table named `baseball_sample` containing a 25% sample of `baseball`. Remember, TABLESAMPLE does not guarantee that the exact percentage of records defined in the clause are returned.

```
=> CREATE TABLE baseball_sample AS SELECT * FROM baseball TABLESAMPLE(25);
CREATE TABLE
=> SELECT * FROM baseball_sample;
id | first_name | last_name | dob      | team   | hr | hits | avg  | salary

Regression Algorithms

Regression is an important and popular machine learning tool that makes predictions from data by learning the relationship between some features of the data and an observed value response. Regression is used to make predictions about profits, sales, temperature, stocks, and more. For example, you could use regression to predict the price of a house based on the location, the square footage, the size of the lot, and so on. In this example, the house's value is the outcome, and the other factors, such as location, are the features.

The optimal set of coefficients found for the regression's equation is known as the model. The relationship between the outcome and the features is summarized in the model, which can then be applied to different data sets, where the outcome value is unknown. The data in regression projects is divided into two data sets - one that is used to build the model, and one that is used to test the model.

Vertica supports two algorithms for regression:

- [Linear Regression](#)
- [SVM \(Support Vector Machine\) for Regression](#)

Linear Regression

Using linear regression, you can model the linear relationship between independent variables, or features, and a dependent variable, or outcome. You can build linear regression models to:

- Fit a predictive model to a training data set of independent variables and some dependent variable. Doing so allows you to use feature variable values to make predictions on outcomes. For example, you can predict the amount of rain that will fall on a particular day of the year.
- Determine the strength of the relationship between an independent variable and some outcome variable. For example, suppose you want to determine the importance of various weather variables on the outcome of how much rain will fall. You can build a linear regression model based on observations of weather patterns and rainfall to find the answer.

Unlike [Logistic Regression](#), which you use to determine a binary classification outcome, linear regression is primarily used to predict continuous numerical outcomes in linear relationships.

You can use the following functions to build a linear regression model, view the model, and use the model to make predictions on a set of test data:

- [LINEAR_REG](#)
- [PREDICT_LINEAR_REG](#)
- [SUMMARIZE_MODEL](#)

For a complete programming example of how to use linear regression on a table in Vertica, see [Building a Linear Regression Model](#).

Building a Linear Regression Model

This linear regression example uses a small data set named `faithful`. The example shows how you can build a model to predict the value of `eruptions`, given the value of the `waiting` feature.

Before you begin the example, make sure that you have [loaded the Machine Learning sample data](#).

1. Create the linear regression model, named `linear_reg_faithful`, using the `faithful_training` training data:

```
=> SELECT LINEAR_REG('linear_reg_faithful', 'faithful_training', 'eruptions', 'waiting'
                    USING PARAMETERS optimizer='BFGS');
      LINEAR_REG
-----
Finished in 6 iterations

(1 row)
```

2. View the summary output of `linear_reg_faithful`:

```
=> SELECT SUMMARIZE_MODEL('linear_reg_faithful');
-[ RECORD 1 ]-----+-----
SUMMARIZE_MODEL | coeff names : {Intercept, waiting}
coefficients:   {-2.067947819, 0.07875927383}
std_err:        {0.21063, 0.0029203}
t_value:        {-9.8178, 26.969}
p_value:        {4.2157e-18, 2.1094e-61}
Number of iterations: 6, Number of skipped samples: 0, Number of processed samples: 162
```

```
Call: linearReg(model_name=linear_reg_faithful, input_table=faithful_training, response_
column=eruptions,
predictor_columns=waiting,
exclude_columns=, optimizer=bfgs, epsilon=0.0001, max_iterations=50)
```

3. Create a new table that contains the response values from running the PREDICT_LINEAR_REG function on your test data. Name this table pred_faithful_results:

```
=> CREATE TABLE pred_faithful_results AS
      (SELECT id, eruptions, PREDICT_LINEAR_REG(waiting USING PARAMETERS model_name='linear_
reg_faithful')
      AS pred FROM faithful_testing);
CREATE TABLE
```

4. View the results in the pred_faithful_results table:

```
=> SELECT * FROM pred_faithful_results ORDER BY id;
 id | eruptions |      pred
-----+-----+-----
  4 |    2.283 | 2.8151271587036
  5 |    4.533 | 4.62659045686076
  8 |     3.6 | 4.62659045686076
  9 |     1.95 | 1.94877514654148
 11 |     1.833 | 2.18505296804024
 12 |     3.917 | 4.54783118302784
 14 |     1.75 | 1.6337380512098
 20 |     4.25 | 4.15403481386324
 22 |     1.75 | 1.6337380512098
.
.
.
(110 rows)
```

Calculating the Mean Squared Error (MSE)

Another way that you can calculate how well your model fits the data is by using the MSE function. MSE returns the average of the squared differences between actual value and predicted values.

```
=> SELECT MSE (eruptions::float, pred::float) OVER() FROM
      (SELECT eruptions, pred FROM pred_faithful_results) AS prediction_output;
      mse |      Comments
-----+-----
 0.252925741352641 | Of 110 rows, 110 were used and 0 were ignored
(1 row)
```

SVM (Support Vector Machine) for Regression

Support Vector Machine (SVM) for regression predicts continuous ordered variables based on the training data. This supervised learning method has a number of applications, including:

- Predicting time series
- Pattern recognition
- Function estimation

Unlike [Logistic Regression](#), which you use to determine a binary classification outcome, SVM for regression is primarily used to predict continuous numerical outcomes.

You can use the following functions to build an SVM for regression model, view the model, and use the model to make predictions on a set of test data:

- [SVM_REGRESSOR](#)
- [PREDICT_SVM_REGRESSOR](#)
- [SUMMARIZE_MODEL](#)

For a complete example of how to use the SVM algorithm in Vertica, see [Building an SVM for Regression Model](#) .

Building an SVM for Regression Model

This SVM for regression example uses a small data set named `faithful`, based on the Old Faithful geyser in Yellowstone National Park. The data set contains values about the waiting

time between eruptions and the duration of eruptions of the geyser. The example shows how you can build a model to predict the value of eruptions, given the value of the waiting feature.

Before you begin the example, make sure that you have [loaded the Machine Learning sample data](#).

1. Create the SVM model, named `svm_faithful`, using the `faithful_training` training data:

```
=> SELECT SVM_REGRESSOR('svm_faithful', 'faithful_training', 'eruptions', 'waiting'
                        USING PARAMETERS error_tolerance=0.1, max_iterations=100);
SVM_REGRESSOR
-----
Finished in 5 iterations
Accepted Rows: 162   Rejected Rows: 0
(1 row)
```

2. View the summary output of `svm_faithful`:

```
=> SELECT SUMMARIZE_MODEL('svm_faithful');
-----
=====
Predictors and Coefficients
=====
      |Coefficients
-----+-----
Intercept|  -1.59007
waiting  |   0.07217
=====
Notes
=====
Call string:
SELECT svm_regressor('svm_faithful', 'faithful_training', "eruptions", 'waiting'
USING PARAMETERS error_tolerance = 0.1, C=1, max_iterations=100, epsilon=0.001);
Number of rows accepted: 162
Number of rows rejected: 0
Training finished in 5 iterations.
(1 row)
```

3. Create a new table that contains the response values from running the `PREDICT_SVM_REGRESSOR` function on your test data. Name this table `pred_faithful_results`:

```
=> CREATE TABLE pred_faithful AS
      (SELECT id, eruptions, PREDICT_SVM_REGRESSOR(waiting USING PARAMETERS model_name='svm_
faithful')
      AS pred FROM faithful_testing);
CREATE TABLE
```

4. View the results in the `pred_faithful_results` table:

```
=> SELECT * FROM pred_faithful ORDER BY id;
id | eruptions |      pred
-----+-----+-----
 4 |    2.283 | 2.88444568755189
 5 |    4.533 | 4.54434581879796

Classification Algorithms

Classification is an important and popular machine learning tool that assigns items in a data set to different categories. Classification is used to predict risk over time, in fraud detection, text categorization, and more. Classification functions begin with a data set where the different

categories are known. For example, suppose you want to classify students based on how likely they are to get into graduate school. In addition to factors like admission score exams and grades, you could also track work experience.

Binary classification means the outcome, in this case, admission, only has two possible values: admit or do not admit. Multiclass outcomes have more than two values. For example, low, medium, or high chance of admission. During the training process, classification algorithms find the relationship between the outcome and the features. This relationship is summarized in the model, which can then be applied to different data sets, where the categories are unknown. The data in classification projects is divided into two data sets - one that is used to build the model, and one that is used to test the model.

Vertica supports four algorithms for classification:

- [Logistic Regression](#)
- [Naive Bayes](#)
- [Random Forest](#)
- [SVM \(Support Vector Machine\) for Classification](#)

Logistic Regression

Using logistic regression, you can model the relationship between independent variables, or features, and some dependent variable, or outcome. The outcome of logistic regression is always a binary value.

You can build logistic regression models to:

- Fit a predictive model to a training data set of independent variables and some binary dependent variable. Doing so allows you to make predictions on outcomes, such as whether a piece of email is spam mail or not.
- Determine the strength of the relationship between an independent variable and some binary outcome variable. For example, suppose you want to determine whether an email is spam or not. You can build a logistic regression model, based on observations of the properties of email messages. Then, you can determine the importance of various properties of an email message on that outcome.

You can use the following functions to build a logistic regression model, view the model, and use the model to make predictions on a set of test data:

- [LOGISTIC_REG](#)
- [PREDICT_LOGISTIC_REG](#)
- [SUMMARIZE_MODEL](#)

For a complete programming example of how to use logistic regression on a table in Vertica, see [Building a Logistic Regression Model](#).

Building a Logistic Regression Model

This logistic regression example uses a small data set named `mtcars`. The example shows you how to build a model to predict the value of `am` (whether the car has an automatic or a manual transmission). It uses the given values of all the other features in the data set.

In this example, roughly 60% of the data is used as training data to create a model. The remaining 40% of the data is used as testing data against which you can test your logistic regression model.

Before you begin the example, make sure that you have [loaded the Machine Learning sample data](#).

1. Create the logistic regression model, named `logistic_reg_mtcars`, using the `mtcars_train` training data.

```
=> SELECT LOGISTIC_REG('logistic_reg_mtcars', 'mtcars_train', 'am', 'cyl, hp, wt'
                        USING PARAMETERS exclude_columns='hp');
LOGISTIC_REG
-----
Finished in 15 iterations

(1 row)
```

2. View the summary output of `logistic_reg_mtcars`.

```
=> SELECT SUMMARIZE_MODEL('logistic_reg_mtcars');
-[ RECORD 1 ]-----+-----
coeff names : {Intercept, cyl, wt}
coefficients: {174.4571914, 5.878990016, -70.06270163}
std_err:     {1236.6, 46.252, 500.04}
z_value:     {0.14108, 0.12711, -0.14011}
p_value:     {0.88781, 0.89886, 0.88857}
Number of iterations: 15, Number of skipped samples: 0, Number of processed samples: 20
Call: logisticReg(model_name=logistic_reg_mtcars, input_table=mtcars_train, response_column=am,
predictor_columns=cyl, hp, wt,
```

```
exclude_columns='hp', optimizer=bfgs, epsilon=0.0001, max_iterations=100)
```

3. Create a new table, named `mtcars_predict_results`. Populate this table with the prediction outputs you obtain from running the `PREDICT_LOGISTIC_REG` function on your test data.

```
=> CREATE TABLE mtcars_predict_results AS
      (SELECT car_model, am, PREDICT_LOGISTIC_REG(cyl, hp, wt
                                                USING PARAMETERS model_name='logistic_reg_mtcars')
      AS Prediction FROM mtcars_test);

CREATE TABLE
```

4. View the results in the `mtcars_predict_results` table.

```
=> SELECT * FROM mtcars_predict_results;
  car_model | am | Prediction
-----+---+-----
AMC Javelin | 0 |          0
Hornet 4 Drive | 0 |          0
Maserati Bora | 1 |          0
Merc 280 | 0 |          0
Merc 450SL | 0 |          0
Toyota Corona | 0 |          1
Volvo 142E | 1 |          1
Camaro Z28 | 0 |          0
Datsun 710 | 1 |          1
Honda Civic | 1 |          1
Porsche 914-2 | 1 |          1
Valiant | 0 |          0
(12 rows)
```

5. Evaluate the accuracy of the `PREDICT_LOGISTIC_REG` function, using the [CONFUSION_MATRIX](#) evaluation function.

```
=> SELECT CONFUSION_MATRIX(obs::int, pred::int USING PARAMETERS num_classes=2) OVER()
      FROM (SELECT am AS obs, Prediction AS pred FROM mtcars_predict_results) AS prediction_
output;
  class | 0 | 1 |
-----+---+---+-----
      0 | 6 | 1 |
      1 | 1 | 4 | Of 12 rows, 12 were used and 0 were ignored
(2 rows)
```

In this case, `PREDICT_LOGISTIC_REG` correctly predicted that all five of the cars with a value of 1 in the `am` column have a value of 1. Out of the seven cars which had a value of 0 in the `am` column, six were correctly predicted to have the value 0. One car was incorrectly classified as having the value 1.

Naive Bayes

You can use the Naive Bayes algorithm to classify your data when features can be assumed independent. The algorithm uses independent features to calculate the probability of a specific class. For example, you might want to predict the probability that an email is spam. In that case, you would use a corpus of words associated with spam to calculate the probability the email's content is spam.

This supervised machine learning algorithm has a number of applications, including:

- Spam filtering
- Classifying documents
- Image classification

You can use the following functions to build a Naive Bayes model, view the model, and use the model to make predictions on a set of test data:

- [NAIVE_BAYES](#)
- [PREDICT_NAIVE_BAYES](#)
- [PREDICT_NAIVE_BAYES_CLASSES](#)
- [SUMMARIZE_MODEL](#)

For a complete example of how to use the Naive Bayes algorithm in Vertica, see [Classifying Data Using Naive Bayes](#).

Classifying Data Using Naive Bayes

This Naive Bayes example uses the HouseVotes84 data set to show you how to build a model. With this model, you can predict which party the member of the United States Congress is affiliated based on their voting record. To aid in classifying the data it has been cleaned, and any missed votes have been replaced. The cleaned data replaces missed votes with the voter's party majority vote. For example, suppose a member of the Democrats had a missing value for vote1 and majority of the Democrats voted in favor. This example replaces all missing Democrats' votes for vote1 with a vote in favor.

In this example, approximately 75% of the cleaned HouseVotes84 data is randomly selected and copied to a training table. The remaining cleaned HouseVotes84 data is used as a testing table.

Before you begin the example, make sure that you have [loaded the Machine Learning sample data](#).

1. Create the Naive Bayes model, named `naive_house84_model`, using the `house84_train` training data.

```
=> SELECT NAIVE_BAYES('naive_house84_model', 'house84_train', 'party',
                    '*' USING PARAMETERS exclude_columns='party, id');
                    NAIVE_BAYES
-----
Finished. Accepted Rows: 315 Rejected Rows: 0
(1 row)
```

2. View the summary output of `naive_house84_model`.

```
=> SELECT SUMMARIZE_MODEL('naive_house84_model');
                    SUMMARIZE_MODEL

Random Forest

The Random Forest algorithm creates an ensemble model of decision trees. Each tree is trained on a randomly selected subset of the training data. This supervised learning method has a number of applications, including:

- Predicting genetic outcomes
- Financial analysis
- Medical diagnosis

You can use the following functions to train the Random Forest model, and use the model to make predictions on a set of test data:

- [RF_CLASSIFIER](#)
- [PREDICT_RF_CLASSIFIER](#)
- [PREDICT_RF_CLASSIFIER_CLASSES](#)
- [SUMMARIZE_MODEL](#)

For a complete example of how to use the Random Forest algorithm in Vertica, see [Classifying Data Using Random Forest](#).

Classifying Data Using Random Forest

This random forest example uses a data set named iris. The example contains four variables that measure various parts of the iris flower to predict its species.

Before you begin the example, make sure that you have followed the steps in [Downloading the Machine Learning Example Data](#).

1. Create the random forest model, named `rf_iris`, using the `iris` data.

```
=> SELECT RF_CLASSIFIER ('rf_iris', 'iris', 'Species', 'Sepal_Length, Sepal_Width, Petal_Length,
Petal_Width'
USING PARAMETERS ntree=100, sampling_size=0.5);

      RF_CLASSIFIER
-----
The random forest is trained

(1 row)
```

2. View the summary output of `rf_iris`.

```
=> SELECT SUMMARIZE_MODEL('rf_iris');
Number of trees: 100
Number of skipped samples: 0, Number of processed samples: 150
Call string:
SELECT rf_classifier('rf_iris', 'iris', '"species"', 'Sepal_Length, Sepal_Width, Petal_Length,
Petal_Width'
USING PARAMETERS exclude_columns='', ntree=100, mtry='2', sampling_size=0.5, max_depth=5, max_
breadth=32, min_leaf_size=1, min_info_gain=0, nbins=32);
Predictor names and types:
sepal_length: float, sepal_width: float, petal_length: float, petal_width: float
(1 row)
```

3. Apply the classifier to the test data:

```
=> SELECT PREDICT_RF_CLASSIFIER (Sepal_Length, Sepal_Width, Petal_Length, Petal_Width
                                USING PARAMETERS model_name='rf_iris') FROM iris1;

PREDICT_RF_CLASSIFIER
-----

setosa
.
.
.
versicolor
versicolor
versicolor
.
.
.
virginica
virginica
virginica
.
.
.
(90 rows)
```

4. Use `PREDICT_RF_CLASSES` to view the probability of the classes:

```
=> SELECT PREDICT_RF_CLASSIFIER_CLASSES(Sepal_Length, Sepal_Width, Petal_Length, Petal_Width
      USING PARAMETERS model_name='rf_iris') OVER () FROM iris1;
predicted | probability
-----+-----
setosa    |             1
setosa    |             0.99
.
.
.
(90 rows)
```

SVM (Support Vector Machine) for Classification

Support Vector Machine (SVM) is a classification algorithm that assigns data to one category or the other based on the training data. This algorithm implements linear SVM, which is highly scalable. This supervised learning method has a number of applications, including:

- Image classification
- Text categorization
- Handwritten digit identification

You can use the following functions to train the SVM model, and use the model to make predictions on a set of test data:

- [SVM_CLASSIFIER](#)
- [PREDICT_SVM_CLASSIFIER](#)
- [SUMMARIZE_MODEL](#)

You can also use the following evaluation functions to gain further insights:

- [CONFUSION_MATRIX](#)
- [DETECT_OUTLIERS](#)
- [ERROR_RATE](#)
- [ROC](#)

For a complete example of how to use the SVM algorithm in Vertica, see [Classifying Data Using SVM \(Support Vector Machine\)](#).

The implementation of the SVM algorithm in Vertica is based on the paper [Distributed Newton Methods for Regularized Logistic Regression](#).

Classifying Data Using SVM (Support Vector Machine)

This SVM example uses a small data set named `mtcars`. The example shows how you can use the `SVM_CLASSIFIER` function to train the model to predict the value of `am` (the transmission type, where 0 = automatic and 1 = manual) using the `PREDICT_SVM_CLASSIFIER` function.

Before you begin the example, make sure that you have [Downloading the Machine Learning Example Data](#).

1. Create the SVM model, named `svm_class`, using the `mtcars_train` training data.

```
=> SELECT SVM_CLASSIFIER('svm_class', 'mtcars_train', 'am', 'cyl, mpg, wt, hp, gear'
                          USING PARAMETERS exclude_columns='gear');

SVM_CLASSIFIER
-----
Finished in 12 iterations.
Accepted Rows: 20 Rejected Rows: 0
(1 row)
```

2. View the summary output of `svm_class`.

```
=> SELECT SUMMARIZE_MODEL('svm_class');
-----
=====
Predictors and Coefficients
=====
      |Coefficients
-----+-----
Intercept| -0.02006
cyl      |  0.15367
mpg      |  0.15698
wt       | -1.78157
hp       |  0.00957
=====
Notes
=====
Call string:
SELECT svm_classifier('svm_class', 'mtcars_train', '"am"', 'cyl, mpg, wt, hp, gear'
USING PARAMETERS exclude columns = 'gear', C=1, max_iterations=100, epsilon=0.001);
Number of rows accepted: 20
Number of rows rejected: 0
Training finished in 12 iterations.
(1 row)
```

3. Create a new table, named `svm_mtcars_predict`. Populate this table with the prediction outputs you obtain from running the `PREDICT_SVM_CLASSIFIER` function on your test data.

```
=> CREATE TABLE svm_mtcars_predict AS
      (SELECT car_model, am, PREDICT_SVM_CLASSIFIER(cyl, mpg, wt, hp
                                                    USING PARAMETERS model_name='svm_class')
      AS Prediction FROM mtcars_test);

CREATE TABLE
```

4. View the results in the `svm_mtcars_predict` table.

```
=> SELECT * FROM svm_mtcars_predict;
car_model      | am | Prediction
-----+-----
Toyota Corona |  0 |          1
Camaro Z28     |  0 |          0
Datsun 710     |  1 |          1
Valiant        |  0 |          0
Volvo 142E     |  1 |          1
AMC Javelin    |  0 |          0
Honda Civic    |  1 |          1
Hornet 4 Drive|  0 |          0
Maserati Bora  |  1 |          1
Merc 280       |  0 |          0
Merc 450SL     |  0 |          0
Porsche 914-2 |  1 |          1
(12 rows)
```

5. Evaluate the accuracy of the `PREDICT_SVM_CLASSIFIER` function, using the `CONFUSION_MATRIX` evaluation function.

```
=> SELECT CONFUSION_MATRIX(obs::int, pred::int USING PARAMETERS num_classes=2) OVER()  
      FROM (SELECT am AS obs, Prediction AS pred FROM svm_mtcars_predict1) AS prediction_  
output;  
  class | 0 | 1 |  
-----+-----+-----  
      0 | 6 | 1 |  
      1 | 0 | 5 | Of 12 rows, 12 were used and 0 were ignored  
(2 rows)
```

In this case, `PREDICT_SVM_CLASSIFIER` correctly predicted that the cars with a value of 1 in the `am` column have a value of 1. No cars were incorrectly classified. Out of the seven cars which had a value of 0 in the `am` column, six were correctly predicted to have the value 0. One car was incorrectly classified as having the value 1.

Clustering Algorithms

Clustering is an important and popular machine learning tool used to find clusters of items in a data set that are similar to one another. The goal of clustering is to create clusters with a high number of objects that are similar. Similar to classification, clustering segments the data. However, in clustering, the categorical groups are not defined. Clustering can be used to find anomalies in data and find natural groups of data. For example, you can use clustering to analyze a region and determine which areas of that region are most likely to be hit by an earthquake.

In Vertica, clustering is computed based on distance. Through this computation, data points are assigned to the cluster with the nearest mean.

Vertica supports one algorithm for clustering:

- [k-means](#)

k-means

You can use the clustering algorithm, *k-means clustering*, to cluster data points into k different groups based on similarities between the data points. This unsupervised machine learning algorithm has a wide number of applications, including:

- Search engines
- Finding groups of similar customers based on characteristics
- Spam detection
- Cybersecurity

The purpose of k-means is to partition n observations into k clusters. Through this partitioning, k-means assigns each observation to the cluster with the nearest mean. That nearest mean is also known as the *cluster center*.

For a complete programming example of how to use k-means on a table in Vertica, see [Clustering Data Using k-means](#).

Clustering Data Using k-means

This k-means example uses two small data sets named `agar_dish_1` and `agar_dish_2`. Using the numeric data in the `agar_dish_1` data set, you can cluster the data into k clusters. Then, using the created k-means model, you can run `APPLY_KMEANS` on `agar_dish_2` and assign them to the clusters created in your original model.

Before you begin the example, make sure that you have [loaded the Machine Learning sample data](#).

Clustering Training Data into k Clusters

1. Using the `KMEANS` function, run k-means on the `agar_dish_1` table.

```
=> SELECT KMEANS('agar_dish_kmeans', 'agar_dish_1', '*', 5
                USING PARAMETERS exclude_columns='id', max_iterations=20, output_view=agar_1_
view,
                key_columns='id');
                KMEANS
```

```
-----  
Finished in 7 iterations  
  
(1 row)
```

The example creates a model named `agar_dish_kmeans` and a view containing the results of the model named `agar_1_view`. You might get different results when you run the clustering algorithm. This is because KMEANS randomly picks initial centers by default.

2. View the output of `agar_1_view`.

```
=> SELECT * FROM agar_1_view;  
id | cluster_id  
-----+-----  
2 | 4  
5 | 4  
7 | 4  
9 | 4  
13 | 4  
.  
.  
.  
(375 rows)
```

3. Because you specified the number of clusters as 5, verify that the function created five clusters. Count the number of data points within each cluster.

```
=> SELECT cluster_id, COUNT(cluster_id) as Total_count  
FROM agar_1_view  
GROUP BY cluster_id;  
cluster_id | Total_count  
-----+-----  
0 | 76  
2 | 80  
1 | 74  
3 | 73  
4 | 72  
(5 rows)
```

From the output, you can see that five clusters were created: 0, 1, 2, 3, and 4.

You have now successfully clustered the data from `agar_dish_1.csv` into five distinct clusters.

Summarizing Your Model

You can also view a summary of the model you created using the [SUMMARIZE_MODEL](#) function. This summary tells you how many cluster centers your model contains, along with other metrics.

```
=> SELECT SUMMARIZE_MODEL('agar_dish_kmeans');
-[ RECORD 1 ]-----+-----
SUMMARIZE_MODEL | k-Means Model Summary:

Number of clusters: 5
Input columns: x, y
Cluster centers:
  0: {x: -7.4811859, y: -7.5257672}
  1: {x: -3.5061558, y: -3.5570295}
  2: {x: -5.5205715, y: -5.4919726}
  3: {x: -1.5623823, y: -1.5056116}
  4: {x:  0.4970753, y:  0.5111612}
Evaluation metrics:
  Total Sum of Squares: 6008.4619
  Within-Cluster Sum of Squares:
    Cluster 0: 12.389038
    Cluster 1: 11.210146
    Cluster 2: 12.994356
    Cluster 3: 12.639238
    Cluster 4: 12.083548
  Total Within-Cluster Sum of Squares: 61.316326
  Between-Cluster Sum of Squares: 5947.1456
  Between-Cluster SS / Total SS: 98.98%
Number of iterations performed: 6
Converged: True
Call:
kmeans(model_name=agar_dish_kmeans, input_table=agar_dish_training, input_columns=*, num_clusters=5,
exclude_columns=id, max_iterations=20, epsilon=0.0001, init_method=random, initial_centers_table=,
distance_method=euclidean, outputView=agar_training_view, key_columns=id
)
```

Clustering Data Using a k-means Model

Using `agar_dish_kmeans`, the k-means model you just created, you can classify the `agar_dish_2` data set.

Create a table named `kmeans_results`, using the `agar_dish_2` table as your input table and the `agar_dish_kmeans` model for your initial cluster centers.

Add only the relevant feature columns to the arguments in the `APPLY_KMEANS` function.

```
=> CREATE TABLE kmeans_results AS
      (SELECT id,
           APPLY_KMEANS(x, y
                       USING PARAMETERS
                           model_name='agar_dish_kmeans') AS cluster_id
      FROM agar_dish_2);
```

The `kmeans_results` table shows that the `agar_dish_kmeans` model correctly clustered the `agar_dish_2` data.

Model Management

The following topics explain how to manage your models:

- [Altering Models](#)
- [Drop Models](#)
- [Managing Model Security](#)
- [Summarizing Models](#)
- [Viewing Models](#)

As of 8.0.x, Vertica supports upgrading models.

Altering Models

After you create a model, you can alter it in three ways: renaming the model, changing the owner, and changing the schema.

The following example shows how you can use `ALTER_MODEL` to rename a model:

1. Find the model you want to alter.

```
=> SELECT * FROM V_CATALOG.MODELS WHERE model_name='mymodel';  
-[ RECORD 1 ]-----  
model_id      | 45035996273816618  
model_name    | mymodel  
schema_id    | 45035996273704978  
schema_name   | public  
owner_id     | 45035996273704962  
owner_name    | dbadmin
```

```
category      | VERTICA_MODELS  
model_type    | kmeans  
is_complete   | t  
create_time   | 2017-03-02 11:16:04.990626-05  
size          | 964
```

2. Rename the model.

```
=> ALTER MODEL mymodel RENAME TO mykmeansmodel;  
ALTER MODEL
```

3. Review V_CATALOG.MODELS to verify that the model name was changed.

```
=> SELECT * FROM V_CATALOG.MODELS WHERE model_name='mykmeansmodel';  
-[ RECORD 1 ]-----  
model_id      | 45035996273816618  
model_name    | mykmeansmodel  
schema_id     | 45035996273704978  
schema_name   | public  
owner_id      | 45035996273704962  
owner_name    | dbadmin  
category      | VERTICA_MODELS  
model_type    | kmeans  
is_complete   | t  
create_time   | 2017-03-02 11:16:04.990626-05  
size          | 964
```

The following example shows how you can use ALTER_MODEL to change the model owner:

1. Find the model you want to alter.

```
=> SELECT * FROM V_CATALOG.MODELS WHERE model_name='mykmeansmodel';  
-[ RECORD 1 ]-----  
model_id      | 45035996273816618  
model_name    | mykmeansmodel  
schema_id     | 45035996273704978  
schema_name   | public  
owner_id      | 45035996273704962  
owner_name    | dbadmin  
category      | VERTICA_MODELS  
model_type    | kmeans  
is_complete   | t  
create_time   | 2017-03-02 11:16:04.990626-05  
size          | 964
```

2. Change the model owner.

```
=> ALTER MODEL mykmeansmodel OWNER TO user1;  
ALTER MODEL
```

3. Review V_CATALOG.MODELS to verify that the owner was changed.

```
=> SELECT * FROM V_CATALOG.MODELS WHERE model_name='mykmeansmodel';  
-[ RECORD 1 ]-----  
model_id      | 45035996273816618  
model_name    | mykmeansmodel  
schema_id     | 45035996273704978  
schema_name   | public  
owner_id      | 45035996273704962  
owner_name    | user1  
category      | VERTICA_MODELS  
model_type    | kmeans  
is_complete   | t  
create_time   | 2017-03-02 11:16:04.990626-05  
size          | 964
```

The following example shows how you can use ALTER_MODEL to change the model schema:

1. Find the model you want to alter.

```
=> SELECT * FROM V_CATALOG.MODELS WHERE model_name='mykmeansmodel';  
-[ RECORD 1 ]-----  
model_id      | 45035996273816618  
model_name    | mykmeansmodel  
schema_id     | 45035996273704978  
schema_name   | public  
owner_id      | 45035996273704962  
owner_name    | dbadmin  
category      | VERTICA_MODELS  
model_type    | kmeans  
is_complete   | t  
create_time   | 2017-03-02 11:16:04.990626-05  
size          | 964
```

2. Change the model schema.

```
=> ALTER MODEL mykmeansmodel SET SCHEMA test;  
ALTER MODEL
```

3. Review V_CATALOG.MODELS to verify that the owner was changed.

```
=> SELECT * FROM V_CATALOG.MODELS WHERE model_name='mykmeansmodel';  
-[ RECORD 1 ]-----  
model_id      | 45035996273816618  
model_name    | mykmeansmodel  
schema_id     | 45035996273704978  
schema_name   | test  
owner_id      | 45035996273704962  
owner_name    | dbadmin  
category      | VERTICA_MODELS  
model_type    | kmeans  
is_complete   | t  
create_time   | 2017-03-02 11:16:04.990626-05  
size          | 964
```

Any user who creates a model can drop or alter his or her own model. If you are the dbadmin user, you can drop or alter any model in the database.

See Also

- [ALTER MODEL](#)

Drop Models

If you want to remove a model from the database, then you can drop it. To drop a model you must either be the model owner or the dbadmin.

1. Find the model you want to drop.

```
=> SELECT * FROM V_CATALOG.MODELS WHERE model_name='mySvmClassModel';  
-[ RECORD 1 ]-----  
model_id      | 45035996273765414  
model_name    | mySvmClassModel  
schema_id     | 45035996273704978  
schema_name   | public  
owner_id      | 45035996273704962  
owner_name    | dbadmin  
category      | VERTICA_MODELS  
model_type    | SVM_CLASSIFIER  
is_complete   | t  
create_time   | 2017-02-14 10:30:44.903946-05  
size          | 525
```

2. Drop the model.

```
=> DROP MODEL mySvmClassModel;  
DROP MODEL
```

3. Review V_CATALOG.MODELS to verify that the model was dropped.

```
=> SELECT * FROM V_CATALOG.MODELS WHERE model_name='mySvmClassModel';  
(0 rows)
```

Any user who creates a model can drop or alter his or her own model. If you are the dbadmin user, you can drop or alter any model in the database.

See Also

- [DROP MODEL](#)

Managing Model Security

You can manage the security privileges on your models by using the GRANT and REVOKE statements. The following examples show how you can change privileges on user1 and user2 using the faithful table using the linearReg model.

- In the following example, the dbadmin grants the SELECT privilege to user1:

```
=> GRANT SELECT ON TABLE faithful TO user1;  
GRANT PRIVILEGE
```

- Then, the dbadmin grants the CREATE privilege on the public schema to user1:

```
=> GRANT CREATE ON SCHEMA public TO user1;  
GRANT PRIVILEGE
```

- Connect to the database as user1:

```
=> \c - user1
```

- As user1, build the linearReg model:

```
=> SELECT LINEAR_REG('linearReg', 'faithful', 'waiting', 'eruptions');  
LINEAR_REG  
-----  
Finished in 1 iterations  
(1 row)
```

- As user1, grant USAGE privileges to user2:

```
=> GRANT USAGE ON MODEL linearReg TO user2;  
GRANT PRIVILEGE
```

- Connect to the database as user2:

```
=> \c - user2
```

- To confirm privileges were granted to user2, run the SUMMARIZE_MODEL function. A user with the USAGE privilege on a model can run SUMMARIZE_MODEL on that model:

```
=> SELECT SUMMARIZE_MODEL('linearReg');

summarize_model
-----
-----
-----
-----
-----
coeff names : {Intercept, eruptions}
coefficients: {33.47439702, 10.7296414}
std_err:      {1.155, 0.3148}
t_value:      {28.99, 34.09}
p_value:      {< 1e-20, < 1e-20}
Number of iterations: 1, Number of skipped samples: 0, Number of processed samples: 272
Call:linear_reg('linearReg', 'faithful', '"waiting"', 'eruptions'
USING PARAMETERS optimizer='newton', epsilon=1e-06, max_iterations=100)
(1 row)
```

- Connect to the database as user1:

```
=> \c - user1
```

- Then, you can use the REVOKE statement to revoke privileges from user2:

```
=> REVOKE USAGE ON MODEL linearReg FROM user2;
REVOKE PRIVILEGE
```

- To confirm the privileges were revoked, connect as user 2 and run the SUMMARIZE_MODEL function:

```
=> \c - user2
=>SELECT SUMMARIZE_MODEL('linearReg');
ERROR 7523: Problem in summarize_model.
Detail: Permission denied for model linearReg
```

Geospatial Analytics

Vertica provides functions that allows you to manipulate complex two- and three-dimensional spatial objects. These functions follow the Open Geospatial Consortium (OGC) standards. Vertica also provides data types and SQL functions that allow you to specify and store spatial objects in a database according to OGC standards.

Convert Well-Known Text (WKT) and Well-Known Binary (WKB)

Convert WKT and WKB.

Optimized Spatial Joins

Perform fast spatial joins using `ST_Intersects` and `STV_Intersects`.

Load and Export Spatial Data From Shapefiles

Easily load and export shapefiles.

Store and Retrieve Objects

Determine if:

- An object contains self-intersection or self-tangency points.
- One object is entirely within another object, such as a point within a polygon.

Test the relationships between objects

For example, if they intersect or touch:

- Identify the boundary of an object.
- Identify vertices of an object.

Calculate

- Shortest distance between two objects.
- Size of an object (length, area).
- Centroid for one or more objects.
- Buffer around one or more objects.

Best Practices for Geospatial Analytics

Micro Focus recommends the following best practices when performing geospatial analytics in Vertica.

Performance Optimization

Recommendation	Details
Use the minimum column size for spatial data.	Performance degrades as column widths increase. When creating columns for your spatial data, use the smallest size column that can accommodate your data. For example, use GEOMETRY(85) for point data.
Use GEOMETRY types where possible.	Performance of functions on GEOGRAPHY types is slower than functions that support GEOMETRY types. Use GEOMETRY types where possible.
To improve the performance of the following functions, sort projections on spatial columns:	You may improve the pruning efficiency of these functions by sorting the projection on the GEOMETRY column. However, sorting on a large GEOMETRY column may slow down data load.

Recommendation	Details
<ul style="list-style-type: none"> • STV_Intersect scalar function • ST_Distance • ST_Area • ST_Length 	

Spatial Joins with Points and Polygons

Vertica provides two ways to identify whether a set of points intersect with a set of polygons. Depending on the size of your data set, choose the approach that gives the best performance.

For a detailed example of best practices with spatial joins, see [Best Practices for Spatial Joins](#).

Recommendation	Details
Create a spatial index only when performing spatial joins with STV_Intersect.	Spatial indexes should only be used with STV_Intersect. Creating a spatial index and then performing spatial joins with ST_Intersects will not improve performance.
Use the STV_Intersect function when you intersect a set of points with a set of polygons.	Determine if a set of points intersects with a set of polygons in a medium to large data set. First, create a spatial index using STV_Create_Index. Then, use one of the STV_Intersect functions to return the set of pairs that intersect. Spatial indexes provide the best performance for accessing a large number of polygons.
When using the STV_Intersect transform function, partition the data and use an OVER(PARTITION BEST) clause.	The STV_Intersect Transform Function does not require that you partition the data. However, you may improve performance by partitioning the data and using an OVER(PARTITION BEST) clause.

Spatial Indexes

The STV_Create_Index function can consume large amounts of processing time and memory. When you index new data for the first time, monitor memory usage to be sure it stays within

safe limits. Memory usage depends on:

- Number of polygons
- Number of vertices
- Amount of overlap among polygons

Recommendation	Details
Segment polygon data when a table contains a large number of polygons.	Segmenting the data allows the index creation process to run in parallel. This is advantageous because sometimes STV_Create_Index tasks cannot be completed when large tables that are not segmented prior to index creation.
Adjust STV_Create_Index parameters as needed for memory allocation and CPU usage.	<p>The <i>max_mem_mb</i> parameter can affect the resource usage of STV_Create_Index. <i>max_mem_mb</i> assigns a limit to the amount of memory that STV_Create_Index can allocate.</p> <p>Default value: 256</p> <p>Valid values: Any value less than or equal to the amount of memory in the GENERAL resource pool. Assigning a higher value results in an error.</p>
Make changes if STV_Create_Index cannot allocate 300 MB memory.	<p>Before STV_Create_Index starts creating the index, it tries to allocate about 300 MB of memory. If that much memory is not available, the function fails. If you get a failure message, try these solutions:</p> <ul style="list-style-type: none"> • Create the index at a time of less load on the system. • Avoid concurrent index creation. • Add more memory to your system.
Create misplaced indexes again, if needed.	When you back up your Vertica database, spatial index files are not included. If you misplace an index, use STV_Create_Index to re-create it.
Use STV_Refresh_Index to add new or updated polygons to an existing	Instead of rebuilding your spatial index each time you add new or updated polygons to a table, you

Recommendation	Details
index.	can use <code>STV_Refresh_Index</code> to append the polygons to your existing spatial index.

Checking Polygon Validity

Recommendation	Details
Run <code>ST_IsValid</code> to check if polygons are valid.	<p>Many spatial functions do not check the validity of polygons.</p> <ul style="list-style-type: none">• Run <code>ST_IsValid</code> on all polygons to determine if they are valid.• If your object is not valid, run <code>STV_IsValidReason</code> to get information about the location of the invalid polygon. <p>For more information, see Ensuring Polygon Validity Before Creating or Refreshing an Index.</p>

Spatial Objects

Vertica implements several data types for storing spatial objects, Well-Known Text (WKT) strings, and Well-Known Binary (WKB) representations. These data types include:

- [Supported Spatial Objects](#)
- [Spatial Reference Identifiers \(SRIDs\)](#)

Supported Spatial Objects

Vertica uses two spatial data types. These data types store two- and three-dimensional spatial objects in a table column:

- A GEOMETRY object is a spatial object with coordinates expressed as (x,y) pairs, defined in the Cartesian plane. All calculations use Cartesian coordinates.
- A GEOGRAPHY object is a spatial object defined as on the surface of a perfect sphere, or a spatial object in the WGS84 coordinate system. Coordinates are expressed in longitude/latitude angular values, measured in degrees. All calculations are in meters. For perfect sphere calculations, the sphere has a radius of 6371 kilometers, which approximates the shape of the earth.

Note: Other spatial programs may use an ellipsoid to model the earth, resulting in slightly different data.

The maximum size of a GEOMETRY or GEOGRAPHY data type is 10,000,000 bytes (10 MB). You cannot use a GEOMETRY or GEOGRAPHY type as the primary key for a table in a Vertica database.

Spatial Reference Identifiers (SRIDs)

A *spatial reference identifier* (SRID) is an integer value that represents a method for projecting coordinates on the plane. A SRID is metadata that indicates the coordinate system in which a spatial object is defined.

Geospatial functions using Geometry arguments must contain the same SRID. If the functions do not contain the same SRID, then the query returns an error.

For example, in this query the two points have different SRIDs. As a result the query returns an error:

```
=> SELECT ST_Distance(ST_GeomFromText('POINT(34 9)',2749), ST_GeomFromText('POINT(70 12)', 3359));  
ERROR 5861: Error calling processBlock() in User Function ST_Distance at [src/Distance.cpp:65],  
error code: 0, message: Geometries with different SRIDs found: 2749, 3359
```

Supported SRIDs

Vertica supports SRIDs derived from the EPSG standards. Geospatial functions using Geometry arguments must use supported SRIDs when performing calculations. SRID values of 0 to $2^{32}-1$ are valid. Queries with SRID values outside of this range will return an error.

Working with Spatial Objects in Tables

- [Defining Table Columns for Spatial Data](#)
- [Exporting Spatial Data from a Table](#)
- [Identifying Null Spatial Objects](#)
- [Loading Spatial Data from Shapefiles](#)
- [Loading Spatial Data into Tables Using COPY](#)
- [Retrieving Spatial Data from a Table as Well-Known Text \(WKT\)](#)

Defining Table Columns for Spatial Data

To define columns to contain GEOMETRY and GEOGRAPHY data, use this command:

```
=> CREATE TABLE [[db-name.]schema.]table-name (  
  column-name GEOMETRY[(length)],  
  column-name GEOGRAPHY[(length)]);
```

If you omit the length specification, the default column size is 1 MB. The maximum column size is 10 MB. The upper limit is not enforced, but the geospatial functions can only accept or return spatial data up to 10 MB.

You cannot modify the size or data type of a GEOMETRY or GEOGRAPHY column after creation. If the column size you created is not sufficient, create a new column with the desired size. Then copy the data from the old column, and drop the old column from the table.

You cannot import data to or export data from tables that contain spatial data from another Vertica database.

Important: A column width that is too large could impact performance. Use a column width that fits the data without being excessively large. See [STV_MemSize](#).

Exporting Spatial Data from a Table

You can export spatial data from a table in your Vertica database to a shapefile.

To export spatial data from a table to a shapefile:

1. As the superuser., set the shapefile export directory.

```
=> SELECT STV_SetExportShapefileDirectory(USING PARAMETERS path = '/home/geo/temp');
          STV_SetExportShapefileDirectory
-----
SUCCESS. Set shapefile export directory: [/home/geo/temp]
(1 row)
```

2. Export your spatial data to a shapefile.

```
=> SELECT STV_Export2Shapefile(*
          USING PARAMETERS shapefile = 'visualizations/city-data.shp',
                           shape = 'Polygon') OVER() FROM spatial_data;
Rows Exported | File Path
-----+-----
185873 | v_geo-db_node0001: /home/geo/temp/visualizations/city-data.shp
(1 row)
```

- The value asterisk (*) is the equivalent to listing all columns in the FROM clause.
- You can specify sub-directories when exporting your shapefile.
- Your shapefile must end with the file extension .shp.

3. Verify that three files now appear in the shapefile export directory.

```
$ ls
city-data.dbf  city-data.shp  city-data.shx
```

Identifying Null Spatial Objects

You can identify null GEOMETRY and GEOGRAPHY objects using the Vertica IS NULL and IS NOT NULL constructs.

This example uses the following table, where the row with `id=2` has a null value in the `geog` field.

```
=> SELECT id, ST_AsText(geom), ST_AsText(geog) FROM locations
       ORDER BY 1 ASC;
id | ST_AsText | ST_AsText
-----+-----+-----
1 | POINT (2 3) | POINT (-85 15)
2 | POINT (4 5) | 
3 | POLYGON ((-1 2, 0 3, 1 2, -1 2)) | POLYGON ((-24 12, -15 23, -20 27, -24 12))
4 | LINESTRING (-1 2, 1 5) | LINESTRING (-42.74 23.98, -62.19 23.78)
(4 rows)
```

Identify all the rows that have a null `geog` value:

```
=> SELECT id, ST_AsText(geom), (ST_AsText(geom) IS NULL) FROM locations
ORDER BY 1 ASC;
id |          ST_AsText          | ?column?
-----+-----+-----
 1 | POINT (2 3)                 | f
 2 | POINT (4 5)                 | t
 3 | POLYGON ((-1 2, 0 3, 1 2, -1 2)) | f
 4 | LINESTRING (-1 2, 1 5)      | f
(4 rows)
```

Identify the rows where the geom value is not null:

```
=> SELECT id, ST_AsText(geom), (ST_AsText(geom) IS NOT NULL) FROM locations
ORDER BY 1 ASC;
id |          st_astext          | ?column?
-----+-----+-----
 1 | POINT (2 3)                 | t
 2 | POINT (4 5)                 | f
 3 | LINESTRING (-1 2, 1 5)      | t
 4 | POLYGON ((-1 2, 0 3, 1 2, -1 2)) | t
(4 rows)
```

Loading Spatial Data from Shapefiles

Vertica provides the capability to load and parse spatial data that is stored in shapefiles. Shapefiles describe points, lines, and polygons. A shapefile is made up of three required files; all three files must be present and in the same directory to define the geometries:

- .shp—Contains the geometry data.
- .shx—Contains the positional index of the geometry.
- .dbf—Contains the attributes for each geometry.

To load spatial data from a shapefile:

1. Use `STV_ShpCreateTable` to generate a `CREATE TABLE` statement.

```
=> SELECT STV_ShpCreateTable ( USING PARAMETERS file = '/home/geo/temp/shp-files/spatial_
data.shp')
                                OVER() AS spatial_data;
                                spatial_data
-----+-----+-----
CREATE TABLE spatial_data(
  gid IDENTITY(64) PRIMARY KEY,
  uniq_id INT8,
  geom GEOMETRY(85)
);
(5 rows)
```

2. Create the table.

```
=> CREATE TABLE spatial_data(  
  gid IDENTITY(64) PRIMARY KEY,  
  uniq_id INT8,  
  geom GEOMETRY(85));
```

3. Load the shapefile.

```
=> COPY spatial_data WITH SOURCE STV_ShpSource(file='/home/geo/temp/shp-files/spatial_data.shp')  
  PARSER STV_ShpParser();  
Rows Loaded  
-----  
          10  
(1 row)
```

Supported Shapefile Shape Types

The following table lists the shapefile shape types that Vertica supports.

Shapefile Shape Type	Supported
Null shape	Yes
Point	Yes
Polyline	Yes
Polygon	Yes
MultiPoint	Yes
PointZ	No
PolylineZ	No
PolygonZ	No
MultiPointZ	No
PointM	No
PolylineM	No
PolygonM	No
MultiPointM	No

Shapefile Shape Type	Supported
MultiPatch	No

Loading Spatial Data into Tables Using COPY

You can load spatial data into a table in Vertica using a COPY statement.

To load data into Vertica using a COPY statement:

1. Create a table.

```
=> CREATE TABLE spatial_data (id INTEGER, geom GEOMETRY(200));  
CREATE TABLE
```

2. Create a text file named `spatial.dat` with the following data.

```
1|POINT(2 3)  
2|LINESTRING(-1 2, 1 5)  
3|POLYGON((-1 2, 0 3, 1 2, -1 2))
```

3. Use COPY to load the data into the table.

```
=> COPY spatial_data (id, gx FILLER LONG VARCHAR(605), geom AS ST_GeomFromText(gx)) FROM LOCAL  
'spatial.dat';  
Rows Loaded  
-----  
3  
(1 row)
```

The statement specifies a LONG VARCHAR(32000000) filler, which is the maximum size of WKT. You must specify a filler value large enough to hold the largest WKT you want to insert into the table.

Retrieving Spatial Data from a Table as Well-Known Text (WKT)

GEOMETRY and GEOGRAPHY data is stored in Vertica tables as LONG VARBINARY, which isn't human readable. You can use [ST_AsText](#) to return the spatial data as Well-Known Text (WKT).

To return spatial data as WKT:

```
=> SELECT id, ST_AsText(geom) AS WKT FROM spatial_data;  
id | WKT
```

```
-----+-----  
1 | POINT (2 3)  
2 | LINESTRING (-1 2, 1 5)  
3 | POLYGON ((-1 2, 0 3, 1 2, -1 2))  
(3 rows)
```

Working with GeoHash Data

Vertica supports [GeoHashes](#). A GeoHash is a geocoding system for hierarchically encoding increasingly granular spatial references. Each additional character in a GeoHash drills down to a smaller section of a map.

You can use Vertica to generate spatial data from GeoHashes and GeoHashes from spatial data. Vertica supports the following functions for use with GeoHashes:

- [ST_GeoHash](#) - Returns a GeoHash in the shape of the specified geometry.
- [ST_GeomFromGeoHash](#) - Returns a polygon in the shape of the specified GeoHash.
- [ST_PointFromGeoHash](#) - Returns the center point of the specified GeoHash.

For example, to generate a full precision and partial precision GeoHash from a single point.

```
=> SELECT ST_GeoHash(ST_GeographyFromText('POINT(3.14 -1.34)'), LENGTH(ST_GeoHash(ST_
GeographyFromText('POINT(3.14 -1.34)'))),
           ST_GeoHash(ST_GeographyFromText('POINT(3.14 -1.34)') USING PARAMETERS
numchars=5) partial_hash;
   ST_GeoHash | LENGTH | partial_hash
-----+-----+-----
 kpf0rk3zmcswks75010 |    20 | kpf0r
(1 row)
```

This example shows how to generate a GeoHash from a multipoint point object. The returned polygon is a geometry object of the smallest tile that encloses that GeoHash.

```
=> SELECT ST_AsText(ST_GeomFromGeoHash(ST_GeoHash(ST_GeomFromText('MULTIPOINT(0 0, 0.0002
0.0001)')))) AS region_1,
           ST_AsText(ST_GeomFromGeoHash(ST_GeoHash(ST_GeomFromText('MULTIPOINT(0.0001
0.0001, 0.0003 0.0002)')))) AS region_2;
-[ RECORD 1 ]-----+-----+-----
   region_1 | POLYGON ((0 0, 0.00137329101562 0, 0.00137329101562 0.00137329101562, 0
0.00137329101562, 0 0))
   region_2 | POLYGON ((0 0, 0.010986328125 0, 0.010986328125 0.0054931640625, 0 0.0054931640625, 0
0))
```

Spatial Joins with ST_Intersects and STV_Intersect

Spatial joins allow you to identify spatial relationships between two sets of spatial data. For example, you can use spatial joins to:

- Calculate the density of mobile calls in various regions to determine the location of a new cell phone tower.
- Identify homes that fall within the impact zone of a hurricane.
- Calculate the number of users who live within a certain ZIP code.
- Calculate the number of customers in a retail store at any given time.

Best Practices for Spatial Joins

Use these best practices to improve overall performance and optimize your spatial queries.

Best practices for using spatial joins in Vertica include:

- Table segmentation to speed up index creation
- Adequately sizing a geometry column to store point data
- Loading Well-Known Text (WKT) directly into a Geometry column, using STV_GeometryPoint in a COPY statement
- Using OVER (PARTITION BEST) with STV_Intersect transform queries

Best Practices Example

Note: The following example was originally published in an Vertica blog post about using spatial data in museums. To read the entire blog, go to:

<https://my.vertica.com/blog/using-location-data-with-hp-vertica-placeba-p227636/>

Before performing the steps in the following example, download `place_output.csv.zip` from the Vertica Place GitHub repository (<https://github.com/vertica/Vertica-Geospatial>). You need to use the data set from this repository.

1. Create the table for the polygons. Use a GEOMETRY column width that fits your data without being excessively large. A good column-width fit improves performance. In addition, segmenting the table by HASH provides the advantages of parallel computation.

```
=> CREATE TABLE artworks (gid int, g GEOMETRY(700)) SEGMENTED BY HASH(gid) ALL NODES;
```

2. Use a copy statement with ST_Buffer to create and load the polygons on which to run the intersect. By using ST_Buffer in your copy statement, you can use that function to create the polygons.

```
=> COPY artworks(gid, gx FILLER LONG VARCHAR, g AS ST_Buffer(ST_GeomFromText(gx),8)) FROM STDIN  
DELIMITER ',';  
>> 1, POINT(10 45)  
>> 2, POINT(25 45)  
>> 3, POINT(35 45)  
>> 4, POINT(35 15)  
>> 5, POINT(30 5)  
>> 6, POINT(15 5)  
>> \.
```

3. Create a table for the location data, represented by points. You can store point data in a GEOMETRY column of 100 bytes. Avoid over-fitting your GEOMETRY column. Doing so can significantly degrade spatial intersection performance. Also, segment this table by HASH, to take advantage of parallel computation.

```
=> CREATE TABLE usr_data (gid identity, usr_id int, date_time timestamp, g GEOMETRY(100))  
SEGMENTED BY HASH(gid) ALL NODES;
```

4. During the copy statement, transform the raw location data to GEOMETRY data. You must perform this transformation because your location data needs to use the GEOMETRY data type. Use the function STV_GeometryPoint to transform the x and y columns of the source table.

```
=> COPY usr_data (usr_id, date_time, x FILLER LONG VARCHAR,  
y FILLER LONG VARCHAR, g AS STV_GeometryPoint(x, y))  
FROM LOCAL 'place_output.csv' DELIMITER ',' ENCLOSED BY '';
```

5. Create the spatial index for the polygons. This index helps you speed up intersection calculations.

```
=> SELECT STV_Create_Index(gid, g USING PARAMETERS index='art_index', overwrite=true) OVER() FROM  
artworks;
```

6. Write an analytic query that returns the number of intersections per polygon. Specify that Vertica ignore any usr_id that intersects less than 20 times with a given polygon.

```
=> SELECT pol_gid,  
        COUNT(DISTINCT(usr_id)) AS count_user_visit  
FROM  
  (SELECT pol_gid,  
         usr_id,  
         COUNT(usr_id) AS user_points_in  
   FROM  
     (SELECT STV_Intersect(usr_id, g USING PARAMETERS INDEX='art_index') OVER(PARTITION BEST) AS  
      (usr_id,  
       pol_gid)  
    FROM usr_data  
     WHERE date_time BETWEEN '2014-07-02 09:30:20' AND '2014-07-02 17:05:00') AS c  
   GROUP BY pol_gid,  
            usr_id HAVING COUNT(usr_id) > 20) AS real_visits  
GROUP BY pol_gid  
ORDER BY count_user_visit DESC;
```

Optimizations in the Example Query

This query has the following optimizations:

- The time predicated appears in the subquery.
- Using the location data table avoids the need for an expensive join.
- The query uses OVER (PARTITION BEST), to improve performance by partitioning the data.
- The user_points_in provides an estimate of the combined time spent intersecting with the artwork by all visitors.

Ensuring Polygon Validity Before Creating or Refreshing an Index

When Vertica creates or updates a spatial index it does not check polygon validity. To prevent getting invalid results when you query your spatial index, you should check the validity of your polygons prior to creating or updating your spatial index.

The following example shows you how to check the validity of polygons.

1. Create a table and load spatial data.

```
=> CREATE TABLE polygon_validity_test (gid INT, geom GEOMETRY);  
CREATE TABLE  
=> COPY polygon_validity_test (gid, gx FILLER LONG VARCHAR, geom AS St_GeomFromText(gx)) FROM  
STDIN;
```

```
Enter data to be copied followed by a newline.  
End with a backslash and a period on a line by itself.  
>> 2|POLYGON((-31 74,8 70,8 50,-36 53,-31 74))  
>> 3|POLYGON((-38 50,4 13,11 45,0 65,-38 50))  
>> 4|POLYGON((-12 42,-12 42,27 48,14 26,-12 42))  
>> 5|POLYGON((0 0,1 1,0 0,2 1,1 1,0 0))  
>> 6|POLYGON((3 3,2 2,2 1,2 3,3 3))  
>> \.
```

2. Use ST_IsValid and STV_IsValidReason to find any invalid polygons.

```
=> SELECT gid, ST_IsValid(geom), STV_IsValidReason(geom) FROM polygon_validity_test;  
gid | ST_IsValid | STV_IsValidReason  
-----+-----+-----  
4 | t |  
6 | f | Self-intersection at or near POINT (2 1)  
2 | t |  
3 | t |  
5 | f | Self-intersection at or near POINT (0 0)  
(5 rows)
```

Now that we have identified the invalid polygons in our table, there are a couple different ways you can handle the invalid polygons when creating or refreshing a spatial index.

Filtering Invalid Polygons Using a WHERE Clause

This method is slower than filtering before creating an index because it checks the validity of each polygon at execution time.

The following example shows you how to exclude invalid polygons using a WHERE clause.

```
=> SELECT STV_Create_Index(gid, geom USING PARAMETERS index = 'valid_polygons') OVER()  
FROM polygon_validity_test  
WHERE ST_IsValid(geom) = 't';
```

Filtering Invalid Polygons Before Creating or Refreshing an Index

This method is faster than filtering using a WHERE clause because you incur the performance cost prior to building the index.

The following example shows you how to exclude invalid polygons by creating a new table excluding invalid polygons.

```
=> CREATE TABLE polygon_validity_clean AS  
SELECT *  
FROM polygon_validity_test  
WHERE ST_IsValid(geom) = 't';
```

```
CREATE TABLE
=> SELECT STV_Create_Index(gid, geom USING PARAMETERS index = 'valid_polygons') OVER()
FROM polygon_validity_clean;
```

STV_Intersect: Scalar Function vs. Transform Function

The STV_Intersect functions are similar in purpose, but you use them differently.

STV_Intersect Function Type	Description	Performance
Scalar	Matches a point to a polygon. If several polygons contain the point, this function returns a <code>gid</code> value. The result is a polygon <code>gid</code> or, if no polygon contains the point, the result is NULL.	Eliminates points that do not intersect with any indexed polygons, avoiding unnecessary comparisons.
Transform	Matches a point to all the polygons that contain it. When a point does not intersect with any polygon in the index, the function returns no rows.	Processes all input points regardless of whether or not they intersect with the indexed polygons.

In the following example, the STV_Intersect scalar function compares the points in the `points` table to the polygons in a spatial index named `my_polygons`. STV_Intersect returns all points and polygons that match exactly:

```
=> SELECT gid AS pt_gid
      STV_Intersect(geom USING PARAMETERS index='my_polygons') AS pol_gid
FROM points ORDER BY pt_gid;
pt_gid | pol_gid
-----+-----
  100 |      2
  101 |
  102 |      2
  103 |
  104 |
  105 |      3
  106 |
  107 |
(8 rows)
```

The following example shows how to use the STV_Intersect transform function to return information about the three point-polygon pairs that match and each of the polygons they match:

```
=> SELECT STV_Intersect(gid, geom
  USING PARAMETERS index='my_polygons')
  OVER (PARTITION BEST) AS (pt_gid, pol_id)
  FROM points;
pt_gid | pol_id
-----+-----
  100 |     1

Performing Spatial Joins with STV_Intersect Functions

Suppose you want to process a medium-to-large spatial data set and determine which points intersect with which polygons. In that case, first create a spatial index using `STV_Create_Index`. A spatial index provides efficient access to the set of polygons.

Then, use the `STV_Intersect` scalar or transform function to identify which point-polygon pairs match.

Spatial Indexes and STV_Intersect

Before performing a spatial join using one of the `STV_Intersect` functions, you must first run `STV_Create_Index` to create a database object that contains information about polygons. This object is called a *spatial index* of the set of polygons. The spatial index improves the time it takes for the `STV_Intersect` functions to access the polygon data.

Vertica creates spatial indexes in a global space. Thus, any user with access to the `STV_*_Index` functions can describe, rename, or drop indexes created by any other user.

Vertica provides functions that work with spatial indexes:

- [STV_Create_Index](#)—Stores information about polygons in an index to improve performance.
- [STV_Describe_Index](#)—Retrieves information about an index.
- [STV_Drop_Index](#)—Deletes a spatial index.

- [STV_Refresh_Index](#)—Refreshes a spatial index.
- [STV_Rename_Index](#)—Renames a spatial index.

When to Use ST_Intersects vs. STV_Intersect

Vertica provides two capabilities to identify whether a set of points intersect with a set of polygons. Depending on the size of your data set, choose the approach that gives the best performance:

- When comparing a set of geometries to a single geometry to see if they intersect, use the [ST_Intersects](#) function.
- To determine if a set of points intersects with a set of polygons in a medium-to-large data set, first create a spatial index using [STV_Create_Index](#). Then, use one of the [STV_Intersect](#) functions to return the set of pairs that intersect.

Note: You can only perform spatial joins on GEOMETRY data.

Performing Spatial Joins with ST_Intersects

The [ST_Intersects](#) function determines if two GEOMETRY objects intersect or touch at a single point.

Use [ST_Intersects](#) when you want to identify if a small set of geometries in a column intersect with a given geometry.

Example

The following example uses `ST_Intersects` to compare a column of point geometries to a single polygon. The table that contains the points has 1 million rows.

`ST_Intersects` returns only the points that intersect with the polygon. Those points represent about 0.01% of the points in the table:

```
=> CREATE TABLE points_1m(gid IDENTITY, g GEOMETRY(100)) ORDER BY gid;
=> COPY points_1m(wkt FILLER LONG VARCHAR(100), g AS ST_GeomFromText(wkt))
  FROM LOCAL '/data/points.dat' DIRECT;
Rows Loaded
-----
      1000000
(1 row)
=> SELECT ST_AsText(g) FROM points_1m WHERE
  ST_Intersects
  (
    g,
    ST_GeomFromText('POLYGON((-71 42, -70.9 42, -70.9 42.1, -71 42.1, -71 42))')
  );
      st_astext
-----
POINT (-70.97532 42.03538)
POINT (-70.97421 42.0376)
POINT (-70.99004 42.07538)
POINT (-70.99477 42.08454)
POINT (-70.99088 42.08177)
POINT (-70.98643 42.07593)
POINT (-70.98032 42.07982)
POINT (-70.95921 42.00982)
POINT (-70.95115 42.02177)
...
(116 rows)
```

Micro Focus recommends that you test the intersections of two columns of geometries by creating a spatial index. Use one of the `STV_Intersect` functions as described in [STV_Intersect: Scalar Function vs. Transform Function](#).

Working with Spatial Objects from Client Applications

The Vertica client driver libraries provide interfaces for connecting your client applications to your Vertica database. The drivers simplify exchanging data for loading, report generation, and other common database tasks.

There are three separate client drivers:

- Open Database Connectivity (ODBC)—The most commonly-used interface for third-party applications and clients written in C, Python, PHP, Perl, and most other languages.
- Java Database Connectivity (JDBC)—Used by clients written in the Java programming language.
- ActiveX Data Objects for .NET (ADO.NET)—Used by clients developed using Microsoft's .NET Framework and written in C#, Visual Basic .NET, and other .NET languages.

Vertica Place supports the following new data types:

- LONG VARCHAR
- LONG VARBINARY
- GEOMETRY
- GEOGRAPHY

The client driver libraries support these data types; the following sections describe that support and provide examples.

Using LONG VARCHAR and LONG VARBINARY Data Types with ODBC

The ODBC drivers support the LONG VARCHAR and LONG VARBINARY data types similarly to VARCHAR and VARBINARY data types. When binding input or output parameters to a LONG VARCHAR or LONG VARBINARY column in a query, use the SQL_LONGVARCHAR and SQL_LONGVARBINARY constants to set the column's data type. For example, to bind an input parameter to a LONG VARCHAR column, you would use a statement that looks like this:

```
rc = SQLBindParameter(hdIStmt, 1, SQL_PARAM_INPUT, SQL_C_CHAR, SQL_LONGVARCHAR,
    80000, 0, (SQLPOINTER)myLongString, sizeof(myLongString), NULL);
```

Note: Do not use inefficient encoding formats for LONG VARBINARY and LONG VARCHAR values. Vertica cannot load encoded values larger than 32MB, even if the decoded value is less than 32 MB in size. For example, Vertica returns an error if you attempt to load a 32MB LONG VARBINARY value encoded in octal format, since the octal encoding quadruples the size of the value (each byte is converted into a backslash followed by three digits).

Using LONG VARCHAR and LONG VARBINARY Data Types with JDBC

Using LONG VARCHAR and LONG VARBINARY data types in a JDBC client application is similar to using VARCHAR and VARBINARY data types. The JDBC driver transparently handles the conversion (for example, between a Java `String` object and a LONG VARCHAR). The following example code demonstrates inserting and retrieving a LONG VARCHAR string. It uses the JDBC `Types` class to determine the data type of the string returned by Vertica, although it does not actually need to know whether the database column is a LONG VARCHAR or just a VARCHAR in order to retrieve the value.

```
import java.sql.*;
import java.util.Properties;

public class LongVarcharExample {
    public static void main(String[] args) {
        try {
            Class.forName("com.vertica.jdbc.Driver");
        } catch (ClassNotFoundException e) {
            System.err.println("Could not find the JDBC driver class.");
            e.printStackTrace();
            return;
        }
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        Connection conn;
        try {
            conn = DriverManager.getConnection(
                "jdbc:vertica://VerticaHost:5433/ExampleDB",
                myProp);
            // establish connection and make a table for the data.
            Statement stmt = conn.createStatement();

            // How long we want the example string to be. This is
            // larger than can fit into a traditional VARCHAR (which is limited
            // to 65000.
            int length = 100000;

            // Create a table with a LONG VARCHAR column that can store
            // the string we want to insert.
            stmt.execute("DROP TABLE IF EXISTS longtable CASCADE");
            stmt.execute("CREATE TABLE longtable (text LONG VARCHAR(" + length
                + "))");
            // Build a long string by appending an integer to a string builder
            // until we hit the size limit. Will result in a string
            // containing 01234567890123....
            StringBuilder sb = new StringBuilder(length);
            for (int i = 0; i < length; i++)
            {
                sb.append(i % 10);
            }
        }
    }
}
```

```
}
String value = sb.toString();

System.out.println("String value is " + value.length() +
    " characters long.");

// Create the prepared statement
PreparedStatement pstmt = conn.prepareStatement(
    "INSERT INTO longtable (text)" +
    " VALUES(?)");
try {
    // Insert LONG VARCHAR value
    System.out.println("Inserting LONG VARCHAR value");
    pstmt.setString(1, value);
    pstmt.addBatch();
    pstmt.executeBatch();

    // Query the table we created to get the value back.
    ResultSet rs = null;
    rs = stmt.executeQuery("SELECT * FROM longtable");

    // Get metadata about the result set.
    ResultSetMetaData rsmd = rs.getMetaData();
    // Print the type of the first column. Should be
    // LONG VARCHAR. Also check it against the Types class, to
    // recognize it programmatically.
    System.out.println("Column #1 data type is: " +
        rsmd.getColumnTypeName(1));
    if (rsmd.getColumnType(1) == Types.LONGVARCHAR) {
        System.out.println("It is a LONG VARCHAR");
    } else {
        System.out.println("It is NOT a LONG VARCHAR");
    }
}

// Print out the string length of the returned value.
while (rs.next()) {
    // Use the same getString method to get the value that you
    // use to get the value of a VARCHAR.
    System.out.println("Returned string length: " +
        rs.getString(1).length());
}
} catch (SQLException e) {
    System.out.println("Error message: " + e.getMessage());
    return; // Exit if there was an error
}
// Cleanup
conn.close();
} catch (SQLException e) {
    e.printStackTrace();
}
}
```

Note: Do not use inefficient encoding formats for LONG VARBINARY and LONG VARCHAR values. Vertica cannot load encoded values larger than 32MB, even if the decoded value is less than 32 MB in size. For example, Vertica returns an error if you

attempt to load a 32MB LONG VARBINARY value encoded in octal format, since the octal encoding quadruples the size of the value (each byte is converted into a backslash followed by three digits).

Using GEOMETRY and GEOGRAPHY Data Types in ODBC

Vertica GEOMETRY and GEOGRAPHY data types are backed by LONG VARBINARY native types and ODBC client applications treat them as binary data. However, these data types have a format that is unique to Vertica. To manipulate this data in your C++ application, you must use the functions in Vertica that convert them to a recognized format.

To convert a WKT or WKB to the GEOMETRY or GEOGRAPHY format, use one of the following SQL functions:

- [ST_GeographyFromText](#)—Converts a WKT to a GEOGRAPHY type.
- [ST_GeographyFromWKB](#)—Converts a WKB to a GEOGRAPHY type.
- [ST_GeomFromText](#)—Converts a WKT to a GEOMETRY type.
- [ST_GeomFromWKB](#)—Converts a WKB to GEOMETRY type.

To convert a GEOMETRY or GEOGRAPHY object to its corresponding WKT or WKB, use one of the following SQL functions:

- [ST_AsText](#)—Converts a GEOMETRY or GEOGRAPHY object to a WKT, returns a LONGVARCHAR.
- [ST_AsBinary](#)—Converts a GEOMETRY or GEOGRAPHY object to a WKB, returns a LONG VARBINARY.

The following code example converts WKT data into GEOMETRY data using `ST_GeomFromText` and stores it in a table. Later, this example retrieves the GEOMETRY data from the table and converts it to WKT and WKB format using `ST_AsText` and `ST_AsBinary`.

```
// Compile on Linux using:  
// g++ -g -I/opt/vertica/include -L/opt/vertica/lib64 -lodbc -o SpatialData SpatialData.cpp  
// Some standard headers  
#include <stdio.h>  
#include <stdlib.h>  
#include <string.h>  
#include <assert.h>  
#include <sstream>  
// Only needed for Windows clients
```

```
// #include <windows.h>
// Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>
// Helper function to print SQL error messages.
template <typename HandleT>
void reportError(int handleTypeEnum, HandleT hdl)
{
    // Get the status records.
    SQLSMALLINT    i, MsgLen;
    SQLRETURN      ret2;
    SQLCHAR        SqlState[6], Msg[SQL_MAX_MESSAGE_LENGTH];
    SQLINTEGER     NativeError;
    i = 1;
    printf("\n");
    while ((ret2 = SQLGetDiagRec(handleTypeEnum, hdl, i, SqlState, &NativeError,
                               Msg, sizeof(Msg), &MsgLen)) != SQL_NO_DATA) {
        printf("error record %d\n", i);
        printf("sqlstate: %s\n", SqlState);
        printf("detailed msg: %s\n", Msg);
        printf("native error code: %d\n\n", NativeError);
        i++;
    }
    exit(EXIT_FAILURE); // bad form... but Ok for this demo
}
int main()
{
    // Set up the ODBC environment
    SQLRETURN ret;
    SQLHENV hdlEnv;
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
    assert(SQL_SUCCEEDED(ret));
    // Tell ODBC that the application uses ODBC 3.
    ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION,

Using GEOMETRY and GEOGRAPHY Data Types in ADO.NET

Vertica GEOMETRY and GEOGRAPHY data types are backed by LONG VARBINARY native types and ADO.NET client applications treat them as binary data. However, these data types have a format that is unique to Vertica. To manipulate this data in your C# application, you must use the functions in Vertica that convert them to a recognized format.

To convert a WKT or WKB to the GEOMETRY or GEOGRAPHY format, use one of the following SQL functions:

- [ST_GeographyFromText](#)—Converts a WKT to a GEOGRAPHY type.
- [ST_GeographyFromWKB](#)—Converts a WKB to a GEOGRAPHY type.
- [ST_GeomFromText](#)—Converts a WKT to a GEOMETRY type.
- [ST_GeomFromWKB](#)—Converts a WKB to GEOMETRY type.

To convert a GEOMETRY or GEOGRAPHY object to its corresponding WKT or WKB, use one of the following SQL functions:

- [ST_AsText](#)—Converts a GEOMETRY or GEOGRAPHY object to a WKT, returns a LONGVARCHAR.
- [ST_AsBinary](#)—Converts a GEOMETRY or GEOGRAPHY object to a WKB, returns a LONG VARBINARY.

The following C# code example converts WKT data into GEOMETRY data using `ST_GeomFromText` and stores it in a table. Later, this example retrieves the GEOMETRY data from the table and converts it to WKT and WKB format using `ST_AsText` and `ST_AsBinary`.

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder =
                new VerticaConnectionStringBuilder();
            builder.Host = "VerticaHost";
            builder.Database = "VMart";
            builder.User = "ExampleUser";
            builder.Password = "password123";
            VerticaConnection _conn = new
                VerticaConnection(builder.ToString());
            _conn.Open();

            VerticaCommand command = _conn.CreateCommand();
            command.CommandText = "DROP TABLE IF EXISTS polygons";
            command.ExecuteNonQuery();
            command.CommandText =
                "CREATE TABLE polygons (id INTEGER PRIMARY KEY, poly GEOMETRY)";
            command.ExecuteNonQuery();
            // Prepare to insert a polygon using a prepared statement. Use the
            // ST_GeomFromText SQL function to convert from WKT to GEOMETRY.
            VerticaTransaction txn = _conn.BeginTransaction();
```

```
command.CommandText =
    "INSERT into polygons VALUES(@id, ST_GeomFromText(@polygon));";
command.Parameters.Add(new
    VerticaParameter("id", VerticaType.BigInt));
command.Parameters.Add(new
    VerticaParameter("polygon", VerticaType.VarChar));
command.Prepare();
// Set the values for the parameters
command.Parameters["id"].Value = 0;
//
command.Parameters["polygon"].Value =
    "polygon((1 1, 1 2, 2 2, 2 1, 1 1));";
// Execute the query to insert the value
command.ExecuteNonQuery();

// Now query the table
VerticaCommand query = _conn.CreateCommand();
query.CommandText =
    "SELECT id, ST_AsText(poly), ST_AsBinary(poly) FROM polygons;";
VerticaDataReader dr = query.ExecuteReader();
while (dr.Read())
{
    Console.WriteLine("ID: " + dr[0]);
    Console.WriteLine("Polygon WKT format data type: "
        + dr.GetDataTypeName(1) +
        " Value: " + dr[1]);
    // Get the WKB format of the polygon and print it out as hex.
    Console.WriteLine("Polygon WKB format data type: "
        + dr.GetDataTypeName(2));
    Console.WriteLine(" Value: "
        + BitConverter.ToString((byte[])dr[2]));
}
_conn.Close();
}
}
```

The example code prints the following on the system console:

```
ID: 0
Polygon WKT format data type: LONG VARCHAR Value: POLYGON ((1 1, 1 2,
2 2, 2 1,1 1))
Polygon WKB format data type: LONG VARBINARY Value: 01-03-00-00-00-01
-00-00-00-05-00-00-00-00-00-00-00-00-00-00-F0-3F-00-00-00-00-00-00-F0-3F
-00-00-00-00-00-00-F0-3F-00-00-00-00-00-00-00-00-40-00-00-00-00-00-00
-40-00-00-00-00-00-00-00-40-00-00-00-00-00-00-00-40-00-00-00-00-00
-F0-3F-00-00-00-00-00-00-F0-3F-00-00-00-00-00-00-F0-3F
```

OGC Spatial Definitions

Using Vertica requires an understanding of the Open Geospatial Consortium (OGC) concepts and capabilities. For more information, see the [OGC Simple Feature Access Part 1 - Common Architecture](#) specification.

Spatial Classes

Vertica supports several classes of objects, as defined in the OGC standards.

Point

A location in two-dimensional space that is identified by one of the following:

- X and Y coordinates
- Longitude and latitude values

A point has dimension 0 and no boundary.

Examples

The following example uses a GEOMETRY point:

```
=> CREATE TABLE point_geo (gid int, geom GEOMETRY(100));
CREATE TABLE
=> COPY point_geo(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter ',';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>1, POINT(3 5)
>>\.
=> SELECT gid, ST_AsText(geom) FROM point_geo;
gid | ST_AsText
-----+-----
  1 | POINT (3 5)
(1 row)
```

The following example uses a GEOGRAPHY point:

```
=> CREATE TABLE point_geog (gid int, geog geography(100));
CREATE TABLE
=> COPY point_geog(gid, gx filler LONG VARCHAR, geog AS ST_GeographyFromText(gx)) FROM stdin
delimiter ',';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>1, POINT(42 71)
>>\.
=> SELECT gid, ST_AsText(geog) FROM point_geog;
gid | ST_AsText
-----+-----
  1 | POINT (42 71)
(1 row)
```

Multipoint

A set of one or more points. A multipoint object has dimension 0 and no boundary.

Examples

The following example uses a GEOMETRY multipoint:

```
=> CREATE TABLE mpoint_geo (gid int, geom GEOMETRY(1000));
CREATE TABLE
=> COPY mpoint_geo(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter
'|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>1|MULTIPOINT(4 7, 8 10)
>>\.
=> SELECT gid, ST_AsText(geom) FROM mpoint_geo;
gid |          st_astext
-----+-----
  1 | MULTIPOINT (7 8, 6 9)
(1 row)
```

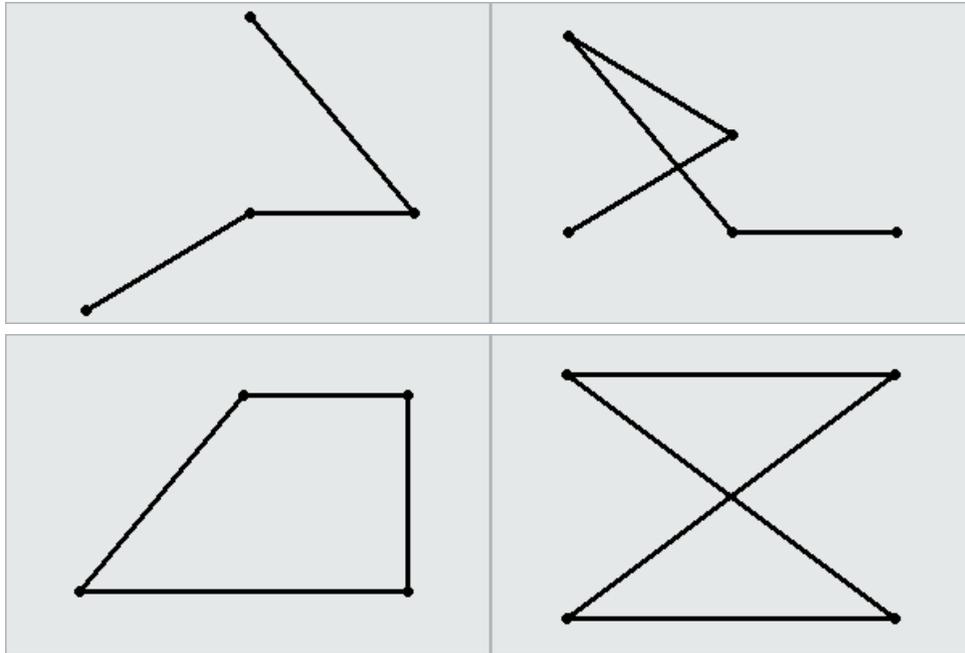

The following example uses a GEOGRAPHY multipoint:

```
=> CREATE TABLE mpoint_geog (gid int, geog GEOGRAPHY(1000));
CREATE TABLE
=> COPY mpoint_geog(gid, gx filler LONG VARCHAR, geog AS ST_GeographyFromText(gx)) FROM stdin
delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>1|MULTIPOINT(42 71, 41.4 70)
>>\.
=> SELECT gid, ST_AsText(geom) FROM mpoint_geo;
gid |          st_astext
-----+-----
  1 | MULTIPOINT (42 71, 41.4 70)
(1 row)
```

Linestring

One or more connected lines, identified by pairs of consecutive points. A linestring has dimension 1. The boundary of a linestring is a multipoint object containing its start and end points.

The following are examples of linestrings:

Examples

The following example uses the GEOMETRY type to create a table, use copy to load a linestring to the table, and then queries the table to view the linestring:

```
=> CREATE TABLE linestring_geom (gid int, geom GEOMETRY(1000));
CREATE TABLE
=> COPY linestring_geom(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin
delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>1|LINESTRING(0 0, 1 1, 2 2, 3 4, 2 4, 1 5)
>>\.
=> SELECT gid, ST_AsText(geom) FROM linestring_geom;
gid |          ST_AsText
-----+-----
  1 | LINESTRING (0 0, 1 1, 2 2, 3 4, 2 4, 1 5)
(1 row)
```

The following example uses the GEOGRAPHY type to create a table, use copy to load a linestring to the table, and then queries the table to view the linestring:

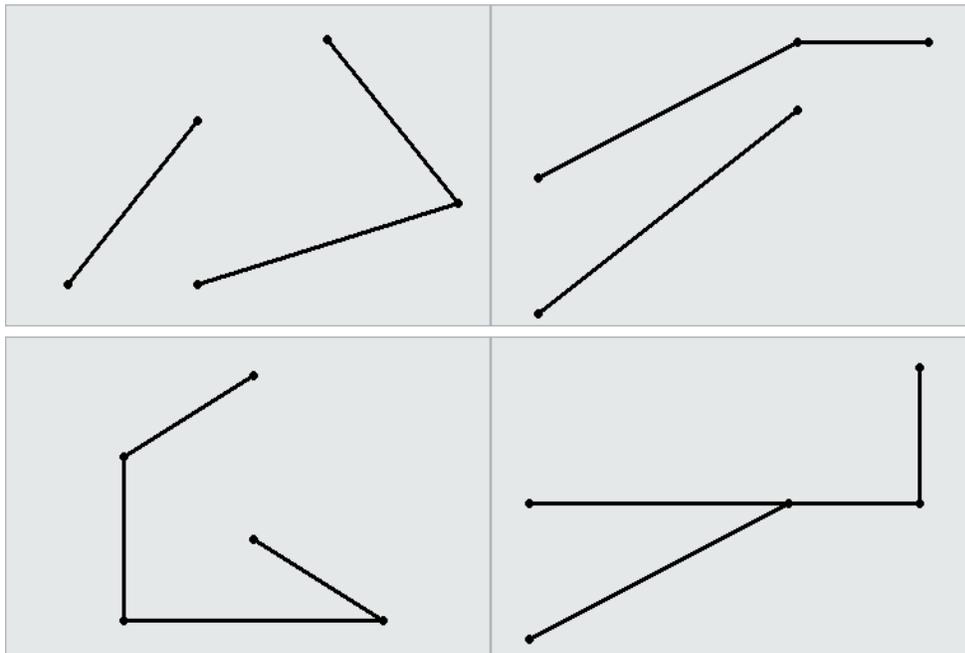

```
=> CREATE TABLE linestring_geog (gid int, geog GEOGRAPHY(1000));
CREATE TABLE
=> COPY linestring_geog(gid, gx filler LONG VARCHAR, geog AS ST_GeographyFromText(gx)) FROM stdin
delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>1|LINESTRING(42.1 71, 41.4 70, 41.3 72.9, 42.99 71.46, 44.47 73.21)
>>\.
=> SELECT gid, ST_AsText(geog) FROM linestring_geog;
gid |          ST_AsText
```

```
-----+-----
 1 | LINESTRING (42.1 71, 41.4 70, 41.3 72.9, 42.99 71.46, 44.47 73.21)
(1 row)
```

Multilinestring

A collection of zero or more linestrings. A multilinestring has no dimension. The boundary of a multilinestring is a multipoint object containing the start and end points of all the linestrings.

The following are examples of multilinestrings:

Examples

The following example uses the GEOMETRY type to create a table, use copy to load a multilinestring to the table, and then queries the table to view the multilinestring:

```
=> CREATE TABLE multilinestring_geom (gid int, geom GEOMETRY(1000));
CREATE TABLE
=> COPY multilinestring_geom(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin
delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>1|MULTILINESTRING((1 5, 2 4, 5 3, 6 6),(3 5, 3 7))
>>\.
=> SELECT gid, ST_AsText(geom) FROM multilinestring_geom;
gid | ST_AsText
-----+-----
 1 | MULTILINESTRING ((1 5, 2 4, 5 3, 6 6), (3 5, 3 7))
```

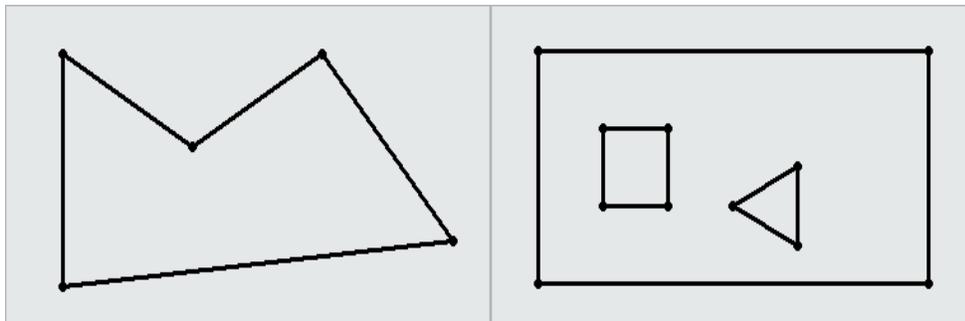

(1 row)

The following example uses the GEOGRAPHY type to create a table, use copy to load a multilinestring to the table, and then queries the table to view the multilinestring:

```
=> CREATE TABLE multilinestring_geog (gid int, geog GEOGRAPHY(1000));
CREATE TABLE
=> COPY multilinestring_geog(gid, gx filler LONG VARCHAR, geog AS ST_GeographyFromText(gx)) FROM
stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>1|MULTILINESTRING((42.1 71, 41.4 70, 41.3 72.9), (42.99 71.46, 44.47 73.21))
>>\.
=> SELECT gid, ST_AsText(geog) FROM multilinestring_geog;
gid | ST_AsText
-----+-----
1 | MULTILINESTRING((42.1 71, 41.4 70, 41.3 72.9), (42.99 71.46, 44.47 73.21))
(1 row)
```

Polygon

An object identified by a set of closed linestrings. A polygon can have one or more holes, as defined by interior boundaries, but all points must be connected. Two examples of polygons are:

Inclusive and Exclusive Polygons

Polygons that include their points in clockwise order include all space inside the perimeter of the polygon and exclude all space outside that perimeter. Polygons that include their points in counterclockwise order exclude all space inside the perimeter and include all space outside that perimeter.

Examples

The following example uses the GEOMETRY type to create a table, use copy to load a polygon into the table, and then queries the table to view the polygon:

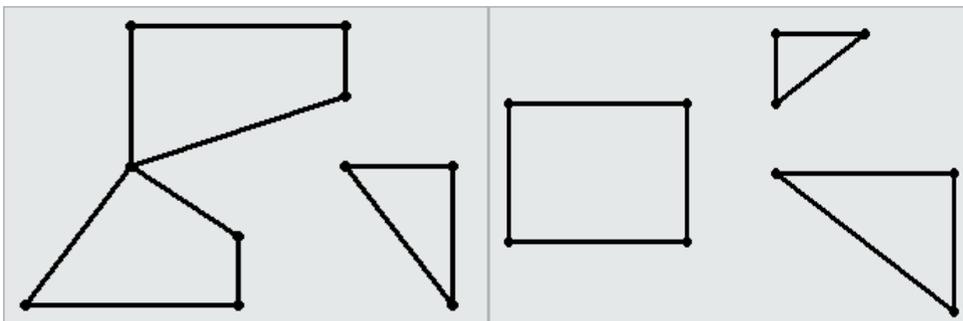

```
=> CREATE TABLE polygon_geom (gid int, geom GEOMETRY(1000));
CREATE TABLE
=> COPY polygon_geom(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter
'|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>1|POLYGON(( 2 6, 2 9, 6 9, 7 7, 4 6, 2 6))
>>\.
=> SELECT gid, ST_AsText(geom) FROM polygon_geom;
gid |          ST_AsText
-----+-----
  1 | POLYGON((2 6, 2 9, 6 9, 7 7, 4 6, 2 6))
(1 row)
```

The following example uses the GEOGRAPHY type to create a table, use copy to load a polygon into the table, and then queries the table to view the polygon:

```
=> CREATE TABLE polygon_geog (gid int, geog GEOGRAPHY(1000));
CREATE TABLE
=> COPY polygon_geog(gid, gx filler LONG VARCHAR, geog AS ST_GeographyFromText(gx)) FROM stdin
delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>1|POLYGON((42.1 71, 41.4 70, 41.3 72.9, 44.47 73.21, 42.99 71.46, 42.1 71))
>>\.
=> SELECT gid, ST_AsText(geog) FROM polygon_geog;
gid |          ST_AsText
-----+-----
  1 | POLYGON((42.1 71, 41.4 70, 41.3 72.9, 44.47 73.21, 42.99 71.46, 42.1 71))
(1 row)
```

Multipolygon

A collection of zero or more polygons that do not overlap.

Examples

The following example uses the GEOMETRY type to create a table, use copy to load a multipolygon into the table, and then queries the table to view the polygon:

```
=> CREATE TABLE multipolygon_geom (gid int, geom GEOMETRY(1000));
CREATE TABLE
=> COPY multipolygon_geom(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin
delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>9|MULTIPOLYGON(((2 6, 2 9, 6 9, 7 7, 4 6, 2 6)),((0 0, 0 5, 1 0, 0 0)),((0 2, 2 5, 4 5, 0 2)))
>>\.
=> SELECT gid, ST_AsText(geom) FROM polygon_geom;
gid | ST_AsText
-----+-----
  9 | MULTIPOLYGON(((2 6, 2 9, 6 9, 7 7, 4 6, 2 6)),((0 0, 0 5, 1 0, 0 0)),((0 2, 2 5, 4 5, 0 2)))
(1 row)
```

The following example uses the GEOGRAPHY type to create a table, use copy to load a multipolygon into the table, and then queries the table to view the polygon:

```
=> CREATE TABLE multipolygon_geog (gid int, geog GEOGRAPHY(1000));
CREATE TABLE
=> COPY polygon_geog(gid, gx filler LONG VARCHAR, geog AS ST_GeographyFromText(gx)) FROM stdin
delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>1|POLYGON(((42.1 71, 41.4 70, 41.3 72.9, 44.47 73.21, 42.99 71.46, 42.1 71)))
>>\.
=> SELECT gid, ST_AsText(geog) FROM polygon_geog;
gid | ST_AsText
-----+-----
  1 | POLYGON(((42.1 71, 41.4 70, 41.3 72.9, 42.1 71)),((44.47 73.21, 42.99 71.46, 42.1 71, 44.47
73.21)))
(1 row)
```

Spatial Object Representations

The OGC defines two ways to represent spatial objects:

- Well-Known Text (WKT)
- Well-Known Binary (WKB)

Well-Known Text (WKT)

Well-Known Text (WKT) is an ASCII representation of a spatial object.

WKTs are not case sensitive; Vertica recognizes any combination of lowercase and uppercase letters.

Some examples of valid WKTs are:

WKT Example	Description
POINT(1 2)	The point (1,2)
MULTIPOINT(0 0,1 1)	A set made up of the points (0,0) and (1,1)
LINSTRING(1.5 2.45,3.21 4)	The line from the point (1.5,2.45) to the point (3.21,4)
MULTILINESTRING((0 0,-1 -2,-3 -4),(2 3,3 4,6 7))	Two linestrings, one that passes through (0,0), (-1,-2), and (-3,-4), and one that passes through (2,3), (3,4), and (6,7).
POLYGON((1 2,1 4,3 4,3 2,1 2))	The rectangle whose four corners are indicated by (1,2), (1,4), (3,4), and (3,2). A polygon must be closed, so the first and last points in the WKT must match.
POLYGON((0.5 0.5,5 0,5 0 5,0 5,0.5 0.5), (1.5 1,4 3,4 1,1.5 1))	A polygon (0.5 0.5,5 0,5 0 5,0.5 0.5) with a hole in it (1.5 1,4 3,4 1,1.5 1).
MULTIPOLYGON(((0 1,3 0,4 3,0 4,0 1)), ((3 4,6 3,5 5,3 4)), ((0 0,-1 -2,-3 -2,-2 -1,0 0)))	A set of three polygons
GEOMETRYCOLLECTION(POINT (5 8), LINSTRING(-1 3,1 4))	A set containing the point (5,8) and the line from (-1,3) to (1,4)
POINT EMPTY MULTIPOINT EMPTY LINSTRING EMPTY MULTILINESTRING EMPTY MULTILINESTRING(EMPTY) POLYGON EMPTY POLYGON(EMPTY) MULTIPOLYGON EMPTY MULTIPOLYGON(EMPTY)	Empty spatial objects; empty objects have no points.

Invalid WKTs are:

- POINT(1 NAN), POINT(1 INF)—Coordinates must be numbers.
- POLYGON((1 2, 1 4, 3 4, 3 2))—A polygon must be closed.
- POLYGON((1 4, 2 4))—A linestring is not a valid polygon.

Well-Known Binary (WKB)

Well-Known Binary (WKB) is a binary representation of a spatial object. This format is primarily used to port spatial data between applications.

Spatial Definitions

The OGC defines properties that describe

- Characteristics of spatial objects
- Spatial relationships that can exist among objects

Vertica provides functions that test for and analyze the following properties and relationships.

Boundary

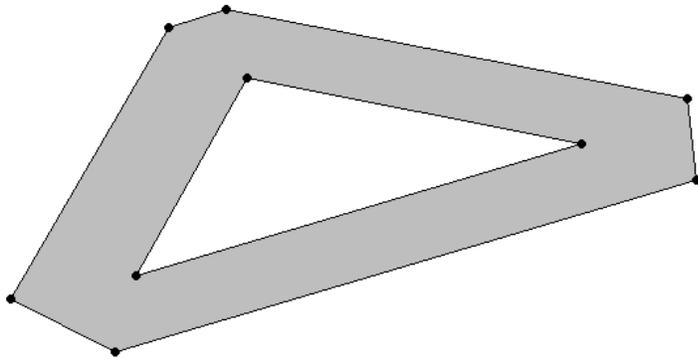

The set of points that define the limit of a spatial object:

- Points, multipoints, and geometrycollections do not have boundaries.
- The boundary of a linestring is a multipoint object. This object contains its start and end points.
- The boundary of a multilinestring is a multipoint object. This object contains the start and end points of all the linestrings that make up the multilinestring.
- The boundary of a polygon is a linestring that begins and ends at the same point. If the polygon has one or more holes, the boundary is a multilinestring that contains the boundaries of the exterior polygon and any interior polygons.
- The boundary of a multipolygon is a multilinestring that contains the boundaries of all the polygons that make up the multipolygon.

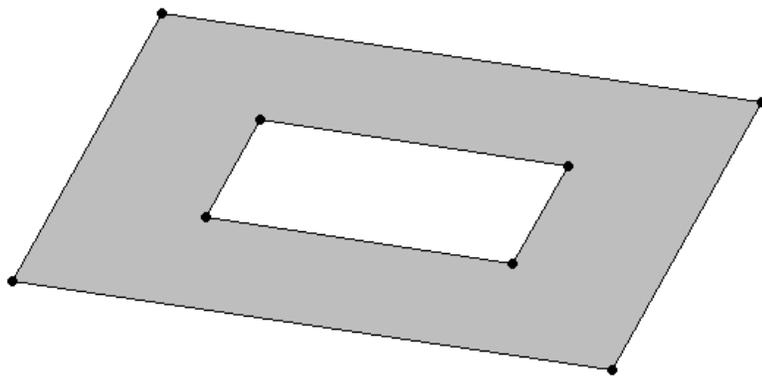

Buffer

The set of all points that are within or equal to a specified distance from the boundary of a spatial object. The distance can be positive or negative.

Positive buffer:

Negative buffer:

Contains

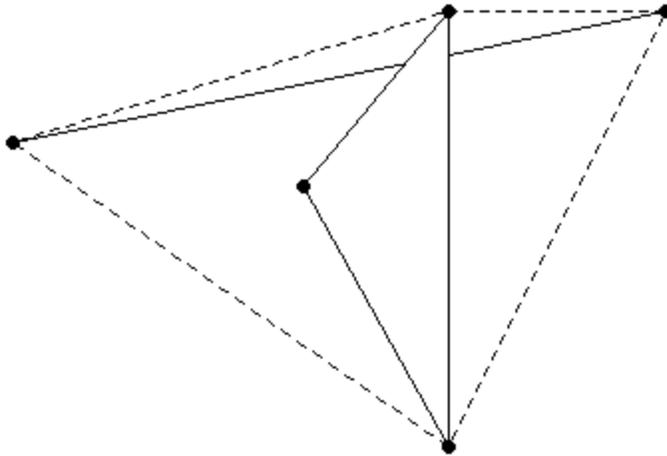

One spatial object contains another spatial object if its interior includes all points of the other object. If an object such as a point or linestring only exists along a polygon's boundary, the polygon does not contain it. If a point is on a linestring, the linestring contains it; the interior of a linestring is all the points on the linestring *except* the start and end points.

Contains(a, b) is spatially equivalent to within(b, a).

Convex Hull

The smallest convex polygon that contains one or more spatial objects.

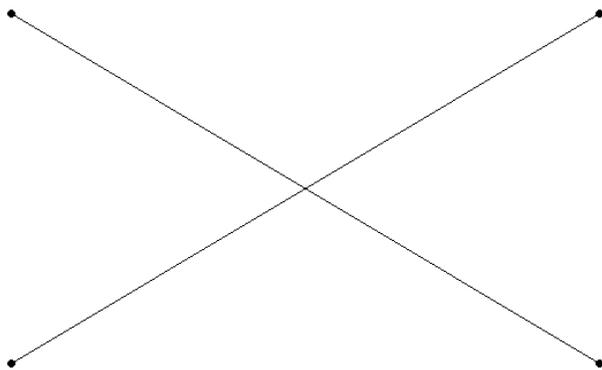

In the following figure, the dotted lines represent the convex hull for a linestring and a triangle.

Crosses

Two spatial objects cross if both of the following are true:

- The two objects have some but not all interior points in common.
- The dimension of the result of their intersection is less than the maximum dimension of the two objects.

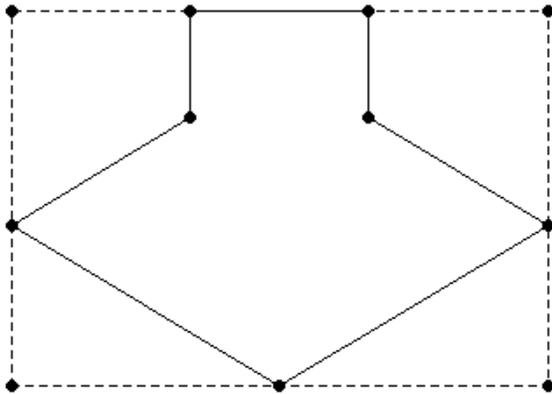

Disjoint

Two spatial objects have no points in common; they do not intersect or touch.

Envelope

The minimum bounding rectangle that contains a spatial object.

The envelope for the following polygon is represented by the dotted lines in the following figure.

Equals

Two spatial objects are equal when their coordinates match exactly. Synonymous with *spatially equivalent*.

The order of the points do not matter in determining spatial equivalence:

- `LINestring(1 2, 4 3)` equals `LINestring(4 3, 1 2)`.
- `POLYGON ((0 0, 1 1, 1 2, 2 2, 2 1, 3 0, 1.5 -1.5, 0 0))` equals `POLYGON((1 1, 1 2, 2 2, 2 1, 3 0, 1.5 -1.5, 0 0, 1 1))`.
- `MULTILINESTRING((1 2, 4 3),(0 0, -1 -4))` equals `MULTILINESTRING((0 0, -1 -4),(1 2, 4 3))`.

Exterior

The set of points not contained within a spatial object nor on its boundary.

GeometryCollection

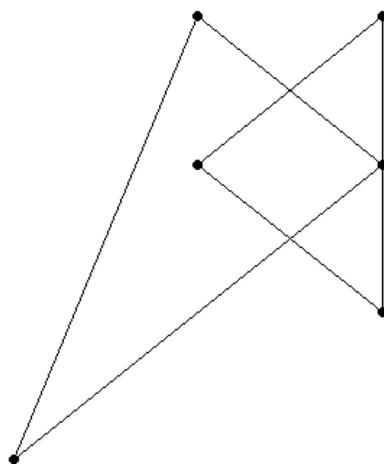

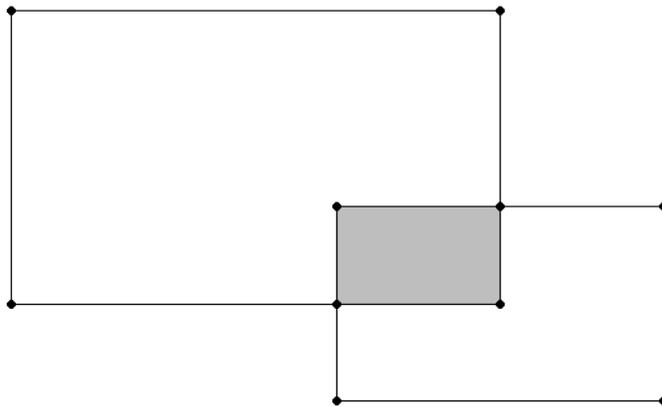

A set of zero or more objects from any of the supported classes of spatial objects.

Interior

The set of points contained in a spatial object, excluding its boundary.

Intersection

The set of points that two or more spatial objects have in common.

Overlaps

If a spatial object shares space with another object, but is not contained within that object, the objects overlap. The objects must overlap at their interiors; if two objects touch at a single point or intersect only along a boundary, they do not overlap.

Relates

When a spatial object is spatially related to another object as defined by a DE-9IM pattern matrix string.

A DE-9IM pattern matrix string identifies how two spatial objects are spatially related to each other. For more information about the DE-9IM standard, see [Understanding Spatial Relations](#).

Simple

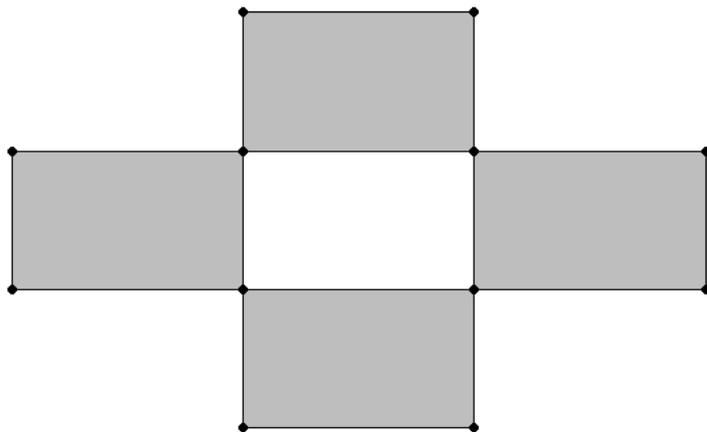

For points, multipoints, linestrings, or multilinestrings, a spatial object is simple if it does not intersect itself or has no self-tangency points.

Polygons, multipolygons, and geometrycollections are always simple.

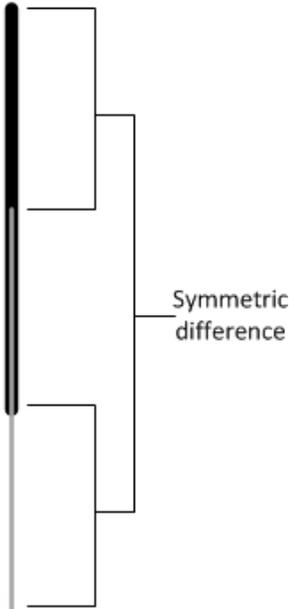

Symmetric Difference

The set of all points of a pair of spatial objects where the objects do not intersect. This difference is spatially equivalent to the union of the two objects less their intersection. The symmetric difference contains the boundaries of the intersections.

In the following figure, the shaded areas represent the symmetric difference of the two rectangles.

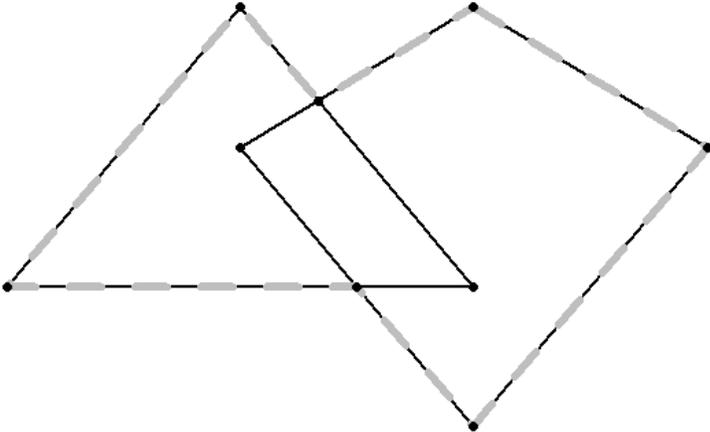

The following figure shows the symmetric difference of two overlapping linestrings.

Union

For two or more spatial objects, the set of all points in all the objects.

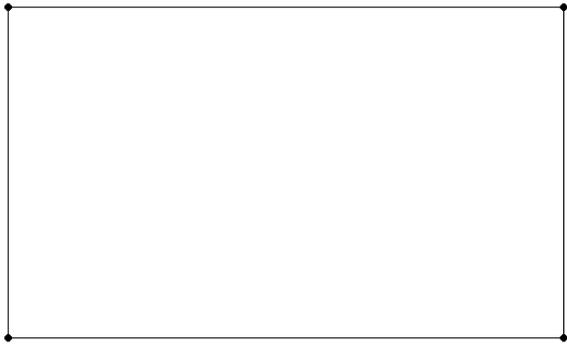

Validity

For a polygon or multipolygon, when all of the following are true:

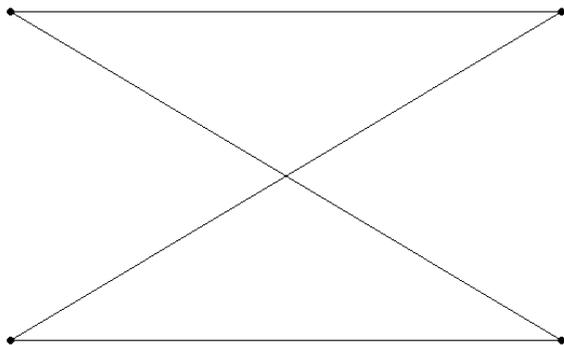

- It is closed; its start point is the same as its end point.
- Its boundary is a set of linestrings.

- No two linestrings in the boundary cross. The linestrings in the boundary may touch at a point but they cannot cross.
- Any polygons in the interior must be completely contained; they cannot touch the boundary of the exterior polygon *except* at a vertex.

Valid polygons:

Invalid polygon:

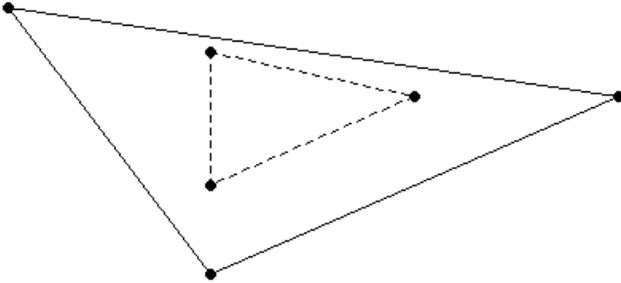

Within

A spatial object is considered within another spatial object when all its points are inside the other object's interior. Thus, if a point or linestring only exists along a polygon's boundary, it is not considered within the polygon. The polygon boundary is not part of its interior.

If a point is on a linestring, it is considered within the linestring. The interior of a linestring is all the points along the linestring, except the start and end points.

`Within(a, b)` is spatially equivalent to `contains(b, a)`.

Spatial Data Type Support Limitations

Vertica does not support all types of GEOMETRY and GEOGRAPHY objects. See the respective function page for a list of objects that function supports. Spherical geometry is generally more complex than Euclidean geometry. Thus, there are fewer spatial functions that support the GEOGRAPHY data type.

Limitations of spatial data type support:

- A non-WGS84 GEOGRAPHY object is a spatial object defined on the surface of a perfect sphere of radius 6371 kilometers. This sphere approximates the shape of the earth. Other spatial programs may use an ellipsoid to model the earth, resulting in slightly different data.
- You cannot modify the size or data type of a GEOMETRY or GEOGRAPHY column after creation.
- You cannot import data to or export data from tables that contain spatial data from another Vertica database.
- You can only use the STV_Intersect functions with points and polygons.
- GEOGRAPHY objects of type GEOMETRYCOLLECTION are not supported.
- Values for longitude must be between -180 and +180 degrees. Values for latitude must be between -90 and +90 degrees. The Vertica geospatial functions do not validate these values.
- GEOMETRYCOLLECTION objects cannot contain empty objects. For example, you cannot specify `GEOMETRYCOLLECTION (LINESTRING(1 2, 3 4), POINT(5 6), POINT EMPTY)`.
- If you pass a spatial function a NULL geometry, the function returns NULL, unless otherwise specified. A result of NULL has no value.

- Polymorphic functions, such as NVL and GREATEST, do not accept GEOMETRY and GEOGRAPHY arguments.

Time Series Analytics

Time series analytics evaluate the values of a given set of variables over time and group those values into a window (based on a time interval) for analysis and aggregation. Common scenarios for using time series analytics include: stock market trades and portfolio performance changes over time, and charting trend lines over data.

Since both time and the state of data within a time series are continuous, it can be challenging to evaluate SQL queries over time. Input records often occur at non-uniform intervals, which can create gaps. To solve this problem Vertica provides:

- Gap-filling functionality, which fills in missing data points
- Interpolation scheme, which constructs new data points within the range of a discrete set of known data points.

Vertica interpolates the non-time series columns in the data (such as analytic function results computed over time slices) and adds the missing data points to the output. This section describes gap filling and interpolation in detail.

You can use [event-based windows](#) to break time series data into windows that border on significant events within the data. This is especially relevant in financial data, where analysis might focus on specific events as triggers to other activity.

[Sessionization](#) is a special case of event-based windows that is frequently used to analyze click streams, such as identifying web browsing sessions from recorded web clicks.

Vertica provides additional support for time series analytics with the following SQL extensions:

- [TIMESERIES clause](#) in a SELECT statement supports gap-filling and interpolation (GFI) computation.
- [TS_FIRST_VALUE](#) and [TS_LAST_VALUE](#) are time series aggregate functions that return the value at the start or end of a time slice, respectively, which is determined by the interpolation scheme.
- [TIME_SLICE](#) is a (SQL extension) date/time function that aggregates data by different fixed-time intervals and returns a rounded-up input `TIMESTAMP` value to a value that corresponds with the start or end of the time slice interval.

See Also

- [SQL Analytics](#)
- [Event-Based Windows](#)
- [Sessionization with Event-Based Windows](#)

Gap Filling and Interpolation (GFI)

The examples and graphics that explain the concepts in this topic use the following simple schema:

```
CREATE TABLE TickStore (ts TIMESTAMP, symbol VARCHAR(8), bid FLOAT);
INSERT INTO TickStore VALUES ('2009-01-01 03:00:00', 'XYZ', 10.0);
INSERT INTO TickStore VALUES ('2009-01-01 03:00:05', 'XYZ', 10.5);
COMMIT;
```

In Vertica, time series data is represented by a sequence of rows that conforms to a particular table schema, where one of the columns stores the time information.

Both time and the state of data within a time series are continuous. Thus, evaluating SQL queries over time can be challenging because input records usually occur at non-uniform intervals and can contain gaps.

For example, the following table contains two input rows five seconds apart: 3:00:00 and 3:00:05.

```
=> SELECT * FROM TickStore;
      ts          | symbol | bid
-----+-----+----
2009-01-01 03:00:00 | XYZ   | 10
2009-01-01 03:00:05 | XYZ   | 10.5
(2 rows)
```

Given those two inputs, how can you determine a bid price that falls between the two points, such as at 3:00:03 PM?

The [TIME_SLICE](#) function normalizes timestamps into corresponding time slices; however, [TIME_SLICE](#) does not solve the problem of missing inputs (time slices) in the data. Instead, Vertica provides gap-filling and interpolation (GFI) functionality, which fills in missing data points and adds new (missing) data points within a range of known data points to the output. It accomplishes these tasks with [time series aggregate functions](#) and the SQL [TIMESERIES Clause](#).

But first, we'll illustrate the components that make up gap filling and interpolation in Vertica, starting with [Constant Interpolation](#).

The images in the following topics use the following legend:

- The x-axis represents the timestamp (ts) column
- The y-axis represents the bid column.
- The vertical blue lines delimit the time slices.

- The red dots represent the input records in the table, \$10.0 and \$10.5.
- The blue stars represent the output values, including interpolated values.

Constant Interpolation

Given known input timestamps at 03:00:00 and 03:00:05 in the [sample TickStore schema](#), how might you determine the bid price at 03:00:03?

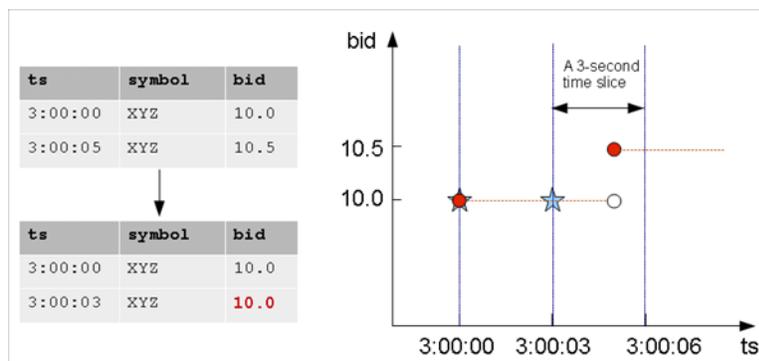

A common interpolation scheme used on financial data is to set the bid price to *the last seen value so far*. This scheme is referred to as **constant interpolation**, in which Vertica computes a new value based on the previous input records.

Note: Constant is Vertica's default interpolation scheme. Another interpolation scheme, [linear](#), is discussed in an upcoming topic.

Returning to the problem query, here is the table output, which shows a 5-second lag between bids at 03:00:00 and 03:00:05:

```
=> SELECT * FROM TickStore;
      ts          | symbol | bid
-----+-----+----
2009-01-01 03:00:00 | XYZ   | 10
2009-01-01 03:00:05 | XYZ   | 10.5
(2 rows)
```

Using constant interpolation, the interpolated bid price of XYZ remains at \$10.0 at 3:00:03, which falls between the two known data inputs (3:00:00 PM and 3:00:05). At 3:00:05, the value changes to \$10.5. The known data points are represented by a red dot, and the interpolated value at 3:00:03 is represented by the blue star.

In order to write a query that makes the input rows more uniform, you first need to understand the [TIMESERIES clause and time series aggregate functions](#).

TIMESERIES Clause and Aggregates

The SELECT..TIMESERIES clause and time series aggregates help solve the problem of gaps in input records by normalizing the data into 3-second time slices and interpolating the bid price when it finds gaps.

TIMESERIES Clause

The [TIMESERIES Clause](#) is an important component of time series analytics computation. It performs gap filling and interpolation (GFI) to generate time slices missing from the input records. The clause applies to the timestamp columns/expressions in the data, and takes the following form:

```
TIMESERIES slice_time AS 'length_and_time_unit_expression'  
OVER ( ... [ window-partition-clause[ , ... ] ]  
... ORDER BY time_expression )  
... [ ORDER BY table_column [ , ... ] ]
```

Note: The TIMESERIES clause requires an ORDER BY operation on the timestamp column.

Time Series Aggregate Functions

[Timeseries Aggregate \(TSA\) functions](#) evaluate the values of a given set of variables over time and group those values into a window for analysis and aggregation.

TSA functions process the data that belongs to each time slice. One output row is produced per time slice or per partition per time slice if a partition expression is present.

The following table shows 3-second time slices where:

- The first two rows fall within the first time slice, which runs from 3:00:00 to 3:00:02. These are the input rows for the TSA function's output for the time slice starting at 3:00:00.
- The second two rows fall within the second time slice, which runs from 3:00:03 to 3:00:05. These are the input rows for the TSA function's output for the time slice starting at 3:00:03.

The result is the start of each time slice.

ts	symbol	bid		ts	symbol	bid
3:00:00	XYZ	10.0		3:00:00	XYZ	10.0
3:00:01	XYZ	10.1		3:00:03	XYZ	10.1
3:00:04	XYZ	10.3				
3:00:05	XYZ	10.5				

Examples

The following examples compare the values returned with and without the `TS_FIRST_VALUE` TSA function.

This example shows the `TIMESERIES` clause without the `TS_FIRST_VALUE` TSA function.

```
=> SELECT slice_time, bid FROM TickStore TIMESERIES slice_time AS '3 seconds' OVER(PARTITION by TickStore.bid ORDER BY ts);
```

This example shows both the `TIMESERIES` clause and the `TS_FIRST_VALUE` TSA function. The query returns the values of the `bid` column, as determined by the specified constant interpolation scheme.

```
=> SELECT slice_time, TS_FIRST_VALUE(bid, 'CONST') bid FROM TickStore TIMESERIES slice_time AS '3 seconds' OVER(PARTITION by symbol ORDER BY ts);
```

Vertica interpolates the last known value and fills in the missing datapoint, returning 10 at 3:00:03:

First query		Interpolated value
<pre> slice_time bid -----+----- 2009-01-01 03:00:00 10 2009-01-01 03:00:03 10.5 (2 rows) </pre>	==>	<pre> slice_time bid -----+----- 2009-01-01 03:00:00 10 2009-01-01 03:00:03 10 (2 rows) </pre>

Time Series Rounding

Vertica calculates all time series as equal intervals relative to the timestamp `2000-01-01 00:00:00`. Vertica rounds time series timestamps as needed, to conform with this baseline. Start times are also rounded down to the nearest whole unit for the specified interval.

Given this logic, the `TIMESERIES` clause generates series of timestamps as described in the following sections.

Minutes

Time series of minutes are rounded down to full minutes. For example, the following statement specifies a time span of 00:00:03 - 00:05:50:

```
=> SELECT ts FROM (  
  SELECT '2015-01-04 00:00:03'::TIMESTAMP AS tm  
  UNION  
  SELECT '2015-01-04 00:05:50'::TIMESTAMP AS tm  
) t  
TIMESERIES ts AS '1 minute' OVER (ORDER BY tm);
```

Vertica rounds down the time series start and end times to full minutes, 00:00:00 and 00:05:00, respectively:

```
      ts  
-----  
2015-01-04 00:00:00  
2015-01-04 00:01:00  
2015-01-04 00:02:00  
2015-01-04 00:03:00  
2015-01-04 00:04:00  
2015-01-04 00:05:00  
(6 rows)
```

Weeks

Because the baseline timestamp 2000-01-01 00:00:00 is a Saturday, all time series of weeks start on Saturday. Vertica rounds down the series start and end timestamps accordingly. For example, the following statement specifies a time span of 12/10/99 - 01/10/00:

```
=> SELECT ts FROM (  
  SELECT '1999-12-10 00:00:00'::TIMESTAMP AS tm  
  UNION  
  SELECT '2000-01-10 23:59:59'::TIMESTAMP AS tm  
) t  
TIMESERIES ts AS '1 week' OVER (ORDER BY tm);
```

The specified time span starts on Friday (12/10/99), so Vertica starts the time series on the preceding Saturday, 12/04/99. The time series ends on the last Saturday within the time span, 01/08/00:

```
      ts  
-----  
1999-12-04 00:00:00  
1999-12-11 00:00:00  
1999-12-18 00:00:00
```

```
1999-12-25 00:00:00
2000-01-01 00:00:00
2000-01-08 00:00:00
(6 rows)
```

Months

Time series of months are divided into equal 30-day intervals, relative to the baseline timestamp `2000-01-01 00:00:00`. For example, the following statement specifies a time span of `09/01/99 - 12/31/00`:

```
=> SELECT ts FROM (
  SELECT '1999-09-01 00:00:00'::TIMESTAMP AS tm
  UNION
  SELECT '2000-12-31 23:59:59'::TIMESTAMP AS tm
) t
TIMESERIES ts AS '1 month' OVER (ORDER BY tm);
```

Vertica generates a series of 30-day intervals, where each timestamp is rounded up or down, relative to the baseline timestamp:

```
      ts
-----
1999-08-04 00:00:00
1999-09-03 00:00:00
1999-10-03 00:00:00
1999-11-02 00:00:00
1999-12-02 00:00:00
2000-01-01 00:00:00
2000-01-31 00:00:00
2000-03-01 00:00:00
2000-03-31 00:00:00
2000-04-30 00:00:00
2000-05-30 00:00:00
2000-06-29 00:00:00
2000-07-29 00:00:00
2000-08-28 00:00:00
2000-09-27 00:00:00
2000-10-27 00:00:00
2000-11-26 00:00:00
2000-12-26 00:00:00
(18 rows)
```

Years

Time series of years are divided into equal 365-day intervals. If a time span overlaps leap years since or before the baseline timestamp `2000-01-01 00:00:00`, Vertica rounds the series timestamps accordingly.

For example, the following statement specifies a time span of 01/01/95 - 05/08/09, which overlaps four leap years, including the baseline timestamp:

```
=> SELECT ts FROM (  
    SELECT '1995-01-01 00:00:00'::TIMESTAMP AS tm  
    UNION  
    SELECT '2009-05-08'::TIMESTAMP AS tm  
  ) t timeseries ts AS '1 year' over (ORDER BY tm);
```

Vertica generates a series of timestamps that are rounded up or down, relative to the baseline timestamp:

```
      ts  
-----  
1994-01-02 00:00:00  
1995-01-02 00:00:00  
1996-01-02 00:00:00  
1997-01-01 00:00:00  
1998-01-01 00:00:00  
1999-01-01 00:00:00  
2000-01-01 00:00:00  
2000-12-31 00:00:00  
2001-12-31 00:00:00  
2002-12-31 00:00:00  
2003-12-31 00:00:00  
2004-12-30 00:00:00  
2005-12-30 00:00:00  
2006-12-30 00:00:00  
2007-12-30 00:00:00  
2008-12-29 00:00:00  
(16 rows)
```

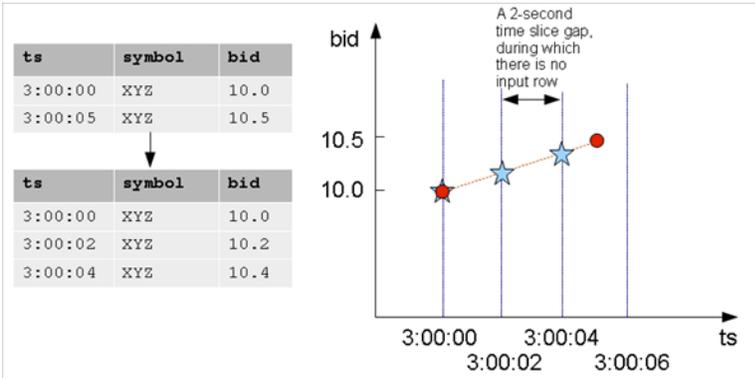

Linear Interpolation

Instead of interpolating data points based on the last seen value ([Constant Interpolation](#)), linear interpolation is where Vertica interpolates values in a linear slope based on the specified time slice.

The query that follows uses linear interpolation to place the input records in 2-second time slices and return the first bid value for each symbol/time slice combination (the value at the start of the time slice):

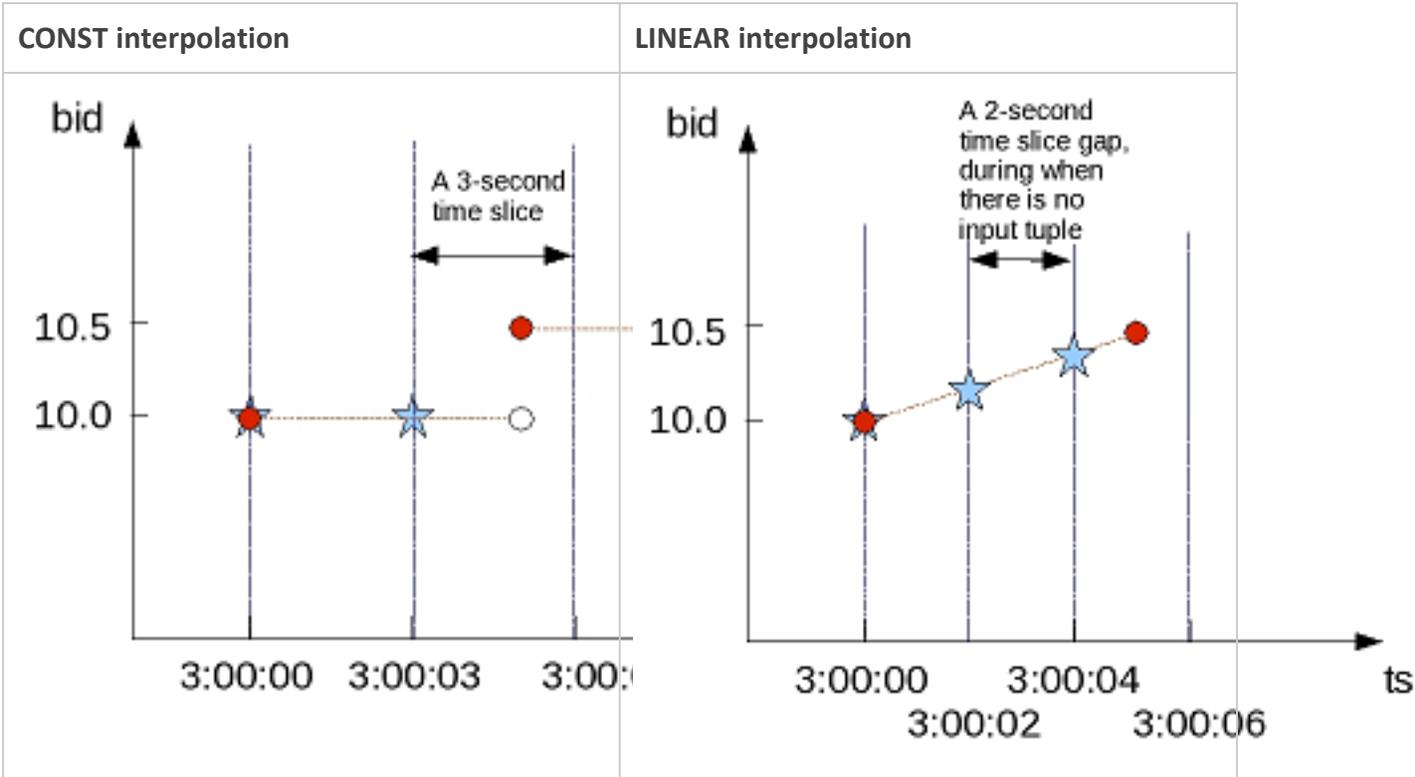

```
=> SELECT slice_time, TS_FIRST_VALUE(bid, 'LINEAR') bid FROM Tickstore  
    TIMESERIES slice_time AS '2 seconds' OVER(PARTITION BY symbol ORDER BY ts);  
    slice_time      | bid  
-----+-----  
2009-01-01 03:00:00 | 10  
2009-01-01 03:00:02 | 10.2  
2009-01-01 03:00:04 | 10.4  
(3 rows)
```

The following figure illustrates the previous query results, showing the 2-second time gaps (3:00:02 and 3:00:04) in which no input record occurs. Note that the interpolated bid price of XYZ changes to 10.2 at 3:00:02 and 10.3 at 3:00:03 and 10.4 at 3:00:04, all of which fall between the two known data inputs (3:00:00 and 3:00:05). At 3:00:05, the value would change to 10.5.

Note: The known data points above are represented by a red dot, and the interpolated values are represented by blue stars.

The following is a side-by-side comparison of constant and linear interpolation schemes.

GFI Examples

This topic illustrates some of the queries you can write using the constant and linear interpolation schemes.

Constant Interpolation

The first query uses `TS_FIRST_VALUE()` and the `TIMESERIES Clause` to place the input records in 3-second time slices and return the first bid value for each symbol/time slice combination (the value at the start of the time slice).

Note: The `TIMESERIES` clause requires an `ORDER BY` operation on the `TIMESTAMP` column.

```
=> SELECT slice_time, symbol, TS_FIRST_VALUE(bid) AS first_bid FROM TickStore
      TIMESERIES slice_time AS '3 seconds' OVER (PARTITION BY symbol ORDER BY ts);
```

Because the bid price of stock XYZ is 10.0 at 3:00:03, the `first_bid` value of the second time slice, which starts at 3:00:03 is till 10.0 (instead of 10.5) because the input value of 10.5 does not occur until 3:00:05. In this case, the interpolated value is inferred from the last value seen on stock XYZ for time 3:00:03:

slice_time	symbol	first_bid
2009-01-01 03:00:00	XYZ	10
2009-01-01 03:00:03	XYZ	10

(2 rows)

The next example places the input records in 2-second time slices to return the first bid value for each symbol/time slice combination:

```
=> SELECT slice_time, symbol, TS_FIRST_VALUE(bid) AS first_bid FROM TickStore
      TIMESERIES slice_time AS '2 seconds' OVER (PARTITION BY symbol ORDER BY ts);
```

The result now contains three records in 2-second increments, all of which occur between the first input row at 03:00:00 and the second input row at 3:00:05. Note that the second and third output record correspond to a time slice where there is no input record:

slice_time	symbol	first_bid
2009-01-01 03:00:00	XYZ	10
2009-01-01 03:00:02	XYZ	10
2009-01-01 03:00:04	XYZ	10

(3 rows)

Using the same table schema, the next query uses `TS_LAST_VALUE()`, with the `TIMESERIES` clause to return the last values of each time slice (the values at the end of the time slices).

Note: Time series aggregate functions process the data that belongs to each time slice. One output row is produced per time slice or per partition per time slice if a partition expression is present.

```
=> SELECT slice_time, symbol, TS_LAST_VALUE(bid) AS last_bid FROM TickStore
      TIMESERIES slice_time AS '2 seconds' OVER (PARTITION BY symbol ORDER BY ts);
```

Notice that the last value output row is 10.5 because the value 10.5 at time 3:00:05 was the last point inside the 2-second time slice that started at 3:00:04:

slice_time	symbol	last_bid
2009-01-01 03:00:00	XYZ	10
2009-01-01 03:00:02	XYZ	10
2009-01-01 03:00:04	XYZ	10.5

(3 rows)

Remember that because constant interpolation is the default, the same results are returned if you write the query using the `CONST` parameter as follows:

```
=> SELECT slice_time, symbol, TS_LAST_VALUE(bid, 'CONST') AS last_bid FROM TickStore
      TIMESERIES slice_time AS '2 seconds' OVER (PARTITION BY symbol ORDER BY ts);
```

Linear Interpolation

Based on the same input records described in the constant interpolation examples, which specify 2-second time slices, the result of `TS_LAST_VALUE` with linear interpolation is as follows:

```
=> SELECT slice_time, symbol, TS_LAST_VALUE(bid, 'linear') AS last_bid FROM TickStore
      TIMESERIES slice_time AS '2 seconds' OVER (PARTITION BY symbol ORDER BY ts);
```

In the results, no `last_bid` value is returned for the last row because the query specified `TS_LAST_VALUE`, and there is no data point after the 3:00:04 time slice to interpolate.

slice_time	symbol	last_bid
2009-01-01 03:00:00	XYZ	10.2
2009-01-01 03:00:02	XYZ	10.4
2009-01-01 03:00:04	XYZ	

(3 rows)

Using Multiple Time Series Aggregate Functions

Multiple time series aggregate functions can exist in the same query. They share the same *gap-filling* policy as defined in the `TIMESERIES` clause; however, each time series aggregate function can specify its own interpolation policy. In the following example, there are two constant and one linear interpolation schemes, but all three functions use a three-second time slice:

```
=> SELECT slice_time, symbol,
        TS_FIRST_VALUE(bid, 'const') fv_c,
        TS_FIRST_VALUE(bid, 'linear') fv_l,
        TS_LAST_VALUE(bid, 'const') lv_c
FROM TickStore
TIMESERIES slice_time AS '3 seconds' OVER(PARTITION BY symbol ORDER BY ts);
```

In the following output, the original output is compared to output returned by multiple time series aggregate functions.

ts	symbol	bid	==>	slice_time	symbol	fv_c	fv_l	lv_c
03:00:00	XYZ	10		2009-01-01 03:00:00	XYZ	10	10	10
03:00:05	XYZ	10.5		2009-01-01 03:00:03	XYZ	10	10.3	10.5
(2 rows)				(2 rows)				

Using the Analytic LAST_VALUE Function

Here's an example using `LAST_VALUE()`, so you can see the difference between it and the GFI syntax.

```
=> SELECT *, LAST_VALUE(bid) OVER(PARTITION by symbol ORDER BY ts)
AS "last bid" FROM TickStore;
```

There is no gap filling and interpolation to the output values.

```
ts | symbol | bid | last bid
-----+-----+-----+-----
2009-01-01 03:00:00 | XYZ | 10 | 10
2009-01-01 03:00:05 | XYZ | 10.5 | 10.5
(2 rows)
```

Using slice_time

In a `TIMESERIES` query, you cannot use the column `slice_time` in the `WHERE` clause because the `WHERE` clause is evaluated before the `TIMESERIES` clause, and the `slice_time` column is

not generated until the `TIMESERIES` clause is evaluated. For example, Vertica does not support the following query:

```
=> SELECT symbol, slice_time, TS_FIRST_VALUE(bid IGNORE NULLS) AS fv
FROM TickStore
WHERE slice_time = '2009-01-01 03:00:00'
TIMESERIES slice_time as '2 seconds' OVER (PARTITION BY symbol ORDER BY ts);
ERROR: Time Series timestamp alias/Time Series Aggregate Functions not allowed in WHERE clause
```

Instead, you could write a subquery and put the predicate on `slice_time` in the outer query:

```
=> SELECT * FROM (
  SELECT symbol, slice_time,
    TS_FIRST_VALUE(bid IGNORE NULLS) AS fv
  FROM TickStore
  TIMESERIES slice_time AS '2 seconds'
  OVER (PARTITION BY symbol ORDER BY ts) ) sq
WHERE slice_time = '2009-01-01 03:00:00';
symbol | slice_time | fv
-----+-----+-----
XYZ | 2009-01-01 03:00:00 | 10
(1 row)
```

Creating a Dense Time Series

The `TIMESERIES` clause provides a convenient way to create a dense time series for use in an outer join with fact data. The results represent every time point, rather than just the time points for which data exists.

The examples that follow use the same `TickStore` schema described in [Gap Filling and Interpolation \(GFI\)](#), along with the addition of a new inner table for the purpose of creating a join:

```
=> CREATE TABLE inner_table (
  ts TIMESTAMP,
  bid FLOAT
);
=> CREATE PROJECTION inner_p (ts, bid) as SELECT * FROM inner_table
ORDER BY ts, bid UNSEGMENTED ALL NODES;
=> INSERT INTO inner_table VALUES ('2009-01-01 03:00:02', 1);
=> INSERT INTO inner_table VALUES ('2009-01-01 03:00:04', 2);
=> COMMIT;
```

You can create a simple union between the start and end range of the timeframe of interest in order to return every time point. This example uses a 1-second time slice:

```
=> SELECT ts FROM (
  SELECT '2009-01-01 03:00:00'::TIMESTAMP AS time FROM TickStore
  UNION
  SELECT '2009-01-01 03:00:05'::TIMESTAMP FROM TickStore) t
TIMESERIES ts AS '1 seconds' OVER(ORDER BY time);
```

```

      ts
-----
2009-01-01 03:00:00
2009-01-01 03:00:01
2009-01-01 03:00:02
2009-01-01 03:00:03
2009-01-01 03:00:04
2009-01-01 03:00:05
(6 rows)

```

The next query creates a union between the start and end range of the timeframe using 500-millisecond time slices:

```

=> SELECT ts FROM (
      SELECT '2009-01-01 03:00:00'::TIMESTAMP AS time
      FROM TickStore
      UNION
      SELECT '2009-01-01 03:00:05'::TIMESTAMP FROM TickStore) t
      TIMESERIES ts AS '500 milliseconds' OVER(ORDER BY time);
      ts
-----
2009-01-01 03:00:00
2009-01-01 03:00:00.5
2009-01-01 03:00:01
2009-01-01 03:00:01.5
2009-01-01 03:00:02
2009-01-01 03:00:02.5
2009-01-01 03:00:03
2009-01-01 03:00:03.5
2009-01-01 03:00:04
2009-01-01 03:00:04.5
2009-01-01 03:00:05
(11 rows)

```

The following query creates a union between the start- and end-range of the timeframe of interest using 1-second time slices:

```

=> SELECT * FROM (
      SELECT ts FROM (
        SELECT '2009-01-01 03:00:00'::timestamp AS time FROM TickStore
        UNION
        SELECT '2009-01-01 03:00:05'::timestamp FROM TickStore) t
        TIMESERIES ts AS '1 seconds' OVER(ORDER BY time) ) AS outer_table
      LEFT OUTER JOIN inner_table ON outer_table.ts = inner_table.ts;

```

The union returns a complete set of records from the left-joined table with the matched records in the right-joined table. Where the query found no match, it extends the right side column with null values:

```

      ts          |          ts          | bid
-----+-----+-----
2009-01-01 03:00:00 |          |
2009-01-01 03:00:01 |          |
2009-01-01 03:00:02 | 2009-01-01 03:00:02 | 1

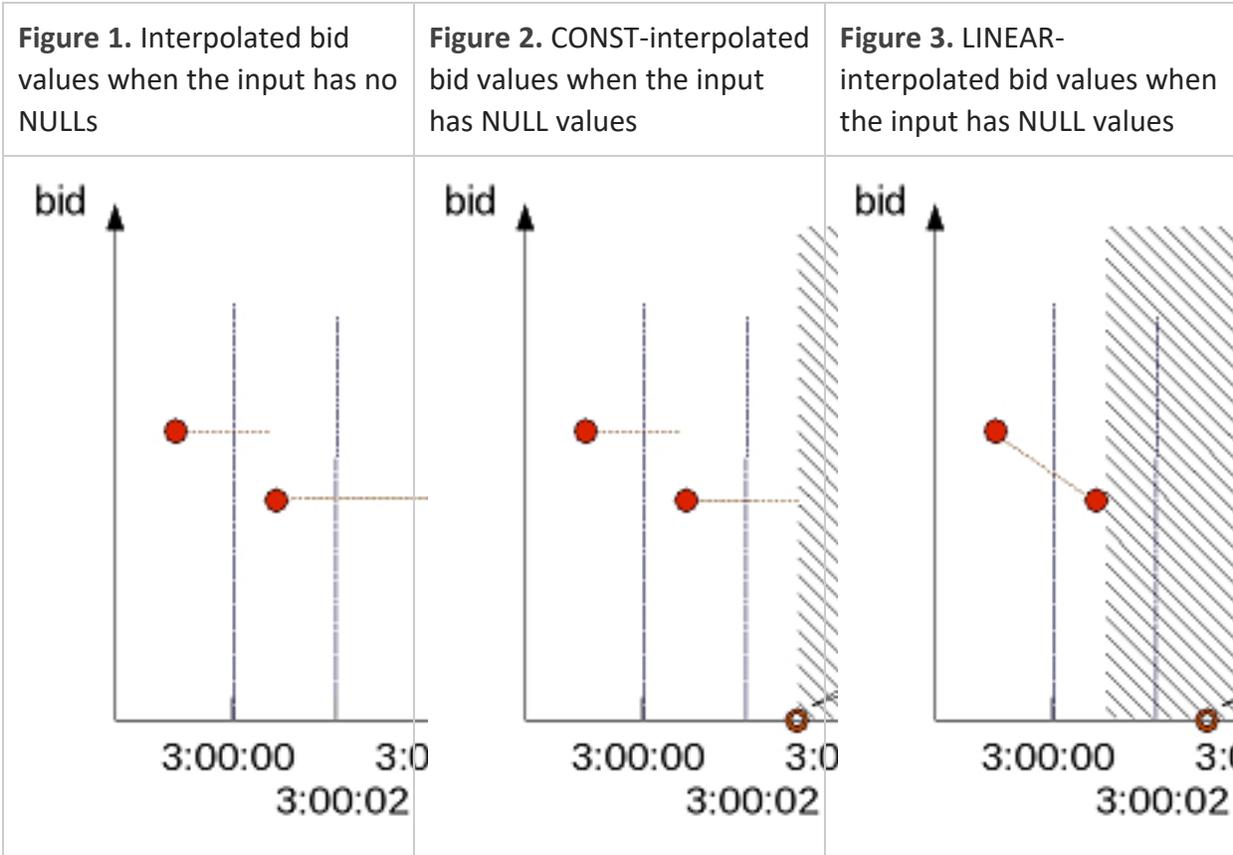

```

```
2009-01-01 03:00:03 | | |  
2009-01-01 03:00:04 | 2009-01-01 03:00:04 | 2  
2009-01-01 03:00:05 | | |  
(6 rows)
```

Null Values in Time Series Data

Null values are not common inputs for gap-filling and interpolation (GFI) computation, but if null values do exist, you can use time series aggregate functions (TS_FIRST_VALUE/TS_LAST_VALUE) with the IGNORE NULLS arguments to affect output of the interpolated values. The TSA functions are treated similarly to their analytic counterparts (FIRST_VALUE/LAST_VALUE) in that if the timestamp itself is null Vertica filter out those rows before gap filling and interpolation occurs.

The three images below will illustrate the points that follow on how Vertica handles time series data that contains null values.

Constant Interpolation with Null Values

Figure 1 illustrates a default (constant) interpolation result on four input rows where none of the inputs contains a NULL value. Figure 2 shows the same input rows with the addition of another input record whose bid value is NULL, and whose timestamp (ts) value is 3:00:03.

For constant interpolation, the bid value starting at 3:00:03 is null until the next non-null bid value appears in time. In Figure 2, the presence of the null row makes the interpolated bid value null in the time interval denoted by the shaded region. As a result, if `TS_FIRST_VALUE (bid)` is evaluated with constant interpolation on the time slice that begins at 3:00:02, its output is non-null. However, `TS_FIRST_VALUE (bid)` on the next time slice produces null. If the last value of the 3:00:02 time slice is null, the first value for the next time slice (3:00:04) is null. However, if you were to use a TSA function with `IGNORE NULLS`, then the value at 3:00:04 would be the same value as it was at 3:00:02.

To illustrate, insert a new row into the TickStore table at 03:00:03 with a null bid value, Vertica will output a row for the 03:00:02 record with a null value but no row for the 03:00:03 input:

```
=> INSERT INTO tickstore VALUES('2009-01-01 03:00:03', 'XYZ', NULL);
=> SELECT slice_time, symbol, TS_LAST_VALUE(bid) AS last_bid FROM TickStore
-> TIMESERIES slice_time AS '2 seconds' OVER (PARTITION BY symbol ORDER BY ts);
  slice_time      | symbol | last_bid
-----+-----+-----
2009-01-01 03:00:00 | XYZ   |      10
2009-01-01 03:00:02 | XYZ   |
2009-01-01 03:00:04 | XYZ   |     10.5
(3 rows)
```

If you specify `IGNORE NULLS`, Vertica fills in the missing data point using a constant interpolation scheme. Here, the bid price at 03:00:02 is interpolated to the last known input record for bid, which was \$10 at 03:00:00:

```
=> SELECT slice_time, symbol, TS_LAST_VALUE(bid IGNORE NULLS) AS last_bid FROM TickStore
-> TIMESERIES slice_time AS '2 seconds' OVER (PARTITION BY symbol ORDER BY ts);
  slice_time      | symbol | last_bid
-----+-----+-----
2009-01-01 03:00:00 | XYZ   |      10
2009-01-01 03:00:02 | XYZ   |      10
2009-01-01 03:00:04 | XYZ   |     10.5
(3 rows)
```

Now if you were to insert a row where the timestamp column contained a null value, Vertica would filter out that row before gap filling and interpolation occurred.

```
=> INSERT INTO tickstore VALUES(NULL, 'XYZ', 11.2);
=> SELECT slice_time, symbol, TS_LAST_VALUE(bid) AS last_bid FROM TickStore
-> TIMESERIES slice_time AS '2 seconds' OVER (PARTITION BY symbol ORDER BY ts);
```

Notice there is no output for the 11.2 bid row:

```
      slice_time      | symbol | last_bid
-----+-----+-----
2009-01-01 03:00:00 | XYZ   |      10
2009-01-01 03:00:02 | XYZ   |
2009-01-01 03:00:04 | XYZ   |     10.5
(3 rows)
```

Linear Interpolation with Null Values

For linear interpolation, the interpolated bid value becomes null in the time interval, which is represented by the shaded region in Figure 3. In the presence of an input null value at 3:00:03, Vertica cannot linearly interpolate the bid value around that time point.

Vertica takes the closest non null value on either side of the time slice and uses that value. For example, if you use a linear interpolation scheme and you do not specify IGNORE NULLS, and your data has one real value and one null, the result is null. If the value on either side is null, the result is null. Therefore, to evaluate `TS_FIRST_VALUE(bid)` with linear interpolation on the time slice that begins at 3:00:02, its output is null. `TS_FIRST_VALUE(bid)` on the next time slice remains null.

```
=> SELECT slice_time, symbol, TS_FIRST_VALUE(bid, 'linear') AS fv_1 FROM TickStore
-> TIMESERIES slice_time AS '2 seconds' OVER (PARTITION BY symbol ORDER BY ts);
      slice_time      | symbol | fv_1
-----+-----+-----
2009-01-01 03:00:00 | XYZ   |      10
2009-01-01 03:00:02 | XYZ   |
2009-01-01 03:00:04 | XYZ   |
(3 rows)
```

Data Aggregation

You can use functions such as [SUM](#) and [COUNT](#) to aggregate the results of `GROUP BY` queries at one or more levels.

Aggregating Data at a Single Level

The simplest `GROUP BY` queries aggregate data at a single level. For example, a table might contain the following information about family expenses:

- Category
- Amount spent on that category during the year
- Year

Table data might look like this:

```
=> SELECT * FROM expenses ORDER BY Category;
Year | Category | Amount
-----+-----+-----
2005 | Books    | 39.98
2007 | Books    | 29.99
2008 | Books    | 29.99
2006 | Electrical | 109.99
2005 | Electrical | 109.99
2007 | Electrical | 229.98
```

You can use aggregate functions to get the total expenses per category or per year:

```
=> SELECT SUM(Amount), Category FROM expenses GROUP BY Category;
SUM      | Category
-----+-----
 99.96   | Books
449.96   | Electrical

=> SELECT SUM(Amount), Year FROM expenses GROUP BY Year;
SUM      | Year
-----+-----
149.97   | 2005
109.99   | 2006
 29.99   | 2008
259.97   | 2007
```

Aggregating Data at Multiple Levels

Over time, tables that are updated frequently can contain large amounts of data. Using the simple table shown earlier, suppose you want a multilevel query, like the number of expenses per category per year.

The following query uses the ROLLUP aggregation with the SUM function to calculate the total expenses by category and the overall expenses total. The NULL fields indicate subtotal values in the aggregation.

- When only the Year column is NULL, the subtotal is for all the Category values.
- When both the Year and Category columns are NULL, the subtotal is for all Amount values for both columns.

Using the ORDER BY clause orders the results by expense category, the year the expenses took place, and the GROUP BY level that the GROUPING_ID function creates:

```
=> SELECT Category, Year, SUM(Amount) FROM expenses
      GROUP BY ROLLUP(Category, Year) ORDER BY Category, Year, GROUPING_ID();
Category | Year | SUM
-----+-----+-----
Books    | 2005 | 39.98
Books    | 2007 | 29.99
Books    | 2008 | 29.99
Books    |      | 99.96
Electrical | 2005 | 109.99
Electrical | 2006 | 109.99
Electrical | 2007 | 229.98
Electrical |      | 449.96
         |      | 549.92
```

Similarly, the following query calculates the total sales by year and the overall sales total and then uses the ORDER BY clause to sort the results:

```
=> SELECT Category, Year, SUM(Amount) FROM expenses
      GROUP BY ROLLUP(Year, Category) ORDER BY 2, 1, GROUPING_ID();
Category | Year | SUM
-----+-----+-----
Books    | 2005 | 39.98
Electrical | 2005 | 109.99
         | 2005 | 149.97
Electrical | 2006 | 109.99
         | 2006 | 109.99
Books    | 2007 | 29.99
Electrical | 2007 | 229.98
         | 2007 | 259.97
Books    | 2008 | 29.99
```

```
      | 2008 | 29.99  
      |      | 549.92  
(11 rows)
```

You can use the CUBE aggregate to perform all possible groupings of the category and year expenses. The following query returns all possible groupings, ordered by grouping:

```
=> SELECT Category, Year, SUM(Amount) FROM expenses  
      GROUP BY CUBE(Category, Year) ORDER BY 1, 2, GROUPING_ID();  
Category | Year | SUM  
-----+-----+-----  
Books    | 2005 | 39.98  
Books    | 2007 | 29.99  
Books    | 2008 | 29.99  
Books    |      | 99.96  
Electrical | 2005 | 109.99  
Electrical | 2006 | 109.99  
Electrical | 2007 | 229.98  
Electrical |      | 449.96  
          | 2005 | 149.97  
          | 2006 | 109.99  
          | 2007 | 259.97  
          | 2008 | 29.99  
          |      | 549.92
```

The results include subtotals for each category and each year and a total (\$549.92) for all transactions, regardless of year or category.

ROLLUP, CUBE, and GROUPING SETS generate NULL values in grouping columns to identify subtotals. If table data includes NULL values, differentiating these from NULL values in subtotals can sometimes be challenging.

In the preceding output, the NULL values in the Year column indicate that the row was grouped on the Category column, rather than on both columns. In this case, ROLLUP added the NULL value to indicate the subtotal row.

To distinguish subtotal rows from NULL values that are part of the input data, use the [GROUPING](#) function.

Aggregate Expressions for GROUP BY

You can include CUBE and ROLLUP aggregates within a GROUPING SETS aggregate. Be aware that the CUBE and ROLLUP aggregates can result in a large amount of output. However, you can avoid large outputs by using GROUPING SETS to return only specified results.

```
...GROUP BY a,b,c,d,ROLLUP(a,b)...  
...GROUP BY a,b,c,d,CUBE((a,b),c,d)...
```

You cannot include any aggregates in a CUBE or ROLLUP aggregate expression.

You can append multiple GROUPING SETS, CUBE, or ROLLUP aggregates in the same query.

```
...GROUP BY a,b,c,d,CUBE(a,b),ROLLUP (c,d)...  
...GROUP BY a,b,c,d,GROUPING SETS ((a,d),(b,c),CUBE(a,b));...  
...GROUP BY a,b,c,d,GROUPING SETS ((a,d),(b,c),(a,b),(a),(b),())...
```

Aggregates and Functions for Multilevel Grouping

Vertica provides several aggregates and functions that group the results of a GROUP BY query at multiple levels.

Aggregates for Multilevel Grouping

Use the following aggregates for multilevel grouping:

- **ROLLUP** automatically performs subtotal aggregations. ROLLUP performs one or more aggregations across multiple dimensions, at different levels.
- **CUBE** performs the aggregation for all permutations of the CUBE expression that you specify.
- **GROUPING SETS** let you specify which groupings of aggregations you need.

You can use CUBE or ROLLUP expressions inside GROUPING SETS expressions. Otherwise, you cannot nest multilevel aggregate expressions.

Grouping Functions

You use one of the following three grouping functions with ROLLUP, CUBE, and GROUPING SETS:

- **GROUP_ID** returns one or more numbers, starting with zero (0), to uniquely identify duplicate sets.
- **GROUPING_ID** produces a unique ID for each grouping combination.

- **GROUPING** identifies for each grouping combination whether a column is a part of this grouping. This function also differentiates NULL values in the data from NULL grouping subtotals.

These functions are typically used with multilevel aggregates.

Pre-Aggregating Data in Projections

Queries that use aggregate functions such as **SUM** and **COUNT** can perform more efficiently when they use projections that already contain the aggregated data. This improved efficiency is especially true for queries on large quantities of data.

For example, a power grid company reads 30 million smart meters that provide data at five-minute intervals. The company records each reading in a database table. Over a given year, three trillion records are added to this table.

The power grid company can analyze these records with queries that include aggregate functions to perform the following tasks:

- Establish usage patterns.
- Detect fraud.
- Measure correlation to external events such as weather patterns or pricing changes.

To optimize query response time, you can create an aggregate projection, which stores the data is stored after it is aggregated.

Aggregate Projections

Vertica provides three types of projections for storing data that is returned from aggregate functions or expressions:

- **Projection that contains expressions:** Projection with columns whose values are calculated from anchor table columns.
- **Live aggregate projection:** Projection that contains columns with values that are aggregated from columns in its anchor table. You can also define live aggregate projections that include **user-defined transform functions**.

- **Top-K projection:** Type of live aggregate projection that returns the top k rows from a partition of selected rows. Create a Top-K projection that satisfies the criteria for a Top-K query.

Recommended Use

- Aggregate projections are most useful for queries against large sets of data.
- For optimal query performance, the size of LAP projections should be a small subset of the anchor table—ideally, between 1 and 10 percent of the anchor table, or smaller, if possible.
- Because you cannot update or delete data in tables that use aggregate projections, use aggregate projections for tables whose data is cumulative and require infrequent updates and deletions.

Requirements

- To use aggregate projections, you must set the appropriate configuration parameters (see [Enabling Live Aggregate Projections and Projections with Expressions](#)).
- In the event of manual recovery from an unclean database shutdown, live aggregate projections might require some time before they are refreshed.

Enabling Live Aggregate Projections and Projections with Expressions

To create live aggregate and Top-K projections, or projections with expressions, the following configuration parameters must be set to 1 (default setting):

Configuration Parameter	Description	Enable	Disable
EnableGroupByProjections	Enables live aggregate projections	1	0
EnableTopKProjections	Enables Top-K projections	1	0
EnableExprsInProjections	Enables projections with expressions.	1	0

To check current settings, use `SHOW CURRENT`. For example:

```
=> SHOW CURRENT EnableGroupByProjections;
 level |          name          | setting
-----+-----+-----
DEFAULT | EnableGroupByProjections | 1
(1 row)
```

Live Aggregate Projections

A live aggregate projection contains columns with values that are aggregated from columns in its anchor table. When you load data into the table, Vertica aggregates the data before loading it into the live aggregate projection. On subsequent loads—for example, through `INSERT` or `COPY`—Vertica recalculates aggregations with the new data and updates the projection.

Functions Supported for Live Aggregate Projections

Vertica can aggregate results in live aggregate projections from the following aggregate functions:

- `SUM`
- `MAX`
- `MIN`
- `COUNT`

Aggregate Functions with `DISTINCT`

Live aggregate projections can support queries that include aggregate functions qualified with the keyword `DISTINCT`. The following requirements apply:

- The aggregated expression must evaluate to a non-constant.
- The projection's `GROUP BY` clause must specify the aggregated expression.

For example, the following query uses `SUM(DISTINCT)` to calculate the total of all unique salaries in a given region:

```
SELECT customer_region, SUM(DISTINCT annual_income)::INT
FROM customer_dimension GROUP BY customer_region;
```

This query can use the following live aggregate projection, which specifies the aggregated column (`annual_income`) in its `GROUP BY` clause:

```
CREATE PROJECTION public.TotalRegionalIncome
(
  customer_region,
  annual_income,
  Count
)
AS
SELECT customer_dimension.customer_region,
       customer_dimension.annual_income,
       count(*) AS Count
FROM public.customer_dimension
GROUP BY customer_dimension.customer_region,
         customer_dimension.annual_income
;
```

Note: This projection includes the aggregate function `COUNT`, which here serves no logical objective; it is included only because live aggregate projections require at least one aggregate function.

Creating Live Aggregate Projections

You define a live aggregate projection with the following syntax:

```
=> CREATE PROJECTION proj-name AS
     SELECT select-expression FROM table
     GROUP BY group-expression;
```

For full syntax options, see [CREATE PROJECTION \(Live Aggregate Projections\)](#).

For example:

```
=> CREATE PROJECTION clicks_agg AS
     SELECT page_id, click_time::DATE click_date, COUNT(*) num_clicks FROM clicks
     GROUP BY page_id, click_time::DATE KSAFE 1;
```

For an extended discussion, see [Live Aggregate Projection Example](#).

Requirements

The following requirements apply to live aggregate projections:

- [Live aggregate projections must be enabled](#): configuration parameter `EnableGroupByProjections` must be set to 1 (default).
- The projection cannot be unsegmented.

- [SELECT](#) and [GROUP BY](#) columns must be in the same order. [GROUP BY](#) expressions must be at the beginning of the [SELECT](#) list.

Restrictions

The following restrictions apply to live aggregate projections:

- Vertica does not regard the projections as superprojections, even one that includes all table columns.
- You cannot perform the following operations on anchor table data:
[DELETE](#)
[UPDATE](#)
[MERGE](#)

Note: To modify existing anchor table data, you must first drop all live aggregate and Top-K projections that are associated with it, using [DROP PROJECTION](#).

- The projections can reference only one table.

Live Aggregate Projection Example

This example shows how you can track user clicks on a given web page using the following `clicks` table:

```
=> CREATE TABLE clicks(  
    user_id INTEGER,  
    page_id INTEGER,  
    click_time TIMESTAMP NOT NULL);
```

You can aggregate user-specific activity with the following query:

```
=> SELECT page_id, click_time::DATE click_date, COUNT(*) num_clicks FROM clicks  
WHERE click_time::DATE = '2015-04-30'  
GROUP BY page_id, click_time::DATE ORDER BY num_clicks DESC;
```

To facilitate performance of this query, create a live aggregate projection that counts the number of clicks per user:

```
=> CREATE PROJECTION clicks_agg AS  
SELECT page_id, click_time::DATE click_date, COUNT(*) num_clicks FROM clicks  
GROUP BY page_id, click_time::DATE KSAFE 1;
```

When you query the `clicks` table on user clicks, Vertica typically directs the query to the live aggregate projection `clicks_agg`. As additional data is loaded into `clicks`, Vertica pre-

aggregates the new data and updates `clicks_agg`, so queries always return with the latest data.

For example:

```
=> SELECT page_id, click_time::DATE click_date, COUNT(*) num_clicks FROM clicks
      WHERE click_time::DATE = '2015-04-30' GROUP BY page_id, click_time::DATE
      ORDER BY num_clicks DESC;
 page_id | click_date | num_clicks
-----+-----+-----
      2002 | 2015-04-30 |          10
      3003 | 2015-04-30 |           3
      2003 | 2015-04-30 |           1
      2035 | 2015-04-30 |           1
     12034 | 2015-04-30 |           1
(5 rows)
```

Top-K Projections

A Top-K query returns the top k rows from partitions of selected rows. Top-K projections can significantly improve performance of Top-K queries. For example, you can define a table that stores gas meter readings with three columns: gas meter ID, time of meter reading, and the read value:

```
=> CREATE TABLE readings (
      meter_id INT,
      reading_date TIMESTAMP,
      reading_value FLOAT);
```

Given this table, the following Top-K query returns the five most recent meter readings for a given meter:

```
SELECT meter_id, reading_date, reading_value FROM readings
      LIMIT 5 OVER (PARTITION BY meter_id ORDER BY reading_date DESC);
```

To improve the performance of this query, you can create a Top-K projection, which is a special type of live aggregate projection:

```
=> CREATE PROJECTION readings_topk (meter_id, recent_date, recent_value)
      AS SELECT meter_id, reading_date, reading_value FROM readings
      LIMIT 5 OVER (PARTITION BY meter_id ORDER BY reading_date DESC);
```

After you create this Top-K projection and load its data (through [START_REFRESH](#) or [REFRESH](#)), Vertica typically redirects the query to the projection and returns with the pre-aggregated data.

Creating Top-K Projections

You define a Top-K projection with the following syntax:

```
CREATE PROJECTION proj-name [(proj-column-spec)]  
  AS SELECT select-expression FROM table  
  LIMIT num-rows OVER (PARTITION BY expression ORDER BY column-expr);
```

For full syntax options, see [CREATE PROJECTION \(Live Aggregate Projections\)](#).

For example:

```
=> CREATE PROJECTION readings_topk (meter_id, recent_date, recent_value)  
  AS SELECT meter_id, reading_date, reading_value FROM readings  
  LIMIT 5 OVER (PARTITION BY meter_id ORDER BY reading_date DESC);
```

For an extended discussion, see [Top-K Projection Examples](#).

Requirements

The following requirements apply to Top-K projections:

- [Top-K projections must be enabled](#): configuration parameter `EnableTopKProjections` must be set to 1 (default).
- The projection cannot be unsegmented.
- The [window partition clause](#) must use `PARTITION BY`.
- Columns in `PARTITION BY` and `ORDER BY` clauses must be the first columns specified in the `SELECT` list.
- You must use the `LIMIT` option to create a Top-K projection, instead of subqueries. For example, the following `SELECT` statements are equivalent:

```
=> SELECT symbol, trade_time last_trade, price last_price FROM (  
  SELECT symbol, trade_time, price, ROW_NUMBER()  
  OVER(PARTITION BY symbol ORDER BY trade_time DESC) rn FROM trades) trds WHERE rn <=1;  
  
=> SELECT symbol, trade_time last_trade, price last_price FROM trades  
  LIMIT 1 OVER(PARTITION BY symbol ORDER BY trade_time DESC);
```

Both return the same results:

symbol	last_trade	last_price
AAPL	2011-11-10 10:10:20.5	108.4000
HPQ	2012-10-10 10:10:10.4	42.0500

(2 rows)

A Top-K projection that pre-aggregates data for use by both queries must include the LIMIT option:

```
=> CREATE PROJECTION trades_topk AS
  SELECT symbol, trade_time last_trade, price last_price FROM trades
  LIMIT 1 OVER(PARTITION BY symbol ORDER BY trade_time DESC);
```

Restrictions

The following restrictions apply to Top-K projections:

- Vertica does not regard the projections as superprojections, even one that includes all table columns.
- You cannot perform the following operations on anchor table data:

[DELETE](#)

[UPDATE](#)

[MERGE](#)

Note: To modify existing anchor table data, you must first drop all live aggregate and Top-K projections that are associated with it, using [DROP PROJECTION](#).

- The projections can reference only one table.

Top-K Projection Examples

The following examples show how to query a table with two Top-K projections for the most-recent trade and last trade of the day for each stock symbol.

1. Create a table that contains information about individual stock trades:
 - Stock symbol
 - Timestamp
 - Price per share
 - Number of shares

```
=> CREATE TABLE trades(
  symbol CHAR(16) NOT NULL,
  trade_time TIMESTAMP NOT NULL,
  price NUMERIC(12,4),
  volume INT )
PARTITION BY (EXTRACT(year from trade_time) * 100 +
EXTRACT(month from trade_time));
```

2. Load data into the table:

```
INSERT INTO trades VALUES('AAPL','2010-10-10 10:10:10'::TIMESTAMP,100.00,100);
INSERT INTO trades VALUES('AAPL','2010-10-10 10:10:10.3'::TIMESTAMP,101.00,100);
INSERT INTO trades VALUES ('AAPL','2011-10-10 10:10:10.5'::TIMESTAMP,106.1,1000);
INSERT INTO trades VALUES ('AAPL','2011-10-10 10:10:10.2'::TIMESTAMP,105.2,500);
INSERT INTO trades VALUES ('HPQ','2012-10-10 10:10:10.2'::TIMESTAMP,42.01,400);
INSERT INTO trades VALUES ('HPQ','2012-10-10 10:10:10.3'::TIMESTAMP,42.02,1000);
INSERT INTO trades VALUES ('HPQ','2012-10-10 10:10:10.4'::TIMESTAMP,42.05,100);
COMMIT;
```

3. Create two Top-K projections that obtain the following information from the trades table:

- [Return the most recent trades for each stock symbol.](#)
- [Return the last trade on each trading day.](#)

For each stock symbol, return the most recent trade.

```
=> CREATE PROJECTION trades_topk_a AS SELECT symbol, trade_time last_trade, price last_price
FROM trades LIMIT 1 OVER(PARTITION BY symbol ORDER BY trade_time DESC);

=> SELECT symbol, trade_time last_trade, price last_price FROM trades
LIMIT 1 OVER(PARTITION BY symbol ORDER BY trade_time DESC);
```

symbol	last_trade	last_price
HPQ	2012-10-10 10:10:10.4	42.0500
AAPL	2011-10-10 10:10:10.5	106.1000

(2 rows)

For each stock symbol, return the last trade on each trading day.

```
=> CREATE PROJECTION trades_topk_b
AS SELECT symbol, trade_time::DATE trade_date, trade_time, price close_price, volume
FROM trades LIMIT 1 OVER(PARTITION BY symbol, trade_time::DATE ORDER BY trade_time DESC);

=> SELECT symbol, trade_time::DATE trade_date, trade_time, price close_price, volume
FROM trades LIMIT 1 OVER(PARTITION BY symbol, trade_time::DATE ORDER BY trade_time DESC);
```

symbol	trade_date	trade_time	close_price	volume
--------	------------	------------	-------------	--------

```
HPQ          | 2012-10-10 | 2012-10-10 10:10:10.4 | 42.0500 | 100  
AAPL        | 2011-10-10 | 2011-10-10 10:10:10.5 | 106.1000 | 1000  
AAPL        | 2010-10-10 | 2010-10-10 10:10:10.3 | 101.0000 | 100  
(3 rows)
```

In each scenario, Vertica redirects queries on the `trades` table to the appropriate Top-K projection and returns the aggregated data from them. As additional data is loaded into this table, Vertica pre-aggregates the new data and updates the Top-K projections, so queries always return with the latest data.

Pre-Aggregating UDTF Results

`CREATE PROJECTION` can define live aggregate projections that invoke user-defined transform functions (UDTFs). To minimize overhead when you query those projections, Vertica processes these functions in the background and stores their results on disk.

Important: Currently, live aggregate projections can only reference UDTFs that are developed in C++.

Defining Projections with UDTFs

The projection definition characterizes UDTFs in one of two ways:

- Identifies the UDTF as a *pre-pass UDTF*, which transforms newly loaded data before it is stored in the projection ROS containers.
- Identifies the UDTF as a *batch UDTF*, which aggregates and stores projection data.

The projection definition identifies a UDTF as a pre-pass UDTF or batch UDTF in its [window partition clause](#), through the keywords `PREPASS` or `BATCH`. A projection can specify one pre-pass or batch UDTF or include both (see [UDTF Specification Options](#)).

In all cases, the projection is implicitly segmented and ordered on the `PARTITION BY` columns.

UDTF Specification Options

Projections can invoke batch and pre-pass UDTFs singly or in combination.

Single Pre-Pass UDTF

Vertica invokes the pre-pass UDTF when you load data into the projection's anchor table—for example through COPY or INSERT statements. A pre-pass UDTF transforms the new data and then stores the transformed data in the projection's ROS containers.

Use the following syntax:

```
=> CREATE PROJECTION projection-name AS SELECT ..., udtf(args)
      OVER(PARTITION PREPASS BY partition-col-exprs) FROM table-ref;
```

Single Batch UDTF

When invoked singly, a batch UDTF transforms and aggregates projection data on mergeout, data load, and query operations. The UDTF stores aggregated results in the projection's ROS containers. Aggregation is cumulative across mergeout and load operations, and is completed (if necessary) on query execution.

Use the following syntax:

```
=> CREATE PROJECTION projection-name AS SELECT ..., udtf(args)
      OVER(PARTITION BATCH BY partition-cols) AS (batch-output-columns) FROM table-ref;
```

Combined Pre-Pass and Batch UDTFs

You can define a projection with a subquery that invokes a pre-pass UDTF. The pre-pass UDTF returns transformed data to the outer batch query. The batch UDTF then iteratively aggregates results across mergeout operations. It completes aggregation (if necessary) on query execution.

Use the following syntax:

```
=> CREATE PROJECTION projection-name AS SELECT ..., batch-udtf(batch-args)
      OVER ( PARTITION BATCH BY partition-cols ) AS (batch-output-columns)
      FROM ( SELECT ..., prepass-udtf(prepass-args)
            OVER ( PARTITION PREPASS BY partition-cols) AS (prepass-output-columns)
            FROM table-ref ) sq-ref;
```

Important: The outer batch UDTF arguments *batch-args* must exactly match the output columns returned by the pre-pass UDTF, in name and order.

Examples

Single pre-pass UDTF

The following example shows how to use the UDTF `text_index`, which extracts from a text document strings that occur more than once.

The following projection specifies to invoke `text_index` as a pre-pass UDTF:

```
=> CREATE TABLE documents ( doc_id INT PRIMARY KEY, text VARCHAR(140));

=> CREATE PROJECTION index_proj
  AS SELECT doc_id, text_index(doc_id, text)
  OVER (PARTITION PREPASS BY doc_id) FROM documents;
```

The UDTF is invoked whenever data is loaded into the anchor table `documents`. `text_index` transforms the newly loaded data, and Vertica stores the transformed data in the live aggregate projection ROS containers.

So, if you load the following data into `documents`:

```
=> INSERT INTO documents VALUES (100, 'A SQL Query walks into a bar. In one corner of the bar are two
tables.

                                The Query walks up to the tables and asks - Mind if I join you?');

OUTPUT
-----
      1
(1 row)
```

`text_index` transforms the newly loaded data and stores it in the projection ROS containers. When you query the projection, it returns with the following results:

doc_id	frequency	term
100	2	bar
100	2	Query
100	2	tables
100	2	the
100	2	walks

Combined Pre-Pass and Batch UDTFs

The following projection specifies pre-pass and batch UDTFs `stv_intersect` and `aggregate_classified_points`, respectively:

```
CREATE TABLE points( point_id INTEGER, point_type VARCHAR(10), coordinates GEOMETRY(100));

CREATE PROJECTION aggregated_proj
  AS SELECT point_type, aggregate_classified_points( sq.point_id, sq.polygon_id)
  OVER (PARTITION BATCH BY point_type)
  FROM
    (SELECT point_type, stv_intersect(
```

```
point_id, coordinates USING PARAMETERS index='polygons' )  
OVER (PARTITION PREPASS BY point_type) AS (point_id, polygon_id) FROM points) sq;
```

The pre-pass query UDTF `stv_intersect` returns its results (a set of point and matching polygon IDs) to the outer batch query. The outer batch query then invokes the UDTF `aggregate_classified_points`. Vertica aggregates the result set that is returned by `aggregate_classified_points` whenever a mergeout operation consolidates projection data. Final aggregation (if necessary) occurs when the projection is queried.

The batch UDTF arguments must exactly match the output columns returned by the pre-pass UDTF `stv_intersect`, in name and order. In this example, the pre-pass subquery explicitly names the pre-pass UDTF output columns `point_id` and `polygon_id`. Accordingly, the batch UDTF arguments match them in name and order: `sq.point_id` and `sq.polygon_id`.

Aggregating Data Through Expressions

You can create projections where one or more columns are defined by expressions. An expression can reference one or more anchor table columns. For example, the following table contains two integer columns, `a` and `b`:

```
=> CREATE TABLE values (a INT, b INT);
```

You can create a projection with an expression that calculates the value of column `c` as the product of `a` and `b`:

```
=> CREATE PROJECTION values_product (a, b, c)  
AS SELECT a, b, a*b FROM values SEGMENTED BY HASH(a) ALL NODES KSAFE;
```

When you load data into this projection, Vertica resolves the expression `a*b` in column `c`. You can then query the projection instead of the anchor table. Vertica returns the pre-calculated data and avoids the overhead otherwise incurred by resource-intensive computations.

Using expressions in projections also lets you sort or segment data on the calculated results of an expression instead of sorting on single column values.

Note: If a projection with expressions also includes aggregate functions such as [SUM](#) or [COUNT](#), Vertica treats it like a [live aggregate projection](#).

Support for User-Defined Scalar Functions

Important: Currently, support for pre-aggregating UDSF results is limited to C++.

Vertica treats user-defined scalar functions (UDSFs) like other expressions. On each load operation, the UDSF is invoked and returns its results. Vertica stores these results on disk, and returns them when you query the projection directly.

In the following example, the projection `points_p1` specifies the UDSF `zorder`, which is invoked whenever data is loaded in the anchor table `points`. When data is loaded into the projection, Vertica invokes this function and stores its results for fast access by future queries.

```
=> CREATE TABLE points(point_id INTEGER, lat NUMERIC(12,9), long NUMERIC(12,9));  
  
=> CREATE PROJECTION points_p1  
  AS SELECT point_id, lat, long, zorder(lat, long) zorder FROM points  
  ORDER BY zorder(lat, long) SEGMENTED BY hash(point_id) ALL NODES;
```

Requirements

- [Projections with expressions must be enabled.](#)
- Any `ORDER BY` expression must be in the `SELECT` list.
- All projection columns must be named.

Restrictions

- You can delete and update data in the anchor table, but you cannot perform a merge operation.
- Unlike live aggregate projections, Vertica does not redirect queries with expressions to an equivalent existing projection.
- Projection expressions must be immutable—that is, they must always return the same result. For example, a projection cannot include expressions that use `TO CHAR` (depends on locale) or `RANDOM` (returns different value at each invocation).
- Projection expressions cannot include Vertica meta-functions such as `ADVANCE_EPOCH`, `ANALYZE_STATISTICS`, `EXPORT_TABLES`, or `START_REFRESH`.

Querying Data Through Expressions Example

The following example uses a table that contains two integer columns, `a` and `b`:

```
=> CREATE TABLE values (a INT, b INT);
```

You can create a projection with an expression that calculates the value of column *c* as the product of *a* and *b*:

```
=> CREATE PROJECTION values_product (a, b, c)
  AS SELECT a, b, a*b FROM values SEGMENTED BY HASH(a) ALL NODES KSAFE;
```

To query this projection, use the name that Vertica assigns to it or to its buddy projections. For example, the following queries target different instances of the projection defined earlier, and return the same results:

```
=> SELECT * FROM values_product_b0;
=> SELECT * FROM values_product_b1;
```

The following example queries the anchor table:

```
=> SELECT * FROM values;
 a | b
----+----
 3 | 11
 3 | 55
 8 |  9
 8 | 23
16 | 41
22 | 111
```

Given the projection created earlier, querying that projection returns the following values:

```
VMart=> SELECT * FROM values_product_b0;
 a | b | product
----+----+-----
 3 | 11 |      33
 3 | 55 |     165
 8 |  9 |      72
 8 | 23 |     184
16 | 41 |     656
22 | 111 |    2442
```

System Table Fields

You can query the following system table fields for information about live aggregate projections, Top-K projections, and projections with expressions:

Table	Fields
TABLES	HAS_AGGREGATE_PROJECTION

Table	Fields
PROJECTIONS	AGGREGATE_TYPE
	HAS_EXPRESSIONS
	AGGREGATE_TYPE
PROJECTION_COLUMNS	COLUMN_EXPRESSION
	IS_AGGREGATE
	IS_EXPRESSION
	ORDER_BY_POSITION
	ORDER_BY_TYPE
	PARTITION_BY_POSITION

Event Series Joins

An event series join is a Vertica SQL extension that enables the analysis of two series when their measurement intervals don't align precisely, such as with mismatched timestamps. You can compare values from the two series directly, rather than having to normalize the series to the same measurement interval.

Event series joins are an extension of [Outer Joins](#), but instead of padding the non-preserved side with NULL values when there is no match, the event series join pads the non-preserved side values that it interpolates from the previous value.

The difference in how you write a regular join versus an event series join is the INTERPOLATE predicate, which is used in the ON clause. For example, the following two statements show the differences, which are shown in greater detail in [Writing Event Series Joins](#).

Regular full outer join	Event series join
<pre>SELECT * FROM hTicks h FULL OUTER JOIN aTicks a ON (h.time = a.time);</pre>	<pre>SELECT * FROM hTicks h FULL OUTER JOIN aTicks a ON (h.time INTERPOLATE PREVIOUS VALUE a.time);</pre>

Similar to regular joins, an event series join has inner and outer join modes, which are described in the topics that follow.

For full syntax, including notes and restrictions, see [INTERPOLATE](#) in the SQL Reference Manual

Sample Schema for Event Series Joins Examples

If you don't plan to run the queries and just want to look at the examples, you can skip this topic and move straight to [Writing Event Series Joins](#).

Schema of hTicks and aTicks Tables

The examples that follow use the following hTicks and aTicks tables schemas:

```
CREATE TABLE hTicks (
  stock VARCHAR(20),
  time TIME,
  price NUMERIC(8,2)
);
CREATE TABLE aTicks (
```

```
stock VARCHAR(20),
time TIME,
price NUMERIC(8,2)
);
```

Although **TIMESTAMP** is more commonly used for the event series column, the examples in this topic use **TIME** to keep the output simple.

```
INSERT INTO hTicks VALUES ('HPQ', '12:00', 50.00);
INSERT INTO hTicks VALUES ('HPQ', '12:01', 51.00);
INSERT INTO hTicks VALUES ('HPQ', '12:05', 51.00);
INSERT INTO hTicks VALUES ('HPQ', '12:06', 52.00);
INSERT INTO aTicks VALUES ('ACME', '12:00', 340.00);
INSERT INTO aTicks VALUES ('ACME', '12:03', 340.10);
INSERT INTO aTicks VALUES ('ACME', '12:05', 340.20);
INSERT INTO aTicks VALUES ('ACME', '12:05', 333.80);
COMMIT;
```

Output of the two tables:

hTicks	aTicks																														
<pre>=> SELECT * FROM hTicks;</pre> <p>There are no entry records between 12:02–12:04:</p> <table border="1"> <thead> <tr> <th>stock</th> <th>time</th> <th>price</th> </tr> </thead> <tbody> <tr> <td>HPQ</td> <td>12:00:00</td> <td>50.00</td> </tr> <tr> <td>HPQ</td> <td>12:01:00</td> <td>51.00</td> </tr> <tr> <td>HPQ</td> <td>12:05:00</td> <td>51.00</td> </tr> <tr> <td>HPQ</td> <td>12:06:00</td> <td>52.00</td> </tr> </tbody> </table> <p>(4 rows)</p>	stock	time	price	HPQ	12:00:00	50.00	HPQ	12:01:00	51.00	HPQ	12:05:00	51.00	HPQ	12:06:00	52.00	<pre>=> SELECT * FROM aTicks;</pre> <p>There are no entry records at 12:01, 12:02 and at 12:04:</p> <table border="1"> <thead> <tr> <th>stock</th> <th>time</th> <th>price</th> </tr> </thead> <tbody> <tr> <td>ACME</td> <td>12:00:00</td> <td>340.00</td> </tr> <tr> <td>ACME</td> <td>12:03:00</td> <td>340.10</td> </tr> <tr> <td>ACME</td> <td>12:05:00</td> <td>340.20</td> </tr> <tr> <td>ACME</td> <td>12:05:00</td> <td>333.80</td> </tr> </tbody> </table> <p>(4 rows)</p>	stock	time	price	ACME	12:00:00	340.00	ACME	12:03:00	340.10	ACME	12:05:00	340.20	ACME	12:05:00	333.80
stock	time	price																													
HPQ	12:00:00	50.00																													
HPQ	12:01:00	51.00																													
HPQ	12:05:00	51.00																													
HPQ	12:06:00	52.00																													
stock	time	price																													
ACME	12:00:00	340.00																													
ACME	12:03:00	340.10																													
ACME	12:05:00	340.20																													
ACME	12:05:00	333.80																													

Example Query Showing Gaps

A full outer join shows the gaps in the timestamps:

```
=> SELECT * FROM hTicks h FULL OUTER JOIN aTicks a ON h.time = a.time;
```

stock	time	price	stock	time	price
HPQ	12:00:00	50.00	ACME	12:00:00	340.00
HPQ	12:01:00	51.00			
HPQ	12:05:00	51.00	ACME	12:05:00	333.80
HPQ	12:05:00	51.00	ACME	12:05:00	340.20
HPQ	12:06:00	52.00			
			ACME	12:03:00	340.10

(6 rows)

Schema of Bid and Asks Tables

The examples that follow use the following hTicks and aTicks tables.

```
CREATE TABLE bid(stock VARCHAR(20), time TIME, price NUMERIC(8,2));
CREATE TABLE ask(stock VARCHAR(20), time TIME, price NUMERIC(8,2));
INSERT INTO bid VALUES ('HPQ', '12:00', 100.10);
INSERT INTO bid VALUES ('HPQ', '12:01', 100.00);
INSERT INTO bid VALUES ('ACME', '12:00', 80.00);
INSERT INTO bid VALUES ('ACME', '12:03', 79.80);
INSERT INTO bid VALUES ('ACME', '12:05', 79.90);
INSERT INTO ask VALUES ('HPQ', '12:01', 101.00);
INSERT INTO ask VALUES ('ACME', '12:00', 80.00);
INSERT INTO ask VALUES ('ACME', '12:02', 75.00);
COMMIT;
```

Output of the two tables:

bid	ask																														
<pre>=> SELECT * FROM bid;</pre> <p>There are no entry records for stocks HPQ and ACME at 12:02 and at 12:04:</p> <table border="1"> <thead> <tr> <th>stock</th> <th>time</th> <th>price</th> </tr> </thead> <tbody> <tr><td>HPQ</td><td>12:00:00</td><td>100.10</td></tr> <tr><td>HPQ</td><td>12:01:00</td><td>100.00</td></tr> <tr><td>ACME</td><td>12:00:00</td><td>80.00</td></tr> <tr><td>ACME</td><td>12:03:00</td><td>79.80</td></tr> <tr><td>ACME</td><td>12:05:00</td><td>79.90</td></tr> </tbody> </table> <p>(5 rows)</p>	stock	time	price	HPQ	12:00:00	100.10	HPQ	12:01:00	100.00	ACME	12:00:00	80.00	ACME	12:03:00	79.80	ACME	12:05:00	79.90	<pre>=> SELECT * FROM ask;</pre> <p>There are no entry records for stock HPQ at 12:00 and none for ACME at 12:01:</p> <table border="1"> <thead> <tr> <th>stock</th> <th>time</th> <th>price</th> </tr> </thead> <tbody> <tr><td>HPQ</td><td>12:01:00</td><td>101.00</td></tr> <tr><td>ACME</td><td>12:00:00</td><td>80.00</td></tr> <tr><td>ACME</td><td>12:02:00</td><td>75.00</td></tr> </tbody> </table> <p>(3 rows)</p>	stock	time	price	HPQ	12:01:00	101.00	ACME	12:00:00	80.00	ACME	12:02:00	75.00
stock	time	price																													
HPQ	12:00:00	100.10																													
HPQ	12:01:00	100.00																													
ACME	12:00:00	80.00																													
ACME	12:03:00	79.80																													
ACME	12:05:00	79.90																													
stock	time	price																													
HPQ	12:01:00	101.00																													
ACME	12:00:00	80.00																													
ACME	12:02:00	75.00																													

Example Query Showing Gaps

A full outer join shows the gaps in the timestamps:

```
=> SELECT * FROM bid b FULL OUTER JOIN ask a ON b.time = a.time;
```

stock	time	price	stock	time	price
HPQ	12:00:00	100.10	ACME	12:00:00	80.00
HPQ	12:01:00	100.00	HPQ	12:01:00	101.00
ACME	12:00:00	80.00	ACME	12:00:00	80.00
ACME	12:03:00	79.80			
ACME	12:05:00	79.90			
			ACME	12:02:00	75.00

(6 rows)

Writing Event Series Joins

The examples in this topic contains mismatches between timestamps—just as you'd find in real life situations; for example, there could be a period of inactivity on stocks where no trade occurs, which can present challenges when you want to compare two stocks whose timestamps don't match.

The hTicks and aTicks Tables

As described in the [example ticks schema](#), tables, hTicks is missing input rows for 12:02, 12:03, and 12:04, and aTicks is missing inputs at 12:01, 12:02, and 12:04.

hTicks	aTicks
<pre>=> SELECT * FROM hTicks; stock time price -----+-----+----- HPQ 12:00:00 50.00 HPQ 12:01:00 51.00 HPQ 12:05:00 51.00 HPQ 12:06:00 52.00 (4 rows)</pre>	<pre>=> SELECT * FROM aTicks; stock time price -----+-----+----- ACME 12:00:00 340.00 ACME 12:03:00 340.10 ACME 12:05:00 340.20 ACME 12:05:00 333.80 (4 rows)</pre>

Querying Event Series Data with Full Outer Joins

Using a traditional full outer join, this query finds a match between tables hTicks and aTicks at 12:00 and 12:05 and pads the missing data points with NULL values.

```
=> SELECT * FROM hTicks h FULL OUTER JOIN aTicks a ON (h.time = a.time);
stock | time | price | stock | time | price
-----+-----+-----+-----+-----+-----
HPQ   | 12:00:00 | 50.00 | ACME  | 12:00:00 | 340.00
HPQ   | 12:01:00 | 51.00 |      |      |
HPQ   | 12:05:00 | 51.00 | ACME  | 12:05:00 | 333.80
HPQ   | 12:05:00 | 51.00 | ACME  | 12:05:00 | 340.20
HPQ   | 12:06:00 | 52.00 |      |      |
      |      |      | ACME  | 12:03:00 | 340.10
(6 rows)
```

To replace the gaps with interpolated values for those missing data points, use the [INTERPOLATE](#) predicate to create an event series join. The join condition is restricted to the ON clause, which evaluates the equality predicate on the timestamp columns from the two input

tables. In other words, for each row in outer table hTicks, the ON clause predicates are evaluated for each combination of each row in the inner table aTicks.

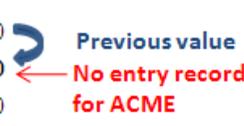

Simply rewrite the full outer join query to use the INTERPOLATE predicate with the required PREVIOUS VALUE keywords. Note that a full outer join on event series data is the most common scenario for event series data, where you keep all rows from both tables

```
=> SELECT * FROM hTicks h FULL OUTER JOIN aTicks a
    ON (h.time INTERPOLATE PREVIOUS VALUE a.time);
```

Vertica interpolates the missing values (which appear as NULL in the full outer join) using that table's previous value:

stock	time	price	stock	time	price
HPQ	12:00:00	50.00	ACME	12:00:00	340.00
HPQ	12:01:00	51.00	ACME	12:00:00	340.00
HPQ	12:01:00	51.00	ACME	12:03:00	340.10
HPQ	12:05:00	51.00	ACME	12:05:00	333.80
HPQ	12:05:00	51.00	ACME	12:05:00	340.20
HPQ	12:06:00	52.00	ACME	12:05:00	340.20

(6 rows)

 A blue arrow points from the ACME price of 340.00 at 12:00:00 to the ACME price of 340.00 at 12:01:00. A red arrow points from the text 'No entry record for ACME' to the ACME price of 340.00 at 12:01:00.

Note: The output ordering above is different from the regular full outer join because in the event series join, interpolation occurs independently for each stock (hTicks and aTicks), where the data is partitioned and sorted based on the equality predicate. This means that interpolation occurs within, not across, partitions.

If you review the regular full outer join output, you can see that both tables have a match in the time column at 12:00 and 12:05, but at 12:01, there is no entry record for ACME. So the operation interpolates a value for ACME (ACME, 12:00, 340) based on the previous value in the aTicks table.

Querying Event Series Data with Left Outer Joins

You can also use left and right outer joins. You might, for example, decide you want to preserve only hTicks values. So you'd write a left outer join:

```
=> SELECT * FROM hTicks h LEFT OUTER JOIN aTicks a
    ON (h.time INTERPOLATE PREVIOUS VALUE a.time);
stock | time   | price | stock | time   | price
-----+-----+-----+-----+-----+-----
HPQ   | 12:00:00 | 50.00 | ACME  | 12:00:00 | 340.00
```

```
HPQ | 12:01:00 | 51.00 | ACME | 12:00:00 | 340.00  
HPQ | 12:05:00 | 51.00 | ACME | 12:05:00 | 333.80  
HPQ | 12:05:00 | 51.00 | ACME | 12:05:00 | 340.20  
HPQ | 12:06:00 | 52.00 | ACME | 12:05:00 | 340.20  
(5 rows)
```

Here's what the same data looks like using a traditional left outer join:

```
=> SELECT * FROM hTicks h LEFT OUTER JOIN aTicks a ON h.time = a.time;  
stock | time | price | stock | time | price  
-----+-----+-----+-----+-----+-----  
HPQ | 12:00:00 | 50.00 | ACME | 12:00:00 | 340.00  
HPQ | 12:01:00 | 51.00 | | | |  
HPQ | 12:05:00 | 51.00 | ACME | 12:05:00 | 333.80  
HPQ | 12:05:00 | 51.00 | ACME | 12:05:00 | 340.20  
HPQ | 12:06:00 | 52.00 | | | |  
(5 rows)
```

Note that a right outer join has the same behavior with the preserved table reversed.

Querying Event Series Data with Inner Joins

Note that INNER event series joins behave the same way as normal ANSI SQL-99 joins, where all gaps are omitted. Thus, there is nothing to interpolate, and the following two queries are equivalent and return the same result set:

A regular inner join:

```
=> SELECT * FROM hTicks h JOIN aTicks a  
ON (h.time INTERPOLATE PREVIOUS VALUE a.time);  
stock | time | price | stock | time | price  
-----+-----+-----+-----+-----+-----  
HPQ | 12:00:00 | 50.00 | ACME | 12:00:00 | 340.00  
HPQ | 12:05:00 | 51.00 | ACME | 12:05:00 | 333.80  
HPQ | 12:05:00 | 51.00 | ACME | 12:05:00 | 340.20  
(3 rows)
```

An event series inner join:

```
=> SELECT * FROM hTicks h INNER JOIN aTicks a ON (h.time = a.time);  
stock | time | price | stock | time | price  
-----+-----+-----+-----+-----+-----  
HPQ | 12:00:00 | 50.00 | ACME | 12:00:00 | 340.00  
HPQ | 12:05:00 | 51.00 | ACME | 12:05:00 | 333.80  
HPQ | 12:05:00 | 51.00 | ACME | 12:05:00 | 340.20  
(3 rows)
```

The Bid and Ask Tables

Using the [example schema](#) for the `bid` and `ask` tables, write a full outer join to interpolate the missing data points:

```
=> SELECT * FROM bid b FULL OUTER JOIN ask a  
      ON (b.stock = a.stock AND b.time INTERPOLATE PREVIOUS VALUE a.time);
```

In the below output, the first row for stock HPQ shows nulls because there is no entry record for HPQ before 12:01.

stock	time	price	stock	time	price
ACME	12:00:00	80.00	ACME	12:00:00	80.00
ACME	12:00:00	80.00	ACME	12:02:00	75.00
ACME	12:03:00	79.80	ACME	12:02:00	75.00
ACME	12:05:00	79.90	ACME	12:02:00	75.00
HPQ	12:00:00	100.10			
HPQ	12:01:00	100.00	HPQ	12:01:00	101.00

(6 rows)

Note also that the same row (ACME, 12:02, 75) from the `ask` table appears three times. The first appearance is because no matching rows are present in the `bid` table for the row in `ask`, so Vertica interpolates the missing value using the ACME value at 12:02 (75.00). The second appearance occurs because the row in `bid` (ACME, 12:05, 79.9) has no matches in `ask`. The row from `ask` that contains (ACME, 12:02, 75) is the closest row; thus, it is used to interpolate the values.

If you write a regular full outer join, you can see where the mismatched timestamps occur:

```
=> SELECT * FROM bid b FULL OUTER JOIN ask a ON (b.time = a.time);
```

stock	time	price	stock	time	price
ACME	12:00:00	80.00	ACME	12:00:00	80.00
ACME	12:03:00	79.80			
ACME	12:05:00	79.90			
HPQ	12:00:00	100.10	ACME	12:00:00	80.00
HPQ	12:01:00	100.00	HPQ	12:01:00	101.00
			ACME	12:02:00	75.00

(6 rows)

Event Series Pattern Matching

The SQL [MATCH Clause](#) syntax (described in the SQL Reference Manual) lets you screen large amounts of historical data in search of event patterns. You specify a pattern as a regular expression and can then search for the pattern within a sequence of input events. MATCH provides subclauses for analytic data partitioning and ordering, and the pattern matching occurs on a contiguous set of rows.

Pattern matching is particularly useful for clickstream analysis where you might want to identify users' actions based on their Web browsing behavior (page clicks). A typical online clickstream funnel is:

Company home page -> product home page -> search -> results -> purchase online

Using the above clickstream funnel, you can search for a match on the user's sequence of web clicks and identify that the user:

- landed on the company home page
- navigated to the product page
- ran a search
- clicked a link from the search results
- made a purchase

Clickstream Funnel Schema

The examples in this topic use this clickstream funnel and the following `clickstream_log` table schema:

```
=> CREATE TABLE clickstream_log (  
  uid INT,           --user ID  
  sid INT,           --browsing session ID, produced by previous sessionization computation  
  ts TIME,           --timestamp that occurred during the user's page visit  
  refURL VARCHAR(20), --URL of the page referencing PageURL  
  pageURL VARCHAR(20), --URL of the page being visited  
  action CHAR(1)     --action the user took after visiting the page ('P' = Purchase, 'V' = View)  
);  
  
INSERT INTO clickstream_log VALUES (1,100,'12:00','website1.com','website2.com/home', 'V');  
INSERT INTO clickstream_log VALUES (1,100,'12:01','website2.com/home','website2.com/floby', 'V');  
INSERT INTO clickstream_log VALUES (1,100,'12:02','website2.com/floby','website2.com/shamwow', 'V');  
INSERT INTO clickstream_log values (1,100,'12:03','website2.com/shamwow','website2.com/buy', 'P');
```

```
INSERT INTO clickstream_log values (2,100,'12:10','website1.com','website2.com/home', 'V');
INSERT INTO clickstream_log values (2,100,'12:11','website2.com/home','website2.com/forks', 'V');
INSERT INTO clickstream_log values (2,100,'12:13','website2.com/forks','website2.com/buy', 'P');
COMMIT;
```

Here's the clickstream_log table's output:

```
=> SELECT * FROM clickstream_log;
uid | sid | ts | refURL | pageURL | action
-----+-----+-----+-----+-----+-----
 1 | 100 | 12:00:00 | website1.com | website2.com/home | V
 1 | 100 | 12:01:00 | website2.com/home | website2.com/floby | V
 1 | 100 | 12:02:00 | website2.com/floby | website2.com/shamwow | V
 1 | 100 | 12:03:00 | website2.com/shamwow | website2.com/buy | P
 2 | 100 | 12:10:00 | website1.com | website2.com/home | V
 2 | 100 | 12:11:00 | website2.com/home | website2.com/forks | V
 2 | 100 | 12:13:00 | website2.com/forks | website2.com/buy | P
(7 rows)
```

Example

This example includes the Vertica [Pattern Matching Functions](#) to analyze users' browsing history over website2.com. It identifies patterns where the user performed the following tasks:

- Landed on website2.com from another web site (Entry)
- Browsed to any number of other pages (Onsite)
- Made a purchase (Purchase)

In the following statement, pattern P (Entry Onsite* Purchase) consist of three event types: Entry, Onsite, and Purchase. When Vertica finds a match in the input table, the associated pattern instance must be an event of type Entry followed by 0 or more events of type Onsite, and an event of type Purchase

```
=> SELECT uid,
       sid,
       ts,
       refurl,
       pageurl,
       action,
       event_name(),
       pattern_id(),
       match_id()
FROM clickstream_log
MATCH
(PARTITION BY uid, sid ORDER BY ts
DEFINE
Entry AS RefURL NOT ILIKE '%website2.com%' AND PageURL ILIKE '%website2.com%',
```

```

Onsite AS PageURL ILIKE '%website2.com%' AND Action='V',
Purchase AS PageURL ILIKE '%website2.com%' AND Action = 'P'
PATTERN
P AS (Entry Onsite* Purchase)
ROWS MATCH FIRST EVENT);

```

In the output below, the first four rows represent the pattern for user 1's browsing activity, while the following three rows show user 2's browsing habits.

uid id	sid match_id	ts	refurl	pageurl	action	event_name	pattern_
1	100	12:00:00	website1.com	website2.com/home	V	Entry	
1	1						
1	100	12:01:00	website2.com/home	website2.com/floby	V	Onsite	
1	2						
1	100	12:02:00	website2.com/floby	website2.com/shamwow	V	Onsite	
1	3						
1	100	12:03:00	website2.com/shamwow	website2.com/buy	P	Purchase	
1	4						
2	100	12:10:00	website1.com	website2.com/home	V	Entry	
1	1						
2	100	12:11:00	website2.com/home	website2.com/forks	V	Onsite	
1	2						
2	100	12:13:00	website2.com/forks	website2.com/buy	P	Purchase	
1	3						

(7 rows)

Using Flex Tables

This guide describes how to use flexible (flex) tables, which are a different kind of database table designed for loading and querying unstructured data, also called *semi-structured* data in your Vertica Analytics Platform. Flex tables can contain only unstructured, raw data, or both unstructured and columnar data. You can create a flex table with or without a schema or real columns. Hybrid tables consist of both unstructured and real columns. Both flex and hybrid tables are fully supported Vertica Analytics Platform tables, stored as projections and with the same K-safety as your database.

Audience

This guide is intended for use by any user or database designer or application developer interested in working with flexible tables in the database.

Prerequisites

This guide assumes that Vertica Analytics Platform Version 8.1.x is installed and running in your environment.

It also assumes that you are familiar with using the Vertica Analytics Platform, especially the following features and commands:

- Loading data with the [COPY](#) statement and its basic parameters
- Using statements to create tables [CREATE TABLE](#) or CTAS (create table as...)
- Altering table definitions with the [ALTER TABLE](#) statement
- Creating and using Views ([CREATE VIEW](#))
- Querying data using the [SELECT](#) statement
- Using functions for your database

If you are not familiar with these tasks and features, see [Getting Started](#).

Getting Started

Getting Started describes the basics of creating, exploring, and using flex tables. The rest of this guide presents *beyond the basics* details using simple examples.

Create a Simple JSON File

Use this JSON data for the exercises in the rest of this section:

```
{"name": "Everest", "type": "mountain", "height": 29029, "hike_safety": 34.1}
{"name": "Mt St Helens", "type": "volcano", "height": 29029, "hike_safety": 15.4}
{"name": "Denali", "type": "mountain", "height": 17000, "hike_safety": 12.2}
{"name": "Kilimanjaro", "type": "mountain", "height": 14000 }
{"name": "Mt Washington", "type": "mountain", "hike_safety": 50.6}
```

1. Copy and paste the JSON data into your favorite editor.
2. Save the file in any convenient location for loading into your Vertica database.

Create a Flex Table and Load Data

1. Create a flex table called mountains:

```
=> CREATE flex table mountains();
```

2. Load the JSON file you saved, using the flex table parser `fjsonparser`:

```
=> COPY mountains from '/home/dbadmin/data/flex/mountains.json'
parser fjsonparser();
  Rows Loaded
-----
                5
(1 row)
```

3. Query values from the sample file:

```
=> SELECT name, type, height from mountains;
  name | type | height
-----+-----+-----
 Everest | mountain | 29029
```

```
Mt St Helens | volcano | 29029
Denali      | mountain | 17000
Kilimanjaro | mountain | 14000
Mt Washington | mountain |
(5 rows)
```

You have now created a flex table and loaded data. Next, learn more about using flex table data in your database.

Query More of Your Flex Table

1. Query your flex table to see the data you loaded as it is stored in the `__raw__` column. The example illustrates the table contents, with Return characters added for illustration:

```
=> \x
Expanded display is on.
=> SELECT * from mountains;
[ RECORD 1 ]+-----
__identity__ | 1
__raw__      | \001\000\000\000,\000\000\000\004\000\000\000\024\000\000\000\031\000\000\000\
035\000\000\000$\000\000\0002902934.1Everestmountain\004\000\000\000\024\000\000\000\032\000\
000\000%\000\000\000)\000\000\000heighthike_safetynametype
[ RECORD 2 ]+-----
__identity__ | 2
__raw__      | \001\000\000\0000\000\000\000\004\000\000\000\024\000\000\000\031\000\000\000\
035\000\000\000)\000\000\0002902915.4Mt St
Helensvolcano\004\000\000\000\024\000\000\000\032\000\
000\000%\000\000\000)\000\000\000heighthike_safetynametype
[ RECORD 3 ]+-----
__identity__ | 3
__raw__      | \001\000\000\000+\000\000\000\004\000\000\000\024\000\000\000\031\000\000\000\
035\000\000\000#\000\000\0001700012.2Denalimountain\004\000\000\000\024\000\000\000\032\000\000\
\000%\000\000\000)\000\000\000heighthike_safetynametype
[ RECORD 4 ]+-----
__identity__ | 4
__raw__      | \001\000\000\000(\000\000\000\003\000\000\000\020\000\000\000\025\000\000\000\
000\000\00014000Kilimanjaromountain\003\000\000\000\020\000\000\000\026\000\000\000\032\000\
000\000heightnametype
[ RECORD 5 ]+-----
__identity__ | 5
__raw__      | \001\000\000\000)\000\000\000\003\000\000\000\020\000\000\000\024\000\000\000\
000\000\00050.6Mt Washingtonmountain\003\000\000\000\020\000\000\000\033\000\000\000\037\000\
000\000hike_safetynametype
```

2. Use the `mapToString()` function (with the `__raw__` column of `mountains`) to inspect its contents in readable JSON text format:

```
=> SELECT maptostring(__raw__) from mountains;
                                MAPTOSTRING
-----
{
  "height" : "29029",
  "hike_safety" : "34.1",
  "name" : "Everest",
  "type" : "mountain"
}
{
  "height" : "29029",
  "hike_safety" : "15.4",
  "name" : "Mt St Helens",
  "type" : "volcano"
}
{
  "height" : "17000",
  "hike_safety" : "12.2",
  "name" : "Denali",
  "type" : "mountain"
}
{
  "height" : "14000",
  "name" : "Kilimanjaro",
  "type" : "mountain"
}
{
  "hike_safety" : "50.6",
  "name" : "Mt Washington",
  "type" : "mountain"
}
```

3. Now, use the `compute_flexible_keys()` function to populate the `mountain_keys` table. Vertica generates this table automatically when you create your flex table.

```
=> SELECT compute_flexible_keys('mountains');
       compute_flexible_keys
-----
Please see public.mountains_keys for updated keys
(1 row)
```

4. Query the keys table (`mountains_keys`), and examine the results:

```
=> SELECT * from public.mountains_keys;
 key_name | frequency | data_type_guess
-----+-----+-----
hike_safety |          4 | varchar(20)
name       |          5 | varchar(26)
height    |          4 | varchar(20)
```

```
type          |          5 | varchar(20)
(4 rows)
```

Build a Flex Table View

1. Use the `build_flextable_view()` function to populate a view generated from the `mountains_keys` table.

```
=> SELECT build_flextable_view('mountains');
          build_flextable_view
-----
The view public.mountains_view is ready for querying
(1 row)
```

2. Query the view `mountains_view`:

```
=> SELECT * from public.mountains_view;
hike_safety | name          | type   | height
-----+-----+-----+-----
50.6       | Mt Washington | mountain |
34.1       | Everest      | mountain | 29029
22.8       | Kilimanjaro  | mountain | 14000
15.4       | Mt St Helens | volcano  | 29029
12.2       | Denali       | mountain | 17000
(5 rows)
```

3. Use the `view_columns` system table to query the `column_name` and `data_type` columns for `mountains_view`:

```
=> SELECT column_name, data_type from view_columns where table_name = 'mountains_view';
column_name | data_type
-----+-----
hike_safety | varchar(20)
name        | varchar(26)
type        | varchar(20)
height      | varchar(20)
(4 rows)
```

4. Review the query results:

- Notice the `data_type` column, its values and sizes. These are calculated when you compute keys for your flex table with `compute_flextable_keys()`.

- Did you also notice the `data_type_guess` column when you queried the `mountains_keys` table after invoking that function?
5. With the `data_type` information from `mountains_view`, override the `data_type_guess` for `hike_safety`. Then, `COMMIT` the change, and rebuild the view with `build_flexitable_view()`:

```
=> UPDATE mountains_keys SET data_type_guess = 'float' where key_name = 'hike_safety';
OUTPUT
-----
      1
(1 row)

=> commit;
=> SELECT build_flexitable_view('mountains');
           build_flexitable_view
-----
The view public.mountains_view is ready for querying
(1 row)
```

6. Next, use the `view_columns` system table. Notice that `hike_safety` is now a float data type:

```
=> SELECT column_name, data_type from view_columns where table_name = 'mountains_view';
column_name | data_type
-----+-----
hike_safety | float
name        | varchar(26)
type        | varchar(20)
height      | varchar(20)
(4 rows)
```

Create a Hybrid Flex Table

If you already know that some of the data you load and query regularly needs full Vertica performance and support, you can create a *hybrid* flex table. A hybrid flex table has one or more real columns that you define, and a `__raw__` column to store any unstructured data you load. Querying real columns is faster than querying flexible data in the `__raw__` column. You can define default values for the columns.

1. Create a hybrid flex table, and load the same sample JSON file:

```
=> CREATE flex table mountains_hybrid(name varchar(41) default name::varchar(41), hike_safety
float
```

```
default hike_safety::float);
=> COPY mountains_hybrid from '/home/dbadmin/Downloads/mountains.json' parser fjsonparser();
  Rows Loaded
-----
                5
(1 row)
```

2. Use the `compute_flexable_keys_and_build_view()` function to populate the keys table and build the view for `mountains_hybrid`:

```
=> SELECT compute_flexable_keys_and_build_view('mountains_hybrid');
           compute_flexable_keys_and_build_view
-----
Please see public.mountains_hybrid_keys for updated keys
The view public.mountains_hybrid_view is ready for querying
(1 row)
```

3. Query the `mountains_hybrid_keys` table. Review the `data_type_guesses` column values again. The types list the column definitions you declared when you created the hybrid table:

```
=> SELECT * from mountains_hybrid_keys;
  key_name | frequency | data_type_guess
-----+-----+-----
height    |          4 | varchar(20)
name      |          5 | varchar(41)
type      |          5 | varchar(20)
hike_safety |          4 | float
(4 rows)
```

If you create a basic flex table, and later find you want to promote one or more virtual columns to real columns, see [Materializing Flex Tables](#) to add columns.

Materialize Virtual Columns in a Hybrid Flex Table

After you explore your flex table data, you can promote one or more virtual columns in your flex table to real columns. You do not need to create a separate columnar table.

1. Invoke the `materialize_flextable_columns()` function on the hybrid table, specifying the number of virtual columns to materialize:

```
=> SELECT materialize_flextable_columns('mountains_hybrid', 3);
           materialize_flextable_columns
-----
The following columns were added to the table public.mountains_hybrid:
  type
For more details, run the following query:
SELECT * FROM v_catalog.materialize_flextable_columns_results WHERE
table_schema = 'public' and table_name = 'mountains_hybrid';

(1 row)
```

2. You specified three (3) columns to materialize, but the table was created with two real columns (`name` and `hike_safety`). To fulfill your three-column specification, the function promotes only one other column, `type`. The next example has expanded display to list the columns vertically. Notice the `ADDED` status for the column that was just materialized, rather than `EXISTS` for the two columns you defined when creating the table:

```
=> \x
Expanded display is on.
=> SELECT * from materialize_flextable_columns_results where table_name = 'mountains_hybrid';
-[ RECORD 1 ]-----
table_id      | 45035996273766044
table_schema  | public
table_name    | mountains_hybrid
creation_time | 2013-11-30 20:09:37.765257-05
key_name      | type
status        | ADDED
message       | Added successfully
-[ RECORD 2 ]-----
table_id      | 45035996273766044
table_schema  | public
table_name    | mountains_hybrid
creation_time | 2013-11-30 20:09:37.765284-05
key_name      | hike_safety
status        | EXISTS
message       | Column of same name already exists in table definition
-[ RECORD 3 ]-----
table_id      | 45035996273766044
table_schema  | public
table_name    | mountains_hybrid
creation_time | 2013-11-30 20:09:37.765296-05
key_name      | name
status        | EXISTS
message       | Column of same name already exists in table definition
```

3. Now, display the hybrid table definition, listing the `__raw__` column and the three materialized columns. Flex table data types are derived from the associated keys tables, so you can update them as necessary. Notice that the `__raw__` column has a default NOT

NULL constraint:

```
=> \d mountains_hybrid
List of Fields by Tables
-[ RECORD 1 ]-----
Schema      | public
Table       | mountains_hybrid
Column      | __raw__
Type        | long varbinary(130000)
Size        | 130000
Default     |
Not Null    | t
Primary Key | f
Foreign Key |
-[ RECORD 2 ]-----
Schema      | public
Table       | mountains_hybrid
Column      | name
Type        | varchar(41)
Size        | 41
Default     | (MapLookup(mountains_hybrid.__raw__, 'name'))::varchar(41)
Not Null    | f
Primary Key | f
Foreign Key |
-[ RECORD 3 ]-----
Schema      | public
Table       | mountains_hybrid
Column      | hike_safety
Type        | float
Size        | 8
Default     | (MapLookup(mountains_hybrid.__raw__, 'hike_safety'))::float
Not Null    | f
Primary Key | f
Foreign Key |
-[ RECORD 4 ]-----
Schema      | public
Table       | mountains_hybrid
Column      | type
Type        | varchar(20)
Size        | 20
Default     | (MapLookup(mountains_hybrid.__raw__, 'type'))::varchar(20)
Not Null    | f
Primary Key | f
Foreign Key |
```

You have now completed getting started with flex table basics, hybrid flex tables, and using flex functions.

Understanding Flex Tables

You can create flex tables and then manage them with their associated helper, data, and map functions. Flex tables:

- Do not require schema definitions
- Do not need column definitions
- Have full Unicode support
- Support SQL queries

You can use flex tables to promote data directly from exploration to analytic operations. Flex table features include:

- Ability to load different formats into one flex table, which lets you handle changing structure over time
- Full support of delimited and JSON data
- Extensive SQL queries and built-in analytics for the data you load
- Usability functions, which let you explore your unstructured data and then use built-in functions to materialize the data

Exploration to Promotion

After you create a flex table, you can quickly load data, including social media content in JSON, log files, delimited files, and other information. Previously, working with such data required significant schema design and preparation. Now, you can load and query flex tables in a few steps.

Creating flex tables is similar to creating other tables, except column definitions are optional. When you create flex tables, with or without column definitions, Vertica implicitly adds a real column to your table, called `__raw__`. This column stores loaded data. The `__raw__` column is a `LONG VARBINARY` column with a `NOT NULL` constraint. It contains the documented limits for its data type (see [Long Data Types](#) in the SQL Reference Manual. The `__raw__` column's default maximum width is 130,000 bytes (with an absolute maximum of 32,000,000 bytes). You can change the default width with the `FlexTablesRawSize` configuration parameter.

If you create a flex table without other column definitions, the table includes a second default column, `__identity__`, declared as an auto-incrementing IDENTITY (1,1) column. When no other columns are defined, flex tables use the `__identity__` column for segmentation and sort order.

Loading data into a flex table encodes the record into a VMap type and populates the `__raw__` column. The VMap is a standard dictionary type, pairing keys with string values as virtual columns.

Flex Table Terms

This guide uses the following terms when describing how you work with flex tables to explore and analyze flexible data:

- VMap: An internal map data format.
- Virtual Columns: Key-value pairs contained in a flex table `__raw__` column.
- Real Columns: Fully featured columns in flex or columnar tables.
- Promoted Columns : Virtual columns that have been materialized to real columns.
- Map Keys: Map keys are the virtual column names within VMap data.

Is There Structure in a Flex Table?

The term *unstructured data* (sometimes called *semi-structured* or *Dark Data*) does not indicate that the data you load into flex tables is entirely without structure. However, you may not know the data's composition or the inconsistencies of its design. In some cases, the data may not be relational.

Your data may have some structure (like JSON and delimited data). Data may be semi-structured or stringently structured, but in ways that you either do not know about or do not expect. In this guide, the term *flexible data* encompasses these and other kinds of data. You can load your flexible data directly into a flex table, and query its contents with your favorite SQL SELECT or other statements.

To summarize, you can load data first, without knowing its structure, and then query its content after a few simple transformations. In some cases, you already know the data structure, such as some tweet map keys, like `user.lang`, `user.screen_name`, and `user.url`. If so, you can query these values explicitly as soon as you load the data.

Storing Flex Table Data

While you can store unstructured data in a flex table `__raw__` column, that column is implemented as a real column.

Vertica compresses `__raw__` column data by about one half (1/2). While this factor is less than the compression rate for real columns, the reduction is significant for large amounts (more than 1TB) of unstructured data. After compression is complete, Vertica writes the data to disk (ROS). This approach maintains K-safety in your cluster and supports standard recovery processes should node failures occur. Flex tables are included in full backups (or, if you choose, in object-level backups).

What Happens When You Create Flex Tables?

Whenever you execute a `CREATE FLEX TABLE` statement, Vertica creates three objects, as follows:

- The flexible table (*flex_table*)
- An associated keys table (*flex_table_keys*)
- A default view for the main table (*flex_table_view*)

The `_keys` and `_view` objects are dependents of the parent, *flex_table*. Dropping the flex table also removes its dependents, although you can drop the `_keys` or `_view` objects independently.

You can create a flex table without specifying any column definitions (such as `darkdata`, in the next example). When you do so, Vertica automatically creates two tables, the named flex table (such as `darkdata`) and its associated keys table, `darkdata_keys`:

```
=> CREATE flex table darkdata();
CREATE TABLE
=> \dt dark*
      List of tables
 Schema |      Name      | Kind | Owner  | Comment
-----+-----+-----+-----+-----
 public | darkdata       | table | dbadmin |
 public | darkdata_keys  | table | dbadmin |
(2 rows)
```

Each flex table has two default columns, `__raw__` and `__identity__`. The `__raw__` column exists in every flex table to hold the data you load. The `__identity__` column is auto-incrementing. Vertica uses the `__identity__` column for segmentation and sort order when no other column definitions exist. The flex keys table (`darkdata_keys`) has three columns, as shown:

```
=> SELECT * FROM darkdata;
__identity__ | __raw__
-----+-----
(0 rows)

=> SELECT * FROM darkdata_keys;
key_name | frequency | data_type_guess
-----+-----
(0 rows)
```

Creating a flex table with column definitions (such as `darkdata1`, in the next example) automatically generates a table with the `__raw__` column. However, the table has no `__identity__` column because columns are specified for segmentation and sort order. Two tables are created automatically, as shown in the following example:

```
=> CREATE FLEX TABLE darkdata1 (name VARCHAR);
CREATE TABLE

=> SELECT * FROM darkdata1;
__raw__ | name
-----+-----
(0 rows)

=> \d darkdata1*

                                List of Fields by Tables
 Schema | Table  | Column |          Type          | Size | Default | Not Null | Primary Key | Foreign Key
-----+-----+-----+-----+-----+-----+-----+-----+-----
 public | darkdata1 | __raw__ | long varbinary(130000) | 130000 |         | t        | f           |
 public | darkdata1 | name    | varchar(80)           | 80    |         | f        | f           |
(2 rows)

=> \dt darkdata1*

                                List of tables
 Schema | Name          | Kind | Owner  | Comment
-----+-----+-----+-----+-----
 public | darkdata1     | table | dbadmin |
 public | darkdata1_keys | table | dbadmin |
(2 rows)
```

Creating a flex table with at least one column definition (`darkdata1` in the next example) also generates a table with the `__raw__` column, but not an `__identity__` column. Instead, the specified columns are used for segmentation and sort order. Two tables are also created automatically, as shown in the following example:

```
=> CREATE FLEX TABLE darkdata1 (name VARCHAR);
CREATE TABLE

=> \d darkdata1*

                          List of Fields by Tables
 Schema | Table | Column | Type | Size | Default | Not Null | Primary Key | Foreign Key
-----+-----+-----+-----+-----+-----+-----+-----+-----
 public | darkdata1 | __raw__ | long varbinary(130000) | 130000 | | t | f |
 public | darkdata1 | name | varchar(80) | 80 | | f | f |
(2 rows)

=> \dt darkdata1*

                          List of tables
 Schema | Name | Kind | Owner | Comment
-----+-----+-----+-----+-----
 public | darkdata1 | table | dbadmin |
 public | darkdata1_keys | table | dbadmin |
(2 rows)
```

For more examples, see [Creating Flex Tables](#).

Creating Superprojections Automatically

In addition to creating two tables for each flex table, Vertica creates superprojections for both the main flex table and its associated keys table. Using the `\dj` command, you can display the projections created automatically for the `darkdata` and `darkdata1` tables in this set of examples:

```
=> \dj darkdata*

                          List of projections
 Schema | Name | Owner | Node | Comment
-----+-----+-----+-----+-----
 public | darkdata1_b0 | dbadmin | |
 public | darkdata1_b1 | dbadmin | |
 public | darkdata1_keys_super | dbadmin | v_vmart_node0001 |
 public | darkdata1_keys_super | dbadmin | v_vmart_node0003 |
 public | darkdata1_keys_super | dbadmin | v_vmart_node0004 |
 public | darkdata_b0 | dbadmin | |
 public | darkdata_b1 | dbadmin | |
 public | darkdata_keys__super | dbadmin | v_vmart_node0001 |
 public | darkdata_keys_super | dbadmin | v_vmart_node0003 |
 public | darkdata_keys_super | dbadmin | v_vmart_node0004 |
(10 rows)
```

Default Flex Table View

When you create a flex table, you also create a default view. This default view uses the table name with a `_view` suffix, as listed in the next example, which shows the list of views for `darkdata` and `darkdata1`. If you query the default view, you are prompted to use the [COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW](#) function. This view enables you to update the view after you load data so that it includes all keys and values.

```
=> \dv darkdata*
          List of View Fields
Schema |      View      | Column |      Type      | Size
-----+-----+-----+-----+-----
public | darkdata_view  | status | varchar(124)   | 124
public | darkdata1_view | status | varchar(124)   | 124
(2 rows)
```

For more information, see [Updating Flex Table Views](#).

Flex Functions

There are three sets of functions to support flex tables and extracting data into VMaps. See the following sections for more information:

- Data (helper) functions ([Flex Data Functions Reference](#))
- Extractor functions ([Flex Extractor Functions Reference](#))
- Map functions ([Flex Map Functions Reference](#))

Using Clients with Flex Tables

You can use the Vertica supported client drivers with flex tables as follows:

- To load data into a flex table, you can use the `INSERT` statement or `COPY LOCAL` with the appropriate flex table parser.
- The driver metadata APIs return only real columns. For example, using a `SELECT * FROM myflex;` statement, when `myflex` has a single materialized column (name), returns the `__raw__` and `name` columns. However, it does not return virtual columns from within `__raw__`

_. To access virtual columns and their values, query the associated `flextable_keys` table, just as you would in `vsq`.

Creating Flex Tables

You can create a flex table or an external flex table without column definitions or other parameters. You can use any CREATE TABLE statement parameters you prefer, as usual.

Unsupported CREATE FLEX TABLE Statements

These statements are not currently supported:

- CREATE FLEX TABLE LIKE...

Creating Basic Flex Tables

Here's how to create the table:

```
=> CREATE FLEX TABLE darkdata();  
CREATE TABLE
```

Selecting from the table before loading any data into it reveals its two real columns, `__identity__` and `__raw__`:

```
=> SELECT * FROM darkdata;  
__identity__ | __raw__  
-----+-----  
(0 rows)
```

Below is an example of creating a flex table with a column definition:

```
=> CREATE FLEX TABLE darkdata1(name VARCHAR);  
CREATE TABLE
```

When flex tables exist, you can add new columns (including those with default derived expressions), as described in [Materializing Flex Tables](#).

Creating Temporary Flex Tables

Before you create temporary global and local flex tables, be aware of the following considerations:

- GLOBAL TEMP flex tables are supported. Creating a temporary global flex table results in the `flexable_keys` table and the `flexable_view` having temporary table restrictions for their content.
- LOCAL TEMP flex tables must include at least one column definition. The reason for this requirement is that local temp tables do not support automatically-incrementing data (such as the flex table default `__identity__` column). Creating a temporary local flex table results in the `flexable_keys` table and the `flexable_view` existing in the local temporary object scope.
- LOCAL TEMP views are supported for flex and columnar temporary tables.

For global or local temp flex tables to function correctly, you must also specify the `ON COMMIT PRESERVE ROWS` clause. You must use the `ON COMMIT` clause for the flex table helper functions, which rely on commits. Create a local temp table as follows:

```
=> CREATE FLEX LOCAL TEMP TABLE good(x int) ON COMMIT PRESERVE ROWS;  
CREATE TABLE
```

After creating a local temporary flex table using this approach, you can then load data into the table, create table keys, and a flex table view:

```
=> COPY good FROM '/home/release/KData/bake.json' PARSER fjsonparser();  
Rows Loaded  
-----  
1  
(1 row)  
  
=> select compute_flexable_keys_and_build_view('good');  
compute_flexable_keys_and_build_view  
-----  
Please see v_temp_schema.good_keys for updated keys  
The view good_view is ready for querying  
(1 row)
```

Similarly, you can create global temp tables as follows:

```
=> CREATE FLEX GLOBAL TEMP TABLE good_global(x int) ON COMMIT PRESERVE ROWS;
```

After creating a global temporary flex table using this approach, you can then load data into the table, create table keys, and a flex table view:

```
=> COPY good_global FROM '/home/dbadmin/data/flex/bake_single.json' PARSER fjsonparser();  
Rows Loaded  
-----  
5  
(1 row)  
  
=> SELECT compute_flexable_keys_and_build_view('good_global');
```

```
compute_flexible_keys_and_build_view
```

```
-----  
Please see v_temp_schema.good_keys for updated keys  
The view good_view is ready for querying  
(1 row)
```

Materializing Flex Table Virtual Columns

After you create your flex table and load data, you compute keys from virtual columns. After completing those tasks, you can materialize some keys by promoting virtual columns to real table columns. By promoting virtual columns, you query real columns rather than the raw data.

You can promote one or more virtual columns — materializing those keys from within the `__raw__` data to real columns. Vertica recommends this approach to get the best query performance for all important keys. You don't need to create new columnar tables from your flex table.

Materializing flex table columns results in a hybrid table. Hybrid tables:

- Maintain the convenience of a flex table for loading unstructured data
- Improve query performance for any real columns

If you have only a few columns to materialize, try altering your flex table progressively, adding columns whenever necessary. You can use the `ALTER TABLE . . . ADD COLUMN` statement to do so, just as you would with a columnar table. See [Materializing Flex Tables](#) for ideas about adding columns.

If you want to materialize columns automatically, use the helper function [MATERIALIZED_FLEXIBLE_COLUMNS](#)

Creating Columnar Tables from Flex Tables

You can create a regular Vertica table from a flex table, but you cannot use one flex table to create another.

Typically, you create a columnar table from a flex table after loading data. Then, you specify the virtual column data you want in a regular table, casting virtual columns to regular data types.

(1 row)

1. Check the keys from the `_keys` table for the results of running the helper application:

```
=> SELECT * FROM appLog_keys;
-----+-----+-----
          key_name                               | frequency | data_type_guess
-----+-----+-----
contributors                                   |          8 | varchar(20)
coordinates                                     |          8 | varchar(20)
created_at                                       |          8 | varchar(60)
entities.hashtags                               |          8 | long varbinary(186)
.
.
.
retweeted_status.user.time_zone                 |          1 | varchar(20)
retweeted_status.user.url                       |          1 | varchar(68)
retweeted_status.user.utc_offset                |          1 | varchar(20)
retweeted_status.user.verified                  |          1 | varchar(20)
(125 rows)
```

2. Query from the external flex table view:

```
=> SELECT "user.lang" FROM appLog_view;
 user.lang
-----
it
en
es
en
en
es
tr
en
(12 rows)
```

Note: External tables are fully supported for both flex and columnar tables. However, using external flex (or columnar) tables is less efficient than using flex tables whose data is stored in the Vertica database. Data that is maintained externally requires reloading each time you query.

Creating a Flex Table from Query Results

You can use the `CREATE FLEX TABLE AS` statement to create a flex table from the results of a query.

You can use this statement to create three types of flex tables:

- Flex table with no materialized columns
- Flex table with some materialized columns
- Flex table with all materialized columns

When a flex `__raw__` column is present in the CTAS query, the entire source VMap is carried to the flex table. If the query has matching column names, the key values are overridden.

Note: ORDER BY and segmentation clauses are only passed to the new flex table if the relevant columns are materialized.

Examples

Creating a flex table with no materialized columns from a regular table causes the results of the query to be stored in the `__raw__` column as a VMap.

1. Create a regular table named `pets` with two columns:

```
=> CREATE TABLE pets(age INT, name VARCHAR);  
CREATE TABLE
```

2. Create a flex table named `family_pets` by using the CTAS statement to copy the columns `age` and `name` from the `pets`:

```
=> CREATE FLEX TABLE family_pets() AS SELECT age, name FROM pets;  
CREATE TABLE
```

3. View the new flex table to confirm the operation has been successful and that the columns `age` and `name` have not been materialized.

```
=> \d family_pets;  
List of Fields by Tables  
Schema | Table      | Column      | Type                               | Size  | Default | Not Null |  
Primary Key | Foreign Key  
-----+-----+-----+-----+-----+-----+-----+-----  
public  | family_pets | __identity__ | int                                | 8     |         | t       | f  
|  
public  | family_pets | __raw__      | long varbinary(130000)           | 130000 |         | t       | f  
|  
(2 rows)
```

You can create a flex table with no materialized columns from the results of a query of another flex table. This inserts all the VMaps from the source flex table into the target. This creates a flex table segmented and ordered by the `__identity__` column.

4. Create a flex table named `city_pets` by using the CTAS statement to copy the `age` and `__raw__` columns from `family_pets`:

```
=> CREATE FLEX TABLE city_pets() AS SELECT age, __raw__ FROM family_pets;  
CREATE TABLE
```

5. View the new flex table to confirm that the operation has been successful and the columns `age` and `__raw__` have not been materialized.

```
=> SELECT * FROM city_pets;  
List of Fields by Tables  
Schema | Table | Column | Type | Size | Default | Not Null |  
Primary Key | Foreign Key  
-----+-----+-----+-----+-----+-----+-----+-----  
public | city_pets | __identity__ | int | 8 | | t | f  
|  
public | city_pets | __raw__ | long varbinary(130000) | 130000 | | t | f  
|  
(2 rows)
```

You can create a flex table with some materialized columns. This uses a syntax similar to the syntax for creating columnar tables with some materialized columns. Unlike columnar tables, however, you need to match the number of columns with the columns that are returned by the query. In the following example, our query returns three columns (`amount`, `type`, and `available`), but Vertica only materializes the first two.

6. Create a table named `animals` with three columns, `amount`, `type`, and `available`:

```
=> CREATE TABLE animals(amount INT, type VARCHAR, available DATE);
```

7. Create a flex table named `inventory` with columns `animal_amount` and `animal_type` using the CTAS statement to copy columns `amount`, `type`, and `available` from `animals`.

```
=> CREATE FLEX TABLE inventory(animal_amount, animal_type) AS SELECT amount, type, available  
FROM animals;  
CREATE TABLE
```

8. View the table data to confirm that columns `amount` and `type` have been materialized under the column names `animal_amount` and `animal_type`. Column `available` from `animals` has also been copied over but was not materialized:

```
=> \d inventory
      List of Fields by Tables
Schema | Table | Column          | Type                | Size  | Default | Not Null |
-----+-----+-----+-----+-----+-----+-----+
public | flex3 | __raw__         | long varbinary(130000) | 130000 |         | t        | f
      |      | animal_amount  | int                  | 8      |         | f        | f
      |      | animal_type    | varchar(80)         | 80     |         | f        | f
(3 rows)
```

Notice that including empty parentheses in the statement results in a flex table with no materialized columns:

9. Create a flex table named `animals_for_sale` using the CTAS statement with empty parentheses to copy columns `amount`, `type`, and `available` from `animals` into a pure flex table:

```
=> CREATE FLEX TABLE animals_for_sale() AS SELECT amount, type, available FROM animals;
CREATE TABLE
```

10. View the table data to confirm that no columns were materialized:

```
=>\d animals_for_sale;
      List of Fields by Tables
Schema | Table          | Column          | Type                | Size  | Default | Not Null |
-----+-----+-----+-----+-----+-----+-----+
public | animals_for_sale | __identity__   | int                 | 8     |         | t        |
      |                  | __raw__       | long varbinary(130000) | 130000 |         | t        |
(2 rows)
```

Omitting any parentheses in the statement causes all columns to be materialized:

11. Create a flex table named `animals_sold` using the CTAS statement without parentheses. This copies columns `amount`, `type`, and `available` from `animals` and materialize all columns:

```
=> CREATE FLEX TABLE animals_sold AS SELECT amount, type, available FROM animals;
CREATE TABLE
```

12. View the table data to confirm that all columns were materialized:

```
=> \d animals_sold;
      List of Fields by Tables
```

Bulk Loading Data into Flex Tables

You bulk load data into a flex table with a COPY statement, specifying one of the flex parsers:

- FAVROPARSER
- FCEFPARSER
- FCSVPARSER
- FDELIMITEDPAIRPARSER
- FDELIMITEDPARSER
- FJSONPARSER
- FREGEXPARSER

All flex parsers store the data as a single-value VMap. They reside in the VARBINARY `__raw__` column, which is a real column with a NOT NULL constraint. The VMap is encoded into a single binary value for storage in the `__raw__` column. The encoding places the value strings in a contiguous block, followed by the key strings. Vertica supports null values within the VMap for keys with NULL-specified columns. The key and value strings represent the virtual columns and their values in your flex table.

If a flex table data row is too large to fit in the VARBINARY `__raw__` column, it is rejected. By default, the rejected data and exceptions files are stored in the standard CopyErrorLogs location, a subdirectory of the catalog directory:

```
v_mart_node003_catalog/CopyErrorLogs/trans-STDIN-copy-from-exceptions.1  
v_mart_node003_catalog/CopyErrorLogs/trans-STDIN-copy-rejections.1
```

Flex tables do not copy any rejected data, due to disk space considerations. The rejected data file exists, but it contains only a new line character for every rejected record. The corresponding exceptions file lists the reason why each record was rejected.

You can specify a different path and file for the rejected data and exceptions files. To do so, use the COPY parameters REJECTED DATA and EXCEPTIONS, respectively. You can also save load rejections and exceptions in a table. For more information, see [Bulk-Loading Data](#).

Basic Flex Table Load and Query

Loading data into your flex table is similar to loading data into a regular columnar table. The difference is that you must use the parser argument with one of the flex parsers:

```
=> COPY darkdata FROM '/home/dbadmin/data/tweets_12.json' PARSER fjsonparser();
Rows Loaded
-----
          12
(1 row)
```

Note: You can use many additional COPY parameters as required but not all are supported.

Loading Data into Flex Table Real Columns

If you create a hybrid flex table with one or more real column definitions, COPY evaluates each virtual column key name during data load. For each real column with a name that is identical to a virtual column key name, COPY does the following:

- Loads the keys and values as part of the VMap data in the `__raw__` column
- Automatically populates real columns with the values from their virtual column counterparts

Subsequent data loads continue loading same-name key-value pairs into both the `__raw__` column and the real column.

Note: Over time, storing values in both column types can impact your licensed data limits. For more information about Vertica licenses, see [Managing Licenses](#) in the Administrator's Guide.

For example, continuing with the JSON data:

1. Create a flex table, `darkdata1`, with a column definition of one of the keys in the data you will load:

```
=> CREATE FLEX TABLE darkdata1 ("user.lang" VARCHAR);
CREATE TABLE
```

2. Load data into darkdata1:

```
=> COPY darkdata1 FROM '/test/vertica/flextable/DATA/tweets_12.json' PARSER fjsonparser();
Rows Loaded
-----
                12
(1 row)
```

3. Query the user.lang column of darkdata1. Loading the JSON data file populated the column you defined:

```
=> SELECT "user.lang" FROM darkdata1;
user.lang
-----
es
es
tr
it
en
en
en
en
(12 rows)
```

Empty column rows indicate NULL values. For more information about how NULLs are handled in flex tables, see [NULL Value](#).

4. You can query for other virtual columns (such as "user.name" in darkdata1), with similar results as for "user.lang":

```
=> SELECT "user.name" FROM darkdata1;
user.name
-----
I'm Toasterâ¸
Flu Beach
seydo shi
The End
Uptown gentleman.
~G A B R I E L A â¸
Frederick Danjou
laughing at clouds.
(12 rows)
```

Note: While the results for these two queries are similar, the difference in accessing the keys and their values is significant. Data for "user.lang" has been materialized into a real table column, while "user.name" remains a virtual column. For production-level data usage (rather than test data sets), materializing flex table data improves query performance significantly.

Handling Default Values During Loading

You can create your flex table with a real column, named for a virtual column that exists in your incoming data. For example, if the data you load has a `user.lang` virtual column, define the flex table with that column. You can also specify a default column value when creating the flex table with real columns. The next example shows how to define a real column (`user.lang`), which has a default value from a virtual column (`user.name`):

```
=> CREATE FLEX TABLE darkdata1 ("user.lang" LONG VARCHAR default "user.name");
```

When you load data into your flex table, COPY uses values from the flex table data, ignoring the default column definition. Loading data into a flex table requires [MAPLOOKUP](#) to find keys that match any real column names. A match exists when the incoming data has a virtual column with the same name as a real column. When COPY detects a match, it populates the column with values. COPY returns either a value or NULL for each row, so real columns always have values.

For example, after creating the `darkdata1` flex table, described in the previous example, load data with COPY:

```
=> COPY darkdata1 FROM '/test/vertica/flexible/DATA/tweets_12.json' PARSER fjsonparser();
Rows Loaded
-----
          12
(1 row)
```

If you query the `darkdata1` table after loading, the data shows that the values for the `user.lang` column were extracted:

- From the data being loaded — values for the `user.lang` virtual column
- With NULL — rows without values

In this case, the table column default value for `user.lang` was ignored:

```
=> SELECT "user.lang" FROM darkdata1;
user.lang
-----
it
en
es
en
en
es
tr
```

```
en  
(12 rows)
```

Using COPY to Specify Default Column Values

You can add an expression to a COPY statement to specify default column values when loading data. For flex tables, specifying any column information requires that you list the `__raw__` column explicitly. The following example shows how to use an expression for the default column value. In this case, loading populates the defined `user.lang` column with data from the input data `user.name` values:

```
=> COPY darkdata1(__raw__, "user.lang" as "user.name"::VARCHAR)  
    FROM '/test/vertica/flexibletable/DATA/tweets_12.json' PARSER fjsonparser();  
Rows Loaded  
-----  
          12  
(1 row)  
=> SELECT "user.lang" FROM darkdata1;  
       user.lang  
-----  
laughing at clouds.  
Avita Desai  
I'm Toasterâ€  
Uptown gentleman.  
~G A B R I E L A â€  
Flu Beach  
seydo shi  
The End  
(12 rows)
```

You can specify default values when adding columns, as described in [Altering Flex Tables](#). When you do so, a different behavior results. For more information about using COPY, its expressions and parameters, see [Bulk-Loading Data](#) in the Administrator's Guide and [COPY](#) in the SQL Reference Manual.

Inserting Data into Flex Tables

You can load data into a Vertica flex table using a standard `INSERT` statement, specifying data for one or more columns. When you use `INSERT`, Vertica populates any materialized columns and stores the VMap data in the `__raw__` column.

Vertica provides two ways to use `INSERT` with flex tables:

- `INSERT ... VALUES`
- `INSERT ... SELECT`

Inserting Values into Flex Tables

To insert data values into a flex table, use an `INSERT ... VALUES` statement. If you do not specify any columns in your `INSERT ... VALUES` statement, Vertica positionally assigns values to the real columns of the flex table.

This example shows two ways to insert values into a simple flex table. For both statements, Vertica assigns the values 1 and 'x' to columns a and b, respectively. This example inserts values into the two real columns defined in the flex table:

```
=> CREATE FLEX TABLE flex0 (a INT, b VARCHAR);
CREATE TABLE
=> INSERT INTO flex0 VALUES (1, 'x');
OUTPUT
-----
      1
(1 row)
```

This example inserts values into a flex table without any real columns:

```
=> CREATE FLEX TABLE flex1();
CREATE TABLE
=> INSERT INTO flex1(a,b) VALUES (1, 'x');
OUTPUT
-----
      1
(1 row)
```

For the preceding example, the `__raw__` column contains the inserted data:

```
=> SELECT MapToString(__raw__) FROM flex1;
      MapToString
-----
{
```

```
"a" : "1",  
"b" : "x"  
}  
(1 row)
```

Using INSERT ... SELECT with Flex Tables

Using an INSERT ... SELECT statement with a flex table is similar to using INSERT ... SELECT with a regular table. The SELECT statement returns the data to insert into the target table.

However, Vertica does *not* require that you balance the number of columns and values. If you do not specify a value for a column, Vertica inserts NULL.

In the next example, Vertica copies the a and b values from the flex1 table, and creates columns c, d, e, and f. Because the statement does not specify a value for f, Vertica assigns it a NULL.

```
=> CREATE FLEX TABLE flex2();  
CREATE TABLE  
=> INSERT INTO flex2(a,b) SELECT a,b, '2016-08-10 11:10' c, 'Hello' d, 3.1415 e, f from flex1;  
OUTPUT  
-----  
      1  
(1 row)  
=> SELECT MapToString(__row__) FROM flex2;  
                MapToString  
-----  
{  
"a" : "1",  
"b" : "x",  
"c" : "2016-08-10 11:10",  
  
"d" : "Hello",  
"e" : "3.1415",  
"f" : null  
}  
(1 row)
```

Inserting __row__ Columns into a Flex Table

Inserting a __row__ column into a flex table inserts the entire source VMap into the target table. Vertica does not assign the __row__ column to any target column. Its position in the SELECT statement does not matter.

The following two INSERT statements are equivalent.

```
=> INSERT INTO flex4(a,b) SELECT a, __row__, b FROM flex3;  
=> INSERT INTO flex4(a,b) SELECT a, b, __row__ FROM flex3;
```

Error Handling

Type coercion errors occur only with real columns. The insert operation fails as follows:

```
=> CREATE FLEX TABLE my_table(a INT, b VARCHAR);  
CREATE TABLE  
=> INSERT INTO my_table(a, b) VALUES ('xyz', '5');  
ERROR: Invalid input syntax for integer: "xyz"
```

If you try to insert values into the `__row__` column, the insert fails as follows:

```
=> CREATE FLEX TABLE my_table(a INT, b VARCHAR);  
CREATE TABLE  
=> INSERT INTO my_table(a,b,__row__) VALUES (1,'x','abcdef');  
ERROR 7372: Cannot assign value to "__row__" column
```

Using Flex Tables for IDOL Data

You can create flex tables to use with the IDOL Connector Framework Server (CFS) and an ODBC client. The CFS VerticalIndexer module uses the connector to retrieve data. CFS then indexes the data into your Vertica database.

CFS supports many connectors for interfacing to different unstructured file types stored in repositories. Examples of repositories include Microsoft Exchange (email), file systems (including Word documents, images, and videos), Microsoft SharePoint, and Twitter (containing Tweets).

Connectors retrieve and aggregate data from repositories. CFS indexes the data, sending it to IDOL, IDOL OnDemand, or Vertica. The following figure illustrates a basic setup with a repository and a connector.

After you configure CFS and connect it to your Vertica database, the connector monitors the repository for changes and deletions to loaded documents, and for new files not previously added to the server. CFS then updates its server destinations automatically.

To achieve the best query results with ongoing CFS updates and deletes, Micro Focus recommends using live aggregate projections and top-K projections. For more information about how these projections work, and for examples of using them, see [Working with Projections](#) in the Administrator's Guide.

ODBC Connection String for CFS

There are several steps to setting up the CFS VerticalIndexer to load IDOL metadata into your database.

One of the first steps is to add information to the CFS configuration file. To do so, add an Indexing section to the configuration file that specifies the ODBC ConnectionString details.

Successfully loading data requires a valid database user with write permissions to the destination table. Two ODBC connection parameters (UID and PWD) specify the Vertica user and password. The following example shows a sample CFS Indexing section. The section includes a ConnectionString with the basic parameters, including a sample user (UID=fjones) and password (PWD=fjones_password):

```
[Indexing]
IndexerSections=vertica
IndexTimeInterval=30

[vertica]
IndexerType = Library
ConnectionString=Driver=Vertica;Server=123.456.478.900;Database=myDB;UID=fjones;PWD=fjones_password
TableName = marcomm.myFlexTable
LibraryDirectory = ./shared_library_indexers
LibraryName = verticaIndexer
```

For more information about ODBC connection parameters, see [ODBC Configuration Parameters](#).

CFS COPY LOCAL Statement

CFS first indexes and processes metadata from a document repository to add to your database. Then, CFS uses the Indexing information you added to the configuration file to create an ODBC connection. After establishing a connection, CFS generates a standard COPY LOCAL statement, specifying the fjsonparser. CFS loads data directly into your pre-existing flex table with a statement such as the following:

```
=> COPY myFlexTable FROM LOCAL path_to_compressed_temporary_json_file PARSER fjsonparser();
```

```
=> SELECT * FROM myavro;
__identity__ | __raw__
-----+-----
(0 rows)
```

When your IDOL metadata appears in a flex table, you can optionally add new table columns, or materialize other data, as described in [Altering Flex Tables](#).

Using Flex Table Parsers

You can load flex tables with one of several parsers. You can load data using the options that the flex parsers support:

- [Loading Avro Data](#)
- [Loading Common Event Format \(CEF\) Data](#)
- [Loading CSV Data](#)
- [Loading Delimited Data](#)
- [Loading JSON Data](#)
- [Loading Matches from Regular Expressions](#)

Using Flex Parsers for Columnar Tables

You can use any of the flex parsers to load data into columnar tables. Using the flex table parsers to load columnar tables gives you the capability to mix data loads in one table. For example, you can load JSON data in one session and delimited data in another.

Note: For Avro data, you can load only data into a columnar table, not the schema. For flex tables, Avro schema information is required to be embedded in the data.

The following basic examples illustrate how you can use flex parsers with columnar tables.

1. Create a columnar table, `super`, with two columns, `age` and `name`:

```
=> CREATE TABLE super(age INT, name VARCHAR);  
CREATE TABLE
```

2. Enter JSON values from STDIN, using the `fjsonparser()`:

```
=> COPY super FROM stdin PARSER fjsonparser();  
Enter data to be copied followed by a newline.  
End with a backslash and a period on a line by itself.  
>> {"age": 5, "name": "Tim"}  
>> {"age": 3}  
>> {"name": "Fred"}  
>> {"name": "Bob", "age": 10}
```

```
>> \.
```

3. Query the table to see the values you entered:

```
=> SELECT * FROM super;
 age | name
-----+-----
      | Fred
  10 | Bob
   5 | Tim
   3 |
(4 rows)
```

4. Enter some delimited values from STDIN, using the `fdelimitedparser()`:

```
=> COPY super FROM stdin PARSER fdelimitedparser();
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> name |age
>> Tim|50
>> |30
>> Fred|
>> Bob|100
>> \.
```

5. Query the flex table. Both JSON and delimited data are saved in the same columnar table, `super`.

```
=> SELECT * FROM super;
 age | name
-----+-----
  50 | Tim
  30 |
   3 |
   5 | Tim
 100 | Bob
      | Fred
  10 | Bob
      | Fred
(8 rows)
```

Use the `reject_on_materialized_type_error` parameter to avoid loading data with type mismatch. If `reject_on_materialized_type_error` is set to `false`, the flex parser will accept the data with type mismatch. Consider the following example:

Assume that the CSV file to be loaded has the following sample contents:

```
$ cat json.dat
{"created_by":"system","site_source":"flipkart_india_kol","updated_by":"system1","invoice_id":"INVDPKOL100",
"vendor_id":"VEN15731","total_quantity":12,"created_at":"2012-01-09 23:15:52.0"}
```

```
{"created_by":"system","site_source":"flipkart_india_kol","updated_by":"system2","invoice_id":"INVDPKOL101",  
"vendor_id":"VEN15732","total_quantity":14,"created_at":"hello"}
```

1. Create a columnar table.

```
=> CREATE TABLE hdf5_test (  
  site_source VARCHAR(200),  
  total_quantity int ,  
  vendor_id varchar(200),  
  invoice_id varchar(200),  
  updated_by varchar(200),  
  created_by varchar(200),  
  created_at timestamp  
);
```

2. Load JSON data.

```
=> COPY hdf5_test FROM '/home/dbadmin/json.dat' PARSER fjsonparser() ABORT ON ERROR;  
Rows Loaded  
-----  
2  
(1 row)
```

3. View the contents.

```
=> SELECT * FROM hdf5_test;  
site_source | total_quantity | vendor_id | invoice_id | updated_by | created_by | created_at  
-----+-----+-----+-----+-----+-----+-----  
flipkart_india_kol | 12 | VEN15731 | INVDPKOL100 | system1 | system | 2012-01-09 23:15:52  
flipkart_india_kol | 14 | VEN15732 | INVDPKOL101 | system2 | system |  
(2 rows)
```

4. If `reject_on_materialized_type_error` parameter is set to `true`, you will receive errors when loading the sample JSON data.

```
=> COPY hdf5_test FROM '/home/dbadmin/data/flex/json.dat' PARSER fjsonparser(reject_on_ materialized_type_error=true) ABORT ON ERROR;  
ERROR 2035: COPY: Input record 2 has been rejected (Rejected by user-defined parser)
```

Loading Avro Data

You can load Avro data files into flex tables and columnar tables using the parser, `favroparser`. Before loading, verify that Avro files are encoded in the Avro binary serialization encoding format, described in the [Apache Avro standard](#). The parser also supports Snappy compression. You cannot load Avro data directly from STDIN.

Note: The parser `favroparser` does not support Avro files with separate schema files. The Avro file must have its related schema in the file you are loading.

You can use the following data types and optional parameters for `favroparser`.

The `favroparser` supports two data types:

- [Primitive Data Types for favroparser](#)
- [Complex Data Types for favroparser](#)

Rejecting Data on Materialized Column Type Errors

The `favroparser` has a Boolean parameter, `reject_on_materialized_type_error`. If you set this parameter to `true`, Vertica rejects rows when the input data presents *both* of the following conditions:

- Includes keys matching an existing materialized column
- Has a value that cannot be coerced into the materialized column's data type

Suppose the flex table has a materialized column, `Temperature`, declared as a `FLOAT`. If you try to load a row with a `Temperature` key that has a `VARCHAR` value, `favroparser` rejects the data row.

See Also

- [Using COPY with Data Streaming](#)

Primitive Data Types for favroparser

The `favroparser` supports the following primitive data types:

AVRO Data Type	Vertica Data Type	Value
NULL	NULL Value	No value
boolean	Boolean Data Type	A binary value
int	<code>INTEGER</code>	32-bit

		signed integer
long	INTEGER	64-bit signed integer
float	DOUBLE PRECISION (FLOAT) Synonymous with 64-bit IEEE FLOAT	Single precision (32-bit) IEEE 754 floating-point number
double	DOUBLE PRECISION (FLOAT)	Double precision (64-bit) IEEE 754 floating-point number
bytes	BYTES	Sequence of 8-bit unsigned bytes
string	VARCHAR	Unicode character sequence

Note: Vertica does not have an explicit 4-byte (32-bit integer) or smaller types. Instead, Vertica encoding and compression automatically eliminate the storage overhead of values that require less than 64 bits.

Vertica copies each primitive type into the `__raw__` column of the flex table. In this copy operation, the name of the primitive type becomes a virtual column key with its corresponding value as the value of the virtual column.

If the flex table has materialized columns, `favroparser` loads the primitive data type into the corresponding Vertica type for the column. If the parsing is successful, Vertica copies the data into the materialized column; otherwise, it rejects the row.

Complex Data Types for favroparser

You specify the data type of a record in the Avro file using the `type` parameter for `favroparser`. The `favroparser` supports these complex data types:

- [Records](#)
- [Enums](#)
- [Arrays](#)
- [Maps](#)
- [Unions](#)
- [Fixed](#)

This section describes attributes associated with the complex data types.

Records

Records have the following attributes:

Attribute	Description
name	A JSON string for the name of the record
fields	A JSON array used to list fields. Each field is a JSON object: <ul style="list-style-type: none">• name: A JSON string for the name of the field• type: A JSON object used to define a schema or a JSON string used for naming a record definition

The name of each field is used as a virtual column name. If `flatten_records = true` and several nesting levels are present, Vertica concatenates the record names to create the `key_name`, as follows:

```
{
  "type": "record",
  "name": "Profile",
  "fields" : [
    {"name": "UserName", "type": "string"},
    {"name": "Address", "type": "string"}
  ]
}
```

```
{
  "type": "record",
  "name": "Profile",
  "fields" : [
    {VerticaUser},
    {VerticaUser Address}
  ]
}
```

Vertica creates virtual columns for the records as follows:

Names	Values
UserName	VerticaUser
Address	VerticaUser Address

Enums

Enums (enumerated values) use the type name enum and support the following attributes:

Attribute	Description
name	A JSON string for the name of the enum
symbols	A JSON array used to list symbols as JSON strings. All symbols in an enum must be unique and duplicates are prohibited

Example:

```
{
  "type": "enum",
  "name": "suit",
  "symbols" : ["SPADES", "HEARTS", "DIAMONDS", "CLUBS"]
}
```

Consider the preceding Avro schema with a record that contains a field with the value HEARTS. In this case, the key value pair copied into the `__raw__` column has `suit` as the key and HEARTS as the value.

Arrays

Arrays use the type name `array` and support one attribute:

Attribute	Description
items	The schema of the array's items

For example, declare an array of strings:

```
{"type": "array", "items": "string"}
```

Similar to the capabilities for Records, you can nest and flatten Arrays using `flatten_arrays=true`:

```
{
  "__name__" : "Order",                                <-- artificial __name__ key for record
  "customer_id" : "111222",
  "order_details" : {                                  <-- array of records
    "0" : {                                           <-- array index 0
      "__name__" : "OrderDetail",
      "product_detail" : {
        "__name__" : "Product",
        "price" : "46.21",
        "product_category" : {                        <- array of strings
          "0" : "electronics",
          "1" : "printers",
          "2" : "computers"
        },
        "product_name" : "hp printer X11ew",
        "product_status" : "ONLY_FEW_LEFT"
      }
    },
    "order_id" : "2389646",
    "total" : "132.43"
  }
}
```

Here is the result of flattening the array:

```
{
  "0.order_details.__name__" : "OrderDetail",
  "0.order_details.product_detail.0.product_category" : "electronics",
  "0.order_details.product_detail.1.product_category" : "prnters",
  "0.order_details.product_detail.2.product_category" : "computers",
  "0.order_details.product_detail.__name__" : "Product",
  "0.order_details.product_detail.price" : "46.21",
  "0.order_details.product_detail.product_name" : "hp printer X11ew",
}
```

```
"0.order_details.product_detail.product_status" : "ONLY_FEW_LEFT",  
  "__name__" : "Order",  
  "customer_id" : "111222",  
  "order_id" : "2389646",  
  "total" : "132.43"  
}
```

Maps

Maps use the type name `map` and support one attribute:

Attribute	Description
values	The schema of the map's items

The `favroparser` treats map keys as strings. For example, you can declare the `map` type as a long as follows:

```
{"type": "map", "values": "long"}
```

Similar to Records types, Maps can also be nested and flattened using `flatten_maps=true`.

The `favroparser` inserts key-value pairs from the Avro map as key-value pairs in the `__raw__column`. For an Avro record that has `KeyX` with value `10`, and `KeyY` with value `20`, `favroparser` loads the key-value pairs as virtual columns `KeyX` and `KeyY`, with values `10` and `20`, respectively.

Unions

Vertica uses JSON arrays to represent Avro Unions. Consider this example:

```
{"name": "TransactionID", "type": ["string", "null"]}
```

The field `TransactionID` can be a string or null.

Fixed

Fixed (`fixed`) Avro types support two attributes:

Attribute	Description
name	A string for the name of this

	data type
size	An integer, specifying the number of bytes per value

For example, you can declare a 16-byte quantity:

```
{"type": "fixed", "size": 16, "name": "md5"}
```

With the preceding declaration is the Avro file schema, consider a record that contains a field with the following byte values for the key md5:

```
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 0, 1, 2, 3, 4, 5]
```

The favroparser loads the key value pair as an md5 key with the preceding byte values.

Loading Common Event Format (CEF) Data

Use the flex parser `fcefparser` to load Micro Focus ArcSight or other Common Event Format (CEF) log file data into columnar and flexible tables. For more information, see the [ArcSight Common Event Format \(CEF\) Guide](#).

When you use the parser to load arbitrary CEF-format files, it interprets key names in the data as virtual columns in your flex table. After loading, you can query your CEF data directly, regardless of which set of keys exist in each row. You can also use the associated flex table data and map functions to manage CEF data access.

Create a Flex Table and Load CEF Data

This section uses a sample set of CEF data. All IP addresses have been purposely changed to be inaccurate, and Return characters added for illustration.

To use this sample data, copy the following text and remove all Return characters. Save the file as `CEF_sample.cef`, which is the name used throughout these examples.

```
CEF:0|ArcSight|ArcSight|6.0.3.6664.0|agent:030|Agent [test] type [testalertng] started|Low|  
eventId=1 mrt=1396328238973 categorySignificance=/Normal categoryBehavior=/Execute/Start  
categoryDeviceGroup=/Application catdt=Security Mangement categoryOutcome=/Success

```

1. Create a flex table logs:

```
=> CREATE FLEX TABLE logs();  
CREATE TABLE
```

2. Load the sample CEF file, using the flex parser fcefparser:

```
=> COPY logs FROM '/home/dbadmin/data/CEF_sample.cef' PARSER fcefparser();  
Rows Loaded  
-----  
1  
(1 row)
```

3. Use the maptostring() function to see the contents of the logs flex table:

```
=> SELECT maptostring(__raw__) FROM logs;  
maptostring  
-----  
{  
  "_cefver" : "0.1",  
  "agentzoneuri" : "/All Zones/ArcSight System/Private Address

"rt" : "1396328238937",  
"severity" : "Low",  
"signatureid" : "agent:030",  
"version" : "0"  
}  
  
(1 row)
```

Create a Columnar Table and Load CEF Data

This example lets you compare the flex table for CEF data with a columnar table. You do so by creating a new table and load the same `CEF_sample.cef` file used in the preceding flex table example.

1. Create a columnar table, `col_logs`, defining the prefix names that are hard coded in `fcefparser`:

```
=> CREATE TABLE col_logs(version INT,  
devicevendor VARCHAR,  
deviceproduct VARCHAR,  
deviceversion VARCHAR,  
signatureid VARCHAR,  
name VARCHAR,  
severity VARCHAR);  
CREATE TABLE
```

2. Load the sample file into `col_logs`, as you did for the flex table:

```
=> COPY col_logs FROM '/home/dbadmin/data/CEF_sample.cef' PARSER fcefparser();  
Rows Loaded  
-----  
1  
(1 row)
```

3. Query the table. You can find the identical information in the flex table output.

```
=> \x  
Expanded display is on.  
VMart=> SELECT * FROM col_logs;  
-[ RECORD 1 ]+-----  
version      | 0  
devicevendor | ArcSight
```

```
deviceproduct | ArcSight  
deviceversion | 6.0.3.6664.0  
signatureid   | agent:030  
name          | Agent [test] type [testalertng] started  
severity      | Low
```

Compute Keys and Build a Flex Table View

In this example, you use a flex helper function to compute keys and build a view for the logs flex table.

1. Use the `compute_flextable_keys_and_build_view` function to compute keys and populate a view generated from the logs flex table:

```
=> SELECT compute_flextable_keys_and_build_view('logs');  
           compute_flextable_keys_and_build_view  
-----  
Please see public.logs_keys for updated keys  
The view public.logs_view is ready for querying  
(1 row)
```

2. Query the `logs_keys` table to see what the function computed from the sample CEF data:

```
=> SELECT * FROM logs_keys;  
   key_name | frequency | data_type_guess  
-----+-----+-----  
c6a4       |          1 | varchar(60)  
c6a4label  |          1 | varchar(36)  
categoryobject |          1 | varchar(50)  
categoryoutcome |          1 | varchar(20)  
categorysignificance |          1 | varchar(20)  
cs2        |          1 | varchar(84)  
cs2label   |          1 | varchar(44)  
deviceproduct |          1 | varchar(20)  
deviceversion |          1 | varchar(24)  
devicezoneuri |          1 | varchar(180)  
dvchost     |          1 | varchar(20)  
version     |          1 | varchar(20)  
ahost       |          1 | varchar(20)  
art         |          1 | varchar(26)  
at          |          1 | varchar(22)  
cat         |          1 | varchar(28)  
catdt       |          1 | varchar(36)  
devicevendor |          1 | varchar(20)  
dtz         |          1 | varchar(32)  
dvc         |          1 | varchar(24)
```

```
filetype          |          1 | varchar(20)
mrt               |          1 | varchar(26)
_cefver          |          1 | varchar(20)
agentzoneuri     |          1 | varchar(180)
agt              |          1 | varchar(24)
aid              |          1 | varchar(50)
atz              |          1 | varchar(32)
av               |          1 | varchar(24)
categorybehavior |          1 | varchar(28)
categorydevicegroup |          1 | varchar(24)
deviceseverity   |          1 | varchar(20)
eventid          |          1 | varchar(20)
name             |          1 | varchar(78)
rt               |          1 | varchar(26)
severity         |          1 | varchar(20)
signatureid      |          1 | varchar(20)
(36 rows)
```

3. Query several columns from the logs_view:

```
=> \x
Expanded display is on.
VMart=> select version, devicevendor, deviceversion, name, severity, signatureid
        from logs_view;
-[ RECORD 1 ]-+-----
version      | 0
devicevendor | ArcSight
deviceversion | 6.0.3.6664.0
name         | Agent [test] type [testalertng] started
severity     | Low
signatureid  | agent:030
```

Use the fcefparsers Delimiter Parameter

In this example, you use the `fcefparsers delimiter` parameter to query events located in California, New Mexico, and Arizona.

1. Create a new columnar table, CEFDData3:

```
=> CREATE TABLE CEFDData3(eventId INT, location VARCHAR(20));
CREATE TABLE
```

2. Using the `delimiter=' , '` parameter, load some CEF data into the table:

```
=> COPY CEFDData3 FROM stdin PARSER fcefparsers(delimiter=' , ');
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
```

```
>> eventId=1,location=California
>> eventId=2,location=New Mexico
>> eventId=3,location=Arizona
>> \.
```

3. Query the table:

```
=> SELECT eventId, location FROM CEFDData3;
eventId | location
-----+-----
      1 | California
      2 | New Mexico
      3 | Arizona
(3 rows)
```

Loading CSV Data

Use the `fcsvparser` to load data in CSV format (comma-separated values). Since no formal CSV standard exists, Vertica supports the [RFC 4180](#) standard as the default behavior for `fcsvparser`. Other parser parameters simplify various combinations of CSV options into columnar or flex tables. Using `fcsvparser` parses the following CSV data formats:

- **RFC 4180:** The RFC4180 CSV format parser for Vertica flex tables. The parameters for this format are fixed and cannot be changed.
- **Traditional:** The traditional CSV parser lets you specify the parameter values such as delimiter or record terminator. For a detailed list of parameters, please refer the [FCSVPARSER](#)

Using Default Parser Settings

These fixed parameter settings apply to the RCF4180 format.

Note: While you can change the default parser parameter values for Traditional format files, each value must be unique. For example, you can specify an ampersand (&) as a delimiter. If you do, you cannot also use an ampersand for the escape or other parameter value.

Parameter	Data Type	Fixed Value (RCF4180)	Default Value (Traditional)
-----------	-----------	-----------------------	-----------------------------

delimiter	CHAR	,	,
enclosed_by	CHAR	"	"
escape	CHAR	"	\
record_terminator	CHAR	\n or \r\n	\n or \r\n

Use the `type` parameter to indicate either an RFC 4180-compliant file or a traditional-compliant file. You can specify `type` as `RCF4180`. However, you must first verify that the data is compatible with the preceding fixed values for parameters of the RFC4180 format. The default value of the `type` parameter is `RCF4180`.

Loading CSV Data (RFC4180)

Follow these steps to use `fcsvparser` to load data in the RFC4180 CSV data format.

To perform this task, assume that the CSV file to be loaded has the following sample contents:

```
$ more /home/dbadmin/flex/flexData1.csv
sno,name,age,gender
1,John,14,male
2,Mary,23,female
3,Mark,35,male
```

1. Create a flex table:

```
=> CREATE FLEX TABLE csv_basic();
CREATE TABLE
```

2. Load the data from the CSV file using `fcsvparser`:

```
=> COPY csv_basic FROM '/home/dbadmin/flex/flexData1.csv' PARSER fcsvparser();
Rows Loaded
-----
3
(1 row)
```

3. View the data loaded in the flex table:

```
=> SELECT maptostring(__raw__) FROM csv_basic;
maptostring
-----
{
"age" : "14",
"gender" : "male",
"name" : "John",
```

```
"sno" : "1"  
}  
{  
  "age" : "23",  
  "gender" : "female",  
  "name" : "Mary",  
  "sno" : "2"  
}  
{  
  "age" : "35",  
  "gender" : "male",  
  "name" : "Mark",  
  "sno" : "3"  
}  
(3 rows)
```

Loading CSV Data (Traditional)

Follow these steps to use `fcsvparser` to load data in traditional CSV data format using `fcsvparser`.

In this example, the CSV file uses `$` as a delimiter and `#` as a record_terminator. The sample CSV file to load has the following contents:

```
$ more /home/dbadmin/flex/flexData1.csv  
sno$name$age$gender#  
1$John$14$male#  
2$Mary$23$female#  
3$Mark$35$male#
```

1. Create a flex table:

```
=> CREATE FLEX TABLE csv_basic();  
CREATE TABLE
```

2. Load the data in flex table using `fscvparser` with parameters `type='traditional'`, `delimiter='$'` and `record_terminator='#'`:

```
=> COPY csv_basic FROM '/home/dbadmin/flex/flexData2.csv' PARSER fscvparser(type='traditional',  
delimiter='$', record_terminator='#');  
Rows Loaded  
-----  
3  
(1 row)
```

3. View the data loaded in the flex table:

```
=> SELECT maptostring(__raw__) FROM csv_basic;  
maptostring
```

```
-----  
{  
  "age" : "14",  
  "gender" : "male",  
  "name" : "John",  
  "sno" : "1"  
}  
{  
  "age" : "23",  
  "gender" : "female",  
  "name" : "Mary",  
  "sno" : "2"  
}  
{  
  "age" : "35",  
  "gender" : "male",  
  "name" : "Mark",  
  "sno" : "3"  
}  
(3 rows)
```

Rejecting Duplicate Values

You can reject duplicate values using the `reject_on_duplicate=true` option with the `fcsvparser`. The load continues after it rejects a duplicate value. The next example shows how to use this parameter and then displays the specified exception and rejected data files. Saving rejected data to a table, rather than a file, includes both the data and its exception.

```
=> CREATE FLEX TABLE csv_basic();  
CREATE TABLE  
  
=> COPY csv_basic FROM stdin PARSER fcsvparser(reject_on_duplicate=true)  
exceptions '/home/dbadmin/load_errors/except.out' rejected data '/home/dbadmin/load_  
errors/reject.out';  
Enter data to be copied followed by a newline.  
End with a backslash and a period on a line by itself.  
  
>> A|A  
>> 1|2  
>> \.  
  
=> \! cat /home/dbadmin/load_errors/reject.out  
A|A  
=> \! cat /home/dbadmin/load_errors/except.out  
COPY: Input record 1 has been rejected (Processed a header row with duplicate keys with  
reject_on_duplicate specified; rejecting.). Please see /home/dbadmin/load_errors/reject.out,  
record 1 for the rejected record.  
COPY: Loaded 0 rows, rejected 1 rows.
```

Rejecting Data on Materialized Column Type Errors

The `fcsvparser` parser has a Boolean parameter, `reject_on_materialized_type_error`. Setting this parameter to `true` causes rows to be rejected if *both* the following conditions exist in the input data:

- Includes keys matching an existing materialized column
- Has a key value that cannot be coerced into the materialized column's data type

The following examples illustrate setting this parameter.

1. Create a table, `reject_true_false`, with two real columns:

```
=> CREATE FLEX TABLE reject_true_false(one int, two int);  
CREATE TABLE
```

2. Load CSV data into the table (from STDIN), using the `fcsvparser` with `reject_on_materialized_type_error=false`. While `false` is the default value, you can specify it explicitly, as shown. Additionally, set the parameter `header=true` to specify the columns for input values:

```
=> COPY reject_true_false FROM stdin PARSER fcsvparser(reject_on_materialized_type_  
error=false,header=true);  
Enter data to be copied followed by a newline.  
End with a backslash and a period on a line by itself.  
>> one,two  
>> 1,2  
>> "3","four"  
>> "five",6  
>> 7,8  
>> \.
```

3. Invoke `maptostring` to display the table values after loading data:

```
=> SELECT maptostring(__raw__), one, two FROM reject_true_false;  
maptostring      | one | two  
-----+-----  
{  
"one" : "1",  
"two" : "2"  
}  
|  1 |  2  
{  
"one" : "3",  
"two" : "four"
```

```
}  
| 3 |  
{  
"one" : "five",  
"two" : "6"  
}  
| | 6  
{  
"one" : "7",  
"two" : "8"  
}  
| 7 | 8  
(4 rows)
```

4. Truncate the table to empty the data stored in the table:

```
=> TRUNCATE TABLE reject_true_false;  
TRUNCATE TABLE
```

5. Reload the same data again, but this time, set `reject_on_materialized_type_error=true`:

```
=> COPY reject_true_false FROM stdin PARSER fcsvparser(reject_on_materialized_type_  
error=true,header=true);  
Enter data to be copied followed by a newline.  
End with a backslash and a period on a line by itself.  
>> one,two  
>> 1,2  
>> "3","four"  
>> "five",6  
>> 7,8  
>> \.
```

6. Call `maptostring` to display the table contents. Only two rows are currently loaded, whereas the previous results had four rows. The rows having input values with incorrect data type have been rejected:

```
=> SELECT maptostring(__row__), one, two FROM reject_true_false;  
maptostring      | one | two  
-----+-----+-----  
{  
"one" : "1",  
"two" : "2"  
}  
| 1 | 2  
{  
"one" : "7",  
"two" : "8"  
}  
| 7 | 8  
(2 rows)
```

Note: The parser `fcsvparser` uses `null` values if there is a type mismatch and you set the `reject_on_materialized_type_error` parameter to `false`.

Rejecting or Omitting Empty Rows

Valid CSV files can include empty key and value pairs. Such rows are invalid for SQL. You can control the behavior for empty rows by either rejecting or omitting them, using two boolean `FCSVPARSER` parameters:

- `reject_on_empty_key`
- `omit_empty_keys`

The following example illustrates how to set these parameters:

1. Create a flex table:

```
=> CREATE FLEX TABLE csv_basic();  
CREATE TABLE
```

2. Load CSV data into the table (from STDIN), using the `fcsvparser` with `reject_on_empty_key=false`. While `false` is the default value, you can specify it explicitly, as shown. Additionally, set the parameter `header=true` to specify the columns for input values:

```
=> COPY csv_basic FROM stdin PARSER fcsvparser(reject_on_empty_key=false,header=true);  
Enter data to be copied followed by a newline.  
End with a backslash and a period on a line by itself.  
>> ,num  
>> 1,2  
>> \.
```

3. Invoke `maptostring` to display the table values after loading data:

```
=>SELECT maptostring(__raw__) FROM csv_basic;  
maptostring  
-----  
{  
  "" : "1",  
  "num" : "2"  
}  
  
(1 row)
```

4. Truncate the table to empty the data stored in the table:

```
=> TRUNCATE TABLE csv_basic;  
TRUNCATE TABLE
```

5. Reload the same data again, but this time, set `reject_on_empty_key=true`:

```
=> COPY csv_basic FROM stdin PARSER fcsvparser(reject_on_empty_key=true,header=true);  
Enter data to be copied followed by a newline.  
End with a backslash and a period on a line by itself.  
>> ,num  
>> 1,2  
>> \.
```

6. Call `maptostring` to display the table contents. No rows are loaded because one of the keys is empty:

```
=>SELECT maptostring(__raw__) FROM csv_basic;  
maptostring  
-----  
(0 rows)
```

7. Truncate the table to empty the data stored in the table:

```
=> TRUNCATE TABLE csv_basic;  
TRUNCATE TABLE
```

8. Reload the same data again, but this time, set `omit_empty_keys=true`:

```
=> COPY csv_basic FROM stdin PARSER fcsvparser(omit_empty_keys=true,header=true);  
Enter data to be copied followed by a newline.  
End with a backslash and a period on a line by itself.  
>> ,num  
>> 1,2  
>> \.
```

9. Call `maptostring` to display the table contents. One row is now loaded, and the rows with empty keys are omitted:

```
=> SELECT maptostring(__raw__) FROM csv_basic;  
maptostring  
-----  
{  
"num" : "2"  
}  
(1 row)
```

Note: If no header names exist, `fcsvparser` uses a default header of `ucoln`, where `n` is the column offset number. If a table header name and key name match, the parser loads

the column with values associated with the matching key name.

Using the NULL Parameter

Use the COPY NULL metadata parameter with `fcsvparser` to load NULL values into a flex table.

The next example uses this parameter:

1. Create a flex table.

```
=> CREATE FLEX TABLE fcsv(c1 int);  
CREATE TABLE
```

2. Load CSV data in flex table using STDIN and NULL parameter.

```
=> COPY fcsv FROM STDIN PARSER fcsvparser() NULL 'NULL' ;  
Enter data to be copied followed by a newline.  
End with a backslash and a period on a line by itself.  
>> a,b,c1  
>> 10,20,NULL  
>> 20,30,50  
>> 20,30,40  
>> \.
```

3. Use `compute_flexible_keys_and_build_view` function to compute keys and build flex view.

```
=> SELECT compute_flexible_keys_and_build_view('fcsv');  
compute_flexible_keys_and_build_view  
-----  
Please see public.fcsv_keys for updated keys  
The view public.fcsv_view is ready for querying  
(1 row)
```

4. View the flex view and replace the NULL values.

```
=> SELECT * FROM public.fcsv_view;  
a | b | c1  
-----  
20 | 30 | 50  
10 | 20 |  
20 | 30 | 40  
(3 rows)  
  
=> SELECT a,b, ISNULL(c1,-1) from public.fcsv_view;  
a | b | ISNULL  
-----  
20 | 30 | 50  
10 | 20 | -1
```

```
20 | 30 | 40  
(3 rows)
```

Handling Column Headings

The `fcsvparser` lets you specify your own column headings with the `HEADER_NAMES=` parameter. This parameter entirely replaces column names in the CSV source header row.

For example, to use these six column headings for a CSV file you are loading, use the `fcsvparser` parameter as follows:

```
HEADER_NAMES='FIRST, LAST, SOCIAL_SECURITY, TOWN, STATE, COUNTRY'
```

Supplying fewer header names than existing data columns causes `fcsvparser` to use default names after those you supply. Default header names consist of `ucoln`, where n is the column offset number, starting at 0 for the first column. For example, if you supply four header names for a 6-column table, `fcsvparser` supplies the default names `ucol4` and `ucol5`, following the fourth header name you provide.

If you supply more headings than the existing table columns, any additional headings remain unused.

Loading Delimited Data

You can load flex tables with one of two delimited parsers, `fdelimitedparser` or `fdelimitedpairparser`.

- Use `fdelimitedpairparser` when the data specifies column names with the data in each row.

- Use `fdelimitedparser` when the data does not specify column names or has a header row for column names.

This section describes using some options that `fdelimitedpairparser` and `fdelimitedparser` support.

Rejecting Duplicate Values

You can reject duplicate values using the `reject_on_duplicate=true` option with the `fdelimitedparser`. The load continues after it rejects a duplicate value. The next example shows how to use this parameter and then displays the specified exception and rejected data files. Saving rejected data to a table, rather than a file, includes both the data and its exception.

```
=> CREATE FLEX TABLE delim_dupes();
CREATE TABLE

=> COPY delim_dupes FROM stdin PARSER fdelimitedparser(reject_on_duplicate=true)
exceptions '/home/dbadmin/load_errors/except.out' rejected data '/home/dbadmin/load_
errors/reject.out';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.

>> A|A
>> 1|2
>> \.

=> \! cat /home/dbadmin/load_errors/reject.out
A|A
=> \! cat /home/dbadmin/load_errors/except.out
COPY: Input record 1 has been rejected (Processed a header row with duplicate keys with
reject_on_duplicate specified; rejecting.). Please see /home/dbadmin/load_errors/reject.out,
record 1 for the rejected record.
COPY: Loaded 0 rows, rejected 1 rows.
```

Rejecting Materialized Column Type Errors

Both the `fjsonparser` and `fdelimitedparser` parsers have a boolean parameter, `reject_on_materialized_type_error`. Setting this parameter to `true` causes rows to be rejected if *both* the following conditions exist in the input data:

- Includes keys matching an existing materialized column
- Has a value that cannot be coerced into the materialized column's data type

Suppose the flex table has a materialized column, `OwnerPercent`, declared as a `FLOAT`. Trying to load a row with an `OwnerPercent` key that has a `VARCHAR` value causes `fdelimitedparser` to reject the data row.

The following examples illustrate setting this parameter.

1. Create a table, `reject_true_false`, with two real columns:

```
=> CREATE FLEX TABLE reject_true_false(one VARCHAR, two INT);  
CREATE TABLE
```

2. Load JSON data into the table (from STDIN), using the `fjsonparser` with `reject_on_materialized_type_error=false`. While `false` is the default value, the following example specifies it explicitly for illustration:

```
=> COPY reject_true_false FROM stdin PARSER fjsonparser(reject_on_materialized_type_error=false);  
Enter data to be copied followed by a newline.  
End with a backslash and a period on a line by itself.  
>> {"one": 1, "two": 2}  
>> {"one": "one", "two": "two"}  
>> {"one": "one", "two": 2}  
>> \.
```

3. Invoke `maptostring` to display the table values after loading data:

```
=> SELECT maptostring(__raw__), one, two FROM reject_true_false;  
          maptostring      | one | two  
-----+-----+-----  
 {  
  "one" : "one",  
  "two" : "2"  
 }  
 | one | 2  
 {  
  "one" : "1",  
  "two" : "2"  
 }  
 | 1 | 2  
 {  
  "one" : "one",  
  "two" : "two"  
 }  
 | one |  
(3 rows)
```

4. Truncate the table:

```
=> TRUNCATE TABLE reject_true_false;
```

5. Reload the same data again, but this time, set `reject_on_materialized_type_error=true`:

```
=> COPY reject_true_false FROM stdin PARSER fjsonparser(reject_on_materialized_type_error=true);  
Enter data to be copied followed by a newline.
```

```
End with a backslash and a period on a line by itself.  
>> {"one": 1, "two": 2}  
>> {"one": "one", "two": "two"}  
>> {"one": "one", "two": 2}  
>> \.
```

6. Call `maptostring` to display the table contents. Only two rows were loaded, whereas the previous results had three rows:

```
=> SELECT maptostring(__raw__), one, two FROM reject_true_false;  
      maptostring      | one | two  
-----+-----  
 {  
   "one" : "1",  
   "two" : "2"  
 }  
 | 1 | 2  
 {  
   "one" : "one",  
   "two" : "2"  
 }  
 | one | 2  
(2 rows)
```

Loading JSON Data

You can load JSON data into flex or columnar tables. This section describes some examples of using the `fjsonparser` with several of the parser options.

Checking JSON Integrity

Before loading any JSON data, be sure that the data is valid. You can verify JSON data integrity using a web tool such as [JSONLint](#). Copy your JSON data into the tool. If any data is invalid, the tool returns a message similar to the one in this example:

```
Parse error on line 170:...257914002502451200}{  
"id_str": "257  
-----^  
Expecting 'EOF', '}', ',', ']', ''
```

Using `flatten_maps` and `flatten_arrays` Parameters

When loading JSON data, the `fjsonparser` uses the parameters `flatten_maps` and `flatten_arrays` to control how the parser handles the data it is loading. Here are the default settings for these two parameters:

Parameter	Default	Change Default
<code>flatten_maps</code>	TRUE: Flatten all maps.	<code>flatten_maps=FALSE</code>
<code>flatten_arrays</code>	FALSE: Do not flatten arrays.	<code>flatten_arrays=TRUE</code>

You control the default the behavior by using one or both `flatten_` parameters.

For JSON maps, the parser flattens all submaps, separating the levels with a period (`.`). Consider the following input data with a submap:

```
{ grade: { level: 4 } }
```

The default parser behavior results in the following map:

```
{ "grade.level" -> "4" }
```

Note: To use the bracket operators (`[]`) to access deeply nested JSON in VMap data, you must load the data with `flatten_maps=FALSE`, as described in [Querying Nested Data](#).

For JSON arrays, the parser maintains the array. Consider the following input data containing a 2-element array, with values 1 and 2:

```
{ grade: [ 1 2 ] }
```

The default parser behavior results in the following array:

```
{ "grade": { "0" -> "1", "1" -> "2" } }
```

Note: Using the parameters `flatten_maps` and `flatten_arrays` is recursive, and affects all data.

Loading from a Specific Start Point

You can use the `fjsonparser start_point` parameter to load JSON data beginning at a specific key, rather than at the beginning of a file. Data is parsed from after the `start_point` key until the end of the file, or to the end of the first `start_point`'s value. The `fjsonparser` ignores any subsequent instance of the `start_point`, even if that key appears multiple times in the input file. If the input data contains only one copy of the `start_point` key, and that value is a list of JSON elements, the parser loads each element in the list as a row.

This section uses the following sample JSON data, saved to a file (`alphanums.json`):

```
{ "A": { "B": { "C": [ { "d": 1, "e": 2, "f": 3 }, { "g": 4, "h": 5, "i": 6 },  
{ "j": 7, "k": 8, "l": 9 } ] } } }
```

1. Create a flex table, `start_json`:

```
=> CREATE FLEX TABLE start_json();  
CREATE TABLE
```

2. Load `alphanums.json` into `start_json` using the `fjsonparser` without any parameters:

```
=> COPY start_json FROM '/home/dbadmin/data/flex/alphanums.json' PARSER fjsonparser();  
Rows Loaded  
-----  
1  
(1 row)
```

3. Use `maptostring` to see the results of loading all of `alphanums.json`:

```
=> SELECT maptostring(__raw__) FROM start_json;  
maptostring  
-----  
{  
  "A.B.C" : {  
    "0.d" : "1",  
    "0.e" : "2",  
    "0.f" : "3",  
    "1.g" : "4",  
    "1.h" : "5",  
    "1.i" : "6",  
    "2.j" : "7",  
    "2.k" : "8",  
    "2.l" : "9"  
  }  
}
```

```
(1 row)
```

4. Truncate `start_json` and load `alphanums.json` with the `start_point` parameter:

```
=> TRUNCATE TABLE start_json;
TRUNCATE TABLE
=> COPY start_json FROM '/home/dbadmin/data/flex/alphanums.json' PARSE
-> fjsonparser(start_point='B');
Rows Loaded
-----
          1
(1 row)
```

5. Next, call `maptostring` again to compare the results of loading `alphanums.json` from `start_point='B'`:

```
=> SELECT maptostring(__raw__) FROM start_json;
          maptostring
-----
{
  "C" : {
    "0.d" : "1",
    "0.e" : "2",
    "0.f" : "3",
    "1.g" : "4",
    "1.h" : "5",
    "1.i" : "6",
    "2.j" : "7",
    "2.k" : "8",
    "2.l" : "9"
  }
}
(1 row)
```

Parsing From a Start Point Occurrence

If a `start_point` value occurs in multiple locations in your JSON data, you can use the `start_point_occurrence` integer parameter to specify the occurrence at which to start parsing. By defining `start_point_occurrence`, `fjsonparser` begins at the `n`th occurrence of `start_point`.

Controlling Column Name Separators

By default, `fjsonparser` produces column names by concatenating JSON field names with a period (.). You can change the default separator by specifying a different character with the

key_separator parameter.

Handling Special Characters

Some input JSON data can have special characters in field names. You can replace these characters by setting the `suppress_nonalphanumeric_key_chars` to `TRUE`. With this parameter setting, all special characters are converted to an underscore (`_`) character.

Dealing with Invalid JSON Records

If your JSON data is not perfectly formatted, your load may fail due to invalid records. You can use the `RECORD_TERMINATOR` parameter to skip these invalid records if your JSON records are consistently delimited by a character like a line break. Setting a record terminator will allow the `FJSONPARSER` to skip over invalid records and continue parsing the rest of the data.

If your records are not consistently marked by a character, you can use the `COPY` parameter `ERROR TOLERANCE`. `ERROR TOLERANCE` skips entire source files with invalid JSON records, while `RECORD_TERMINATOR` skips individual malformed JSON records. Using both `ERROR TOLERANCE` and `RECORD_TERMINATOR` within the statement will work, but if your records are consistently marked, `RECORD_TERMINATOR` should sufficiently deal with imperfect records.

1. Create a flex table named "fruits".

```
=> CREATE FLEX TABLE fruits();  
CREATE TABLE
```

2. Use the `FJSONPARSER` and call the `RECORD_TERMINATOR` parameter with a termination key of `E'\n'` (which denotes a new line). Insert records, including an invalid record.

```
=> COPY fruits FROM STDIN PARSER FJSONPARSER(RECORD_TERMINATOR=E'\n');  
Enter data to be copied followed by a newline.  
End with a backslash and a period on a line by itself  
>> {"name": "orange", "type": "fruit", "color": "orange", "rating": 5 }  
>> {"name": "apple", "type": "fruit", "color": "green" }  
>> {"name": "blueberry", "type": "fruit", "color": "blue", "rating": 10 }  
>> "type": "fruit", "rating": 7 }  
>> {"name": "banana", "type": "fruit", "color": "yellow", "rating": 3 }  
>> \.
```

3. View the flex table using `MAPTOSTRING` to confirm that the invalid record was skipped while the rest of the records were successfully loaded.

```
=> SELECT MAPTOSTRING(__raw__) FROM fruits;  
maptostring  
-----
```

```
{
  "color" : "orange",
  "name" : "orange",
  "rating" : "5",
  "type" : "fruit"
}

{
  "color" : "green",
  "name" : "apple",
  "type" : "fruit"
}

{
  "color" : "blue",
  "name" : "blueberry",
  "rating" : "10",
  "type" : "fruit"
}

{
  "color" : "yellow",
  "name" : "banana",
  "rating" : "3",
  "type" : "fruit"
}
(4 rows)
```

Rejecting Duplicate Values

You can reject duplicate values by using the `reject_on_duplicate=true` option with the `fjsonparser`. The next example uses this option while loading data and then displays the specified exception and rejected data files. Saving rejected data to a table, rather than a file, includes both the data and its exception.

```
=> CREATE FLEX TABLE json_dupes();
CREATE TABLE

=> COPY json_dupes FROM stdin PARSER fjsonparser(reject_on_duplicate=true)
exceptions '/home/dbadmin/load_errors/json_e.out'
rejected data '/home/dbadmin/load_errors/json_r.out';

Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.

>> {"a":"1","a":"2","b":"3"}
>> \.

=> \!cat /home/dbadmin/load_errors/json_e.out
COPY: Input record 1 has been rejected (Rejected by user-defined parser).
Please see /home/dbadmin/load_errors/json_r.out, record 1 for the rejected record.
COPY: Loaded 0 rows, rejected 1 rows.
```

Rejecting Data on Materialized Column Type Errors

Both the `fjsonparser` and `fdelimitedparser` parsers have a Boolean parameter, `reject_on_materialized_type_error`. Setting this parameter to `true` causes rows to be rejected if the input data:

- Includes keys matching an existing materialized column
- Has a key value that cannot be coerced into the materialized column's data type.

The following examples illustrate setting this parameter.

1. Create a table, `reject_true_false`, with two real columns:

```
=> CREATE FLEX TABLE reject_true_false(one VARCHAR, two INT);  
CREATE TABLE
```

2. Load JSON data into the table (from STDIN), using the `fjsonparser` with `reject_on_materialized_type_error=false`. While `false` is the default value, the following example specifies it explicitly for illustration:

```
=> COPY reject_true_false FROM stdin PARSER  
-> fjsonparser(reject_on_materialized_type_error=false);  
Enter data to be copied followed by a newline.  
End with a backslash and a period on a line by itself.  
>> {"one": 1, "two": 2}  
>> {"one": "one", "two": "two"}  
>> {"one": "one", "two": 2}  
>> \.
```

3. Invoke `maptostring` to display the table values after loading data:

```
=> SELECT maptostring(__raw__), one, two FROM reject_true_false;  
maptostring      | one | two  
-----+-----  
{  
  "one" : "one",  
  "two" : "2"  
}  
| one |  2  
{  
  "one" : "1",  
  "two" : "2"  
}  
| 1  |  2  
{  
  "one" : "one",  
  "two" : "two"
```

```
}  
 | one |  
(3 rows)
```

4. Truncate the table:

```
=> TRUNCATE TABLE reject_true_false;
```

5. Reload the same data again, but this time, set `reject_on_materialized_type_error=true`:

```
=> COPY reject_true_false FROM stdin PARSER fjsonparser(reject_on_materialized_type_error=true);  
Enter data to be copied followed by a newline.  
End with a backslash and a period on a line by itself.  
>> {"one": 1, "two": 2}  
>> {"one": "one", "two": "two"}  
>> {"one": "one", "two": 2}  
>> \.
```

6. Call `maptostring` to display the table contents. Only two rows were loaded, whereas the previous results had three rows:

```
=> SELECT maptostring(__raw__), one, two FROM reject_true_false;  
      maptostring          | one | two  
-----+-----  
 {  
  "one" : "1",  
  "two" : "2"  
 }  
 | 1 | 2  
 {  
  "one" : "one",  
  "two" : "2"  
 }  
 | one | 2  
(2 rows)
```

Rejecting or Omitting Empty Rows

Valid JSON files Micro Focus can include empty key and value pairs, such as this one:

```
{"": 1 "}
```

Such rows are invalid for SQL. To prevent this situation, you can control the behavior for empty rows, either rejecting or omitting them. You do so using two boolean parameters for the parsers `FDELIMITEDPARSER` or `FJSONPARSER`:

- `reject_on_empty_key`
- `omit_empty_keys`

Loading Matches from Regular Expressions

You can load flex or columnar tables with the matched results of a regular expression, using the `fregexparser`. This section describes some examples of using the options that the flex parsers support.

Sample Regular Expression

These examples use the following regular expression, which searches information that includes the timestamp, date, thread_name, and thread_id strings.

Caution: For display purposes, this sample regular expression adds new line characters to split long lines of text. To use this expression in a query, first copy and edit the example to remove any new line characters.

This example expression loads any `thread_id` hex value, regardless of whether it has a `0x` prefix, (`<thread_id>(?:0x)?[0-9a-f]+`).

```
'^(?<time>\d\d\d\d-\d\d-\d\d \d\d:\d\d:\d\d\.\d+)  
(?<thread_name>[A-Za-z ]+):(?<thread_id>(?:0x)?[0-9a-f]+)  
-?(?<transaction_id>[0-9a-f])?(?:[(?<component>\w+)]  
\<(?<level>\w+)\> )?(?:<(?<element>\w+)\> @[(?<enode>\w+)]?: )  
?(?<text>.*).'
```

Using Regular Expression Matches for a Flex Table

You can load the results from a regular expression into a flex table, using the `fregexparser`. For a complete example of doing so, see [FREGEXPARSER](#).

Using fregexparser for Columnar Tables

This section illustrates how to load the results of a regular expression used with a sample log file for a Vertica database. By using an external table definition, the section presents an example of using fregexparser to load data into a columnar table. Using a flex table parser for a columnar tables gives you the capability to mix data loads in one table. For example, you can load the results of a regular expression in one session, and JSON data in another.

The following basic examples illustrate this usage.

1. Create a columnar table, vlog, with the following columns:

```
=> CREATE TABLE vlog (  
  "text"          varchar(2322),  
  thread_id      varchar(28),  
  thread_name    varchar(44),  
  "time"         varchar(46),  
  component      varchar(30),  
  level          varchar(20),  
  transaction_id varchar(32),  
  elevel         varchar(20),  
  enode          varchar(34)  
);
```

2. Use COPY to load parts of a log file using the sample regular expression presented above, with the fregexparser. Be sure to remove any line characters from this expression example before trying it yourself:

```
=> COPY v_log FROM '/home/dbadmin/data/flex/vertica.log' PARSER  
FRegexParser(pattern='^(?<time>\d\d\d\d-\d\d-\d\d \d\d:\d\d:\d\d\.\d+)  
(?<thread_name>[A-Za-z ]+):(?(?<thread_id>(?:0x)?[0-9a-f]+)  
-?(?(?<transaction_id>[0-9a-f])?(?:[(?(?<component>\w+)]  
\<(?(?<level>\w+)\> )?(?:<(?(?<elevel>\w+)\> @[(?(?<enode>\w+)\>)]?: )  
?(?(?<text>.*))') rejected data as table fregex_reject;
```

3. Query the time column:

```
=> SELECT time FROM flogs limit 10;  
      time  
-----  
2014-04-02 04:02:02.613  
2014-04-02 04:02:02.613  
2014-04-02 04:02:02.614  
2014-04-02 04:02:51.008  
2014-04-02 04:02:51.010  
2014-04-02 04:02:51.012  
2014-04-02 04:02:51.012  
2014-04-02 04:02:51.013
```

```
2014-04-02 04:02:51.014  
2014-04-02 04:02:51.017  
(10 rows)
```

Using External Tables with fregexparser

By creating an external columnar table for your Vertica log file, querying the table will return updated log information. The following basic example illustrate this usage.

1. Create a columnar table, `vertica_log`, using the `AS COPY` clause and `fregexparser` to load matched results from the regular expression. For illustrative purposes, this regular expression has new line characters to split long text lines. Remove any line returns before testing with this expression:

```
=> CREATE EXTERNAL TABLE public.vertica_log  
(  
  "text" varchar(2322),  
  thread_id varchar(28),  
  thread_name varchar(44),  
  "time" varchar(46),  
  component varchar(30),  
  level varchar(20),  
  transaction_id varchar(32),  
  elevel varchar(20),  
  enode varchar(34)  
)  
AS COPY  
FROM '/home/dbadmin/data/vertica.log'  
PARSER FRegexParser(pattern='^(?<time>\d\d\d\d-\d\d-\d\d \d\d:\d\d:\d\d\.\d+)  
(?<thread_name>[A-Za-z ]+):(?<thread_id>(?:0x)?[0-9a-f]+)  
-?(?<transaction_id>[0-9a-f]+)?(?:[(?<component>\w+)]  
\<(?!<level>\w+)\> )?(?:<(?!<elevel>\w+)\> @[(?!<enode>\w+)\>]?:  
?(?<text>.*\n)');
```

2. Query from the external table to get updated results:

```
=> SELECT component, thread_id, time FROM vertica_log limit 10;  
component | thread_id | time  
-----+-----+-----  
Init      | 0x16321430 | 2014-04-02 04:02:02.613  
Init      | 0x16321430 | 2014-04-02 04:02:02.614  
Init      | 0x16321430 | 2014-04-02 04:02:02.614
```

(10 rows) | 0x16321430 | 2014-04-02 04:02:02.614

Computing Flex Table Keys

After loading data into a flex table, you can determine the set of keys that exist in the `__raw__` column (the map data). Two helper functions compute keys from flex table map data:

- [COMPUTE_FLEXTABLE_KEYS](#)— Determines which keys exist as virtual columns in the flex map.
- [COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW](#)— Performs the same functionality as [COMPUTE_FLEXTABLE_KEYS](#), additionally building a new view. See also [Updating Flex Table Views](#).

Using COMPUTE_FLEXTABLE_KEYS

During execution, this function calculates the following information for the flex keys table columns:

Column	Description
key_name	The name of the virtual column (key).
frequency	The number of times the key occurs in the map.
data_type_guess	The type guess that the helper functions determine for each distinct key in the map data. The function determines the type of each non-string value, depending on the length of the key, and whether the key includes nested maps. Changing the default value of the <code>EnableBetterFlexTypeGuessing</code> configuration parameter to 0 (OFF) results in the functions determining all flex table keys as string types (<code>[LONG]VARCHAR</code>) or (<code>[LONG] VARBINARY</code>).

Determining Key Data Types

By default, using `COMPUTE_FLEXTABLE_KEYS` determines non-string key values from the `__raw__` column `LONG VARBINARY` type. The non-string keys include these data types (and others listed in [SQL Data Types](#)):

- BOOLEAN
- INTEGER
- FLOAT
- TIMESTAMP
- DATE

Assigning Flex Key Data Types

Use the sample CSV data in this section to compare the results of using or not using the `EnableBetterFlexTypeGuessing` configuration parameter. When the parameter is ON, the function determines key non-string data types in your map data more accurately. The default for the parameter is 1 (ON).

```
Year,Quarter,Region,Species,Grade,Pond Value,Number of Quotes,Available
2015,1,2 - Northwest Oregon & Willamette,Douglas-fir,1P,$615.12 ,12,No
2015,1,2 - Northwest Oregon & Willamette,Douglas-fir,SM,$610.78 ,12,Yes
2015,1,2 - Northwest Oregon & Willamette,Douglas-fir,2S,$596.00 ,20,Yes
2015,1,2 - Northwest Oregon & Willamette,Hemlock,P,$520.00 ,6,Yes
2015,1,2 - Northwest Oregon & Willamette,Hemlock,SM,$510.00 ,6,No
2015,1,2 - Northwest Oregon & Willamette,Hemlock,2S,$490.00 ,14,No
```

To compare the data type assignment results, complete the following steps:

1. Save the CSV data file (here, as `trees.csv`).
2. Create a flex table (`trees`) and load `trees.csv` using the `fcsvparser`:

```
=> CREATE FLEX TABLE trees();
=> COPY trees FROM '/home/dbadmin/tempdat/trees.csv' PARSER fcsvparser();
```

3. Use `COMPUTE_FLEXTABLE_KEYS` with the `trees` flex table.

```
=> SELECT COMPUTE_FLEXTABLE_KEYS('trees');
      COMPUTE_FLEXTABLE_KEYS
-----
Please see public.trees_keys for updated keys
(1 row)
```

4. Query the `trees_keys` table output.:

```
=> SELECT * FROM trees_keys;
  key_name | frequency | data_type_guess
-----+-----+-----
Year      |         6 | Integer
Quarter   |         6 | Integer
Region    |         6 | Varchar(66)
Available |         6 | Boolean
Number of Quotes |         6 | Integer
Grade     |         6 | Varchar(20)
Species   |         6 | Varchar(22)
Pond Value |         6 | Numeric(8,3)
(8 rows)
```

5. Set the `EnableBetterFlexTypeGuessing` parameter to 0 (OFF).
6. Call `COMPUTE_FLEXTABLE_KEYS` with the `trees` flex table again.
7. Query the `trees_keys` table to compare the `data_type_guess` values with the previous results. Without the configuration parameter set, all of the non-string data types are `VARCHARS` of various lengths:

```
=> SELECT * FROM trees_keys;
  key_name | frequency | data_type_guess
-----+-----+-----
Year      |         6 | varchar(20)
Quarter   |         6 | varchar(20)
Region    |         6 | varchar(66)
Available |         6 | varchar(20)
Grade     |         6 | varchar(20)
Number of Quotes |         6 | varchar(20)
Pond Value |         6 | varchar(20)
Species   |         6 | varchar(22)
(8 rows)
```

8. To maintain accurate results for non-string data types, set the `EnableBetterFlexTypeGuessing` parameter back to 1 (ON).

For more information about setting the `EnableBetterFlexTypeGuessing` configuration parameter, see [Setting Flex Table Configuration Parameters](#).

Calculating Key Value Column Widths

The `COMPUTE_FLEXTABLE_KEYS` function determines the column width for keys by determining the length of the largest value for each key, multiplied by the `FlexTableDataTypeGuessMultiplier` factor. For more about this configuration parameter, see [Setting Flex Table Configuration Parameters](#).

The next example shows the results of populating the `_keys` table after creating a flex table (`darkdata1`) and loading data. The column widths are shown in parentheses, where applicable, after the value of the `data_type_guess` column:

```
=> SELECT compute_flextable_keys('darkdata1');
           compute_flextable_keys
-----
Please see public.darkdata1_keys for updated keys
(1 row)

=> SELECT * from darkdata1_keys;
           key_name | frequency | data_type_guess
-----+-----+-----
created_at        |          8 | TimestampTz
delete.status.id_str |          4 | Integer
delete.status.user_id |          4 | Integer
entities.hashtags |          8 | long varbinary(186)
favorited         |          8 | Boolean
id_str            |          8 | Integer
in_reply_to_screen_name |          8 | Varchar(24)
retweeted_status.contributors |          1 | Varchar(20)
retweeted_status.coordinates |          1 | Varchar(20)
retweeted_status.created_at |          1 | TimestampTz
.
.
.
(125 rows)
```

Materializing Flex Tables

Once flex tables exist, you can change the table structure to promote virtual columns to materialized (real) columns. If your table is already a hybrid table, you can change existing real columns and promote other important virtual columns. This section describes some key aspects of promoting columns, adding columns, specifying constraints, and declaring default values. It also presents some differences when loading flex or hybrid tables, compared with columnar tables.

Note: Materializing virtual columns by promoting them to real columns can significantly improve query performance. Vertica recommends that you materialize important virtual columns before running large and complex queries. Promoted columns cause a small decrease in load performance.

Adding Columns to Flex Tables

Add columns to your flex tables to promote virtual columns:

1. Add a real column with the same name as a virtual column (user.name):

```
=> ALTER TABLE darkdata1 ADD COLUMN "user.name" VARCHAR;  
ALTER TABLE
```

2. Load some data into the table.

```
=> COPY darkdata1 FROM '/vertica/flextable/DATA/tweets_12.json' PARSER fjsonparser();  
Rows Loaded  
-----  
12  
(1 row)
```

3. Query the materialized column. Notice that loading data populates the column automatically. Blank rows indicate no values or NULLs:

```
=> SELECT "user.name" FROM darkdata1;  
user.name  
-----  
I'm Toasterã¥  
Flu Beach  
seydo shi
```

```
The End
Uptown gentleman.
~G A B R I E L A â€¦
Avita Desai
laughing at clouds.
(12 rows)
```

Adding Columns with Default Values

The section [Bulk Loading Data into Flex Tables](#) describes the use of default values, and how Vertica evaluates them during loading. As with all tables, using COPY to load data ignores any column default values.

Note: Adding a table column default expression to a flex table requires casting the column to an explicit data type.

1. Create a `darkdata1` table with a column definition. The following example uses a column name (`talker`) that does not correspond to a virtual column name. Assign a default value with a virtual column name. In this example, the default value for the column `talker` is (`"user.lang"`). Since `user.lang` is a virtual column in the `LONG VARBINARY __raw__` column, you must cast its value to `VARCHAR` to match the `talker` column definition:

```
=> CREATE FLEX TABLE darkdata1(talker VARCHAR default "user.lang":VARCHAR);
CREATE TABLE
```

2. Load some JSON data, specifying the `__raw__` column:

```
=> COPY darkdata1 (__raw__) FROM '/test/vertica/flexible/DATA/tweets_12.json'
PARSER fjsonparser();
Rows Loaded
-----
          12
(1 row)
```

3. Query the `talker` column. Notice that Vertica used the default column value (`"user.lang"`), because you specified `__raw__`. Blank rows indicate no values or NULLs:

```
=> SELECT "talker" FROM darkdata1;
talker
-----
it
```

```
en
es
en
en
es
tr
en
(12 rows)
```

4. Alter the table to add a column with a known virtual column name (`user.name`), assigning the key name as the default value (recommended), and casting it to a VARCHAR:

```
=> ALTER TABLE darkdata1 ADD COLUMN "user.name" VARCHAR default "user.name"::VARCHAR;
ALTER TABLE
```

5. Load data again, this time without `__raw__`:

```
=> COPY darkdata1 FROM '/test/vertica/flexible/DATA/tweets_12.json' PARSER fjsonparser();
```

6. Query the two real columns. Notice that `talker` has no values, because you did not specify the `__raw__` column. The `user.lang` column contains values from the `user.name` virtual column:

```
=> SELECT "talker", "user.name" FROM darkdata1;
talker |      user.name
-----+-----
      | laughing at clouds.
      | Avita Desai
      | I'm Toasterâ
      |
      |
      | Uptown gentleman.
      | ~G A B R I E L A â¸
      | Flu Beach
      |
      | seydo shi
      | The End
(12 rows)
```

7. Load data once more, this time specifying a COPY statement with a default value expression for `user.name`:

```
=> COPY darkdata1 (__raw__, "user.name" as 'QueenElizabeth'::varchar) FROM
'/test/vertica/flexible/DATA/tweets_12.json' PARSER fjsonparser();
Rows Loaded
-----
      12
```

```
(1 row)
```

8. Query once more. Notice that the real column `talker` has its default values (you used `__raw__`). As specified in `COPY`, the `"user.name"` as `'QueenElizabeth'` expression overrode the `user.name` default column value:

```
=> SELECT "talker", "user.name" FROM darkdata1;
talker | user.name
-----+-----
it     | QueenElizabeth
en     | QueenElizabeth
es     | QueenElizabeth
       | QueenElizabeth
       | QueenElizabeth
       | QueenElizabeth
en     | QueenElizabeth
en     | QueenElizabeth
es     | QueenElizabeth
       | QueenElizabeth
tr     | QueenElizabeth
en     | QueenElizabeth
(12 rows)
```

To summarize, you can set a default column value as part of the `ALTER TABLE . . . ADD COLUMN . . .` operation. For materializing columns, the default value should reference the key name of the virtual column (as in `"user.lang"`). Subsequently loading data with a `COPY` value expression overrides the default value of the column definition.

Changing the `__raw__` Column Size

You can change the default size of the `__raw__` column for flex tables you plan to create, the current size of an existing flex table, or both.

To change the default size for the flex table `__raw__` column, use the following database configuration parameter (described in [Setting Flex Table Configuration Parameters](#)):

```
=> ALTER DATABASE mydb SET FlexTableRowSize = 120000;
```

Changing the configuration parameter affects all flex tables you create after making this change.

To change the size of the `__raw__` column in an existing flex table, use the `ALTER TABLE` statement to change the definition of the `__raw__` column:

```
=> ALTER TABLE tester ALTER COLUMN __raw__ SET DATA TYPE LONG VARBINARY(120000);  
ALTER TABLE
```

Note: An error occurs if you try to reduce the `__raw__` column size to a value smaller than any data the column contains.

Changing Flex Table Real Columns

You can make the following changes to the flex table real columns (`__raw__` and `__identity__`), but not to any virtual columns:

Actions	<code>__raw__</code>	<code>__identity__</code>
Change NOT NULL constraints (default)	Yes	Yes
Add primary key and foreign key (PK/FK) constraints	No	Yes
Create projections	No	Yes
Segment	No	Yes
Partition	No	Yes
Specify a user-defined scalar function (UDSF) as a default column expression in <code>ALTER TABLE x ADD COLUMN y</code> statement	No	No

Note: While segmenting and partitioning the `__raw__` column is permitted, it is not recommended due to its long data type. By default, if you not define any real columns, flex tables are segmented on the `__identity__` column.

Dropping Flex Table Columns

There are two considerations about dropping columns:

- You cannot drop the last column in your flex table's sort order.
- If you have not created a flex table with any real columns, or materialized any columns, you cannot drop the `__identity__` column.

Updating Flex Table Views

Creating a flex table also creates a default view to accompany the table. The view has the name of the flex table with an underscore (`_view`) suffix. When you perform a `select` query from the default view, Vertica prompts you to run the helper function, `compute_flextable_keys_and_build_view`:

```
=> \dv dark*

                List of View Fields
Schema |      View      | Column |      Type      | Size
-----+-----+-----+-----+-----
public | darkdata_view  | status | varchar(124)   | 124
public | darkdata1_view | status | varchar(124)   | 124
(2 rows)

=> SELECT * FROM darkdata_view;

                                status
-----
Please run compute_flextable_keys_and_build_view() to update this view to reflect real and
virtual columns in the flex table
(1 row)
```

There are two helper functions that create views:

- [COMPUTE_FLEXTABLE_KEYS](#)— See also [COMPUTE_FLEXTABLE_KEYS](#)
- [COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW](#)— Performs the same functionality as `BUILD_FLEXTABLE_KEYS` but also computes keys. See also [Using COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW](#).

Using BUILD_FLEXTABLE_VIEW

After computing keys for a flex table ([Computing Flex Table Keys](#)), call this function with one or more arguments. The records under the `key_name` column of the `{flexible}_keys` table are used as view columns, along with any values for the key. If no values exist, the column value is `NULL`.

Regardless of the number of arguments, calling this function replaces the contents of the existing view as follows:

Function Invocation	Results
<code>build_flextable_view ('flexible_table')</code>	Changes the existing view associated with <code>flexible_</code>

Function Invocation	Results
	<i>flexible_table_keystable</i> .
<code>build_flexible_view ('flexible_table', 'view_name')</code>	Changes the view you specify with <i>view_name</i> by using the current contents of the <i>{flexible}_keys</i> table.
<code>build_flexible_view ('flexible_table', 'view_name', 'table_keys')</code>	Changes the view you specify with <i>view_name</i> to the current contents of the <i>flexible_table_keys</i> table. Use this function to change a view of your choice with the contents of the keys of interest.

If you do not specify a *view_name* argument, the default name is the flex table name with a `_view` suffix. For example, if you specify the table `darkdata` as the sole argument to this function, the default view is called `darkdata_view`.

You cannot specify a custom view name with the same name as the default view `flex_table_view`, unless you first drop the default-named view and then create your own view of the same name.

Creating a view stores a definition of the column structure at the time of creation. Thus, if you create a flex table view and then promote virtual columns to real columns, you must rebuild the view. Querying a rebuilt flex table view that has newly promoted real columns produces two results. These results reflect values from both virtual columns in the map data and real columns.

Handling JSON Duplicate Key Names in Views

SQL is a case-insensitive language, so the names `TEST`, `test`, and `TeSt` are identical. JSON data is case sensitive, so that it can validly contain key names of different cases with separate values.

When you build a flex table view, the function generates a warning if it detects same-name keys with different cases in the *{flexible}_keys* table. For example, calling `BUILD_FLEXIBLE_VIEW` or `COMPUTE_FLEXIBLE_KEYS_AND_BUILD_VIEW()` on a flex table with duplicate key names results in these warnings:

```
=> SELECT compute_flexible_keys_and_build_view('dupe');
WARNING 5821: Detected keys sharing the same case-insensitive key name
WARNING 5909: Found and ignored keys with names longer than the maximum column-name length limit

                                compute_flexible_keys_and_build_view
-----
Please see public.dupe_keys for updated keys
The view public.dupe_view is ready for querying
(1 row)
```

While a `{flexible}_keys` table can include duplicate key names with different cases, a view cannot. Creating a flex table view with either of the helper functions consolidates any duplicate key names to one column name, consisting of all lowercase characters. All duplicate key values for that column are saved. For example, if these key names exist in a flex table:

- test
- Test
- tEst

The view will include a virtual column `test` with values from the `test`, `Test`, and `tEst` keys.

Note: The examples in this section include added Return characters to reduce line lengths. The product output may differ.

For example, consider the following query, showing the duplicate `test` key names:

```
=> \x
Expanded display is on.
dbt=> select * from dupe_keys;
-[ RECORD 1 ]-----
key_name      |
TesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttest
TesttestTesttestTesttestTesttest
frequency     | 2
data_type_guess | varchar(20)
-[ RECORD 2 ]-----
key_name      |
TesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttest
TesttestTesttestTesttestTest12345
frequency     | 2
data_type_guess | varchar(20)
-[ RECORD 3 ]-----
key_name      | test
frequency     | 8
data_type_guess | varchar(20)
-[ RECORD 4 ]-----
```

```
en      | Uptown gentleman.  
en      | The End  
it      | laughing at clouds.  
es      | I'm Toasterâ  
        |  
en      | ~G A B R I E L A â¸  
        |  
en      | Avita Desai  
tr      | seydo shi  
        |  
es      | Flu Beach  
(12 rows)
```

This example shows how to call `build_flextable_view` with the original table and the view you previously created, `dd_view`:

```
=> SELECT build_flextable_view ('darkdata', 'dd_view');  
        build_flextable_view  
-----  
The view public.dd_view is ready for querying  
(1 row)
```

Query the view again. You can see that the function populated the view with the contents of the `darkdata_keys` table. Next, review a snippet from the results, with the `key_name` columns and their values:

```
=> \x  
Expanded display is on.
```

```
=> SELECT * FROM dd_view;  
.   
.   
.   
user.following |   
user.friends_count | 791  
user.geo_enabled | F  
user.id | 164464905  
user.id_str | 164464905  
user.is_translator | F  
user.lang | en  
user.listed_count | 4  
user.location | Uptown..  
user.name | Uptown gentleman.  
.   
.   
.
```

When building views, be aware that creating a view stores a definition of the column structure at the time the view is created. If you promote virtual columns to real columns after building a view, the existing view definition is not changed. Querying this view with a select statement such as the following, returns values from only the `__raw__` column:

```
=> SELECT * FROM myflexable_view;
```

Also understand that rebuilding the view after promoting virtual columns changes the resulting value. Future queries return values from both virtual columns in the map data and from real columns.

Using COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW

Call this function with a flex table to compute Flex table keys (see [Computing Flex Table Keys](#)), and create a view in one step.

Querying Flex Tables

After you create your flex table (with or without additional columns) and load data, you can perform these types of queries:

- SELECT
- COPY
- TRUNCATE
- DELETE

You can use SELECT queries for virtual columns that exist in the `__raw__` column and other real columns in your flex tables. Column names are case insensitive.

Unsupported DDL and DML Statements

You cannot use the following DDL and DML statements with flex tables:

- CREATE TABLE *flex_table* AS...
- CREATE TABLE *flex_table* LIKE...
- SELECT INTO
- UPDATE
- MERGE

Determining Flex Table Data Contents

If you do not know what your flex table contains, two helper functions explore the VMap data to determine its contents. Use these functions to compute the keys in the flex table `__raw__` column and, optionally, build a view based on those keys:

- [COMPUTE_FLEXTABLE_KEYS](#)
- [COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW](#)

For more information about these and other helper functions, see [Flex Data Functions Reference](#)

To determine what key value pairs exist as virtual columns:

1. Call the function as follows:

```
=> SELECT compute_flextable_keys('darkdata');
       compute_flextable_keys
-----
Please see public.darkdata_keys for updated keys(1 row)
```

2. View the key names by querying the darkdata_keys table:

```
=> SELECT * FROM darkdata_keys;
```

key_name	frequency	data_type_guess
contributors	8	varchar(20)
coordinates	8	varchar(20)
created_at	8	varchar(60)
entities.hashtags	8	long varbinary(186)
.		
.		
retweeted_status.user.time_zone	1	varchar(20)
retweeted_status.user.url	1	varchar(68)
retweeted_status.user.utc_offset	1	varchar(20)
retweeted_status.user.verified	1	varchar(20)

(125 rows)

Querying Virtual Columns

Continuing with the JSON data example, use a SELECT statement query to explore content from the virtual columns. Then, analyze what is most important to you in case you want to materialize any virtual columns. This example shows how to query some common virtual columns in the VMap data:

```
=> SELECT "user.name", "user.lang", "user.geo_enabled" FROM darkdata1;
       user.name | user.lang | user.geo_enabled
-----+-----+-----
laughing at clouds. | it | T
Avita Desai | en | F
```

```
I'm Toasterâ  | es | T
              |   |   |
              |   |   |
Uptown gentleman. | en | F
~G A B R I E L A â¸ | en | F
Flu Beach        | es | F
              |   |   |
seydo shi       | tr | T
The End         | en | F
(12 rows)
```

Querying Flex Table Keys

If you reference an undefined column ('which_column') in a flex table query, Vertica converts the query to a call to the `maplookup()` function as follows:

```
MAPLOOKUP(__raw__, 'which_column')
```

The `maplookup()` function searches the VMap data for the requested key and returns the following information:

- String values associated with the key for a row.
- NULL if the key is not found.

For more information about handling NULL values, see [MAPCONTAINSKEY\(\)](#).

Using Functions and Casting in Flex Table Queries

You can cast the virtual columns as required and use functions in your `SELECT` statement queries. The next example uses a `SELECT` statement to query the `created_at` and `retweet_count` virtual columns, and to cast their values in the process:

```
=> SELECT "created_at"::TIMESTAMP, "retweet_count"::INT FROM darkdata1 ORDER BY 1 DESC;
  created_at | retweet_count
-----+-----
2012-10-15 14:41:05 |          0
2012-10-15 14:41:05 |          0
2012-10-15 14:41:05 |          0
2012-10-15 14:41:05 |          0
2012-10-15 14:41:05 |          0
```

```
2012-10-15 14:41:05 |           0
2012-10-15 14:41:05 |           0
2012-10-15 14:41:04 |           1
|
|
|
(12 rows)
```

The following query uses the COUNT and AVG functions to determine the average length of text in different languages:

```
=> SELECT "user.lang", count (*), avg(length("text"))::int FROM darkdata1 GROUP BY 1 ORDER BY 2 DESC;
user.lang | count | avg
-----+-----+----
en        |      4 | 42
          |      4 |
es        |      2 | 96
it        |      1 | 50
tr        |      1 | 16
(5 rows)
```

Casting Data Types in a Query

The following query requests the values of the created_at virtual column, without casting to a specific data type:

```
=> SELECT "created_at" FROM darkdata1;
      created_at
-----
Mon Oct 15 18:41:04 +0000 2012
Mon Oct 15 18:41:05 +0000 2012
(12 rows)
```

The next example queries the same virtual column, casting created_at to a TIMESTAMP. Casting results in different output and the regional time:

```
=> SELECT "created_at"::TIMESTAMP FROM darkdata1 ORDER BY 1 DESC;
      created_at
-----
2012-10-15 14:41:05
2012-10-15 14:41:05
2012-10-15 14:41:05
2012-10-15 14:41:05
```

```
2012-10-15 14:41:05  
2012-10-15 14:41:05  
2012-10-15 14:41:05  
2012-10-15 14:41:04
```

Accessing an Epoch Key

The term *EPOCH* (all uppercase letters) is reserved in Vertica for internal use.

If your JSON data includes a virtual column called epoch, you can query it within your flex table. However, use the `maplookup()` function to do so.

Querying Nested Data

If you load JSON or Avro data with `flatten_arrays=FALSE` (the default), VMap data in the `__raw__` column can contain multiple nested structures. In fact, any VMap JSON or Avro data can contain nested structures. This section describes how best to query such data.

Query VMap Nested Values

To query a nested structure, you can use multiple `maplookup()` functions, one for each level. However, the most efficient method is to use bracket (`[]`) operators.

When parsing or extracting VMap data, the default behavior is to flatten data. Flattened VMap data concatenates key names into one long name, delimiting elements with either the default delimiter (`.`), or a user-defined delimiter character.

To use bracket operators for nested structures in your VMap data, the data must not be flattened. Further, you cannot use bracket operators on any existing, flattened VMap data.

To load or extract VMap data correctly, specify `flatten_maps=FALSE` for `fjsonparser`, `favroparser`, and the `mapjsonextractor()` function.

Note: While bracket operator values look similar to array element specifications, they are strings, not integers. You must enter each nested structure as a string, even if the value is an integer. For example, if the value is 2, specify it as `[' 2 ']`, not `[2]`.

Bracket Operators For Nested JSON

This example uses the following JSON data as an example of nested data. Save this data as `restaurant.json`:

```
{
  "restaurant" : {
    "_name_" : "Bob's pizzeria",
    "cuisine" : "Italian",
    "location" : {"city" : "Cambridge", "zip" : "02140"},
    "menu" : [{"item" : "cheese pizza", "price" : "$8.25"},
              {"item" : "chicken pizza", "price" : "$11.99"},
              {"item" : "spinach pizza", "price" : "$10.50"}]
  }
}
```

Create a flex table, `rests`, and load it with the `restaurant.json` file:

```
=> COPY rests FROM '/home/dbadmin/tempdat/restaurant.json' PARSER fjsonparser (flatten_maps=false);
Rows Loaded
-----
          1
(1 row)
```

After loading your data into a flex table, there are two ways to access nested data using brackets:

- Beginning with the `__raw__` column, followed by the character values in brackets
- Starting with the name of the top-most element, followed by the character values in brackets

Both methods are equally efficient. Here are examples of both:

```
=> SELECT __raw__['restaurant']['location']['city'] FROM rests;
__raw__
-----
Cambridge
(1 row)
=> SELECT restaurant['location']['city'] from rests;
restaurant
-----
Cambridge
(1 row)
```

Bracket Operators for Twitter Data

This example shows how to extract some basic information from Twitter data.

After creating a flex table, `tweets`, and loading in some data, the flex table has a block of tweets.

In the following `SELECT` statement, notice how to specify the `__raw__` column of table `tweets`, followed by the bracket operators to define the virtual columns of interest (`['delete']['status']['user_id']`). This query uses the `COUNT()` function to calculate the number of deleted tweets and outputs 10 results:

```
=> SELECT __raw__['delete']['status']['user_id'] as UserId, COUNT(*) as TweetsDelete from tweets
-> WHERE mapcontainskey(__raw__, 'delete')
-> GROUP BY __raw__['delete']['status']['user_id']
-> ORDER BY TweetsDelete DESC, UserID ASC LIMIT 10;
  UserId | TweetsDelete
-----+-----
106079547 |          4
403474369 |          4
181188657 |          3
```

```
223136123 |      3
770139481 |      3
154602299 |      2
192127653 |      2
215011332 |      2
23321883  |      2
242173898 |      2
(10 rows)
```

Querying Flex Views

Flex tables offer the ability of dynamic schema through the application of query rewriting. Use flex views to support restricted access to flex tables. As with flex tables, each time you use a `select` query on a flex table view, internally, Vertica invokes the `maplookup()` function, to return information on all virtual columns. This query behavior occurs for any flex or columnar table that includes a `__raw__` column.

This example illustrates querying a flex view:

1. Create a flex table.

```
=> CREATE FLEX TABLE twitter();
```

2. Load JSON data into flex table using `fjsonparser`.

```
=> COPY twitter FROM '/home/dbadmin/data/flex/tweets_10000.json' PARSER fjsonparser();  
Rows Loaded  
-----  
10000  
(1 row)
```

3. Create a flex view on top of flex table `twitter` with constraint `retweet_count > 0`.

```
=> CREATE VIEW flex_view AS SELECT __raw__ FROM twitter WHERE retweet_count::int > 0;  
CREATE VIEW
```

4. Query the view. First 5 rows are displayed.

```
=> SELECT retweeted,retweet_count,source FROM (select __raw__ from flex_view) t1 limit 5;  
retweeted | retweet_count | source  
-----+-----+-----  
F          | 1              | <a href="http://blackberry.com/twitter" rel="nofollow">Twitter for  
BlackBerry®</a>  
F          | 1              | web  
F          | 1              | <a href="http://twitter.com/download/iphone" rel="nofollow">Twitter  
for iPhone</a>  
F          | 23             | <a href="http://twitter.com/download/android" rel="nofollow">Twitter  
for Android</a>  
F          | 7              | <a href="http://twitter.com/download/iphone" rel="nofollow">Twitter  
for iPhone</a>  
(5 rows)
```

Listing Flex Tables

You can determine which tables in your database are flex tables by querying the `is_flextable` column of the `v_catalog.tables` system table. For example, use a query such as the following to see all tables with a true (t) value in the `is_flextable` column:

```
=> SELECT table_name, table_schema, is_flextable FROM v_catalog.tables;
  table_name | table_schema | is_flextable
-----+-----+-----
bake1       | public      | t
bake1_keys  | public      | f
del         | public      | t
del_keys    | public      | f
delicious   | public      | t
delicious_keys | public      | f
bake        | public      | t
bake_keys   | public      | f
appLog      | public      | t
appLog_keys | public      | f
darkdata    | public      | t
darkdata_keys | public      | f
(12 rows)
```

Setting Flex Table Configuration Parameters

These configuration parameters affect flex table usage:

- `EnableBetterFlexTypeGuessing`
- `FlexTableRowSize`
- `FlexTableDataTypeGuessMultiplier`

This section presents information about each of the parameters.

To change configuration parameters, and to understand parameter scope, see [Setting Configuration Parameter Values](#) and [General Parameters](#) in the Administrator's Guide.

Using `EnableBetterFlexTypeGuessing`

The `EnableBetterFlexTypeGuessing` configuration parameter is 1 (ON) by default. This setting results in the `COMPUTE_FLEXTABLE_KEYS` or `COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW` functions determining data types for string and non-string keys. If you change the configuration parameter to 0 (OFF), the functions determine all flex keys as string types (`[LONG]VARCHAR`) or (`[LONG] VARBINARY`).

You can set this configuration parameter at the database and session level.

For examples of using both settings, see [Computing Flex Table Keys](#).

Specifying the `FlexTableRowSize` Parameter

The `FlexTableRowSize` parameter defines the default width of each flex table `__raw__` column. This column is a `LONG VARBINARY` data type, and contains the map data you load into the table.

Setting this configuration parameter does not affect any existing flex tables, only the default width for new flex tables you create after changing `FlexTableRowSize`.

To change the `__raw__` column width of an existing flex table, use the [ALTER TABLE](#) statement, described in [Materializing Flex Tables](#).

Redefining the FlexTableDataTypeGuessMultiplier

After loading data into a flex table, each key in the `__raw__` column is a `LONG VARBINARY` data type.

When you compute flex table keys with either of the functions, `COMPUTE_FLEXTABLE_KEYS` or `COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW`, the functions cast each key to the applicable Vertica data type. The key value length is determined by the key's largest value, multiplied by the `FlexTableDataTypeGuessMultiplier` factor. Padding the column width with the multiplier supports future data load key values at least twice the largest key value previously loaded.

The flex keys table that both flex functions populate is used to create the associated flex table view.

Note: The `FlexTableDataTypeGuessMultiplier` value is not used to calculate the width of any real columns in a flex table.

Flex Data Functions Reference

The flex table data helper functions supply information you need to query the data you load. For example, suppose you don't know what keys are available in the map data. If not, you can use the [COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW](#) function to populate a keys table and build a view. The functions aid in querying flex table and other VMap data.

Function	Description
COMPUTE_FLEXTABLE_KEYS	Computes map keys from the map data in a <code>flextable_data</code> table, and populates the <code>flextable_data_keys</code> table with the computed keys. Use this function before building a view.
BUILD_FLEXTABLE_VIEW	Uses the keys in the <code>flextable_data_keys</code> table to create a view definition (<code>flextable_data_view</code>) for the <code>flextable_data</code> table. Use this function after computing flex table keys.
COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW	Performs both of the preceding functions in one call.
MATERIALIZE_FLEXTABLE_COLUMNS	Materializes a default number of columns (50) or more or less, if specified.
RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW	Replaces the <code>flextable_data_keys</code> table and the <code>flextable_data_view</code> , linking both the keys table and the view to the parent flex table.

While the functions are available to all users, they are applicable only to:

- Flex tables
- Associated *flex_table_keys* tables
- Associated *flex_table_view* views

By computing keys and creating views from flex table data, the functions allow you to perform SELECT queries. One function restores the original keys table and view that you specified when you first created the flex table.

Flex Table Dependencies

Each flex table (*flextable*) has two dependent objects:

- *flextable_keys*
- *flextable_view*

While both objects are dependent on their parent table, (*flextable*), you can drop either object independently. Dropping the parent table removes both dependents, without a CASCADE option.

Associating Flex Tables and Views

The helper functions automatically use the dependent table and view if they are internally linked with the parent table. You create both when you create the flex table. You can drop either the `_keys` table or the `_view`, and re-create objects of the same name. However, if you do so, the new objects are not internally linked with the parent flex table.

In this case, you can restore the internal links of these objects to the parent table. To do so, drop the `_keys` table and the `_view` before calling the [RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW](#) function. Calling this function re-creates either, or both, the `_keys` table and the `_view`.

The remaining helper functions perform the tasks described in this section.

BUILD_FLEXTABLE_VIEW

Creates, or re-creates, a view for a default or user-defined `_keys` table, ignoring any empty keys.

Syntax

```
build_flextable_view('flex_table' [ [ , 'view_name' ] [ , 'user_keys_table' ] ])
```

Arguments

<i>flex_table</i>	The flex table name. By default, this function builds or rebuilds a view for the input table with the current contents of the associated <i>flex_table_keys</i> table.
<i>view_name</i>	[Optional] A custom view name. Use this option to build a new view for <i>flex_table</i> with the name you specify.
<i>user_keys_table</i>	[Optional] Specifies a keys table from which to create the view. Use this option if you created a custom <i>user_keys</i> table from the flex table map data, rather than from the default <i>flex_table_keys</i> table. The function builds a view from the keys in <i>user_keys</i> table, rather than from the <i>flex_table_keys</i> table.

Examples

The following examples show how to call `build_flextable_view` with 1, 2, or 3 arguments.

Creating a Default View

To create, or re-create, a default view:

1. Call the function with an input flex table, `darkdata`:

```
=> SELECT build_flextable_view('darkdata');
           build_flextable_view
-----
The view public.darkdata_view is ready for querying
(1 row)
```

The function creates a view with the default name (`darkdata_view`) from the `darkdata_keys` table.

2. Query a key name (`user.id`) from the new or updated view:

```
=> SELECT "user.id" from darkdata_view;
   user.id
-----
 340857907
 727774963
```

```
390498773
288187825
164464905
125434448
601328899
352494946
(12 rows)
```

Creating a Custom Name View

To create, or re-create, a view with a custom name:

1. Call the function with two arguments, an input flex table, `darkdata`, and the name of the view to create, `dd_view`:

```
=> SELECT build_flextable_view('darkdata', 'dd_view');
        build_flextable_view
-----
The view public.dd_view is ready for querying
(1 row)
```

2. Query a key name (`user.lang`) from the new or updated view (`dd_view`):

```
=> SELECT "user.lang" from dd_view;
 user.lang
-----
tr
en
es
en
en
it
es
en
(12 rows)
```

Creating a View from a Custom Keys Table

To create a view from a custom `_keys` table with `build_flextable_view`, the custom table must have the same schema and table definition as the default table (`darkdata_keys`).

Create a custom keys table, using any of these three approaches:

1. Create a columnar table with all keys from the default keys table for a flex table (`darkdata_keys`):

```
=> CREATE table new_darkdata_keys as select * from darkdata_keys;
CREATE TABLE
```

2. Create a columnar table without content (LIMIT 0) from the default keys table for a flex table (darkdata_keys):

```
=> CREATE table new_darkdata_keys as select * from darkdata_keys LIMIT 0;
CREATE TABLE
kdb=> select * from new_darkdata_keys;
  key_name | frequency | data_type_guess
-----+-----+-----
(0 rows)
```

3. Create a columnar table without content (LIMIT 0) from the default keys table, and insert two values ('user.lang', 'user.name') into the key_name column:

```
=> CREATE table dd_keys as select * from darkdata_keys limit 0;
CREATE TABLE
=> insert into dd_keys (key_name) values ('user.lang');
  OUTPUT
  -----
         1
(1 row)
=> INSERT into dd_keys (key_name) values ('user.name');
  OUTPUT
  -----
         1
(1 row)
=> SELECT * from dd_keys;
  key_name | frequency | data_type_guess
-----+-----+-----
 user.lang |           |
 user.name |           |
(2 rows)
```

4. After creating a custom keys table, call build_flexable_view with all arguments (an input flex table, the new view name, the custom keys table):

```
=> SELECT BUILD_FLEXTABLE_VIEW('darkdata', 'dd_view', 'dd_keys');
      build_flexable_view
-----
The view public.dd_view is ready for querying
(1 row)
```

5. Query the new view:

```
=> SELECT * from dd_view;
```

See Also

- [COMPUTE_FLEXTABLE_KEYS](#)
- [COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW](#)
- [MATERIALIZER_FLEXTABLE_COLUMNS](#)
- [RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW](#)

COMPUTE_FLEXTABLE_KEYS

Computes the virtual columns (keys and values) from the flex table VMap data. Use this function to compute keys without creating an associated table view. To also build a view, use [COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW](#).

The function stores its results in the associated flex_keys table, which has the following columns:

- key_name
- frequency
- data_type_guess

For more information, see [Computing Flex Table Keys](#).

Syntax

```
compute_flextable_keys('flex_table')
```

Arguments

<i>flex_table</i>	The name of a flex table.
-------------------	---------------------------

Using Data Type Guessing

The results of the flex_keys table data_type_guess column depend on the EnableBetterFlexTypeGuessing configuration parameter. By default, the parameter is 1 (ON). This setting results in the function returning all non-string keys in the data_type_guess column as one of the following types (and others listed in [SQL Data Types](#)):

- BOOLEAN
- INTEGER
- FLOAT
- TIMESTAMP
- DATE

Setting the configuration parameter to 0 (OFF), results in the function returning only string types ([LONG]VARCHAR) or ([LONG] VARBINARY) for all values in the data_type_guess column of the flex_keys table .

Assigning Flex Key Data Types

Use the sample CSV data in this section to compare the results of using or not using the EnableBetterFlexTypeGuessing configuration parameter. When the parameter is ON, the function determines key non-string data types in your map data more accurately. The default for the parameter is 1 (ON).

```
Year,Quarter,Region,Species,Grade,Pond Value,Number of Quotes,Available
2015,1,2 - Northwest Oregon & Willamette,Douglas-fir,1P,$615.12 ,12,No
2015,1,2 - Northwest Oregon & Willamette,Douglas-fir,SM,$610.78 ,12,Yes
2015,1,2 - Northwest Oregon & Willamette,Douglas-fir,2S,$596.00 ,20,Yes
2015,1,2 - Northwest Oregon & Willamette,Hemlock,P,$520.00 ,6,Yes
2015,1,2 - Northwest Oregon & Willamette,Hemlock,SM,$510.00 ,6,No
2015,1,2 - Northwest Oregon & Willamette,Hemlock,2S,$490.00 ,14,No
```

To compare the data type assignment results, complete the following steps:

1. Save the CSV data file (here, as trees.csv).
2. Create a flex table (trees) and load trees.csv using the fcsvparser:

```
=> CREATE FLEX TABLE trees();  
=> COPY trees FROM '/home/dbadmin/tempdat/trees.csv' PARSER fcsvparser();
```

3. Use COMPUTE_FLEXTABLE_KEYS with the trees flex table.

```
=> SELECT COMPUTE_FLEXTABLE_KEYS('trees');  
          COMPUTE_FLEXTABLE_KEYS  
-----  
Please see public.trees_keys for updated keys  
(1 row)
```

4. Query the trees_keys table output.:

```
=> SELECT * FROM trees_keys;  
   key_name | frequency | data_type_guess  
-----+-----+-----  
Year        |          6 | Integer  
Quarter     |          6 | Integer  
Region      |          6 | Varchar(66)  
Available   |          6 | Boolean  
Number of Quotes |          6 | Integer  
Grade       |          6 | Varchar(20)  
Species     |          6 | Varchar(22)  
Pond Value  |          6 | Numeric(8,3)  
(8 rows)
```

5. Set the EnableBetterFlexTypeGuessing parameter to 0 (OFF).
6. Call COMPUTE_FLEXTABLE_KEYS with the trees flex table again.
7. Query the trees_keys table to compare the data_type_guess values with the previous results. Without the configuration parameter set, all of the non-string data types are VARCHARS of various lengths:

```
=> SELECT * FROM trees_keys;  
   key_name | frequency | data_type_guess  
-----+-----+-----  
Year        |          6 | varchar(20)  
Quarter     |          6 | varchar(20)  
Region      |          6 | varchar(66)  
Available   |          6 | varchar(20)  
Grade       |          6 | varchar(20)  
Number of Quotes |          6 | varchar(20)  
Pond Value  |          6 | varchar(20)  
Species     |          6 | varchar(22)  
(8 rows)
```

8. To maintain accurate results for non-string data types, set the EnableBetterFlexTypeGuessing parameter back to 1 (ON).

For more information about setting the `EnableBetterFlexTypeGuessing` configuration parameter, see [Setting Flex Table Configuration Parameters](#).

- [COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW](#)
- [MATERIALIZE_FLEXTABLE_COLUMNS](#)
- [RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW](#)

COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW

Combines the functionality of [BUILD_FLEXTABLE_VIEW](#) and [COMPUTE_FLEXTABLE_KEYS](#) to compute virtual columns (keys) from the VMap data of a flex table and construct a view. Creating a view with this function ignores empty keys. If you do not need to perform both operations together, use one of the single-operation functions instead.

Syntax

```
compute_flextable_keys_and_build_view('flex_table')
```

Arguments

<i>flex_table</i>	The name of a flex table.
-------------------	---------------------------

Examples

This example shows how to call the function for the darkdata flex table.

```
=> SELECT compute_flexible_keys_and_build_view('darkdata');
       compute_flexible_keys_and_build_view
```

```
-----
Please see public.darkdata_keys for updated keys
The view public.darkdata_view is ready for querying
(1 row)
```

See Also

- [BUILD_FLEXIBLE_VIEW](#)
- [COMPUTE_FLEXIBLE_KEYS](#)
- [MATERIALIZER_FLEXIBLE_COLUMNS](#)
- [RESTORE_FLEXIBLE_DEFAULT_KEYS_TABLE_AND_VIEW](#)

MATERIALIZER_FLEXIBLE_COLUMNS

Materializes virtual columns listed as *key_names* in the *flexible_keys* table you compute using either [COMPUTE_FLEXIBLE_KEYS](#) or [COMPUTE_FLEXIBLE_KEYS_AND_BUILD_VIEW](#).

Note: Each column that you materialize with this function counts against the data storage limit of your license. To check your Vertica license compliance, call the `AUDIT()` or `AUDIT_FLEX()` functions.

Syntax

```
materialize_flexible_columns('flex_table' [, n-columns [, keys_table_name] ])
```

Arguments

<i>flex_table</i>	The name of the flex table with columns to materialize. Specifying only the flex table name attempts to materialize up to 50 columns of key names in the default <i>flex_table_keys</i> table. When you use this argument, the function:
-------------------	--

	<ul style="list-style-type: none"> • Skips any columns already materialized • Ignores any empty keys <p>To materialize a specific number of columns, use the optional parameter <code>n_columns</code>, described next.</p>
<i>n-columns</i>	<p>[Optional] The number of columns to materialize. The function attempts to materialize the number of columns from the <code>flex_table_keys</code> table, skipping any columns already materialized.</p> <p>Vertica tables support a total of 1600 columns, which is the largest value you can specify for <code>n-columns</code>. The function orders the materialized results by frequency, descending, <i>key_name</i> when materializing the first <code>n</code> columns.</p>
<i>keys_table_name</i>	<p>[Optional] The name of a <code>flex_keys_table</code> from which to materialize columns. The function:</p> <ul style="list-style-type: none"> • Materializes the number of columns (value of <i>n-columns</i>) from <i>keys_table_name</i> • Skips any columns already materialized • Orders the materialized results by frequency, descending, <i>key_name</i> when materializing the first <code>n</code> columns.

Examples

The following example shows how to call `materialize_flextable_columns` to materialize columns. First, load a sample file of tweets (`tweets_10000.json`) into the flex table `twitter_r`.

After loading data and computing keys for the sample flex table, call `materialize_flextable_columns` to materialize the first four columns:

```
=> COPY twitter_r FROM '/home/release/KData/tweets_10000.json' parser fjsonparser();
Rows Loaded
-----
      10000
(1 row)

=> SELECT compute_flextable_keys ('twitter_r');
           compute_flextable_keys
-----
Please see public.twitter_r_keys for updated keys
(1 row)
```

```
=> select materialize_flextable_columns('twitter_r', 4);
       materialize_flextable_columns
-----
The following columns were added to the table public.twitter_r:
    contributors
    entities.hashtags
    entities.urls
For more details, run the following query:
SELECT * FROM v_catalog.materialize_flextable_columns_results WHERE table_schema = 'public' and
table_name = 'twitter_r';

(1 row)
```

The last message in the example recommends querying the `materialize_flextable_columns_results` system table for the results of materializing the columns, as shown:

```
=> SELECT * FROM v_catalog.materialize_flextable_columns_results WHERE table_schema = 'public' and
table_name = 'twitter_r';
table_id      | table_schema | table_name |      creation_time      |      key_name      |
status |      message
-----+-----+-----+-----+-----+-----+
45035996273733172 | public      | twitter_r | 2013-11-20 17:00:27.945484-05 | contributors      |
ADDED | Added successfully
45035996273733172 | public      | twitter_r | 2013-11-20 17:00:27.94551-05 | entities.hashtags |
ADDED | Added successfully
45035996273733172 | public      | twitter_r | 2013-11-20 17:00:27.945519-05 | entities.urls     |
ADDED | Added successfully
45035996273733172 | public      | twitter_r | 2013-11-20 17:00:27.945532-05 | created_at        |
EXISTS | Column of same name already
(4 rows)
```

See the [MATERIALIZE_FLEXTABLE_COLUMNS_RESULTS](#) system table in the SQL Reference Manual.

See Also

- [BUILD_FLEXTABLE_VIEW](#)
- [COMPUTE_FLEXTABLE_KEYS](#)
- [COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW](#)
- [RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW](#)

RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW

Restores the `_keys` table and the `_view`. The function also links the `_keys` table with its associated flex table, in cases where either table is dropped. The function also indicates whether it restored one or both objects.

Syntax

```
RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW('flex_table')
```

Arguments

<i>flex_table</i>	The name of a flex table.
-------------------	---------------------------

Examples

This example shows how to invoke this function with an existing flex table, restoring both the `_keys` table and `_view`:

```
=> SELECT RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW('darkdata');
          RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW
-----
The keys table public.darkdata_keys was restored successfully.
The view public.darkdata_view was restored successfully.
(1 row)
```

This example illustrates that the function restored `darkdata_view`, but that `darkdata_keys` did not need restoring:

```
=> SELECT RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW('darkdata');
          RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW
-----
The keys table public.darkdata_keys already exists and is linked to darkdata.
The view public.darkdata_view was restored successfully.
(1 row)
```

After restoring the `_keys` table, there is no content. To populate the flex keys, call the [COMPUTE_FLEXTABLE_KEYS](#) meta function.

```
=> SELECT * FROM darkdata_keys;
   key_name | frequency | data_type_guess
-----+-----+-----
(0 rows)
```

Flex Extractor Functions Reference

The following extractor scalar functions process polystructured data:

- MAPDELIMITEDEXTRACTOR
- MAPJSONEXTRACTOR
- MAPREGEXEXTRACTOR

Each function accepts input data that is:

- Existing database content
- A table
- Returned from an expression
- Entered directly

These functions do not parse data from an external file source. All functions return a single VMap value. The extractor functions can return data with NULL-specified columns.

This section describes each extractor function.

MAPDELIMITEDEXTRACTOR

Extracts data with a delimiter character, and other optional arguments, returning a single VMap value. The USING PARAMETERS phrase specifies optional parameters for the function.

Parameters

delimiter	VARCHAR	Single delimiter character. Default value:
header_names	VARCHAR	[Optional] Specifies header names for columns. Default value: uco1n Where <i>n</i> is the column offset number, starting with 0

		for the first column. The function uses default values if you do not specify values for the <code>header_names</code> parameter.
<code>trim</code>	BOOLEAN	[Optional] Trims white space from header names and field values. Default value: <code>true</code>
<code>treat_empty_val_as_null</code>	BOOLEAN	[Optional] Specifies that empty fields become NULLs, rather than empty strings (' '). Default value: <code>true</code>

Examples

These examples use a short set of delimited data:

```
Name|CITY|New city|State|zip
Tom|BOSTON|boston|MA|01
Eric|Burlington|BURLINGTON|MA|02
Jamie|cambridge|CAMBRIDGE|MA|08
```

To begin, save this data as `delim.dat`.

1. Create a flex table, `dflex`:

```
=> CREATE flex table dflex();
CREATE TABLE
```

2. Use `COPY` to load the `delim.dat` file. Use the flex tables `fdelimitedparser` with the `header='false'` option:

```
=> COPY dflex from '/home/release/kmm/flextables/delim.dat' parser fdelimitedparser
(header='false');
Rows Loaded
-----
                4
(1 row)
```

3. Create a columnar table, `dtab`, with an identity `id` column, a `delim` column, and a column to hold a `VMap`, named `vmap`:

```
=> CREATE TABLE dtab (id IDENTITY(1,1), delim varchar(128), vmap long varbinary(512));
CREATE TABLE
```

4. Use COPY to load the `delim.dat` file into the `dtab` table. For the `mapdelimitedextractor` function, add a header row with `USING PARAMETERS header_names=` option to specify the header row for the sample data, along with `delimiter '!'`:

```
=> COPY dtab(delim, vmap as mapdelimitedextractor(delim
  USING PARAMETERS header_names='Name|CITY|New City|State|Zip')) FROM
'/home/dbadmin/data/delim.dat' DELIMITER '!';

Rows Loaded
-----
                4
(1 row)
```

5. Use `maptostring` for the flex table `dflex` to view the `__raw__` column contents. Notice the default header names in use (`ucol0 – ucol4`), since you specified `header='false'` when you loaded the flex table:

```
=> SELECT maptostring(__raw__) from dflex limit 10;
                maptostring
-----
{
  "ucol0" : "Jamie",
  "ucol1" : "cambridge",
  "ucol2" : "CAMBRIDGE",
  "ucol3" : "MA",
  "ucol4" : "08"
}

{
  "ucol0" : "Name",
  "ucol1" : "CITY",
  "ucol2" : "New city",
  "ucol3" : "State",
  "ucol4" : "zip"
}

{
  "ucol0" : "Tom",
  "ucol1" : "BOSTON",
  "ucol2" : "boston",
  "ucol3" : "MA",
  "ucol4" : "01"
}

{
  "ucol0" : "Eric",
  "ucol1" : "Burlington",
  "ucol2" : "BURLINGTON",
  "ucol3" : "MA",
  "ucol4" : "02"
}

(4 rows)
```

6. Use `maptostring` again, this time with the `dtab` table's `vmap` column. Compare the results of this output to those for the flex table. Note that `maptostring` returns the `header_name` parameter values you specified when you loaded the data:

```
=> SELECT maptostring(vmap) from dtab;
                                     maptostring
-----
{
  "CITY" : "CITY",
  "Name" : "Name",
  "New City" : "New city",
  "State" : "State",
  "Zip" : "zip"
}

{
  "CITY" : "BOSTON",
  "Name" : "Tom",
  "New City" : "boston",
  "State" : "MA",
  "Zip" : "02121"
}

{
  "CITY" : "Burlington",
  "Name" : "Eric",
  "New City" : "BURLINGTON",
  "State" : "MA",
  "Zip" : "02482"
}

{
  "CITY" : "cambridge",
  "Name" : "Jamie",
  "New City" : "CAMBRIDGE",
  "State" : "MA",
  "Zip" : "02811"
}

(4 rows)
```

7. Query the `delim` column to view the contents differently:

```
=> SELECT delim from dtab;
      delim
-----
Name|CITY|New city|State|zip
Tom|BOSTON|boston|MA|02121
Eric|Burlington|BURLINGTON|MA|02482
Jamie|cambridge|CAMBRIDGE|MA|02811
(4 rows)
```

- [MAPREGEXEXTRACTOR](#)

MAPJSONEXTRACTOR

Extracts content of repeated JSON data objects, including nested maps, or data with an outer list of JSON elements. The `USING PARAMETERS` phrase specifies optional parameters for the function. Empty input does not generate a Warning or Error.

Note: The function fails if the output size of the function is greater than 65000.

Parameters

<code>flatten_maps</code>	BOOLEAN	[Optional] Flattens sub-maps within the JSON data, separating map levels with a period (.). Default value: true
<code>flatten_arrays</code>	BOOLEAN	[Optional] Converts lists to sub-maps with integer keys. Lists are not flattened by default. Default value: false
<code>reject_on_duplicate</code>	BOOLEAN	[Optional] Specifies whether to ignore duplicate records (false), or to reject duplicates (true). In either case, the load continues. Default value: false
<code>reject_on_empty_key</code>	BOOLEAN	[Optional] Rejects any row containing a key without a value (<code>reject_on_empty_key=true</code>). Default value: false
<code>omit_empty_keys</code>	BOOLEAN	[Optional] Omits any key from the load data that does not have a value (<code>omit_empty_keys=true</code>).

		Default value: false
start_point	CHAR	[Optional] Specifies the name of a key in the JSON load data at which to begin parsing. The parser ignores all data before the start_point value. The parser processes data after the first instance, and up to the second, ignoring any remaining data. Default value: none

Examples

These examples use the following sample JSON data:

```
{ "id": "5001", "type": "None" }  
{ "id": "5002", "type": "Glazed" }  
{ "id": "5005", "type": "Sugar" }  
{ "id": "5007", "type": "Powdered Sugar" }  
{ "id": "5004", "type": "Maple" }
```

Save this example data as `bake_single.json`, and load that file.

1. Create a flex table, `flexjson`:

```
=> CREATE flex table flexjson();  
CREATE TABLE
```

2. Use `COPY` to load the `bake_single.json` file with the `fjsonparser` parser:

```
=> COPY flexjson from '/home/dbadmin/data/bake_single.json' parser fjsonparser();  
Rows Loaded  
-----  
5  
(1 row)
```

3. Create a columnar table, `coljson`, with an identity column (`id`), a json column, and a column to hold a VMap, called `vmap`:

```
=> CREATE table coljson(id IDENTITY(1,1), json varchar(128), vmap long varbinary(10000));  
CREATE TABLE
```

4. Use `COPY` to load the `bake_single.json` file into the `coljson` table, using the `mapjsonextractor` function:

```
=> COPY coljson (json, vmap AS MapJSONExtractor(json)) FROM '/home/dbadmin/data/bake_
single.json';
Rows Loaded
-----
                5
(1 row)
```

5. Use the `maptostring` function for the flex table `flexjson` to output the `__row__` column contents as strings:

```
=> SELECT maptostring(__row__) from flexjson limit 5;
                maptostring
-----
{
  "id" : "5001",
  "type" : "None"
}

{
  "id" : "5002",
  "type" : "Glazed"
}

{
  "id" : "5005",
  "type" : "Sugar"
}

{
  "id" : "5007",
  "type" : "Powdered Sugar"
}

{
  "id" : "5004",
  "type" : "Maple"
}

(5 rows)
```

6. Use the `maptostring` function again, this time with the `coljson` table's `vmap` column and compare the results. The element order differs:

```
=> SELECT maptostring(vmap) from coljson limit 5;
                maptostring
-----
{
  "id" : "5001",
  "type" : "None"
}

{
  "id" : "5002",
  "type" : "Glazed"
}
```

```
}  
  
{  
  "id" : "5004",  
  "type" : "Maple"  
}  
  
{  
  "id" : "5005",  
  "type" : "Sugar"  
}  
  
{  
  "id" : "5007",  
  "type" : "Powdered Sugar"  
}  
  
(5 rows)
```

See Also

- [MAPDELIMITEXTRACTOR](#)
- [MAPREGEXEXTRACTOR](#)

MAPREGEXEXTRACTOR

Extracts data from a regular expression and returns the results as a VMap. Use the USING PARAMETERS `pattern=` phrase, followed by the regular expression.

Parameters

<code>pattern=</code>	VARCHAR	The regular expression as a string. Default value: An empty string ("").
<code>use_jit</code>	BOOLEAN	[Optional] Uses just-in-time compiling when parsing the regular expression. Default value: false.
<code>record_terminator</code>	VARCHAR	[Optional] The character used to separate input records. Default value: \n.

logline_column	VARCHAR	[Optional] The destination column containing the full string that the regular expression matched. Default value: An empty string ("").
----------------	---------	--

Examples

These examples use the following regular expression, which searches for information that includes the timestamp, date, thread_name, and thread_id strings.

Caution: For display purposes, this sample regular expression adds new line characters to split long lines of text. To use this expression in a query, first copy and edit the example to remove any new line characters.

This example expression loads any thread_id hex value, regardless of whether it has a 0x prefix, (<thread_id>(?:0x)?[0-9a-f]+).

```
'^(?<time>\d\d\d\d-\d\d-\d\d \d\d:\d\d:\d\d\.\d+)
(?<thread_name>[A-Za-z ]+):( ?<thread_id>(?:0x)?[0-9a-f]+)
-?(?<transaction_id>[0-9a-f])?(?:[(?<component>\w+)]
\<( ?<level>\w+)\> )?(?:<( ?<level>\w+)\> @[(?<enode>\w+)]?: )
?(?<text>.*)'
```

The following examples may include newline characters for display purposes.

1. Create a flex table, flogs:

```
=> CREATE flex table flogs();
CREATE TABLE
```

2. Use COPY to load a sample log file (vertica.log), using the flex table flogparser. Note that this example includes added line characters for displaying long text lines.

```
=> COPY flogs FROM '/home/dbadmin/tempdat/vertica.log' PARSER FREGEXPARSER(pattern='
^(?<time>\d\d\d\d-\d\d-\d\d \d\d:\d\d:\d\d\.\d+) (?<thread_name>[A-Za-z ]+):
(?<thread_id>(?:0x)?[0-9a-f])-?(?<transaction_id>[0-9a-f])?(?:[(?<component>\w+)]
\<( ?<level>\w+)\> )?(?:<( ?<level>\w+)\> @[(?<enode>\w+)]?: )?(?<text>.*)');
Rows Loaded
-----
81399
(1 row)
```

3. Use MapToString to return the results from calling MapRegexExtractor with a regular expression. The output returns the results of the function in string format.

```
=> SELECT maptostrng(MapregexExtractor(E'2014-04-02 04:02:51.011
TM Moveout:0x2aab9000f860-a000000002067 [Txn] <INFO>
```

```
Begin Txn: a0000000002067 \'Moveout: Tuple Mover\' using PARAMETERS
pattern='^(?<time>\d\d\d\d-\d\d-\d\d \d\d:\d\d:\d\d.\d+)
(?<thread_name>[A-Za-z ]+):(?<thread_id>(?:0x)?[0-9a-f]+)
-?(?<transaction_id>[0-9a-f])?(?:[(?<component>\w+)]
\<(?!<level>\w+)\> )?(?:<(?!<level>\w+)\> @[?!<enode>\w+])?: )
?(?!<text>.*\')) FROM flogs where __identity__=13;

maptostring
-----
--
{
"component" : "Txn",
"level" : "INFO",
"text" : "Begin Txn: a0000000002067 'Moveout: Tuple Mover'",
"thread_id" : "0x2aab9000f860",
"thread_name" : "TM Moveout",
"time" : "2014-04-02 04:02:51.011",
"transaction_id" : "a0000000002067"
}
(1 row)
```

Flex Map Functions Reference

The flex map functions let you extract and manipulate nested map data.

The first argument of all flex map functions (except `emptymap()` and `mapaggregate()`) takes a VMap. The VMap can originate from the `__raw__` column in a flex table or be returned from a map or extraction function.

All map functions (except for `emptymap()` and `mapaggregate()`), accept either a LONG VARBINARY or a LONG VARCHAR map argument.

In the following example, the outer `maplookup()` function operates on the VMap data returned from the inner `maplookup()` function:

```
=> maplookup(maplookup(ret_map, 'batch'), 'scripts')
```

You can use flex map functions with:

- Flex tables
- Their associated `{flexible}_keys` table
- Automatically generated `{flexible}_view` views.

However, use of these functions does not apply to standard Vertica tables.

EMPTYMAP

Constructs a new VMap with one row but without keys or data. Use this transform function to populate a map without using a flex parser. Instead, you use either from SQL queries or from map data present elsewhere in the database.

Syntax

```
emptymap()
```

Arguments

None

- [MAPKEYSINFO](#)
- [MAPLOOKUP](#)
- [MAPSIZE](#)
- [MAPTOSTRING](#)
- [MAPVALUES](#)
- [MAPVERSION](#)

MAPAGGREGATE

Returns a LONG VARBINARY VMap with keys and value pairs supplied from two VARCHAR input columns of an existing columnar table. Using this function requires specifying an over() clause for the source table.

Syntax

```
mapaggregate(source_column1, source_column2)
```

Arguments

<code>source_column1</code>	Table column with values to use as the keys of the key/value pair of the returned VMap data.
<code>source_column2</code>	Table column with values to use as the values in the key/value pair of the returned VMap data.

Examples

This example creates a columnar table `btest`, with two VARCHAR columns, named `keys` and `values`, and adds three sets of values:

```
=> CREATE table btest(keys varchar(10), values varchar(10));  
CREATE TABLE
```

```
=> copy btest from stdin;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> one|1
>> two|2
>> three|3
>> \.
```

After populating the `btest` table, call `mapaggregate()`, using the `over (PARTITION BEST)` clause. This call returns the `raw_map` data:

```
=> SELECT mapaggregate(keys, values) over(PARTITION BEST) from btest;
           raw_map
-----
\001\000\000\000\023\000\000\000\003\000\000\000\020\000\000\000\021\000\000\000\022\000\000\000\000132
\003\000\000\000\020\000\000\000\023\000\000\000\030\000\000\000onethreetwo
(1 row)
```

The next example illustrates using `MAPTOSTRING()` with the returned `raw_map` from `mapaggregate()` to see the values:

```
=> SELECT maptostring(raw_map) from (select mapaggregate(keys, values) over(PARTITION BEST) from
btest) bit;
           maptostring
-----
{
  "one": "1",
  "three": "3",
  "two": "2"
}
(1 row)
```

- [MAPSIZE](#)
- [MAPTOSTRING](#)
- [MAPVALUES](#)
- [MAPVERSION](#)

MAPCONTAINSKEY

Determines whether a VMap contains a virtual column (key). This scalar function returns true (t), if the virtual column exists, or false (f) if it does not. Determining that a key exists before calling `maplookup()` lets you distinguish between NULL returns. The `maplookup()` function uses for both a non-existent key and an existing key with a NULL value.

Syntax

```
mapcontainskey(VMap_data, 'virtual_column_name')
```

Arguments

<code>VMap_data</code>	Any VMap data. The VMap can exist as: <ul style="list-style-type: none">• The <code>__raw__</code> column of a flex table• Data returned from a map function such as <code>maplookup()</code>• Other database content
<code>virtual_column_name</code>	The name of the key to check.

Examples

This example shows how to use the `mapcontainskey()` functions with `maplookup()`. View the results returned from both functions. Check whether the empty fields that `maplookup()` returns indicate a NULL value for the row (t) or no value (f):

You can use `mapcontainskey()` to determine that a key exists before calling `maplookup()`. The `maplookup()` function uses both NULL returns and existing keys with NULL values to indicate a non-existent key.

```
=> SELECT maplookup(__row__, 'user.location'), mapcontainskey(__row__, 'user.location') from darkdata
order by 1;
maplookup | mapcontainskey
-----+-----
          | t
          | t
          | t
          | t
Chile     | t
Narnia    | t
Uptown..  | t
chicago  | t
          | f
          | f
          | f
          | f
(12 rows)
```

- [MAPTOSTRING](#)
- [MAPVALUES](#)
- [MAPVERSION](#)

MAPCONTAINSVALUE

Determines whether a VMap contains a specific value. Use this scalar function to return true (t), if the value exists, or false (f), if it does not.

Syntax

```
mapcontainsvalue(VMap_data, 'virtual_column_value')
```

Arguments

VMap_data	Any VMap data. The VMap can exist as: <ul style="list-style-type: none">• The <code>__raw__</code> column of a flex table• Data returned from a map function such as <code>maplookup()</code>• Other database content
virtual_column_value	The value whose existence you want to confirm.

Examples

This example shows how to use `mapcontainsvalue()` to determine whether or not a virtual column contains a particular value. Create a flex table (`ftest`), and populate it with some virtual columns and values. Name both virtual columns one:

```
=> CREATE flex table ftest();  
CREATE TABLE  
=> copy ftest from stdin parser fjsonparser();  
Enter data to be copied followed by a newline.  
End with a backslash and a period on a line by itself.
```

```
>> {"one":1, "two":2}
>> {"one":"one", "2":"2"}
>> \.
```

Call `mapcontainsvalue()` on the `fctest` map data. The query returns false (f) for the first virtual column, and true (t) for the second, which contains the value one:

```
=> SELECT mapcontainsvalue(__raw__, 'one') from fctest;
mapcontainsvalue
-----
f
t
(2 rows)
```

- [MAPTOSTRING](#)
- [MAPVALUES](#)
- [MAPVERSION](#)

MAPITEMS

Returns information about items in a VMap. Use this transform function with one or more optional arguments to access polystuctured values within the VMap data. This function requires an `OVER()` clause.

Syntax

```
mapItems(VMap_data [, passthrough_arg [,...] ])
```

Arguments

VMap_data	Any VMap data. The VMap can exist as: <ul style="list-style-type: none">• The <code>__raw__</code> column of a flex table• Data returned from a map function such as <code>maplookup()</code>• Other database content
passthrough_arg	[Optional] One or more arguments indicating keys within the map data in VMap_data

Examples

The following examples illustrate using `mapItems()` with the `over(PARTITION BEST)` clause.

This example determines the number of virtual columns in the map data using a flex table, labeled `darkmountain`. Query using the `count()` function to return the number of virtual columns in the map data:

```
=> SELECT count(keys) FROM (select mapitems(darkmountain.__raw__) over(PARTITION BEST) from
darkmountain) as a;
  count
-----
      19
(1 row)
```

The next example determines what items exist in the map data:

```
=> SELECT * FROM (select mapitems(darkmountain.__raw__) over(PARTITION BEST) from darkmountain) as a;
  keys      | values
-----+-----
 hike_safety | 50.6
 name       | Mt Washington
 type      | mountain
 height    | 17000
```

```
hike_safety | 12.2
name        | Denali
type        | mountain
height      | 29029
hike_safety | 34.1
name        | Everest
type        | mountain
height      | 14000
hike_safety | 22.8
name        | Kilimanjaro
type        | mountain
height      | 29029
hike_safety | 15.4
name        | Mt St Helens
type        | volcano
(19 rows)
```

Directly Query a Key Value in a VMap

Review the following JSON input file, `simple.json`. In particular, notice the array called `three_Array`, and its four values:

```
{
  "one": "one",
  "two": 2,
  "three_Array":
  [
    "three_One",
    "three_Two",
    3,
    "three_Four"
  ],
  "four": 4,
  "five_Map":
  {
    "five_One": 51,
    "five_Two": "Fifty-two",
    "five_Three": "fifty three",
    "five_Four": 54,
    "five_Five": "5 x 5"
  },
  "six": 6
}
```

1. Create a flex table, `mapper`:

```
=> CREATE flex table mapper();
CREATE TABLE
```

1. Load `simple.json` into the flex table `mapper`:

```
=> COPY mapper from '/home/dbadmin/data/simple.json' parser fjsonparser (flatten_arrays=false,
flatten_maps=false);
Rows Loaded
-----
```

```
1  
(1 row)
```

2. Call `mapkeys` on the flex table's `__raw__` column to see the flex table's keys, but not the key submaps. The return values indicate `three_Array` as one of the virtual columns:

```
=> SELECT mapkeys(__raw__) over() from mapper;  
keys  
-----  
five_Map  
four  
one  
six  
three_Array  
two  
(6 rows)
```

3. Call `mapitems` on flex table `mapper` with `three_Array` as a pass-through argument to the function. The call returns these array values:

```
=> SELECT __identity__, mapitems(three_Array) OVER(PARTITION BY __identity__) from mapper;  
__identity__ | keys | values  
-----+-----+-----  
1 | 0 | three_One  
1 | 1 | three_Two  
1 | 2 | 3  
1 | 3 | three_Four  
(4 rows)
```

MAPKEYS

Returns the virtual columns (and values) present in any VMap data. This transform function requires an `over(PARTITION BEST)` clause.

Syntax

```
mapkeys(VMap_data)
```

Arguments

VMap_data	<p>Any VMap data. The VMap can exist as:</p> <ul style="list-style-type: none">• The <code>__raw__</code> column of a flex table• Data returned from a map function such as <code>maplookup()</code>• Other database content
-----------	--

Examples

Determine Number of Virtual Columns in Map Data

This example shows how to create a query, using an `over(PARTITION BEST)` clause with a flex table, `darkdata` to find the number of virtual column in the map data. The table is populated with JSON tweet data.

```
=> SELECT count(keys) FROM (SELECT mapkeys(darkdata.__raw__) over(PARTITION BEST) from darkdata) as a;  
count  
-----
```

```
550  
(1 row)
```

Query Ordered List of All Virtual Columns in the Map

This example shows a snippet of the return data when you query an ordered list of all virtual columns in the map data:

```
=> SELECT * FROM (SELECT mapkeys(darkdata.__raw__) over(PARTITION BEST) from darkdata) as a;  
  keys  
-----  
contributors  
coordinates  
created_at  
delete.status.id  
delete.status.id_str  
delete.status.user_id  
delete.status.user_id_str  
entities.hashtags  
entities.media  
entities.urls  
entities.user_mentions  
favorited  
geo  
id  
.  
.  
.  
user.statuses_count  
user.time_zone  
user.url  
user.utc_offset  
user.verified  
(125 rows)
```

MAPKEYSINFO

Returns virtual column information from a given map. This transform function requires an `over(PARTITION BEST)` clause.

Syntax

```
mapkeysinfo(VMap_data)
```

Arguments

<code>VMap_data</code>	<p>Any VMap data. The VMap can exist as:</p> <ul style="list-style-type: none">• The <code>__raw__</code> column of a flex table• Data returned from a map function such as <code>maplookup()</code>• Other database content
------------------------	--

Returns

This function is a superset of the [MAPKEYS\(\)](#) function. It returns the following information about each virtual column:

Column	Description
<code>keys</code>	The virtual column names in the raw data.

Column	Description
length	The data length of the key name, which can differ from the actual string length.
type_oid	The OID type into which the value should be converted. Currently, the type is always 116 for a LONG VARCHAR, or 199 for a nested map that is stored as a LONG VARBINARY.
row_num	The number of rows in which the key was found.
field_num	The field number in which the key exists.

Examples

This example shows a snippet of the return data you receive if you query an ordered list of all virtual columns in the map data:

```
=> SELECT * FROM (SELECT mapkeysinfo(darkdata.__raw__) over(PARTITION BEST) from darkdata) as a;
      keys | length | type_oid | row_num | field_num
-----+-----+-----+-----+-----
contributors | 0 | 116 | 1 | 0
coordinates | 0 | 116 | 1 | 1
created_at | 30 | 116 | 1 | 2
entities.hashtags | 93 | 199 | 1 | 3
entities.media | 772 | 199 | 1 | 4
entities.urls | 16 | 199 | 1 | 5
entities.user_mentions | 16 | 199 | 1 | 6
favorited | 1 | 116 | 1 | 7
geo | 0 | 116 | 1 | 8
id | 18 | 116 | 1 | 9
id_str | 18 | 116 | 1 | 10
.
.
.
delete.status.id | 18 | 116 | 11 | 0
delete.status.id_str | 18 | 116 | 11 | 1
delete.status.user_id | 9 | 116 | 11 | 2
delete.status.user_id_str | 9 | 116 | 11 | 3
delete.status.id | 18 | 116 | 12 | 0
delete.status.id_str | 18 | 116 | 12 | 1
delete.status.user_id | 9 | 116 | 12 | 2
delete.status.user_id_str | 9 | 116 | 12 | 3
(550 rows)
```

- [MAPSIZE](#)
- [MAPTOSTRING](#)
- [MAPVALUES](#)
- [MAPVERSION](#)

MAPLOOKUP

Returns single-key values from VMAP data. This scalar function returns a LONG VARCHAR, with values, or NULL if the virtual column does not have a value.

Using `maplookup` is case insensitive to virtual column names. To avoid loading same-name values, set the `fjsonparser parser reject_on_duplicate` parameter to `true` when data loading.

You can control the behavior for non-scalar values in a VMAP (like arrays), when loading data with the `fjsonparser` or `favroparser` parsers and its `flatten-arrays` argument. See [Loading JSON Data](#) and the [FJSONPARSER](#) reference.

For information about using `maplookup()` to access nested JSON data, see [Querying Nested Data](#).

Syntax

```
maplookup (VMap_data, 'virtual_column_name' [USING PARAMETERS [case_
sensitive={false | true}] [, buffer_size=n] ] )
```

Parameters

<code>VMap_data</code>	<p>Any VMap data. The VMap can exist as:</p> <ul style="list-style-type: none">• The <code>__raw__</code> column of a flex table• Data returned from a map function such as <code>maplookup()</code>• Other database content
<code>virtual_column_name</code>	<p>The name of the virtual column whose values this function returns.</p>
<code>buffer_size</code>	<p>[Optional parameter] Specifies the maximum length (in bytes) of each value returned for <code>virtual_column_name</code>. To return all values for <code>virtual_column_name</code>, specify a <code>buffer_size</code> equal to or greater than (<code>=></code>) the number of bytes for any returned value. Any returned values greater in length than <code>buffer_size</code> are rejected.</p> <p>Default value: 0 (No limit on <code>buffer_size</code>)</p>
<code>case_sensitive</code>	<p>[Optional parameter]</p> <p>Specifies whether to return values for <code>virtual_column_name</code> if keys with different cases exist.</p> <p>Example:</p> <pre>(... USING PARAMETERS case_sensitive=true)</pre> <p>Default value: false</p>

Examples

This example returns the values of one virtual column, `user.location`:

```
=> SELECT maplookup(__raw__, 'user.location') FROM darkdata order by 1;
maplookup
-----
Chile
Nesnia
Uptown
.
.
chicago
(12 rows)
```

Using maplookup buffer_size

Use the `buffer_size=` parameter to indicate the maximum length of any value that `maplookup` returns for the virtual column you specify. If none of the returned key values can be greater than `n` bytes, use this parameter to allocate `n` bytes as the `buffer_size`.

For the next example, save this JSON data to a file, `simple_name.json`:

```
{
  "name": "sierra",
  "age": "63",
  "eyes": "brown",
  "weapon": "doggie"
}
{
  "name": "janis",
  "age": "10",
  "eyes": "blue",
  "weapon": "humor"
}
{
  "name": "ben",
  "age": "43",
  "eyes": "blue",
  "weapon": "sword"
}
{
  "name": "jen",
  "age": "38",
  "eyes": "green",
  "weapon": "shopping"
}
```

1. Create a flex table, `logs`.
2. Load the `simple_name.json` data into `logs`, using the `fjsonparser`. Specify the `flatten_arrays` option as `True`:

```
=> COPY logs FROM '/home/dbadmin/data/simple_name.json'
PARSER fjsonparser(flatten_arrays=True);
```

3. Use `maplookup` with `buffer_size=0` for the `logs` table name key. This query returns all of the values:

```
=> SELECT MapLookup(__raw__, 'name' USING PARAMETERS buffer_size=0) FROM logs;
MapLookup
-----
sierra
ben
janis
jen
(4 rows)
```

4. Next, call `maplookup()` three times, specifying the `buffer_size` parameter as 3, 5, and 6, respectively. Now, `maplookup()` returns values with a byte length less than or equal to (\leq) `buffer_size`:

```
=> SELECT MapLookup(__raw__, 'name' USING PARAMETERS buffer_size=3) FROM logs;
MapLookup
-----

ben

jen
(4 rows)
=> SELECT MapLookup(__raw__, 'name' USING PARAMETERS buffer_size=5) FROM logs;
MapLookup
-----

janis
jen
ben
(4 rows)
=> SELECT MapLookup(__raw__, 'name' USING PARAMETERS buffer_size=6) FROM logs;
MapLookup
-----
sierra
janis
jen
ben
(4 rows)
```

Disambiguate Empty Output Rows

This example shows how to interpret empty rows. Using `maplookup` without first checking whether a key exists can be ambiguous. When you review the following output, 12 empty rows, you cannot determine whether a `user.location` key has:

- A non-NULL value
- A NULL value
- No value

```
=> SELECT maplookup(__raw__, 'user.location') FROM darkdata;
maplookup
-----

(12 rows)
```

To disambiguate empty output rows, use the `mapcontainskey()` function in conjunction with `maplookup()`. When `maplookup` returns an empty field, the corresponding value from `mapcontainskey` indicates `t` for a NULL or other value, or `f` for no value.

The following example output using both functions lists rows with NULL or a name value as `t`, and rows with no value as `f`:

```
=> SELECT maplookup(__raw__, 'user.location'), mapcontainskey(__raw__, 'user.location')
from darkdata order by 1;
maplookup | mapcontainskey
-----+-----
          | t
          | t
          | t
          | t
Chile     | t
Nesnia   | t
Uptown   | t
chicago | t
          | f >>>>>>>>No value
          | f >>>>>>>>No value
          | f >>>>>>>>No value
          | f >>>>>>>>No value

(12 rows)
```

Check for Case-Sensitive Virtual Columns

You can use `maplookup()` with the `case_sensitive` parameter to return results when key names with different cases exist.

1. Save the following sample content as a JSON file. This example saves the file as `repeated_key_name.json`:

```
{
  "test": "lower1"
}
```

- [MAPCONTAINSVALUE](#)
- [MAPITEMS](#)
- [MAPKEYS](#)
- [MAPKEYSINFO](#)
- [MAPSIZE](#)
- [MAPTOSTRING](#)
- [MAPVALUES](#)
- [MAPVERSION](#)

MAPSIZE

Returns the number of virtual columns present in any VMap data. Use this scalar function to determine the size of keys.

Syntax

```
mapsize(VMap_data)
```

Arguments

<code>VMap_data</code>	<p>Any VMap data. The VMap can exist as:</p> <ul style="list-style-type: none">• The <code>__raw__</code> column of a flex table• Data returned from a map function such as <code>maplookup()</code>• Other database content
------------------------	--

Examples

This example shows the returned sizes from the number of keys in the flex table `darkmountain`:

```
=> SELECT mapsize(__raw__) FROM darkmountain;
mapsize
-----
      3
      4
      4
      4
      4
(5 rows)
```

See Also

- [EMPTYMAP](#)
- [MAPAGGREGATE](#)
- [MAPCONTAINSKEY](#)
- [MAPCONTAINSVALUE](#)
- [MAPITEMS](#)
- [MAPKEYS](#)
- [MAPKEYSINFO](#)
- [MAPLOOKUP](#)
- [MAPTOSTRING](#)
- [MAPVALUES](#)
- [MAPVERSION](#)

MAPTOSTRING

Recursively builds a string representation VMap data, including nested JSON maps. Use this transform function to display the VMap contents in a readable LONG VARCHAR format. Use `maptostring` to see how map data is nested before querying virtual columns with `mapvalues()`.

Syntax

```
maptostring(VMap_data [using parameters canonical_json={true  
| false}])
```

Arguments

VMap_data	Any VMap data. The VMap can exist as: <ul style="list-style-type: none">• The <code>__raw__</code> column of a flex table• Data returned from a map function such as <code>maplookup()</code>• Other database content
-----------	---

Parameters

canonical_json	<p><i>=bool</i> [Optional parameter]</p> <p>Produces canonical JSON output by default, using the first instance of any duplicate keys in the map data.</p> <p>Use this parameter as other UDF parameters, preceded by <code>using</code> parameters, as shown in the examples. Setting this argument to <code>false</code> maintains the previous behavior of <code>maptostring()</code> and returns same-name keys and their values.</p> <p>Default value: <code>canonical-json=true</code></p>
----------------	---

Examples

The following example shows how to create a sample flex table, `darkdata` and load JSON data from STDIN. By calling `maptostring()` twice with both values for the `canonical_json` parameter, you can see the different results on the flex table `__raw__` column data.

1. Create sample table:

```
=> CREATE flex table darkdata();  
CREATE TABLE
```

2. Load sample JSON data from STDIN:

```
=> COPY darkdata FROM stdin parser fjsonparser();  
Enter data to be copied followed by a newline.  
End with a backslash and a period on a line by itself.  
>> {"aaa": 1, "aaa": 2, "AAA": 3, "bbb": "aaa\"bbb"}  
>> \.
```

3. Call `maptostring()` with its default behavior using canonical JSON output, and then review the flex table contents. The function returns the first duplicate key and its value (`"aaa" : "1"`) but omits remaining duplicate keys (`"aaa" : "2"`):

```
=> SELECT maptostring (__raw__) FROM darkdata;  
          maptostring  
-----  
{  
  "AAA" : "3",  
  "aaa" : "1",  
  "bbb" : "aaa\"bbb"  
}  
(1 row)
```

4. Next, call `maptostring()` with using parameters `canonical_json=false`). This time, the function returns the first duplicate keys and their values:

```
=> SELECT maptostring(__raw__ using parameters canonical_json=false) FROM darkdata;  
          maptostring  
-----  
{  
  "aaa": "1",  
  "aaa": "2",  
  "AAA": "3",  
  "bbb": "aaa\"bbb"
```

```
}  
(1 row)
```

- [EMPTYMAP](#)
- [MAPAGGREGATE](#)
- [MAPCONTAINSKEY](#)
- [MAPCONTAINSVALUE](#)
- [MAPITEMS](#)
- [MAPKEYS](#)
- [MAPKEYSINFO](#)
- [MAPLOOKUP](#)
- [MAPSIZE](#)
- [MAPVALUES](#)
- [MAPVERSION](#)

MAPVALUES

Returns a string representation of the top-level values from a VMap. This transform function requires an `over()` clause.

Syntax

```
mapvalues(VMap_data)
```

Arguments

VMap_data	<p>The VMap from which values should be returned. The VMap can exist as:</p> <ul style="list-style-type: none">• The <code>__raw__</code> column of a flex table• Data returned from a map function such as <code>maplookup()</code>• Other database content
-----------	--

Examples

The following example shows how to query a `darkmountain` flex table, using an `over()` clause (in this case, the `over(PARTITION BEST)` clause) with `mapvalues()`.

```
=> SELECT * FROM (select mapvalues(darkmountain.__raw__) over(PARTITION BEST) from darkmountain) as
a;
  values
-----
29029
34.1
Everest
mountain
29029
15.4
Mt St Helens
volcano
17000
12.2
Denali
mountain
14000
22.8
Kilimanjaro
mountain
50.6
Mt Washington
mountain
(19 rows)
```

- [MAPCONTAINSVALUE](#)
- [MAPITEMS](#)
- [MAPKEYS](#)
- [MAPKEYSINFO](#)
- [MAPLOOKUP](#)
- [MAPSIZE](#)
- [MAPTOSTRING](#)
- [MAPVERSION](#)

MAPVERSION

Returns the version or invalidity of any map data. This scalar function returns the map version (such as 1) or -1, if the map data is invalid.

Syntax

```
mapversion(VMap_data)
```

Arguments

VMap_data	The VMap data either from a <code>__raw__</code> column in a flex table or from the data returned from a map function such as <code>maplookup()</code> .
-----------	--

Examples

The following example shows how to use `mapversion()` with the `darkmountainflex` table, returning `mapversion 1` for the flex table `map data`:

```
=> SELECT mapversion(__raw__) FROM darkmountain;  
mapversion  
-----  
          1  
          1  
          1  
          1  
          1  
(5 rows)
```

Flex Parsers Reference

Vertica supports several parsers to load different types of data into flex tables:

- [FAVROPARSER](#)
- [FCEFPARSER](#)
- [FCSVPARSER](#)
- [FDELIMITEDPAIRPARSER](#)
- [FDELIMITEDPARSER](#)
- [FJSONPARSER](#)
- [FREGEXPARSER](#)

Unlike with columnar tables, you must specify which parser to use when loading flex tables. You can use each flex parser to load the parser's associated type of data into columnar tables.

All parsers store the data as a single Vmap in the LONG VARBINARY `__raw__` column. If a data row is too large to fit in the column, it is rejected. Vertica supports null values for loading data with NULL-specified columns.

For information about how you can use each type of flex parser, see [Using Flex Table Parsers](#)

FAVROPARSER

Parses data from an Avro file. The input file must use binary serialization encoding. Use this parser to load data into columnar, flex, and hybrid tables.

Note: The parser `favroparser` does not support Avro files with separate schema files. The Avro file must have its related schema in the file you are loading.

Parameters

<code>flatten_arrays</code>	BOOLEAN	[Optional] Flattens all Avro arrays. Key names are concatenated with nested levels.
-----------------------------	---------	---

		Default value: false (Arrays are not flattened.)
flatten_maps	BOOLEAN	[Optional] Flattens all Avro maps. Key names are concatenated with nested levels. Default value: true
flatten_records	BOOLEAN	[Optional] Flattens all Avro records. Key names are concatenated with nested levels. Default value: true
reject_on_materialized_type_error	BOOLEAN	[Optional] Indicates whether to reject any row value for a materialized column that the parser cannot coerce into a compatible data type. See Using Flex Table Parsers . Default value: false

Examples

This example shows how to create and load a flex table with Avro data using favroparser. After loading the data, you can query virtual columns.

1. Create a flex table for Avro data, avro_basic:

```
=> CREATE FLEX TABLE avro_basic();  
CREATE TABLE
```

2. Use the favroparser to load the data from an Avro file (weather.avro).

```
=> COPY avro_basic FROM '/home/dbadmin/data/flexcsv/weather.avro' PARSER favroparser();  
Rows Loaded  
-----  
5  
(1 row)
```

3. Query virtual columns from the avro flex table:

```
=> SELECT station, temp, time FROM avro_basic;  
station | temp | time  
-----+-----+-----  
mohali | 0 | -619524000000  
lucknow | 22 | -619506000000
```

```
norwich | -11 | -619484400000  
ams     | 111 | -655531200000  
baddi   | 78  | -655509600000  
(5 rows)
```

For more information, see [Loading Avro Data](#).

- [FDELIMITEDPAIRPARSER](#)
- [FJSONPARSER](#)
- [FREGEXPARSER](#)

FCEFPARSER

Parses Micro Focus ArcSight Common Event Format (CEF) log files. The `fcefparser` loads values directly into any table column with a column name that matches a source data key. The parser stores the data loaded into a flex table in a single VMap.

Parameters

<code>delimiter</code>	CHAR	[Optional] Specifies a single-character delimiter. Default value: ' '
<code>record_terminator</code>	CHAR	[Optional] Specifies a single-character record terminator. Default value: <code>newline</code>
<code>trim</code>	BOOLEAN	[Optional] Trims white space from

		header names and key values. Default value: true
reject_on_unescaped_delimiter	BOOLEAN	[Optional] Determines whether to reject rows containing unescaped delimiters. The CEF standard does not permit them. Default value: false

Examples

The following example illustrates creating a sample flex table for CEF data, with two real columns, eventId and priority.

1. Create a flex table cefdata:

```
=> create flex table cefdata();  
CREATE TABLE
```

2. Load some basic CEF data, using the flex parser fcefparser:

```
=> copy cefdata from stdin parser fcefparser();  
Enter data to be copied followed by a newline.  
End with a backslash and a period on a line by itself.  
>> CEF:0|ArcSight|ArcSight|2.4.1|machine:20|New alert|High|  
>> \.
```

3. Use the maptostring() function to view the contents of your cefdata flex table:

```
=> select maptostring(__raw__) from cefdata;  
maptostring
```

```
-----  
{  
  "deviceproduct" : "ArcSight",  
  "devicevendor" : "ArcSight",  
  "deviceversion" : "2.4.1",  
  "name" : "New alert",  
  "severity" : "High",  
  "signatureid" : "machine:20",  
  "version" : "0"  
}
```

```
(1 row)
```

4. Select some virtual columns from the `cefdata` flex table:

```
= select deviceproduct, severity, deviceversion from cefdata;
deviceproduct | severity | deviceversion
-----+-----+-----
ArcSight      | High    | 2.4.1
(1 row)
```

For more information, see [Loading Common Event Format \(CEF\) Data](#)

- [FREGEXPARSER](#)

FCSVPARSER

Parses CSV format (comma-separated values) data. Use this parser to load CSV data into columnar, flex, and hybrid tables. All data must be encoded in Unicode UTF-8 format. The parser `fcsvparser` supports the [RFC 4180](#) de facto standard for CSV data, and other options, to accommodate variations in CSV file format definitions. Invalid records will be rejected.

The `fcsvparser` does not support multibyte data. For more information about data formats, see [Checking Data Format Before or After Loading](#).

Parameters

<code>type= {'rfc4180' 'traditional' }</code>	CHAR	<p>[Optional] Specifies the default parameter values for the parser. You do not have to use the type parameter when loading data that conforms to the RFC 4180 standard (such as MS Excel files). See Loading CSV Data for the RFC4180 default parameters, and other options you can specify for traditional CSV files.</p> <p>Default value: RFC4180</p>
<code>delimiter</code>	CHAR	<p>[Optional] Indicates the single-character value used to separate fields in the CSV data.</p> <p>Default value: , (for rfc4180 and traditional)</p>
<code>escape</code>	CHAR	<p>[Optional] Specifies a single-character value. Use an escape character to interpret the next character in the data literally.</p> <p>Default value: " (for rfc4180) Default value: \ (for traditional)</p>
<code>enclosed_by</code>	CHAR	<p>[Optional] Specifies a single-character value. Use and enclosed_by value to include a value that is identical to the delimiter, but should be interpreted literally. For example, if the data delimiter is a comma (,), and you want to use a comma within the data ("my name is jane, and his is jim").</p> <p>Default value: " (for rfc4180 and traditional)</p>
<code>record_terminator</code>	CHAR	<p>[Optional] Indicates the single-character value used to specify the end of a record.</p>

		Default value: <code>\n</code> or <code>\r\n</code> (for rfc4180 and traditional)
header	BOOLEAN	<p>[Optional] Specifies whether to use the first row of data as a header column. When <code>header=true</code> (default), and no header exists, <code>fcsvparser</code> uses a default column heading. The default header consists of <code>ucoln</code>, where <code>n</code> is the column offset number, starting with <code>0</code> for the first column. You can specify custom column heading names using the <code>header_names</code> parameter, described next.</p> <p>If you specify <code>header=false</code>, the <code>fcsvparser</code> parses the first row of input as data, rather than as column headers.</p> <p>Default value: <code>true</code></p>
header_names	CHAR	<p>[Optional] Specifies a list of column header names, delimited by the character defined by the parser's <code>delimiter</code> parameter. Use this parameter to specify header names in a CSV file without a header row, or to override the column names present in the CSV source. To override one or more existing column names, specify the header names to use. This parameter overrides any header row in the data.</p>
trim	BOOLEAN	<p>[Optional] Indicates whether to trim white space from header names and key values.</p> <p>Default value: <code>true</code></p>
omit_empty_keys	BOOLEAN	<p>[Optional] Indicates how the parser handles header keys without values. If <code>omit_empty_keys=true</code>, keys with an empty value in the header row are not loaded.</p> <p>Default value: <code>false</code></p>

<code>reject_on_duplicate</code>	BOOLEAN	[Optional] Specifies whether to ignore duplicate records (<code>false</code>), or to reject duplicates (<code>true</code>). In either case, the load continues. Default value: <code>false</code>
<code>reject_on_empty_key</code>	BOOLEAN	[Optional] Specifies whether to reject any row containing a key without a value. Default value: <code>false</code>
<code>reject_on_materialized_type_error</code>	BOOLEAN	[Optional] Indicates whether to reject any materialized column value that the parser cannot coerce into a compatible data type. See Loading CSV Data . Default value: <code>false</code>

Examples

This example shows how you can use `fcsvparser` to load a flex table, build a view, and then query that view.

1. Create a flex table for CSV data:

```
=> CREATE FLEX TABLE rfc();  
CREATE TABLE
```

2. Use `fcsvparser` to load the data from STDIN. Specify that no header exists, and enter some data as shown:

```
=> COPY rfc FROM stdin PARSER fcsvparser(header='false');  
Enter data to be copied followed by a newline.  
End with a backslash and a period on a line by itself.  
>> 10,10,20  
>> 10,"10",30  
>> 10,"20""5",90  
>> \.
```

3. Run the `compute_flextable_keys_and_build_view` function, and query the `rfc_view`. Notice that the default `enclosed_by` character permits an escape character (`"`)

within a field ("20" "5"). Thus, the resulting value was parsed correctly. Since no header existed in the input data, the function added `ucoln` for each column:

```
=> SELECT compute_flextable_keys_and_build_view('rfc');
           compute_flextable_keys_and_build_view
-----
Please see public.rfc_keys for updated keys
The view public.rfc_view is ready for querying
(1 row)

=> SELECT * FROM rfc_view;
 ucol0 | ucol1 | ucol2
-----+-----+-----
  10   |  10   |  20
  10   |  10   |  30
  10   | 20"5  |  90
(3 rows)
```

For more information and examples of using other parameters of this parser, see [Loading CSV Data](#).

- [FREGEXPARSER](#)

FDELIMITEDPAIRPARSER

Parses delimited data files. This parser provides a subset of the functionality in the parser `fdelimitedparser`. Use the `fdelimitedpairparser` when the data you are loading specifies pairs of column names with data in each row.

Parameters

delimiter	CHAR	[Optional] Specifies a single-character delimiter. Default value: ' '
record_terminator	CHAR	[Optional] Specifies a single-character record terminator. Default value: newline
trim	BOOLEAN	[Optional] Trims white space from header names and key values. Default value: true

Examples

The following example illustrates creating a sample flex table for simple delimited data, with two real columns, `eventId` and `priority`.

1. Create a table:

```
=> create flex table CEFData(eventId int default(eventId::int), priority int default
(priority::int) );
CREATE TABLE
```

2. Load a sample delimited Micro Focus ArcSight log file into the CEFData table, using the `fcefparser`:

```
=> copy CEFData from '/home/release/kmm/flextables/sampleArcSight.txt' parser
fdelimitedpairparser();
Rows Loaded | 200
```

3. After loading the sample data file, use `maptostring()` to display the virtual columns in the `__raw__` column of CEFData:

```
=> select maptostring(__raw__) from CEFData limit 1;
```

maptostring

```

```

(1 row)

4. Select the eventID and priority real columns, along with two virtual columns, atz and destinationgeoregioncode:

```
=> select eventID, priority, atz, destinationgeoregioncode from CEFData limit 10;  
eventID | priority | atz | destinationgeoregioncode  
-----+-----+-----+-----  
1218325417 | 5 | America/Los_Angeles |  
1219383333 | 8 | America/Los_Angeles | TX  
1219533691 | 9 | America/Los_Angeles | TX  
1220034458 | 5 | America/Los_Angeles | TX  
1220034578 | 9 | America/Los_Angeles |  
1220067119 | 5 | America/Los_Angeles | TX  
1220106960 | 5 | America/Los_Angeles | TX  
1220142122 | 5 | America/Los_Angeles | TX  
1220312009 | 5 | America/Los_Angeles | TX  
1220321355 | 5 | America/Los_Angeles | CA  
(10 rows)
```

- [FCSVPARSER](#)
- [FDELIMITEDPARSER](#)

- [FJSONPARSER](#)
- [FREGEXPARSER](#)

FDELIMITEDPARSER

Parses data using a delimiter character to separate values. The `fdelimitedparser` loads delimited data, storing it in a single-value VMap. You can use this parser to load data into columnar and flex tables.

Note: By default, `fdelimitedparser` treats empty fields as NULL, rather than as an empty string (' '). This behavior makes casting easier. Casting a NULL to an integer (`NULL::int`) is valid, while casting an empty string to an integer (`' '::int`) is not. If required, use the `treat_empty_val_as_null` parameter to change the default behavior of `fdelimitedparser`.

Parameters

<code>delimiter</code>	CHAR	[Optional] Indicates a single-character delimiter. Default value:
<code>record_terminator</code>	CHAR	[Optional] Indicates a single-character record terminator. Default value: \n
<code>trim</code>	BOOLEAN	[Optional] Determines whether to trim white space from header names and key values. Default value: true
<code>header</code>	BOOLEAN	[Optional] Specifies that a header column exists. The parser uses <code>col###</code> for the column names if you use this parameter but no header exists. Default value: true

<code>omit_empty_keys</code>	BOOLEAN	[Optional] Indicates how the parser handles header keys without values. If <code>omit_empty_keys=true</code> , keys with an empty value in the header row are not loaded. Default value: <code>false</code>
<code>reject_on_duplicate</code>	BOOLEAN	[Optional] Specifies whether to ignore duplicate records (<code>false</code>), or to reject duplicates (<code>true</code>). In either case, the load continues. Default value: <code>false</code>
<code>reject_on_empty_key</code>	BOOLEAN	[Optional] Specifies whether to reject any row containing a key without a value. Default value: <code>false</code>
<code>reject_on_materialized_type_error</code>	BOOLEAN	[Optional] Indicates whether to reject any row value for a materialized column that the parser cannot coerce into a compatible data type. See Using Flex Table Parsers . Default value: <code>false</code>
<code>treat_empty_val_as_null</code>	BOOLEAN	[Optional] Specifies that empty fields become NULLs, rather than empty strings (<code>' '</code>). Default value: <code>true</code>

Examples

1. Create a flex table for delimited data:

```
t=> CREATE FLEX TABLE delim_flex ();  
CREATE TABLE
```

2. Use the `fdelimitedparser` to load some delimited data from STDIN, specifying a comma (,) column delimiter:

```
=> COPY delim_flex FROM STDIN parser fdelimitedparser (delimiter=',');
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> deviceproduct, severity, deviceversion
>> ArcSight, High, 2.4.1
>> \.
```

You can now query virtual columns in the `delim_flex` flex table:

```
=> SELECT deviceproduct, severity, deviceversion from delim_flex;
deviceproduct | severity | deviceversion
-----+-----+-----
ArcSight      | High    | 2.4.1
(1 row)
```

- [FCEFPARSER](#)
- [FCSVPARSER](#)
- [FDELIMITEDPAIRPARSER](#)
- [FJSONPARSER](#)
- [FREGEXPARSER](#)

FJSONPARSER

Parses and loads a JSON file. This file can contain either repeated JSON data objects (including nested maps), or an outer list of JSON elements. For a flex table, the parser stores the JSON data in a single-value VMap. For a hybrid or columnar table, the parser loads data directly in any table column with a column name that matches a key in the JSON source data.

Parameters

<code>flatten_maps</code>	BOOLEAN	[Optional] Flattens sub-maps within the JSON data, separating map levels with a period (.).
---------------------------	---------	---

		Default value: true
flatten_arrays	BOOLEAN	[Optional] Converts lists to sub-maps with integer keys. Lists are not flattened by default. Default value: false
reject_on_duplicate	BOOLEAN	[Optional] Specifies whether to ignore duplicate records (false), or to reject duplicates (true). In either case, the load continues. Default value: false
reject_on_empty_key	BOOLEAN	[Optional] Rejects any row containing a key without a value (reject_on_empty_key=true). Default value: false
omit_empty_keys	BOOLEAN	[Optional] Omits any key from the load data that does not have a value (omit_empty_keys=true). Default value: false
record_terminator	STRING	[Optional] When set, any invalid JSON records are skipped and parsing continues with the next record. Records must be terminated uniformly. For example, if your input file has JSON records terminated by newline characters, specify <code>fjsonparser(record_terminator=E'\n')</code> . If any invalid JSON records exist, parsing continues after the next <code>record_terminator</code> . When you do not use a <code>record_terminator</code> , parsing ends at the first invalid JSON record. Default value: no default value
reject_on_materialized_type_error	BOOLEAN	[Optional] Rejects a data row that contains a materialized column value that cannot be coerced into a compatible data type (<code>reject_on_materialized_type_error=true</code>). Default value: false
start_point	CHAR	[Optional] Specifies the name of a key in the

		<p>JSON load data at which to begin parsing. The parser ignores all data before the <code>start_point</code> value. The parser processes data after the first instance, and up to the second, ignoring any remaining data.</p> <p>Default value: none</p>
<code>start_point_occurrence</code>	INTEGER	<p>[Optional] Indicates the <i>n</i>th occurrence of the value you specify with <code>start_point</code>. Use in conjunction with <code>start_point</code> when load data has multiple start values and you know the occurrence at which to begin parsing.</p> <p>Default value: 1</p>
<code>suppress_nonalphanumeric_key_chars</code>	BOOLEAN	<p>[Optional] Suppresses non-alphanumeric characters in JSON key values. The parser replaces these characters with an underscore (<code>_</code>) when this parameter is <code>true</code>.</p> <p>Default value: false</p>
<code>key_separator</code>	CHAR	<p>[Optional] Specifies a non-default character for the parser to use when concatenating key names.</p> <p>Default value: ' . '</p>

Examples

Load JSON Data Without Optional Parameters

1. Create a flex table, `super`, with two columns, `age` and `name`:

```
=> create table super(age int, name varchar);  
CREATE TABLE
```

2. Enter values using the `fjsonparser()`, and query the results:

```
=> copy super from stdin parser fjsonparser();  
Enter data to be copied followed by a newline.  
End with a backslash and a period on a line by itself.  
>> {"age": 5, "name": "Tim"}  
>> {"age": 3}
```

```
>> {"name": "Fred"}
>> {"name": "Bob", "age": 10}
>> \.
=> select * from super;
  age | name
-----+-----
      | Fred
  10  | Bob
   5  | Tim
   3  |
(4 rows)
```

For other examples, see [Loading JSON Data](#).

- [FCSVPARSER](#)
- [FDELIMITEDPARSER](#)
- [FDELIMITEDPAIRPARSER](#)
- [FREGEXPARSER](#)

FREGEXPARSER

Parses a regular expression, matching columns to the contents of the named regular expression groups.

Parameters

pattern	VARCHAR	Specifies the regular expression of data to match. Default value: Empty string ("")
use_jit	BOOLEAN	[Optional] Indicates whether to use just-in-time compiling when parsing the regular expression.

		Default value: false
record_terminator	VARCHAR	[Optional] Specifies the character used to separate input records. Default value: \n
logline_column	VARCHAR	[Optional] Captures the destination column containing the full string that the regular expression matched. Default value: Empty string ("")

Example

These examples use the following regular expression, which searches for information that includes the timestamp, date, thread_name, and thread_id strings.

Caution: For display purposes, this sample regular expression adds new line characters to split long lines of text. To use this expression in a query, first copy and edit the example to remove any new line characters.

This example expression loads any thread_id hex value, regardless of whether it has a 0x prefix, (<thread_id>(?:0x)?[0-9a-f]+).

```
'^(?<time>\d\d\d\d-\d\d-\d\d \d\d:\d\d:\d\d\.\d+)
(?<thread_name>[A-Za-z ]+):(?<thread_id>(?:0x)?[0-9a-f]+)
-?(?<transaction_id>[0-9a-f])?(?:[(?<component>\w+)]
\<(?!<level>\w+)\> )?(?:<(?!<level>\w+)\> @[(?!<enode>\w+)]?: )
?(?!<text>.*).'
```

1. Create a flex table (vlog) to contain the results of a Vertica log file. For this example, we made a copy of a log file in the directory /home/dbadmin/data/vertica.log:

```
=> create flex table vlog1();
CREATE TABLE
```

2. Use the fregexparser with the sample regular expression to load data from the log file. Be sure to remove any line characters before using this expression shown here:

```
=> copy vlog1 from '/home/dbadmin/tempdat/KMvertica.log'
PARSER FREGEXPARSER('^(?<time>\d\d\d\d-\d\d-\d\d \d\d:\d\d:\d\d\.\d+)
(?<thread_name>[A-Za-z ]+):(?<thread_id>(?:0x)?[0-9a-f]+)
-?(?<transaction_id>[0-9a-f])?(?:[(?<component>\w+)]
\<(?!<level>\w+)\> )?(?:<(?!<level>\w+)\> @[(?!<enode>\w+)]?: )
?(?!<text>.*)');
```

```
Rows Loaded
-----
      31049
(1 row)
```

3. After successfully loading data, use the `MAPTOSTRING()` function with the table's `__raw__` column. The four rows (`limit 4`) that the query returns are regular expression results of the `KMvertica.log` file, parsed with `fregexparser`. The output shows `thread_id` values with a preceding `0x` or without:

4.

```
=> select maptostring(__raw__) from vlog1 limit 4;
      maptostring
-----
{
  "text" : " [Init] <INFO> Log /home/dbadmin/VMart/v_vmart_node0001_catalog/vertica.log
opened; #2",
  "thread_id" : "0x7f2157e287c0",
  "thread_name" : "Main",
  "time" : "2017-03-21 23:30:01.704"
}

{
  "text" : " [Init] <INFO> Processing command line: /opt/vertica/bin/vertica -D
/home/dbadmin/VMart/v_vmart_node0001_catalog -C VMart -n v_vmart_node0001 -h
10.20.100.247 -p 5433 -P 4803 -Y ipv4",
  "thread_id" : "0x7f2157e287c0",
  "thread_name" : "Main",
  "time" : "2017-03-21 23:30:01.704"
}

{
  "text" : " [Init] <INFO> Starting up Vertica Analytic Database v8.1.1-20170321",
  "thread_id" : "7f2157e287c0",
  "thread_name" : "Main",
  "time" : "2017-03-21 23:30:01.704"
}

{
  "text" : " [Init] <INFO> Compiler Version: 4.8.2 20140120 (Red Hat 4.8.2-15)",
  "thread_id" : "7f2157e287c0",
  "thread_name" : "Main",
  "time" : "2017-03-21 23:30:01.704"
}

(4 rows)
```

Using Management Console

Management Console (MC) is a user-friendly performance monitoring and management tool that provides a unified view of your Vertica database operations. Using a browser, you can create, import, manage, and monitor one or more databases and their associated clusters. You can also create and manage MC users. You can then map the MC users to a Vertica database and manage them through the MC interface.

The MC interface provides tool tips for most of the MC operations. For an introduction to MC functionality, architecture, and security, see [Management Console](#) in Vertica Concepts.

To get started using MC, see [Getting Started with MC](#).

Getting Started with MC

Use Management Console to monitor the performance of your Vertica clusters. This tool provides a graphical view of your Vertica database cluster, nodes, network status, and detailed monitoring charts and graphs.

MC allows you to:

- Create, import, and connect to Vertica database.
- Manage your Vertica database and clusters.
- Receive and view messages regarding the health and performance of your Vertica database and clusters.
- View diagnostics and support information for Management Console.
- Manage application and user settings for Management Console.

MC Installation Process

To install MC, complete these tasks:

1. Verify that you meet the requirements listed in [Before You Install MC](#).
2. Follow the steps listed in [Installing Management Console](#).
3. After you have installed MC, configure it according to the instructions in [Configuring MC](#).

Connecting to MC

To connect to Management Console:

1. Open an HTML-5 compliant browser.
2. Enter the IP address or host name of the host on which you installed MC (or any cluster node if you installed Vertica first), followed by the MC port you assigned when you [configured MC](#).

For example, enter one of:

```
https://00.00.00.00:5450/
```

or

```
https://hostname:5450/
```

3. When the MC logon dialog appears, enter your MC username and password and click **Log in**.

Note: When MC users log in to the MC interface, MC checks their privileges on Vertica Data Collector (DC) tables on MC-monitored databases. Based on DC table privileges, along with the role assigned the MC user, each user's access to the MC's Overview, Activity and Node details pages could be limited. See [About MC Privileges and Roles](#) for more information.

If you do not have an MC username/password, contact your MC administrator.

Viewing the Home Page

After you [connect to MC](#) and sign in, the Home page displays. This page is the entry point to all Vertica database clusters and users managed by MC. Information on this page, as well as throughout the MC interface, will appear or be hidden, based on the permissions ([access levels](#)) of the user who is logged in. The following image is what an MC super administrator sees.

Prepare data and databases

VMart_BR

Tasks

Operations you can perform in Management Console are grouped into the following task-based areas:

- **Provision Databases.** Create and import databases, and connect this includes creating new empty databases and importing existing database clusters into Management Console. You can also set up an Ambari connection to import a Vertica cluster that resides in a Hadoop environment. See [Managing Database Clusters](#).
- **Existing Infrastructure.** View all the clusters and databases monitored by MC, stop and remove databases, and view details about databases and clusters. See [Managing Database Clusters](#).
- **MC Settings.** Configure MC and user settings, as well as use the MC interface to install Vertica on a cluster of hosts. See [Managing MC Settings](#).
- **Message Center.** View, sort, and search database messages and optionally export messages to a file. See [Monitoring Database Messages in MC](#).
- **Diagnostics.** View and resolve MC-related issues, as well as browse Vertica agent and audit logs. See [Troubleshooting with MC Diagnostics](#).

Recent Databases

The **Recent Databases** section displays all databases that you created on or imported into the MC interface. You can install one or more databases, on the same cluster or on different clusters, but you can have only one database running on a single cluster at a time. UP databases appear in green and DOWN databases are red. An empty space under Recent Databases means that you have not yet created or imported a database into the MC interface, or do not have permission to view any databases managed by MC.

Managing MC Users, Roles and Privileges

If you are an administrator, you can use **MC Settings** to grant MC users privileges to one or more Vertica users. MC users are not the same as system (Linux) users. MC users are external to the database, and their information is stored on an internal database on the MC application or web server. See [About MC Users](#) for further details.

You can create MC users using either of two authentication techniques, **LDAP** or **MC (internal)**. See [Creating an MC User](#). After you create the MC users, you can manage them from **MC Settings** page. Refer to [Managing MC Users](#).

To control the level of access for the MC Users, you can grant them privileges (through roles) from the **MC Settings** page. MC supports two groups of privileges:

- [MC Configuration Privileges](#)
- [MC Database Privileges](#)

The MC super account is the default user. The super user needs to create all other MC users. Refer to [About MC Privileges and Roles](#) for further information on MC roles.

For further details about MC Users, Privileges and Roles, see [Managing Users And Privileges](#).

Creating a Cluster Using MC - Process Flow

After you install and configure MC, you can use it to create a Vertica cluster on hosts where Vertica software is not installed. Complete the following tasks:

1. [Prepare the Hosts](#) - Prepare each host that will become a node in the cluster.
2. [Create a Private Key File](#) - MC needs password-less SSH to connect to hosts and install Vertica software. Create a private key to enable MC access to the hosts.
3. [Use the MC Cluster Installation Wizard](#) - Use the wizard to install a Vertica cluster on hosts that do not have Vertica software already installed on them.
4. [Validate Hosts and Create the Cluster](#) - Host validation is the process where the MC runs tests against each host in a [proposed cluster](#). You must validate hosts before the MC can install Vertica on each host.

After you successfully create a cluster using MC, see [Create a Database on a Cluster](#).

Creating a Database Using MC

Follow these steps to create a database on an existing cluster using Management Console.

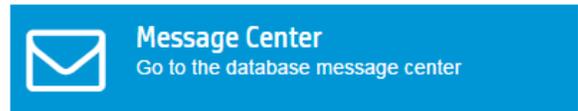

Important: This task assumes that you have already installed Management Console and are familiar with its concepts and layout. For more information, see [Using Management Console](#), [Management Console](#) in the Concepts Guide, and [Installing and Configuring Management Console](#) in the Installation Guide.

1. Connect to Management Console, and log in.
2. On the Home page, under the **Manage Information** pane, click **Existing Infrastructure**.

Prepare data and databases

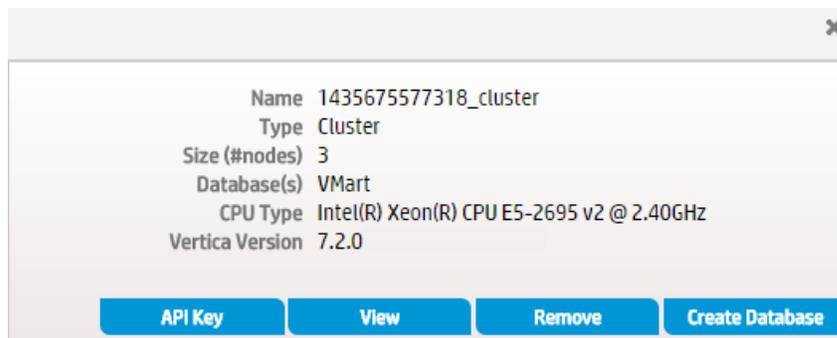

Manage Information

Recent Databases

3. On the following screen, click to select an existing cluster. When a dialog box identifying that cluster appears, click **Create Database**. The database creation wizard starts.

4. Follow the steps in the wizard to successfully create a database.

See Also

- [Create an Empty Database Using MC](#)
- [Import an Existing Database Into MC](#)
- [Creating a Cluster Using MC - Process Flow](#)

Provisioning Databases Using MC

Management Console allows all users to create, import, and connect to Vertica databases using the **MC Provision Databases** tab.

- Import cluster or database using IP discovery
- Create a new cluster
- [Import and Monitor in a Hadoop Environment](#)

Monitoring Existing Infrastructure Using MC

Use the **Management Console Existing Infrastructure** tab to monitor the health of your Vertica databases and clusters. Click the cluster of interest to view the health of the nodes in that cluster and the key information associated with the cluster such as:

- Vertica version
- Number of hosts
- CPU type
- Last updated date
- Node list.

You can also zoom in and out for better view of this page.

Click the database which you want to monitor to go to its Overview page:

Tip: You can also view the **Overview** page by clicking on the desired database on the **MC Home Page**.

You can perform the following tasks from the Overview page:

- View **Quick Stats** to get instant alerts and information about your cluster's status.
- View **Status Summary** that provides a general overview of the status of your cluster (as shown in preceding figure).
- Analyze **System Health** using a comprehensive summary of your system resource usage and node information, with configurable statistics that allow you to specify acceptable ranges of resource usage.
- Use **Query Synopsis** to monitor system query activity and resource pool usage.

Additionally, you can perform the following tasks from the Overview page:

- [Monitoring Cluster Nodes](#)
- [Monitoring Cluster CPU/Memory](#)
- [Monitoring Cluster Performance](#)

Monitoring System Resources

On the main window, you can click the database, and navigate to the **MC Activity** tab to monitor system resources such as:

- [Queries](#)
- [Internal Sessions](#)
- [User Sessions](#)
- [Memory Usage](#)
- [System Bottlenecks](#)
- [User Query Phases](#)
- [Table Treemap](#)
- [Query Monitoring](#)
- [Resource Pool Monitoring](#)

Monitoring Node and MC User Activity

You can use the **MC Manage** page to monitor node activity. When you click the node you want to investigate, the Node Detail page opens and provides:

- Summary information for the node
- Resources consumed by the node for last three hours

You can also browse and export log-level data from AgentTools and Vertica log files. MC retains a maximum of 2000 log records. See [Monitoring Node Activity](#) for further details.

Use **MC Diagnostics** tab and navigate to **Audit Log** page to manage MC User activity. See [Monitoring MC User Activity Using Audit Log](#).

Monitoring messages in Databases managed by MC

You can view critical database related messages from **MC Message Center**. The **MC Message Center** reports on several critical database-related conditions using a color code to indicate the message severity. See [Monitoring Database Messages in MC](#) for further details.

You can also [search](#) and sort database messages, mark messages read or unread and delete them. You can filter messages by message type, and [export](#) messages. Refer to [Searching Database Messages Managed by MC](#) and [Exporting MC-managed Database Messages and Logs](#).

Monitoring and Configuring Resource Pools

Use the **MC Activity** page to monitor resource pools. Select the resource pool you want to monitor. MC displays the following charts for the selected pool:

- Resource Usages in Pool
- Memory Usage in Node
- Average Query Execution and Query Time in Pool
- Resource Rejections in Pool

If you are a database administrator, you can click the database you want on the main window. You can then use the **MC Settings** tab to view and edit the resource pool parameters. Only the database administrator can monitor and configure the resource pools in Management Console. See [Monitoring Resource Pools](#) for further information.

Running Database Designer Using MC

You can use Database Designer to create a comprehensive design, which allows you to create new projections for all tables in your database.

Additionally, you can use Database Designer to create an incremental design. An incremental design creates projections for all tables referenced in the queries you supply.

To run Database Designer using MC, follow the steps listed at [Running Database Designer with Management Console](#) .

Managing Queries Using MC

Management Console allows you to view the query plan of an active query or a manually entered query specified by the user.

1. On the **MC Home Page**, click the database you want to view the **Overview** page.
2. Select the **Activity** tab to view the query activity.
3. Click the **Explain** tab to access the query plan.

See [Managing Queries in MC](#) and [Accessing Query Plans in Management Console](#) for further information.

Management Console provides two options for viewing the query plan: **Path Information** and **Tree Path**. For details on each, refer [Query Plan View Options](#).

Additionally, you can also [Viewing Projection and Column Metadata](#) using the **MC Explain** tab.

See Also

- [Expanding and Collapsing Query Paths](#)
- [Clearing Query Data](#)

Profiling Queries Using MC

Management Console allows you to view profile data for a query.

- On the **MC Home Page**, click the database to view the **Overview** page.
- Click the **Explain** tab to perform tasks related to profiling a query.

See [Viewing Profile Data in MC](#) for further details.

On the **Explain** tab, you can view the following profile data using MC:

- [Query Phase Duration](#)
- [Projection Metadata](#)

- [Execution Events](#)
- [Optimizer Events](#)
- [Profile Metrics](#)

You can use any of the four different formats to view the profile data:

- Path Information view
- Query Drilldown view
- Tree Path view
- Profile Analysis view

See [Viewing Different Profile Outputs](#) for detailed explanation of each view.

Additionally, Management Console supports different color codes for viewing the progress of profiling a query. For an explanation of these color codes, see [Monitoring Profiling Progress](#).

See Also

- [Expanding and Collapsing Query Path Profile Data](#)
- [Clearing Profile Data](#)

Managing Client Connections

Each client session to MC uses a connection from `MaxClientSessions`, a database configuration parameter. This parameter determines the maximum number of sessions that can run on a single database cluster node. Sometimes multiple MC users, mapped to the same database account, are concurrently monitoring the Overview and Activity pages. In such cases, graphs could be slow to update while MC waits for a connection from the pool.

Tip: You can increase the value for `MaxClientSessions` on an MC-monitored database to account for extra sessions. See [Managing Sessions](#) for details.

Managing MC Settings

The **MC Settings** page allows you to configure properties specific to Management Console. You can:

- Change MC and agent default port assignments.
- Enable and disable username and password auto-complete at MC login. (After disabling, clear your browser's cache.)
- Control the following monitoring settings in MC:
 - Enable checks and set alert thresholds for spread retransmit rate. This setting is disabled by default. The recommended alert threshold for spread retransmit rate is 10%.
 - Set alert thresholds for free MC disk space checks. The recommended alert threshold is 500 MB.
 - Exclude MC queries from activity charts.
 - Set refresh intervals for MC charts and pages.
- Upload a new SSL certificate.
- Use LDAP for user authentication.
- Create new MC users and, with their user credentials, map them to a database managed by MC on the Vertica server. See [Creating an MC User](#) and [Managing MC Users](#).
- View your version of Vertica or upload a new Vertica binary file.
- Customize the look and feel of MC with themes. See [Customizing Look and Feel](#).
- Configure MC to use an alternative data source to monitor your database. See [Monitoring External Data Sources in Management Console](#).
- Enable MC to send email alerts. See [Set Up Email](#).
- Configure [Extended Monitoring](#), which allows you to monitor more long-term data in MC:
 - Set up an external storage database for Extended Monitoring. See [Managing the Storage Database](#).

- Enable or disable Extended Monitoring on your databases. See [Managing Extended Monitoring on a Database](#).

Modifying Database-Specific Settings

To inspect or modify settings related to a database managed by MC, go to the **Existing Infrastructure** page. On this page, select a running database to see its Overview page. From the bottom of the Overview page, click the Settings tab to make modifications to database-specific settings.

Backing Up MC

Before you [upgrade MC](#), Micro Focus recommends that you back up your MC metadata (configuration and user settings). Use a storage location external to the server on which you installed MC.

1. On the target server (where you want to store MC metadata), log in as root or a user with sudo privileges.
2. Create a backup directory as in following example:

```
# mkdir /backups/mc/mc-backup-20130425
```

3. Copy the `/opt/vconsole` directory to the new backup folder:

```
# cp -r /opt/vconsole /backups/mc/mc-backup-20130425
```

Upgrading And Uninstalling MC

To upgrade or uninstall MC refer to [Installing Vertica](#)

- To upgrade MC, follow the steps listed on [Upgrading Management Console](#).
- To uninstall MC, refer [Uninstalling Management Console](#).

Managing Users And Privileges

A Management Console administrator can grant MC users access to one or more Vertica databases through the MC interface. In this section, we discuss about MC Users and their privileges.

- [About MC Users](#)
- [About MC Privileges and Roles](#)

About MC Users

Unlike database users, which you create on the Vertica database and then grant privileges and roles through SQL statements, you create MC users on the Management Console interface. MC users are external to the database. Their information is stored on an internal database on the MC application/web server. Their access to both MC and to databases managed by MC is controlled by groups of privileges (also referred to as access levels). MC users are not system (Linux) users; they are entries in the MC internal database.

Permission Group Types

There are two types of permission groups on MC, those that apply to MC configuration and those that apply to database access:

- [MC configuration](#) privileges are made up of roles that control what users can configure on the MC, such as modify MC settings, create and import Vertica databases, restart MC, create a Vertica cluster through the MC interface, and create and manage MC users.
- [MC database](#) privileges are made up of roles that control what users can see or do on a Vertica database monitored by MC, such as view the database cluster state, query and session activity, monitor database messages and read log files, replace cluster nodes, and stop databases.

If you are using MC, you might want to allow one or more users in your organization to configure and manage MC, and you might want other users to have database access only. You can meet these requirements by creating MC users and granting them a role from each privileges group. See [Creating an MC User](#) for details.

MC User Types

There are five types of role-based users on MC:

- The default superuser administrator (Linux account) who gets created when you install and configure MC and oversees all of MC. See [SUPER Role \(mc\)](#).
- Users who can configure all aspects of MC and control all databases managed by MC. See [ADMIN Role \(mc\)](#).

- Users who can configure MC user settings and monitor all databases managed by MC. See [MANAGER Role \(MC\)](#).
- Users who can configure some aspects of MC user settings and monitor all databases managed by MC. See [IT Role \(mc\)](#).
- Users who cannot configure MC and have access to one or more databases managed by MC. See [NONE Role \(mc\)](#).

You create users and grant them privileges (through roles) on the **MC Settings** page in the **User management** tab.

Creating Users and Choosing an Authentication Method

You create users and grant them privileges (through roles) on the **MC Settings** page. You can also choose how to authenticate their access to MC.

- To add users who are authenticated against the MC, click **User Management**
- To add users who are authenticated through your organization's LDAP repository, click **Authentication**

MC supports only one method for authentication, so if you choose MC, all MC users will be authenticated using their MC login credentials.

Default MC Users

The MC super account is the only default user. The super or another MC administrator must create all other MC users.

- [Granting Database Access to MC Users](#)
- [Mapping an MC User to a Database user's Privileges](#)

Creating an MC User

MC provides two authentication schemes for MC users: LDAP or MC (internal). Which method you choose will be the method MC uses to authenticate *all* MC users. It is not possible to authenticate some MC users against LDAP and other MC users against credentials in the database through MC.

- **MC (internal) authentication.** Internal user authorization is specific to MC itself. You create a user with a username and password combination. This method stores MC user information in an internal database on the MC application/web server, and encrypts passwords. Note that these MC users are not system (Linux) users; they are entries in the MC's internal database.
- **LDAP authentication.** All MC users—except for the MC super administrator, which is a Linux account—are authenticated based on search criteria against your organization's LDAP repository. MC uses information from LDAP for authentication purposes only and does not modify LDAP information. Also, MC does not store LDAP passwords but passes them to the LDAP server for authentication.

Instructions for creating new MC users are in this topic.

- If you chose MC authentication, follow the instructions under **Create a New User Authenticated by MC**.
- If you chose LDAP authentication, follow the instructions under **Create a New User from LDAP**.

See [About MC Users](#) and [LDAP Authentication](#) for more information.

Prerequisites

Before you create an MC user, you already:

- Created a database directly on the server or through the MC interface, or you imported an existing database cluster into the MC interface. See [Managing Database Clusters](#).
- Created a database user account (source user) on the server, which has the privileges and/or roles you want to map to the new (target) MC user. See [Creating a Database User](#).

- Know what MC privileges you want to grant the new MC user. See [About MC Privileges and Roles](#).
- Are familiar with the concept of [mapping MC users to database users](#).

If you have not yet met the first two above prerequisites, you can still create new MC users; you just won't be able to map them to a database until after the database and target database user exist. To grant MC users database access later, see [Granting Database Access to MC Users](#).

Create a New User Authenticated by MC

1. Sign in to Management Console as an administrator and navigate to **MC Settings > User management**.
2. Click **Add**.
3. Enter the MC username.

Note: It is not necessary to give the MC user the exact same name as the database user account you'll map the MC user to in Step 7. What matters is that the source database user has privileges and/or roles similar to the database role you want to grant the MC user. The most likely scenario is that you will map multiple MC users to a single database user account. See [MC Database Privileges](#) and [Mapping an MC User to a Database user's Privileges](#) for more information.

4. Let MC generate a password or create one by clicking **Edit password**. If LDAP has been configured, the MC password field will not appear.
5. Optionally enter the user's e-mail address.
6. Select an **MC configuration permissions** level. See [MC Configuration Privileges](#).
7. Next to the **DB access levels** section, click **Add** to grant this user database permissions.
 - i. **Choose a database.** Select a database from the list of MC-discovered (databases that were created on or imported into the MC interface).
 - ii. **Database username.** Enter an existing database user name or, if the database is running, click the ellipses [...] to browse for a list of database users, and select a name from the list.

- iii. **Database password.** Enter the password to the database user account (not this username's password).
 - iv. **Restricted access.** Chose a database level ([ADMIN](#), [IT](#), or [USER](#)) for this user.
 - v. Click **OK** to close the **Add permissions** dialog box.
8. Leave the user's **Status** as enabled (the default). If you need to prevent this user from accessing MC, select disabled.
9. Click **Add User** to finish.

Create a New LDAP-authenticated User

When you add a user from LDAP on the MC interface, options on the **Add a new user** dialog box are slightly different from when you create users without LDAP authentication. Because passwords are store externally (LDAP server) the password field does not appear. An MC administrator can override the default LDAP search string if the user is found in another branch of the tree. The **Add user** field is pre-populated with the default search path entered when LDAP was configured.

1. Sign in to Management Console and navigate to **MC Settings > User management**.
2. Click **Add** and provide the following information:
 - a. LDAP user name.
 - b. LDAP search string.
 - c. User attribute, and click **Verify user**.
 - d. User's email address.
 - e. MC configuration role. NONE is the default. See [MC Configuration Privileges](#) for details.
 - f. Database access level. See [MC Database Privileges](#) for details.
 - g. Accept or change the default user's **Status** (enabled).
3. Click **Add user**.

If you encounter issues when creating new users from LDAP, you'll need to contact your organization's IT department.

How MC Validates New Users

After you click OK to close the Add permissions dialog box, MC tries to validate the database username and password entered against the selected MC-managed database or against your organization's LDAP directory. If the credentials are found to be invalid, you are asked to re-enter them.

If the database is not available at the time you create the new user, MC saves the username/password and prompts for validation when the user accesses the Database and Clusters page later.

- [Creating a Database User](#)

Managing MC Users

You manage MC users through the following pages on the Management Console interface:

- **MC Settings > User management**
- **MC Settings > Resource access**

Who Manages Users

The MC superuser administrator ([SUPER Role \(mc\)](#)) and users granted [ADMIN Role \(mc\)](#) manage all aspects of users, including their access to MC and to MC-managed databases.

Users granted [IT Role \(mc\)](#) can enable and disable user accounts.

See [About MC Users](#) and [About MC Privileges and Roles](#) for more information.

Editing an MC user's information follows the same steps as [creating a new user](#), except the user's information will be pre-populated, which you then edit and save.

The only user account you cannot alter or remove from the MC interface is the MC super account.

What Kind of User Information You Can Manage

You can change the following user properties:

- MC password
- Email address. This field is optional. If the user is authenticated against LDAP, the email field is pre-populated with that user's email address if one exists.
- [MC Configuration Privileges](#) role
- [MC Database Privileges](#) role

You can also change a user's status (enable/disable access to MC) and delete users.

About User Names

After you create and save a user, you cannot change that user's MC user name, but you can delete the user account and create a new user account under a new name. The only thing you lose by deleting a user account is its audit activity, but MC immediately resumes logging activity under the user's new account.

About MC Privileges and Roles

As introduced in [About MC Users](#), you control user access to Management Console through groups of privileges (also referred to as access levels) that fall into two types, those that apply to MC configuration, and those that apply to MC-managed Vertica databases.

MC Permission Groups

- [MC configuration](#) privileges are made up of roles that control what users can configure on the MC, such as modify MC settings, create and import Vertica databases, restart MC, create a Vertica cluster through the MC interface, and create and manage MC users.
- [MC database](#) privileges are made up of roles that control what users can see or do on a Vertica database monitored by MC, such as view the database cluster state, query and session activity, monitor database messages and read log files, replace cluster nodes, and stop databases.

Note: When you grant an MC user a database role, that user inherits the privileges assigned to the database user account to which the MC user is mapped. For maximum access, use the dbadmin username and password.

MC database privileges cannot alter or override the Vertica database user's privileges and roles. MC user/database user association is described in [Mapping an MC User to a Database user's Privileges](#).

- [Managing MC Users, Roles and Privileges](#)
- [MC Database Privileges](#)
- [Creating an MC User](#)

- [Granting Database Access to MC Users](#)
- [Mapping an MC User to a Database user's Privileges](#)

MC Configuration Privileges

When you create an MC user, you assign them an MC configuration access level (role). MC roles control a user's ability to create users and manage MC settings on the MC interface.

In addition to an MC role, users also have a database role that controls their database-specific privileges. See [MC Database Privileges](#).

MC Roles and Privileges You Can Assign Users

You can assign a user one of the following MC access levels:

- [ADMIN Role \(mc\)](#)—Full access to all MC functionality.
- [MANAGER Role \(MC\)](#)—Access to MC user management functionality. Access to non-database MC alerts.
- [IT Role \(mc\)](#)—Limited access to MC user management functionality. Access to MC log and to non-database MC alerts.
- [NONE Role \(mc\)](#)—Database access only, to the databases an administrator assigns to this user.

You grant MC configuration privileges at the same time you create the user's account, on the User Management tab of the MC Settings page. You can change MC access levels using this page. See [Creating an MC User](#) for details.

You can also use the User Management tab to grant users access to one or more databases managed by MC. See [MC Database Privileges](#) for details.

MC Configuration Privileges By User Role

You grant the following configuration privileges by MC role.

MC access privileges	ADMIN	MANAGER	IT	NONE
Configure MC settings:	Yes			

MC access privileges	ADMIN	MANAGER	IT	NONE
<ul style="list-style-type: none"> Configure storage locations and ports Upload new SSL certificates Manage LDAP authentication Update Vertica installation Change MC theme Map to an external data source 				
Configure user settings: <ul style="list-style-type: none"> Add, edit, delete users Add, change, delete user permissions Map users to one or more databases 	Yes	Yes		
Configure user settings: <ul style="list-style-type: none"> Enable or disable user access to MC Reset user passwords 	Yes	Yes	Yes	
Monitor user activity on MC using audit log	Yes			
Create and manage databases and clusters: <ul style="list-style-type: none"> Create a new database or import an existing one Create a new cluster or import an existing one Remove databases and clusters from MC 	Yes			
Reset MC to its original, preconfigured state	Yes			
Restart Management Console	Yes			
View full list of databases monitored by MC	Yes	Yes	Yes	
View MC log	Yes		Yes	

MC access privileges	ADMIN	MANAGER	IT	NONE
View non-database MC alerts	Yes	Yes	Yes	Yes

- [Mapping an MC User to a Database user's Privileges](#)

SUPER Role (mc)

The default superuser administrator, called **Super** on the MC UI, is a Linux user account that gets created when you install and [configure MC](#). During the configuration process, you can assign the Super any name you like; it need not be dbadmin.

The MC SUPER role, a superset of the [ADMIN Role \(mc\)](#), has the following privileges:

- Oversees the entire Management Console, including all MC-managed database clusters

Note: This user inherits the privileges/roles of the user name supplied when importing an Vertica database into MC. Micro Focus recommends that you use the database administrator's credentials.

- Creates the first MC user accounts and assigns them an MC configuration role
- Grants MC users access to one or more MC-managed Vertica databases by assigning [MC Database Privileges](#) to each user

The MC super administrator account is unique. Unlike other MC users you create, including other MC administrators, the MC super account cannot be altered or dropped, and you cannot grant the SUPER role to other MC users. The only property you can change for the MC super is

the password. Otherwise the SUPER role has the same privileges on MC as the [ADMIN Role \(mc\)](#).

On MC-managed Vertica databases, SUPER has the same privileges as [ADMIN Role \(db\)](#).

The MC super account does not exist within the LDAP server. This account is also different from the special dbadmin account that gets created during an Vertica installation, whose privileges are governed by the [DBADMIN Role](#). The Vertica-created dbadmin is a Linux account that owns the database catalog and storage locations and can bypass database authorization rules, such as creating or dropping schemas, roles, and users. The MC super does not have the same privileges as dbadmin.

- [Mapping an MC User to a Database user's Privileges](#)
- [Managing MC Users](#)

ADMIN Role (mc)

This user account is the user who can perform all administrative operations on Management Console, including configure and restart the MC process and add, change, and remove all user accounts. By default, MC administrators inherit the database privileges of the main database user account used to set up the database on the MC interface. Therefore, MC administrators have access to all MC-managed databases. Grant the ADMIN role to users you want to be MC administrators.

The difference between this ADMIN user and the default Linux account, the MC [SUPER role](#), is you cannot alter or delete the MC SUPER account, and you can't grant the SUPER role to any other MC users. You can, however, change the access level for other MC administrators, and you can delete this user's accounts from the MC interface.

The following list highlights privileges granted to the ADMIN role:

- Modify MC settings, such as storage locations and ports, restart the MC process, and reset MC to its original, unconfigured state
- Audit license activity and install/upgrade a Vertica license
- Upload a new SSL certificate
- Use LDAP for user authentication
- View the MC log, alerts and messages
- Add new users and map them to one or more Vertica databases by granting an [MC database-level role](#)
- Select a database and add multiple users at once
- Manage user roles and their access to MC
- Remove users from the MC
- Monitor user activity on the MC interface
- Stop and start any MC-managed database
- Create new databases/clusters and and import existing databases/clusters into MC
- Remove databases/clusters from the MC interface
- View all databases/clusters imported into MC

About the MC Database Administrator Role

There is also an MC database administrator (ADMIN) role that controls a user's access to MC-managed databases. The two ADMIN roles are similar, but they are not the same, and you do not need to grant users with the ADMIN (mc) role an ADMIN (db) role because MC ADMIN users automatically inherit all database privileges of the main database user account that was created on or imported into MC.

The following table summarizes the primary difference between the two ADMIN roles, but see [ADMIN Role \(db\)](#) for details specific to MC-managed database administrators.

MC configuration ADMIN role	MC database ADMIN role
Perform all administrative operations on the MC itself, including restarting the MC process.	Perform database-specific activities, such as stop and start the database, and

MC configuration ADMIN role	MC database ADMIN role
Privileges extend to monitoring all MC-created and imported databases but anything database-related beyond that scope depends on the user's privileges granted on the database through GRANT statements.	monitor query and user activity and resources. Other database operations depend on that user's privileges on the specific database. This ADMIN role cannot configure MC.

MANAGER Role (MC)

Users assigned the Manager role can configure user settings in MC. The Manager role allows full access to the User Management tab in MC Settings. Managers can also view a full list of databases monitored by MC on the Home page, view the MC log, and see non-database MC alerts.

The Manager role has similar configuration privileges to the IT configuration role. Unlike IT users, Managers can also create, edit, and delete users in User Settings.

Managers can:

- Add, edit, delete users
- Add, change, delete user permissions
- Map users to one or more databases
- Enable or disable user access to MC
- Reset user passwords
- View the full list of databases monitored by MC on the MC Home page
- View the MC log
- View non-database MC alerts

IT Role (mc)

MC IT users can monitor all MC-managed databases, view MC-level (non database) messages, logs, and alerts, disable or enable user access to MC, and reset non-LDAP user passwords. You can also assign MC IT users specific database privileges, which you do by mapping IT users to a user on a database. In this way, the MC IT user inherits the privileges assigned to the database user to which he/she is mapped.

About the MC IT (database) Role

There is also an IT database administrator (IT) role that controls a user's access to MC-managed databases. If you grant an MC user both IT roles, it means the user can perform some configuration on MC and also has access to one or more MC-managed databases. The database mapping is not required, but it gives the IT user wider privileges.

The two IT roles are similar, but they are not the same. The following table summarizes the primary difference between them, but see [IT Role \(db\)](#) for details.

MC configuration IT role	MC database IT role
Monitor MC-managed database, view non-database messages, and manage user access	Monitor databases on which the user has privileges, view the database overview and activity pages, monitor the node state view messages and mark them read/unread, view database settings. Can also be mapped to one or more Vertica databases.

NONE Role (mc)

The default role for all newly-created users on MC is NONE, which prevents users granted this role from configuring the MC. When you create MC users with the NONE role, you grant them an [MC database-level role](#). This assignment maps the MC user to a user account on a specific database and specifies that the NONE user inherits the database user's privileges to which he or she is mapped.

Which database-level role you grant this user with NONE privileges—whether ADMIN (db) or IT (db) or USER (db)—depends on the level of access you want the user to have on the MC-managed database. Database roles have no impact on the ADMIN and IT roles at the MC configuration level.

MC Database Privileges

When you [create MC users](#), you first assign them [MC configuration](#) privileges, which controls what they can do on the MC itself. In the same user-creation operation, you grant access to one or more MC-managed databases. MC database access does not give the MC user privileges directly on Vertica; it provides MC users varying levels of access to assigned database functionality through the MC interface.

Assign users an MC database level through one of the following roles:

- [ADMIN Role \(db\)](#)—Full access to all databases managed by MC. Actual privileges ADMINs inherit depend on the database user account used to create or import the Vertica database into the MC interface.
- [Associate Role \(Database\)](#)—Full access to all databases managed by MC. Cannot start, stop, or drop a database. Actual privileges that Associates receive depend on those defined for the database user account to which the Associate user is mapped.
- [IT Role \(db\)](#)—Can start and stop a database but cannot remove it from the MC interface or drop it.
- [USER Role \(db\)](#)—Can view database information through the database Overview and Activities pages but is restricted from viewing more detailed data.

Mapping MC Users to Database to Avoid Conflicts

When you assign an MC database level to an MC user, map the MC user account to a database user account to:

- Inherit the privileges assigned to that database user
- Prevent the MC user from doing or seeing anything not allowed by the privileges for the user account on the server database

Privileges assigned to the database user supersede privileges of the MC user if there is a conflict, such as stopping a database. When the MC user logs into MC using an MC user name and password, Vertica compares privileges for database-related activities to the privileges on the database account to which you mapped the MC user. Vertica allows operations in MC to the user only when that user has both MC privileges and corresponding database privileges.

Tip: As a best practice, you should identify, in advance, the appropriate Vertica database user account that has privileges or roles similar to one of the MC database roles.

See [Creating an MC User](#) and [Mapping an MC user to a database user's privileges](#) for more information.

MC Database Privileges By Role

The following table summarizes MC database-level privileges by user role. The table shows the default privileges each role has. Operations marked "database user privilege" are dependent on the privileges of the Vertica database user account to which the MC user is mapped.

Default database-level privileges	ADMIN	ASSOCIATE	IT	USER
View database Overview page	Yes	Yes	Yes	Yes
View database messages	Yes	Yes	Yes	Yes
Delete messages and mark read/unread	Yes	Yes	Yes	
Audit and install Vertica licenses	Database user privilege	Database user privilege		
View database Activity page: <ul style="list-style-type: none"> • Queries chart • Internal Sessions chart • User Sessions chart • System Bottlenecks chart • User Query Phases chart 	Yes	Database user privilege	Database user privilege	Database user privilege
View database Activity page: <ul style="list-style-type: none"> • Queries chart > Detail page • Table Treemap chart • Query Monitoring chart • Resource Pools Monitoring chart 	Database user privilege	Database user privilege		

Default database-level privileges	ADMIN	ASSOCIATE	IT	USER
Start a database	Yes			
Rebalance, stop, or drop databases	Database user privilege			
View Manage page	Yes	Yes	Yes	Yes
View node details	Yes	Yes	Yes	
Replace, add, or remove nodes	Database user privilege			
Start/stop a node	Yes			
View database Settings page	Yes	Yes	Yes	
Modify database Settings page	Database user privilege	Database user privilege		
View Database Designer	Database user privilege	Database user privilege		

ADMIN Role (db)

ADMIN is a superuser with full privileges to monitor MC-managed database activity and messages. Other database privileges (such as stop or drop the database) are governed by the user account on the Vertica database that this ADMIN (db) user is mapped to. ADMIN is the most permissive role and is a superset of privileges granted to the [Associate Role \(Database\)](#), [IT](#), and [USER](#) roles.

The ADMIN user has the following database privileges by default:

- View the database Overview page
- View and delete database messages
- Mark messages read or unread
- Start the database

- View the Manage page
- View node details
- Start or stop a node
- View database settings
- View the following database Activity page charts:
 - Queries
 - Internal Sessions
 - User Sessions
 - System Bottlenecks
 - User Query Phases

The following database operations depend on the database user's role that you mapped this ADMIN user to:

- Install or audit a license
- Rebalance, stop, or drop databases
- Add, replace, or remove nodes
- Manage database settings
- View Database Designer
- View additional information on the database Activity page:
 - Detailed information in the Queries chart Detail page
 - Table Treemap chart
 - Query Monitoring chart
 - Resource Pools Monitoring chart

Note: Database access granted through Management Console never overrides roles granted on a specific Vertica database.

About the ADMIN (MC configuration) Role

There is also an MC configuration administrator role that defines what the user can change on the MC itself. The two ADMIN roles are not the same. Unlike the MC configuration role of ADMIN, which can manage all MC users and all databases imported into the UI, the MC database ADMIN role has privileges only on the databases you map this user to. The following table summarizes the primary difference between them. See [ADMIN Role \(mc\)](#) for additional details.

MC database ADMIN role	MC configuration ADMIN role
Perform database-specific activities, such as stop and start the database, and monitor query and user activity and resources. Other database operations depend on that user's privileges on the specific database. This ADMIN role cannot configure MC.	Perform all administrative operations on the MC itself, including restarting the MC process. Privileges extend to monitoring all databases created and imported by MC. Anything database-related beyond that scope depends on the user's privileges granted on the database through GRANT statements.

Associate Role (Database)

The Associate role is an MC database access role. It is similar to the Admin role. It has privileges to monitor activity and messages on databases managed by MC. Unlike Admin users, Associate users cannot start, stop, or drop the database. The Associate user role is mapped to a user account on the database. This mapped user role determines what other database privileges the Associate role has (such as modifying settings, installing licenses, and viewing the database designer).

The Associate user has the following database privileges by default:

- View the database Overview page
- View and delete database messages
- Mark messages read or unread
- View the Manage page
- View node details
- View database settings

The following database operations depend on the database user's role that you mapped this Associate user to:

- Install or audit a license
- Manage database settings
- View Database Designer
- View the database Activity page

Note: Database access granted through Management Console never overrides roles granted on a specific Vertica database.

IT Role (db)

IT can view most details about an MC-managed database, such as messages (and mark them read/unread), the database overall health and activity/resources, cluster and node state, and MC settings. You grant and manage user role assignments through the **MC Settings > User management** page on the MC.

About the IT (MC configuration) Role

There is also an IT role at the MC configuration access level. The two IT roles are similar, but they are not the same. If you grant an MC user both IT roles, it means the user can perform some configuration on MC and also has access to one or more MC-managed databases. The following table summarizes the primary difference between them, but see [IT Role \(mc\)](#) for additional details.

MC database IT	MC configuration IT
Monitor databases on which the user has privileges, view the database overview and activity pages, monitor the node state view messages and mark them read/unread, view database settings.	Monitor MC-managed database, view non-database messages, and manage user access.

USER Role (db)

USER has limited database privileges, such as viewing database cluster health, activity/resources, and messages. MC users granted the USER database role might have higher

levels of permission on the MC itself, such as the [IT Role \(mc\)](#). Alternatively, USER users might have no (NONE) privileges to configure MC. How you combine the two levels is up to you.

Granting Database Access to MC Users

If you did not grant an MC user a [database-level role](#) when you created the user account, you can do so in the User Management tab in MC Settings.

Granting the user an MC database-level role associates the MC user with a database user's privileges and ensures that the MC user cannot do or see anything not allowed by the privileges set up for the user account on the server database. When that MC user logs in to MC, his or her MC privileges for database-related activities are compared to that user's privileges on the database itself. Only when the user has both MC privileges and corresponding database privileges will the operations be exposed in the MC interface.

Prerequisites

Before you grant database access to an MC user, see the prerequisites in [Creating an MC User](#).

Grant a Database-Level Role to an MC user

1. Log in to Management Console as an administrator and navigate to **MC Settings > User management**.
2. Select an MC user and click **Edit**.
3. Verify the [MC Configuration Privileges](#) are what you want them to be. NONE is the default.
4. Next to the **DB access levels section**, click **Add** and provide the following database access credentials:
 - i. **Choose a database.** Select a database from the list of MC-discovered (databases that were created on or imported into the MC interface).
 - ii. **Database username.** Enter an existing database user name or, if the database is running, click the ellipses [...] to browse for a list of database users, and select a name from the list.
 - iii. **Database password.** Enter the password to the database user account (not this username's password).

- iv. **Restricted access.** Chose a database level ([ADMIN](#), [IT](#), or [USER](#)) for this user.
 - v. Click **OK** to close the **Add permissions** dialog box.
5. Optionally change the user's **Status** (enabled is the default).
6. Click **Save**.

How MC Validates New Users

After you click OK to close the Add permissions dialog box, MC tries to validate the database username and password entered against the selected MC-managed database or against your organization's LDAP directory. If the credentials are found to be invalid, you are asked to re-enter them.

If the database is not available at the time you create the new user, MC saves the username/password and prompts for validation when the user accesses the Database and Clusters page later.

Managing Client Connections

Each client session to MC uses a connection from `MaxClientSessions`, a database configuration parameter. This parameter determines the maximum number of sessions that can run on a single database cluster node. Sometimes multiple MC users, mapped to the same database account, are concurrently monitoring the Overview and Activity pages. In such cases, graphs could be slow to update while MC waits for a connection from the pool.

Tip: You can increase the value for `MaxClientSessions` on an MC-monitored database to account for extra sessions. See [Managing Sessions](#) for details.

Managing Database Clusters

To perform database/cluster-specific tasks on one or more MC-managed clusters, navigate to the **Databases and Clusters** page.

MC administrators see the Import/Create Database Cluster options, while non-administrative MC users see only the databases on which they have been assigned the appropriate [access levels](#). Depending on your access level, the database-related operations you can perform on the MC interface include:

- [Create a new database/cluster](#).
- [Import an existing database/cluster](#) into the MC interface.
- Start the database, unless it is already running (green).
- Stop the database, but only if no users are connected.
- Remove the database from the MC interface.

Note: Remove does not drop the database. A Remove operation leaves it in the cluster, hidden from the UI. To add the database back to the MC interface, import it using the IP address of any cluster node. A Remove operation also stops metrics gathering on that database, but statistics gathering automatically resumes after you re-import.

- Drop the database after you ensure no users are connected. Drop is a permanent action that drops the database from the cluster.
- View the Overview page, a dashboard view into the health of your database cluster. From this page you can drill down into more detailed database-specific information by clicking data points in the graphs.
- View the Manage page, which shows all nodes in the cluster, as well as each node's state. You can also see a list of monitored databases on the selected cluster and its state. For example, a green arrow indicates a database in an UP state. For node-specific information, click any node to open the Node Details page.

Create an Empty Database Using MC

You can create a new database on an existing Vertica cluster through the Management Console interface.

Database creation can be a long-running process, lasting from minutes to hours, depending on the size of the target database. You can close the web browser during the process and sign back in to MC later; the creation process continues unless an unexpected error occurs. See the **Notes** section below the procedure on this page.

You currently need to use command line scripts to define the database schema and load data. Refer to the topics in [Configuration Procedure](#). You should also run the Database Designer, which you access through the Administration Tools, to create either a comprehensive or incremental design. Consider using the [Tutorial](#) in Getting Started to create a sample database you can start monitoring immediately.

How to Create an Empty Database on an MC-managed Cluster

1. If you are already on the **Databases and Clusters** page, skip to the next step; otherwise:
 - a. [Connect](#) to MC and sign in as an MC administrator.
 - b. On the [Home page](#), click **Existing Infrastructure** to view the Databases and Clusters page.
2. If no databases exist on the cluster, continue to the next step; otherwise:
 - a. If a database is running on the cluster on which you want to add a new database, select the database and click **Stop**.
 - b. Wait for the running database to have a status of *Stopped*.
3. Click the cluster on which you want to create the new database and click **Create Database**.
4. The Create Database wizard opens. Provide the following information:

- Database name and password. See [Creating a Database Name and Password](#) for rules.
- Optionally click **Advanced** to open the advanced settings and change the port, catalog path, and data path. By default the MC application/web server port is 5450 and paths are /home/dbadmin, or whatever you defined for the paths when you ran the Cluster Creation Wizard or the `install_vertica` script. Do not use the default agent port 5444 as a new setting for the MC port. See **MC Settings > Configuration** for port values.

5. Click **Continue**.

6. Select nodes to include in the database.

The Database Configuration window opens with the options you provided and a graphical representation of the nodes appears on the page. By default, all nodes are selected to be part of this database (denoted by a green check mark). You can optionally click each node and clear **Include host in new database** to exclude that node from the database. Excluded nodes are gray. If you change your mind, click the node and select the **Include** check box.

7. Click **Create** in the **Database Configuration** window to create the database on the nodes.

The creation process takes a few moments, after which the database starts and a **Success** message appears on the interface.

8. Click **OK** to close the success message.

The Manage page opens and displays the database nodes. Nodes not included in the database are colored gray, which means they are standby nodes you can include later. To add nodes to or remove nodes from your Vertica cluster, which are not shown in standby mode, you must run the `install_vertica` script.

Notes

- If warnings occur during database creation, nodes will be marked on the UI with an Alert icon and a message.
 - Warnings do not prevent the database from being created, but you should address warnings after the database creation process completes by viewing the database **Message Center** from the MC Home page.

- Failure messages display on the database **Manage** page with a link to more detailed information and a hint with an actionable task that you must complete before you can continue. Problem nodes are colored red for quick identification.
- To view more detailed information about a node in the cluster, double-click the node from the Manage page, which opens the **Node Details** page.
- To create MC users and grant them access to an MC-managed database, see [About MC Users](#) and [Creating an MC User](#).

Import an Existing Database Into MC

If you have already upgraded your database to the current version of Vertica, MC automatically discovers the cluster and any databases installed on it, regardless of whether those databases are currently running or are down.

Note: If you haven't created a database and want to create one through the MC, see [Create an Empty Database Using MC](#).

How to Import an Existing Database on the Cluster

The following procedure describes how to import an existing database into the MC interface so you can monitor it.

1. [Connect](#) to Management Console and sign in as an MC administrator.
2. On the MC [Home page](#), click **Existing Infrastructure**.

3. On the Databases and Clusters page, click the cluster and click **View** in the dialog box that opens.
4. On the left side of the page under the Databases heading, and click **Import Discovered**.

Tip: A running database appears as Monitored, and any non-running databases appear as Discovered. MC supports only one running database on a single cluster at a time. You must shut down a running database on a cluster in order to monitor another database on that cluster.

5. In the **Import Database** dialog box:
 - a. Select the database you want to import.
 - b. Optionally clear auto-discovered databases you don't want to import.
 - c. Supply the database administrator username and password and click **Import**.
(Supplying a non-administrator username prevents MC from displaying some charts after import.)

After Management Console connects to the database it opens the **Manage** page, which provides a view of the cluster nodes. See [Monitoring Cluster Status](#) for more information.

You perform the import process once per existing database. Next time you connect to Management Console, your database appears under the Recent Databases section on the Home page, as well as on the Databases and Clusters page.

Note: The system clocks in your cluster must be synchronized with the system that is running Management Console to allow automatic discovery of local clusters.

Import and Monitor in a Hadoop Environment

You can use Management Console to connect to and monitor a Vertica database that resides in an Apache Hadoop environment.

Connecting to Ambari and Importing Vertica Within a Hadoop Environment

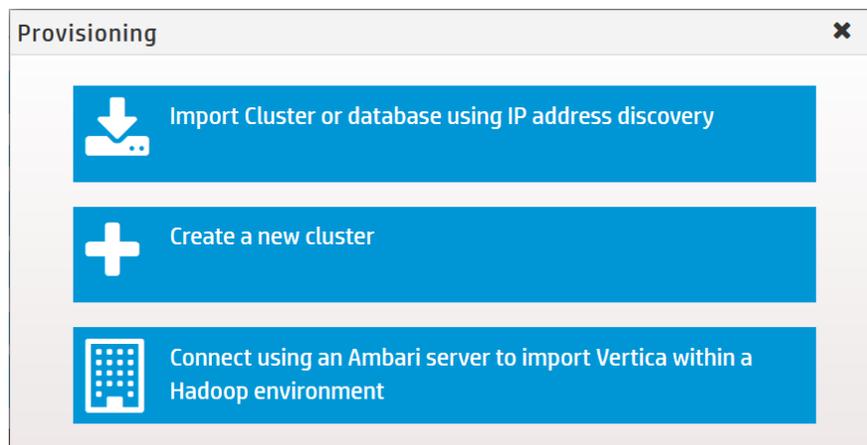

To import your Vertica database that resides in a Hadoop environment, connect to that Hadoop environment in Management Console through an Apache Ambari server. Then, through that connection, import Vertica.

Before you connect and import, you must:

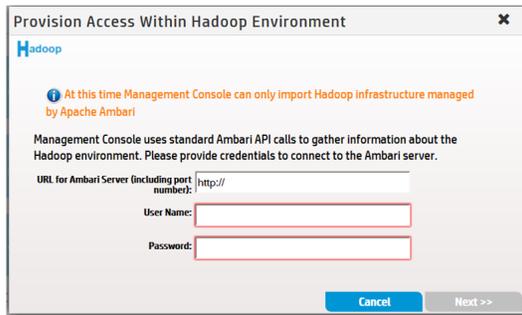

- Install Vertica on a Hadoop cluster
- Install Apache Ambari version 1.6.1 or 2.1.0
- Enable Ganglia on your Hadoop cluster, to get the most information from your Hadoop environment

To connect to an Ambari server:

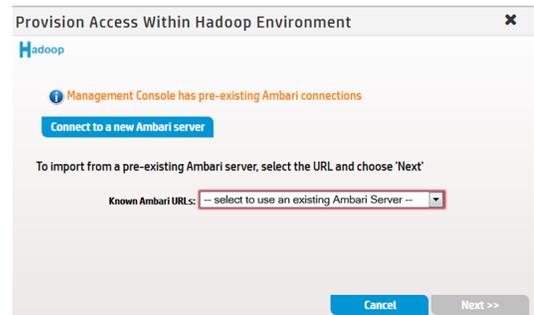

1. From the Management Console home page, select **Provisioning**. Then, click **Connect using an Ambari server to import Vertica within a Hadoop environment**.

2. In the **Provision Access within Hadoop Environment** window, enter a new Ambari connection with your username and password . If have already have an existing connection,a window opens that allows you to select an existing connection from the drop-down menu.

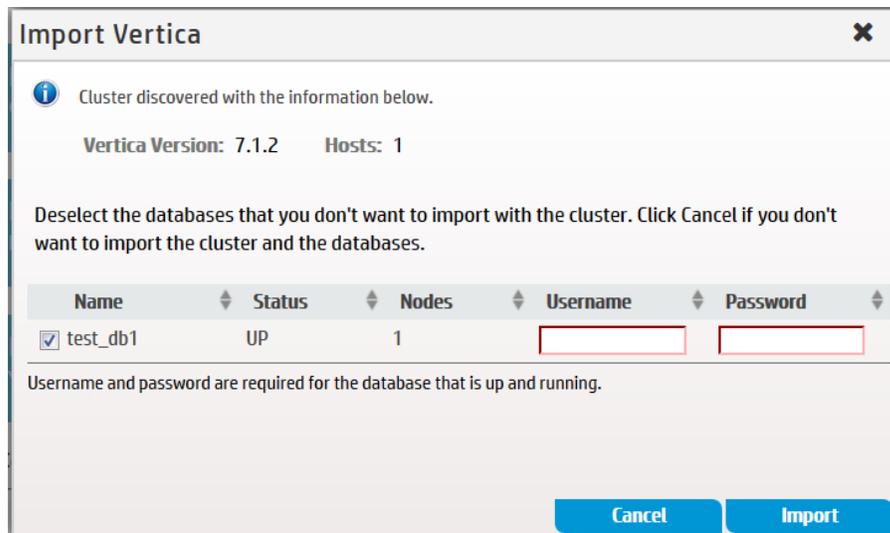

OR

3. In the next window, select the Hadoop cluster where the Vertica database you want to monitor resides. MC will discover Hadoop clusters that are currently monitored by the Ambari server you specify.

A window appears confirming that your Hadoop cluster is saved. If MC currently does not monitor Vertica clusters in the specified Hadoop environment, you have the option to import Vertica clusters at this time.

4. Enter the IP address for the Vertica database you want to import and monitor. If Vertica is running on multiple hosts, enter the IP address of one of them.
5. Enter the API key for the Vertica cluster. The API key is generated during Vertica installation and you can find it in the `/opt/vertica/config/apikeys.dat` file.
6. When the next window displays the discovered databases, select one or more database you want to import, along with the database username and password.

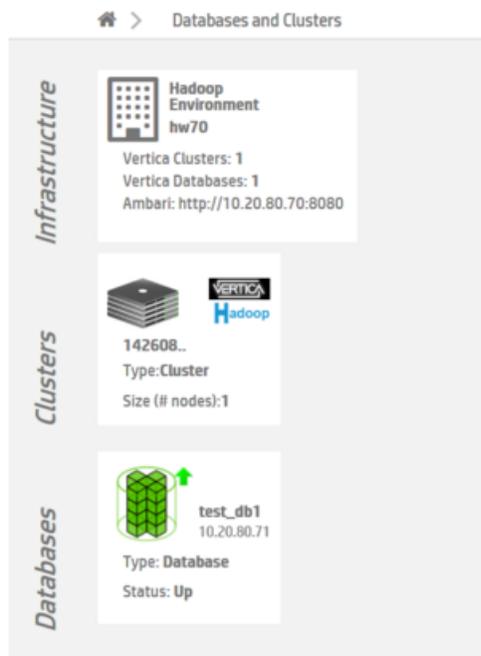

7. Confirm that the import is successful. If it is, a success message appears. Click **Done** to go to the **Existing Infrastructure** page.

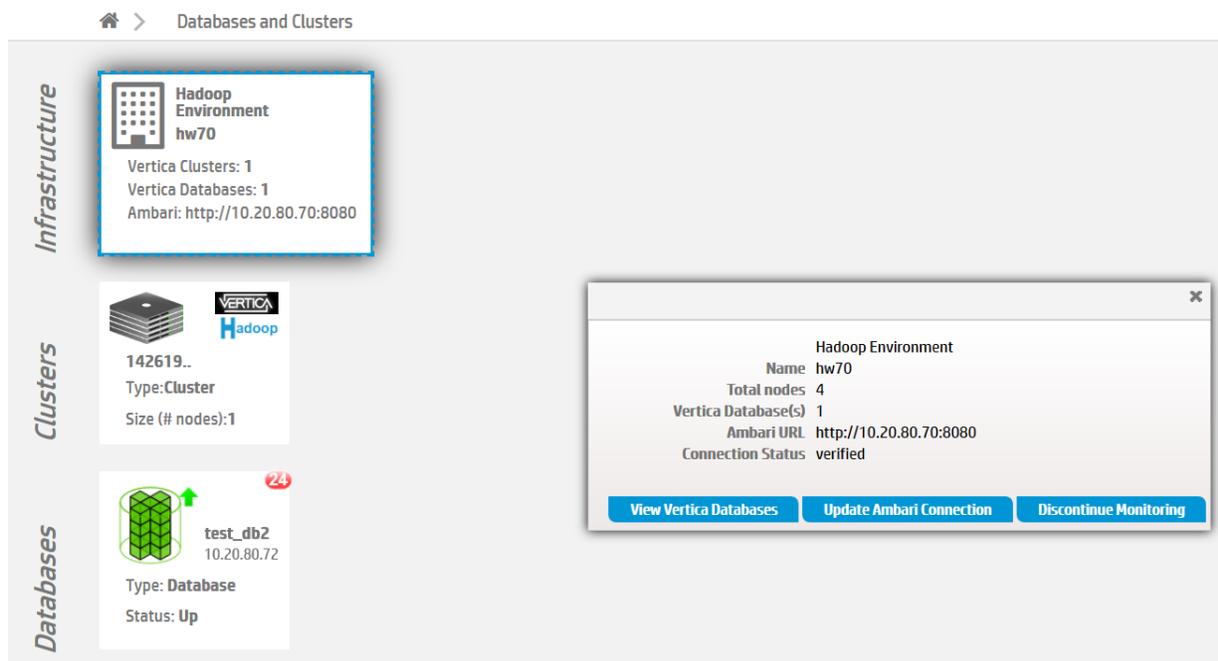

To import an additional Vertica cluster within a Hadoop environment, click **Import Cluster or database using IP address discovery** under **Provisioning**. Management Console will automatically associate the cluster with the existing Hadoop environment.

Monitoring Vertica Within a Hadoop Environment

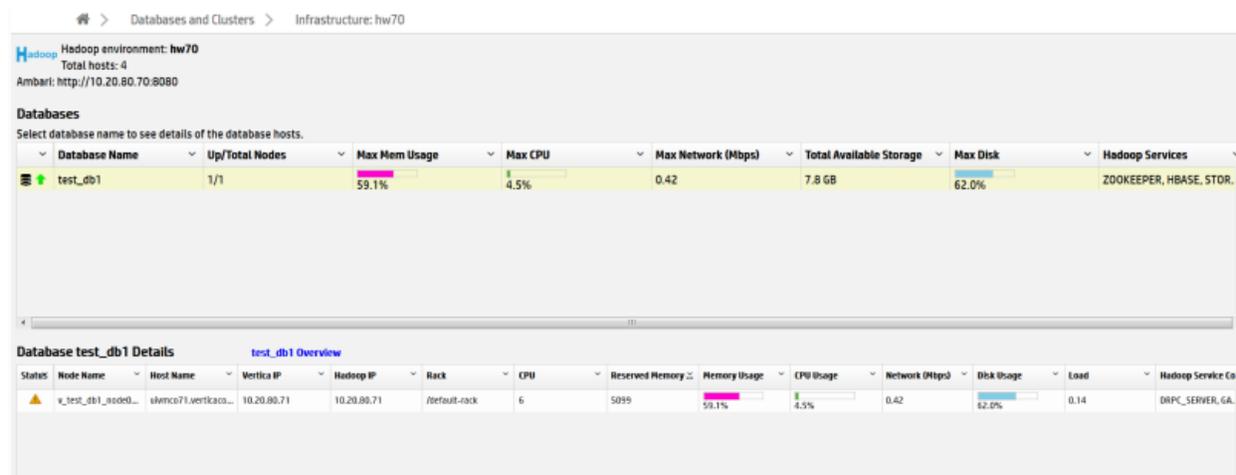

To monitor the Vertica clusters in a Hadoop environment, navigate to the **Existing Infrastructure** page:

Click to select the Hadoop environment, and then click **View Vertica Databases**.

The resulting screen displays information about the Vertica databases that reside in a Hadoop environment:

You can monitor information like resource usage, Hadoop services, and database and connection status.

Updating and Removing an Ambari Connection

To update or remove an existing Ambari connection, go to the MC **Existing Infrastructure** page, and click on the relevant Hadoop environment.

To update a connection, click **Update Ambari Connection**. Step through the wizard to update the connection.

To remove a connection, select **Update Ambari Connection** and choose **Remove Connection**, or click **Discontinue Monitoring** and then confirm that you want to remove the connection. Removing the connection also removes all Vertica databases associated with this connection from MC monitoring. You can re-import the databases later if needed.

[Integrating with Apache Hadoop](#)

Managing MC Settings

The **MC Settings** page allows you to configure properties specific to Management Console. You can:

- Change MC and agent default port assignments.
- Enable and disable username and password auto-complete at MC login. (After disabling, clear your browser's cache.)
- Control the following monitoring settings in MC:
 - Enable checks and set alert thresholds for spread retransmit rate. This setting is disabled by default. The recommended alert threshold for spread retransmit rate is 10%.
 - Set alert thresholds for free MC disk space checks. The recommended alert threshold is 500 MB.
 - Exclude MC queries from activity charts.
 - Set refresh intervals for MC charts and pages.
- Upload a new SSL certificate.
- Use LDAP for user authentication.
- Create new MC users and, with their user credentials, map them to an database managed by MC on the Vertica server. See [Creating an MC User](#) and [Managing MC Users](#).
- View your version of Vertica or upload a new Vertica binary file.
- Customize the look and feel of MC with themes. See [Customizing Look and Feel](#).
- Configure MC to use an alternative data source to monitor your database. See [Monitoring External Data Sources in Management Console](#).
- Enable MC to send email alerts. See [Set Up Email](#) .
- Configure [Extended Monitoring](#), which allows you to monitor more long-term data in MC:
 - Set up an external storage database for Extended Monitoring. See [Managing the Storage Database](#).
 - Enable or disable Extended Monitoring on your databases. See [Managing Extended Monitoring on a Database](#).

Modifying Database-Specific Settings

To inspect or modify settings related to a database managed by MC, go to the **Existing Infrastructure** page. On this page, select a running database to see its Overview page. From the bottom of the Overview page, click the Settings tab to make modifications to database-specific settings.

Customizing Look and Feel

Management Console themes provide a unique look and feel to the Management Console interface. Access these themes through the Theme page in MC Settings.

Changing Themes

Only administrators, who have access to MC Settings, can alter themes. The selected theme is visible to all Management Console users.

To apply a new theme on Management Console, go to MC Settings > Theme. On the Theme page, select a theme from the drop-down menu. A preview of the selected theme appears. Click Apply in the upper right hand of the page to apply the change.

Changing MC or Agent Ports

When you configure MC, the Configuration Wizard sets up the following default ports:

- 5450—Used to connect a web browser session to MC and allows communication from Vertica cluster nodes to the MC application/web server
- 5444—Provides MC-to-node and node-to-node (agent) communications for database create/import and monitoring activities

If You Need to Change the MC Default Ports

A scenario might arise where you need to change the default port assignments for MC or its agents. For example, perhaps one of the default ports is not available on your Vertica cluster, or you encounter connection problems between MC and the agents. The following topics describe how to change port assignments for MC or its agents.

See Also

- [Ensure Ports Are Available](#)

How to Change the Agent Port

Changing the agent port takes place in two steps: at the command line, where you modify the `config.py` file and through a browser, where you modify MC settings.

Change the Agent Port in `config.py`

1. Log in as root on any cluster node and change to the agent directory:

```
# cd /opt/vertica/agent
```

2. Use any text editor to open `config.py`.

3. Scroll down to the `agent_port = 5444` entry and replace 5444 with a different port number.
4. Save and close the file.
5. Copy `config.py` to the `/opt/vertica/agent` directory on all nodes in the cluster.
6. Restart the agent process by running the following command:

```
# /etc/init.d/vertica_agent restart
```

Note: If you are using Red Hat Enterprise Linux/CentOS 7, use the following command instead:

```
# /opt/vertica/sbin/vertica_agent restart
```

7. Repeat (as root) Step 6 on each cluster node where you copied the `config.py` file.

Change the Agent Port on MC

1. Open a web browser and [connect to MC](#) as a user with [MC ADMIN](#) privileges.
2. Navigate to **MC Settings > Configuration**.
3. Change Default Vertica agent port from 5444 to the new value you specified in the `config.py` file.
4. Click **Apply** and click **Done**.
5. Restart MC so MC can connect to the agent at its new port. See [Restarting MC](#).

How to Change the MC Port

Use this procedure to change the default port for MC's application server from 5450 to a different value.

1. Open a web browser and [connect to MC](#) as a user with [MC ADMIN](#) privileges.
2. On the MC Home page, navigate to **MC Settings > Configuration** and change the *Application server running port* value from 5450 to a new value.
3. In the change-port dialog, click **OK**.
4. [Restart MC](#).
5. Reconnect your browser session using the new port. For example, if you changed the port from 5450 to 5555, use one of the following formats:

```
https://00.00.00.00:5555/
```

OR

```
https://hostname:5555/
```

Backing Up MC

Before you [upgrade MC](#), Micro Focus recommends that you back up your MC metadata (configuration and user settings). Use a storage location external to the server on which you installed MC.

1. On the target server (where you want to store MC metadata), log in as root or a user with sudo privileges.
2. Create a backup directory as in following example:

```
# mkdir /backups/mc/mc-backup-20130425
```

3. Copy the /opt/vconsole directory to the new backup folder:

```
# cp -r /opt/vconsole /backups/mc/mc-backup-20130425
```

Troubleshooting with MC Diagnostics

The Management Console **Diagnostics** page, which you access from the Home page, helps you resolve issues within the MC process, not the database.

What You Can Diagnose

- View Management Console logs, which you can sort by column headings, such as type, component, or message).
- [Search](#) within messages for key words or phrases and search for log entries within a specific time frame.
- [Export](#) database messages to a file.
- Reset console parameters to their original configuration.

Caution: Reset removes all data (monitoring and configuration information) from storage and forces you to [reconfigure MC](#) as if it were the first time.

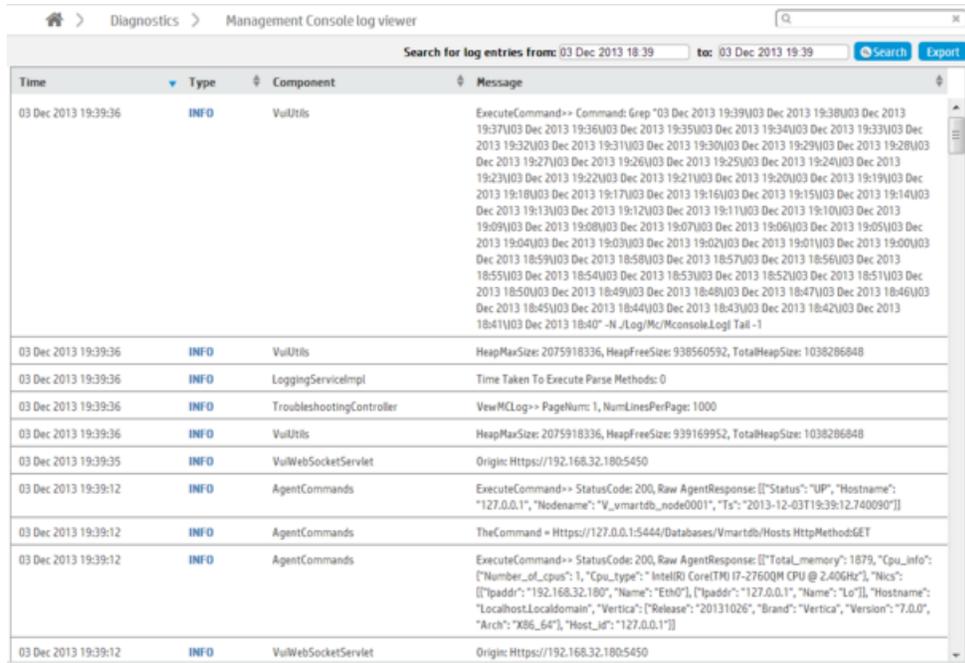

- [Restart the Management Console process](#). When the process completes, you are directed back to the login page.

Viewing the MC Log

If you want to browse MC logs (not database logs), navigate to the **Diagnostics > MC Log** page.

This page provides a tabular view of the contents at `/opt/vconsole/log/mc/mconsole.log`, letting you more easily identify and troubleshoot issues related to MC.

You can sort log entries by clicking the column header and search within messages for key words, phrases, and log entries within a specific time frame. You can also export log messages to a file.

The screenshot shows the Management Console log viewer interface. At the top, there is a search bar with the text "Search for log entries from: 03 Dec 2013 18:39 to: 03 Dec 2013 19:39" and buttons for "Search" and "Export". Below the search bar is a table with the following columns: Time, Type, Component, and Message. The table contains several log entries, including:

Time	Type	Component	Message
03 Dec 2013 19:39:36	INFO	VulUtils	ExecuteCommand-> Command: Grep *03 Dec 2013 19:39:03 Dec 2013 19:38:03 Dec 2013 19:37:03 Dec 2013 19:36:03 Dec 2013 19:35:03 Dec 2013 19:34:03 Dec 2013 19:33:03 Dec 2013 19:32:03 Dec 2013 19:31:03 Dec 2013 19:30:03 Dec 2013 19:29:03 Dec 2013 19:28:03 Dec 2013 19:27:03 Dec 2013 19:26:03 Dec 2013 19:25:03 Dec 2013 19:24:03 Dec 2013 19:23:03 Dec 2013 19:22:03 Dec 2013 19:21:03 Dec 2013 19:20:03 Dec 2013 19:19:03 Dec 2013 19:18:03 Dec 2013 19:17:03 Dec 2013 19:16:03 Dec 2013 19:15:03 Dec 2013 19:14:03 Dec 2013 19:13:03 Dec 2013 19:12:03 Dec 2013 19:11:03 Dec 2013 19:10:03 Dec 2013 19:09:03 Dec 2013 19:08:03 Dec 2013 19:07:03 Dec 2013 19:06:03 Dec 2013 19:05:03 Dec 2013 19:04:03 Dec 2013 19:03:03 Dec 2013 19:02:03 Dec 2013 19:01:03 Dec 2013 19:00:03 Dec 2013 18:59:03 Dec 2013 18:58:03 Dec 2013 18:57:03 Dec 2013 18:56:03 Dec 2013 18:55:03 Dec 2013 18:54:03 Dec 2013 18:53:03 Dec 2013 18:52:03 Dec 2013 18:51:03 Dec 2013 18:50:03 Dec 2013 18:49:03 Dec 2013 18:48:03 Dec 2013 18:47:03 Dec 2013 18:46:03 Dec 2013 18:45:03 Dec 2013 18:44:03 Dec 2013 18:43:03 Dec 2013 18:42:03 Dec 2013 18:41:03 Dec 2013 18:40 -N./Log/Mc/Mconsole.Log Tail -1

Exporting the User Audit Log

When an MC user makes changes on Management Console, whether to an MC-managed database or to the MC itself, their action generates a log entry that contains data you can export to a file.

If you perform an MC factory reset (restore MC to its pre-configured state), you automatically have the opportunity to export audit records before the reset occurs.

To Manually Export MC User Activity

1. From the MC Home page, click **Diagnostics** and then click **Audit Log**.
2. On the Audit log viewer page, click **Export** and save the file to a location on the server.

To see what types of user operations the audit logger records, see [Monitoring MC User Activity Using Audit Log](#).

Restarting MC

You might need to restart the MC web/application server for a number of reasons, such as after you change port assignments, use the MC interface to import a new SSL certificate, or if the MC interface or Vertica-related tasks become unresponsive.

Restarting MC requires [ADMIN Role \(mc\)](#) or [SUPER Role \(mc\)](#) privileges.

How to Restart MC through the MC Interface (Using Your Browser)

1. Open a web browser and [connect to MC](#) as an administrator.
2. On MC's Home page, click **Diagnostics**.
3. Click **Restart Console** and then click OK to continue or Cancel to return to the Diagnostics page..

The MC process shuts down for a few seconds and automatically restarts. After the process completes, you are directed back to the sign-in page.

How to Restart MC at the Command Line

If you are unable to connect to MC through a web browser for any reason, such as if the MC interface or Vertica-related tasks become unresponsive, you can run the `vertica-consoled` script with `start`, `stop`, or `restart` arguments.

Follow these steps to start, stop, or restart MC.

1. As root, open a terminal window on the server on which MC is installed.
2. Run the `vertica-consoled` script:

```
# /etc/init.d/vertica-consoled { stop | start | restart }
```

For versions CentOS 7 and above, run:

```
# systemctl { stop | start | restart } vertica-consoled
```

Important: The `systemctl` function requires you to both start and stop services explicitly. If you kill or stop the `vertica-consoled` process without using `systemctl stop`, you cannot start the MC process again with the original `systemctl start` command. Instead, you must run `systemctl stop vertica-consoled` before running `systemctl start vertica-consoled`.

<code>stop</code>	Stops the MC application/web server.
<code>start</code>	Starts the MC application/web server. Caution: Use <code>start</code> only if you are certain MC is not already running. As a best practice, stop MC before you issue the <code>start</code> command.
<code>restart</code>	Restarts the MC application/web server. This process will report that the stop didn't work if MC is not already running.

How to Restart MC on an AMI

You can use the following steps to restart an MC AMI instance.

1. SSH into the MC host as user `dbadmin`:

```
$ ssh -i example.pem dbadmin@52.xx.xx.xx
```

2. Run the `vertica-consoled` script using `sudo`:

```
# sudo /etc/init.d/vertica-consoled { stop | start | restart }
```

Starting over

If you need to return MC to its original state (a "factory reset"), see [Resetting MC to Pre-Configured State](#).

Resetting MC to Pre-Configured State

If you decide to reset MC to its original, preconfigured state, you can do so on the **Diagnostics** page by clicking **Factory Reset**.

Tip: Consider trying one of the options described in [Restarting MC](#) first.

A factory reset removes all metadata (about a week's worth of database monitoring/configuration information and MC users) from storage and forces you to reconfigure MC again, as described in [Configuring MC](#) in *Installing Vertica*.

After you click **Factory Reset**, you have the chance to export audit records to a file by clicking **Yes**. If you click **No** (do not export audit records), the process begins. There is no undo.

Keep the following in mind concerning user accounts and the MC.

- When you first configure MC, during the configuration process you create an MC superuser (a Linux account). Issuing a **Factory Reset** on the MC does not create a new MC superuser, nor does it delete the existing MC superuser. When initializing after a **Factory Reset**, you must logon using the original MC superuser account.
- Note that, once MC is configured, you can add users that are specific to MC. Users created through the MC interface are MC specific. When you subsequently change a password through the MC, you only change the password for the specific MC user. Passwords external to MC (i.e., system Linux users and Vertica database passwords) remain unchanged.

For information on MC users, refer to the sections, [Creating an MC User](#) and [MC configuration privileges](#).

Avoiding MC Self-Signed Certificate Expiration

When you [connect to MC](#) through a client browser, Vertica assigns each HTTPS request a self-signed certificate, which includes a timestamp. To increase security and protect against password replay attacks, the timestamp is valid for several seconds only, after which it expires.

To avoid being blocked out of MC, synchronize time on the hosts in your Vertica cluster, and on the MC host if it resides on a dedicated server. To recover from loss or lack of synchronization, resync system time and the Network Time Protocol. See [Set Up Time Synchronization](#) in *Installing Vertica*.

Running Queries in Management Console

You can use the Query Runner to run SQL queries on your database through Management Console (MC). After executing a query, you can also get the query plan and profile information for the query on this page.

To reach the Query Runner, select your database from the Home page or the Databases and Clusters page to view your database's Overview page. Select Query Execution at the bottom of the Overview page.

Query History

Filter previous queries

```
1 SELECT sales_quantity, sales_dollar_amount, transaction_type, cc_name
2 FROM online_sales.online_sales_fact
3 INNER JOIN online_sales.call_center_dimension
4 ON (online_sales.online_sales_fact.call_center_key
5     = online_sales.call_center_dimension.call_center_key
6     AND sale_date_key = 156)
7 ORDER BY sales_dollar_amount DESC;
8 SELECT order_number, date_ordered
9 FROM store.store_orders_fact orders
10 WHERE orders.store_key IN (
11     SELECT store_key
12     FROM store.store_dimension
13     WHERE store_state = 'MA')
14     AND orders.vendor_key NOT IN (
15     SELECT vendor_key
16     FROM public.vendor_dimension
17     WHERE vendor_state = 'MA')
18     AND date_ordered < '2012-03-01';
19 SELECT store_key, order_number, date_ordered
```

Execute Queries

SELECT sales_qu SELECT order_nu SELECT store_ke

Overview Activity Manage Design Load **Query Execution** Query Plan License Settings

+

To familiarize yourself with how queries work in Vertica, you can refer to the [Queries](#) section of the documentation, as well as the [SQL Reference Manual](#).

Limitations

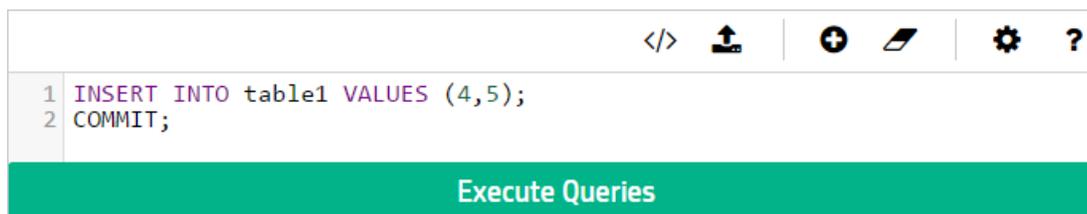

You cannot execute COPY LOCAL statements using the Query Runner. To do so, use the vsq client installed on the server. See [Using vsq](#). (To use MC to import data from Amazon S3

storage to your Vertica database, see [Loading Data Using MC.](#))

Manually commit any transactions (INSERT and COPY statements) you perform by adding the COMMIT statement in the text box after the transaction statements. If you do not do so, the transaction rolls back.

In the following example, to insert values into table1, include a COMMIT statement in the text box and execute the two statements together:

```
INSERT INTO table1 VALUES (1,2);  
COMMIT;
```

Format

To input a series of queries, delimit them with a semicolon (;).

To automatically format the SQL text you have input, click the Format icon (</>).

Privileges

It is important when running queries in MC that the database administrator has correctly set up MC user privileges. The administrator must map all MC user profiles to their corresponding database user.

The Query Runner only permits MC users to perform actions that their corresponding Vertica database roles allow.

To set up user mappings, go to Home > MC Settings > User Management.

For more about how mapping MC user profiles to database users works, see [Granting Database Access to MC Users](#). For information about database-level users and privileges, see the [Managing Users and Privileges](#) section of the documentation.

Execute a Query

The Query Runner provides several ways to input a query to run:

- **Input text.** Enter the text for a query or series of queries into the text box.
- **Import a SQL script.** Click the Upload icon () to the top right of the text box to upload a SQL script (plain text file, typically with an extension of .sql). The queries from that file appears in the text box.
- **Enter a previous query from the Query History tab.** The Query History tab, on the left side of the page, displays the last 100 queries you have executed using the Query Runner on your current device and browser. Click any previous query in this tab to enter that query into the text box.

Hover over a query in the Query History tab to view all the query text. To clear queries from your history, hover over an individual query and click **x**, or click **Clear all** at the top of the tab. Click the star to the left of any query to favorite it, so it won't be cleared when you click **Clear all**.

Click **Execute Query** to run the queries you have input.

You can also execute only a portion of the text entered into the text box, as long as the selected text is a valid query. To do so, select that portion of the text. The **Execute selected text as query** button then appears below the text box.

For example, you might execute only a part of the entered text if you have uploaded a SQL script that containing multiple queries, but you decide to run only one of those queries.

To customize your execution settings, click the Settings icon () at the top right of the text box:

- **Row Limit:** Set the maximum number of rows to return. By default, the limit is 10000 rows.
- **Search Path:** Specify the schema to query.

```
1 SELECT sales_quantity, sales_dollar_amount, transaction_type, cc_name
2 FROM online_sales.online_sales_fact
3 INNER JOIN online_sales.call_center_dimension
4 ON (online_sales.online_sales_fact.call_center_key
5     = online_sales.call_center_dimension.call_center_key
6     AND sale_date_key = 156)
7 ORDER BY sales_dollar_amount DESC;
8 SELECT order_number, date_ordered
9 FROM store.store_orders_fact orders
10 WHERE orders.store_key IN (
11     SELECT store_key
12     FROM store.store_dimension
13     WHERE store_state = 'MA')
14     AND orders.vendor_key NOT IN (
15     SELECT vendor_key
16     FROM public.vendor_dimension
17     WHERE vendor_state = 'MA')
18     AND date_ordered < '2012-03-01';
19 SELECT store_key, order_number, date_ordered
```

Execute Queries Execute selected text as query

Get Query Results

The Query Runner returns results in a table format. If you ran multiple queries simultaneously, the results window displays a tab for each set of results. View the number of rows returned and the query execution time at the bottom of the results window.

If your result returns many columns, you can click **Auto-resize all columns** in the top right of the results window for a better fit, or click and drag column borders to manually resize individual columns.

Sort results by clicking on a column name, or use the search bar to narrow down results.

Execute Queries

SELECT fat_cont SELECT sales_qu ↑ ↓

Query Results Query Plan Query Profile Export Data Auto-Resize all columns Search query results

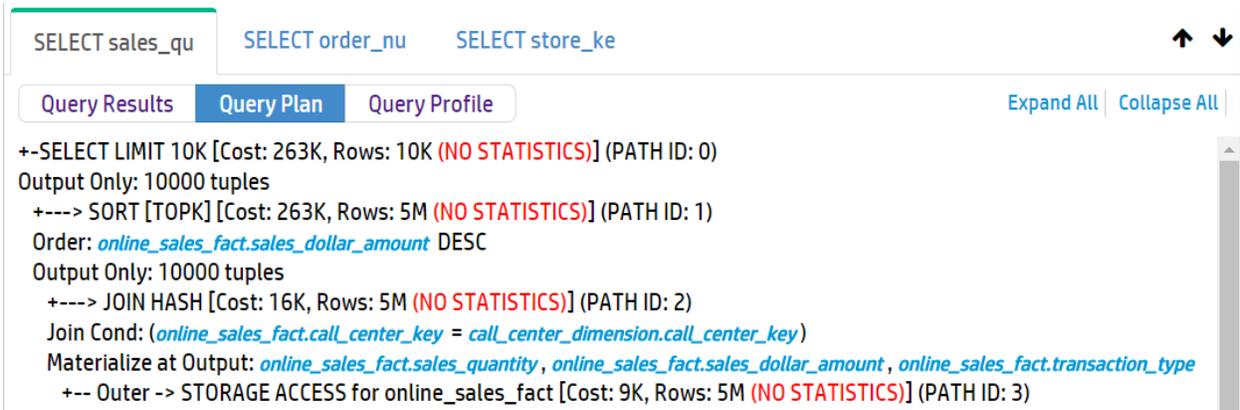

sales_quantity	sales_dollar_amount	transaction_type	cc_name
8	589	purchase	California
7	589	purchase	Central Midwest
8	589	purchase	South Midwest
1	587	purchase	New England
1	586	purchase	Other

2514 rows | Execution time: 0.176s

Query Plans and Profiles

Each query result also displays an option to retrieve the plan or profile for that query.

After retrieving a plan or profile, you can expand or collapse the results view to see different levels of detail. To view metadata for a projection or a column, click the object name in the path output. A pop-up window displays the metadata, if it is available.

The screenshot shows the Vertica Query Runner interface. At the top, there are three tabs: "SELECT sales_qu", "SELECT order_nu", and "SELECT store_ke". Below the tabs are three buttons: "Query Results", "Query Plan", and "Query Profile". To the right of these buttons are "Expand All" and "Collapse All" links. The main content area displays the following query plan:

```
+--SELECT LIMIT 10K [Cost: 263K, Rows: 10K (NO STATISTICS)] (PATH ID: 0)
Output Only: 10000 tuples
+----> SORT [TOPK] [Cost: 263K, Rows: 5M (NO STATISTICS)] (PATH ID: 1)
Order: online\_sales\_fact.sales\_dollar\_amount DESC
Output Only: 10000 tuples
+----> JOIN HASH [Cost: 16K, Rows: 5M (NO STATISTICS)] (PATH ID: 2)
Join Cond: (online\_sales\_fact.call\_center\_key = call\_center\_dimension.call\_center\_key)
Materialize at Output: online\_sales\_fact.sales\_quantity, online\_sales\_fact.sales\_dollar\_amount, online\_sales\_fact.transaction\_type
+-- Outer -> STORAGE ACCESS for online\_sales\_fact [Cost: 9K, Rows: 5M (NO STATISTICS)] (PATH ID: 3)
```

Note that the Query Runner does not automatically provide query profiles for queries that run for less than 1 second. To do so, prepend the word PROFILE to the query and run it.

You can also profile your query on the **Query Plan** page. The Query Plan page provides more details about both plan and profile results, including a query plan drilldown by node, a tree path view, and a profile analysis.

Keyboard Shortcuts

The Query Runner provides the following keyboard shortcuts:

- **?**: Press the question mark to display or dismiss a list of the available keyboard shortcuts. (You can also click the question mark icon at the top right of the text box to view this list.)
- **alt + ↑**: Press alt + up arrow to decrease the height of the text box.
- **alt + ↓**: Press alt + down arrow to increase the height of the text box.
- **ctrl + enter**: Press ctrl + enter to run the query.
- **ctrl + shift + enter**: Press ctrl + shift + enter to run selected text.

Managing Queries in MC

Management Console can show you a query plan in easy-to-read format, where you can review the optimizer's strategy for executing a specific query. You can view a query plan in either of two ways:

- View the plan of an active query.
- View the plan for any query that you manually specify.

Access the Plan of an Active Query

1. At the bottom of the Management Console window, click the **Activity** tab.
2. From the list at the top of the page, select **Queries**.
3. On the activity graph, click the data point that corresponds to the query you want to view.
4. In the View Plan column, click **Explain** next to the command for which you want to view the query plan. Only certain queries use query plans—for example, SELECT, INSERT, DELETE, and UPDATE.
5. In the Explain Plan window, click **Explain**. Vertica generates the query plan.
6. (Optional) View the output in Path Information view or Tree Path view. To do so, click the respective view buttons on the left of the output box.

Access the Plan for a Specific Query

1. Locate the query for which you want to see the query plan in either of the following ways:
 - **Queries Not Running** — In the Explain window, type or paste the query text into the text box.
 - **Queries Currently Running** — In the Find a Query By ID input window, perform one of the following actions:

- Enter the query statement and transaction ID.
- Click the **Browse Running Queries** link.

Caution: Entering the word EXPLAIN before the query results in a syntax error.

2. Click **Explain**. Verticagenerates the plan.

If the query is invalid, Management Console highlights in red the parts of your query that might have caused a syntax error.

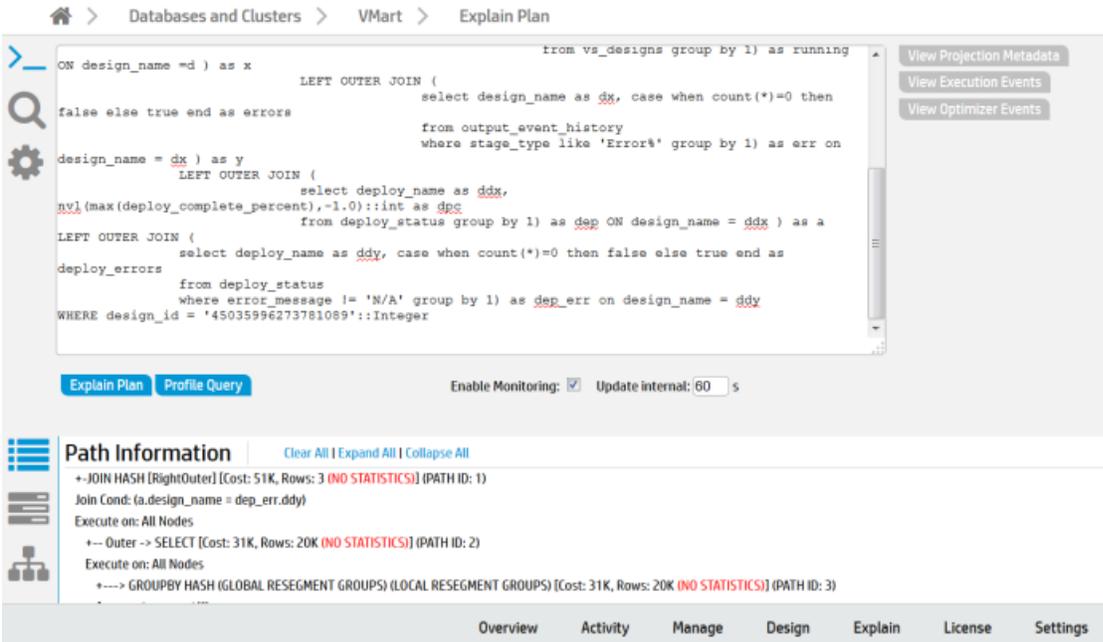

3. (Optional) View the output in Path Information view or Tree Path view. To do so, click the respective view buttons on the left of the output box.

Accessing Query Plans in Management Console

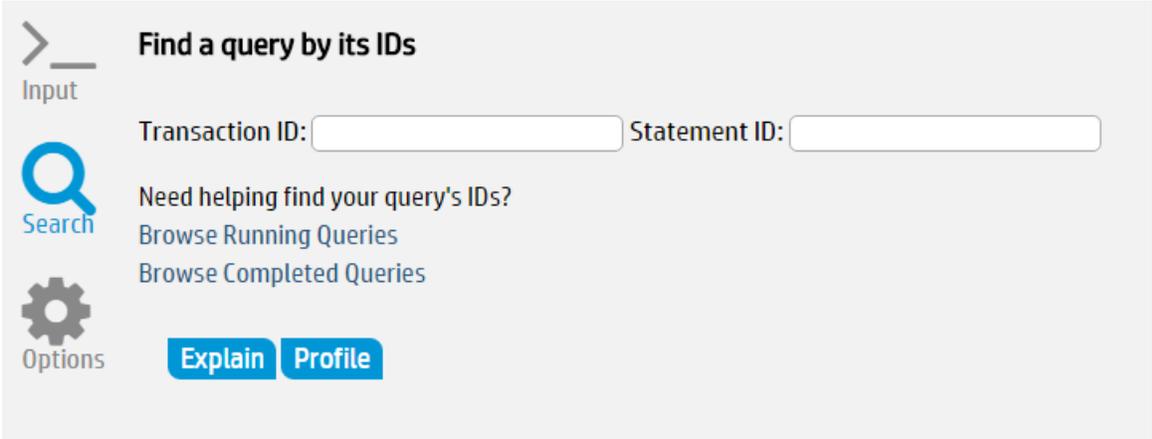

You can access query plans in Management Console in two ways:

- In the Detail page for query-related charts on the database's Activity page, click **Explain** next to a query to view a plan for that query.
- Enter a query manually on the Explain page and click **Explain Plan**.

In both cases, the following window opens:

You can also enter the transaction ID and statement ID or browse running or completed queries in the Find a Query input window:

In the output window, you can perform the following tasks related to the query you entered:

- [Expand and collapse query paths.](#)
- [Clearing query data.](#)
- [View projection and column metadata.](#)
- [Use different query plan views.](#)

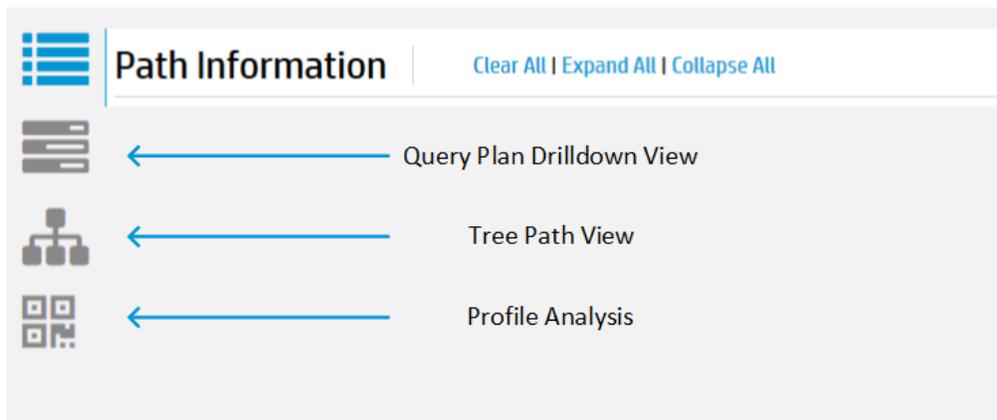

Query Plan View Options

Vertica Management Console provides two views for displaying query plans:

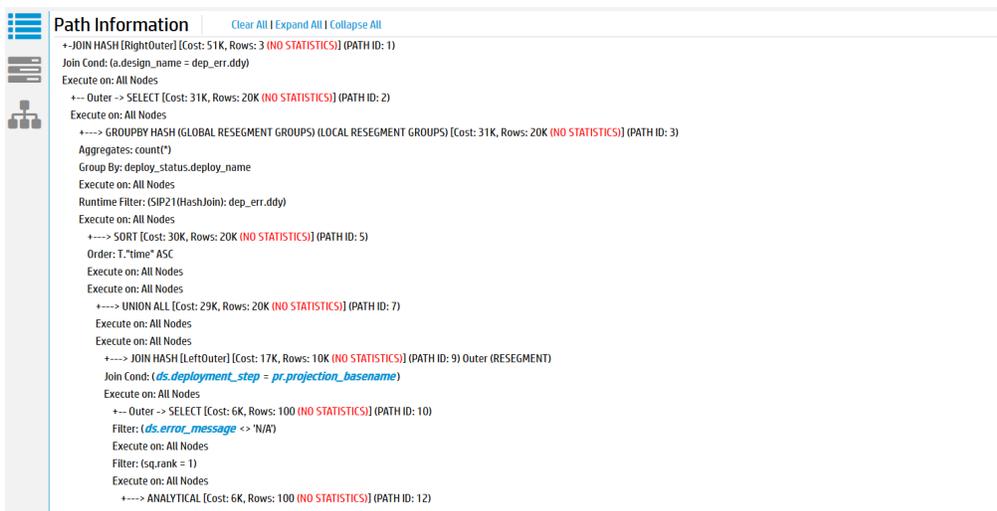

- Path Information
- Tree Path

Note: Query Plan Drilldown and Profile Analysis output views are only available when you run [PROFILE](#).

You can change the query plan view using the icons on the bottom portion of the **Explain** page.

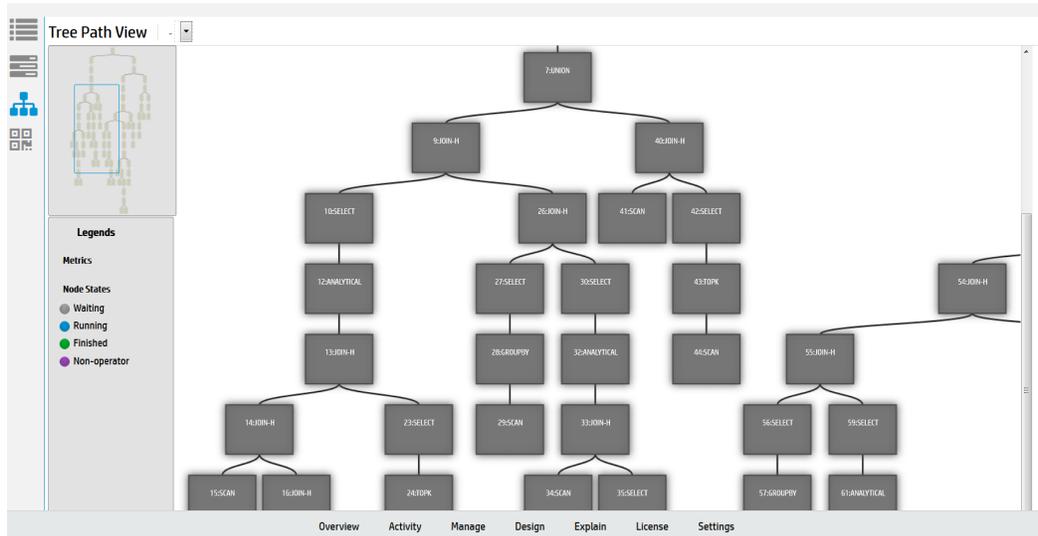

The **Path Information** view displays the query plan path. You can expand or collapse the view to see different levels of detail. To view metadata for a projection or a column, click the object name in the path output. A pop-up window displays the metadata, if it is available.

The

The **Tree Path** view details the query plan in the form of a tree. When you run EXPLAIN, the tree view does not contain any metrics because the query has not yet executed.

Expanding and Collapsing Query Paths

The EXPLAIN window initially displays the full query plan as generated by the [EXPLAIN](#) command. Query plans can be lengthy, so you might want to modify the display so you can focus only on areas of interest:

- Collapse All collapses all query paths, and displays only a summary of each path.
- Expand All expands all query paths.
- Click the first line of a path to display details for that path. To collapse that path, click its first line again.

For details about EXPLAIN command output, see [EXPLAIN-Generated Query Plans](#).

Clearing Query Data

After you finish reviewing the current query data, click Clear All to clear the query text and data. Alternatively, to display information about another query, enter the query text and click

Explain or Profile.

Viewing Projection and Column Metadata

In the Management Console EXPLAIN window, when query paths are expanded in the Path Information view, Projection lines contain a projection name and Materialize lines contain one or more column names.

To view metadata for a projection or a column, click the object name. A pop-up window displays the metadata. The following image on the left shows example projection metadata and the image on the right shows example column metadata.

Note: Most system tables do not have metadata.

Details [x]	
name	online_sales_fac
id	450359962765!
owner	uidbadmin
schema	online_sales
node	null
anchor_table	online_sales_fac
isprejoin	false
create_type	DESIGNER
verified_fault_tolerance	0
isuptodate	true
hasstatistics	true
issegmented	true
issuperprojection	true

Details [x]	
name	cc_name
max	Southwest
position	3
min	California
ndv	11
sort_order	4

When you are done viewing the metadata, close the pop-up window.

Creating a Database Design in Management Console

[Database Designer](#) creates a design that provides excellent performance for ad-hoc queries and specific queries while using disk space efficiently. Database Designer analyzes the logical schema definition, sample data, and sample queries, and creates a physical schema that you can deploy.

For more about how Database Designer works, see the [Creating a Database Design](#) section of the documentation, and [About Database Designer](#).

To use Management Console to create an optimized design for your database, you must be a DBADMIN user or have been assigned the DBDUSER role.

Management Console provides two ways to create a design:

- **Wizard**—This option walks you through the process of configuring a new design. Click **Back** and **Next** to navigate through the Wizard steps, or **Cancel** to cancel creating a new design.

To learn how to use the Wizard to create a design, see [Using the Wizard to Create a Design](#).

- **Manual**—This option creates and saves a design with the default parameters.

To learn how to create a design manually, see [Creating a Design Manually](#).

Tip: If you have many design tables that you want Database Designer to consider, it might be easier to use the Wizard to create your design. In the Wizard, you can submit all the tables in a schema at once; creating a design manually requires that you submit the design tables one at a time.

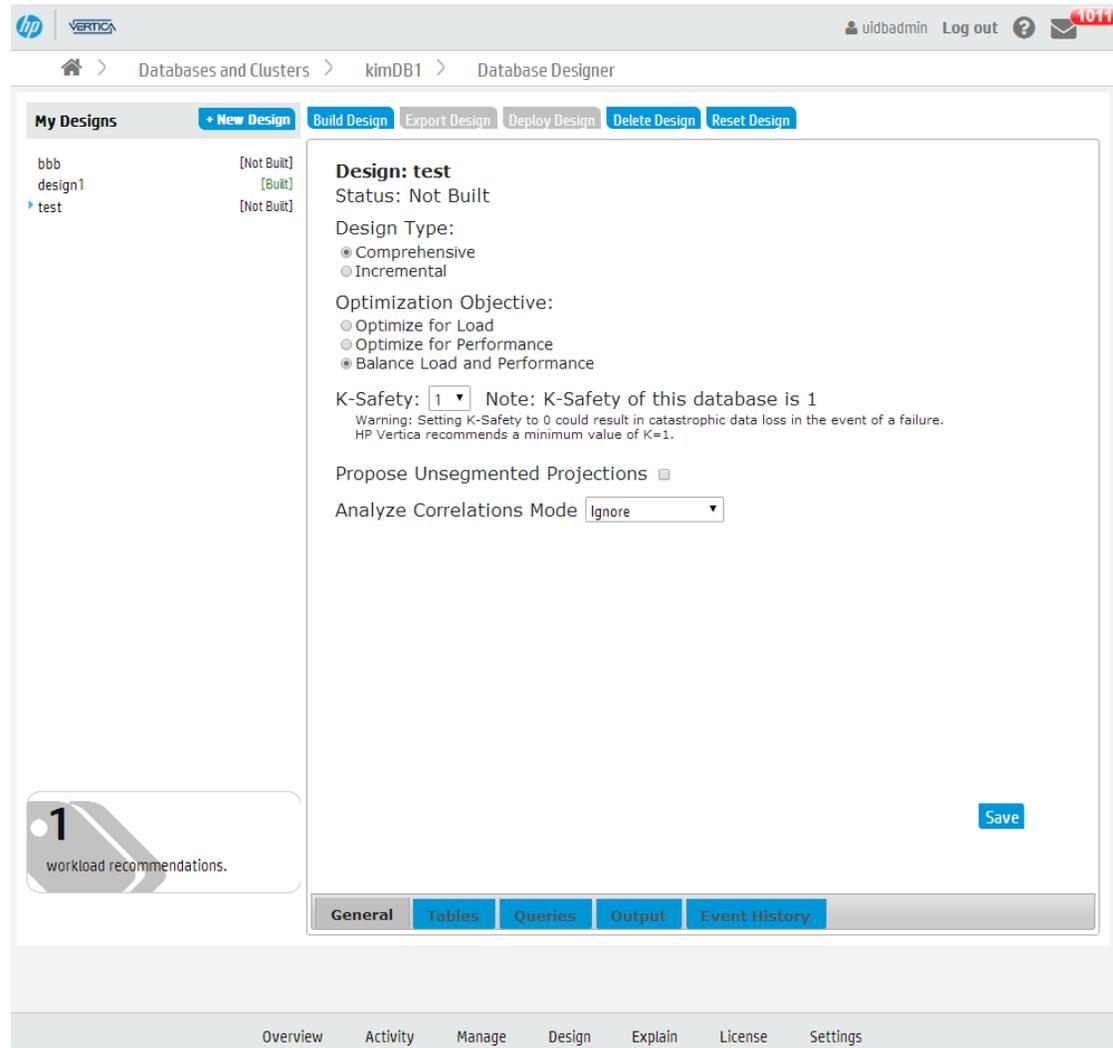

Using the Wizard to Create a Design

Take these steps to create a design using the Management Console's Wizard:

1. On your database's dashboard, click the **Design** tab at the bottom of the page to navigate to the Database Designer page.

The left side of the Database Designer page lists the database designs you own, with the most recent design you worked on highlighted. That pane also lists the current status of the design. Details about the most recent design appear in the main pane.

The main pane contains details about the selected design.

2. To create a new design, click **New Design**.
3. Enter a name for your design, and click **Wizard**.

For more information, see [Design Name](#).

4. Navigate through the Wizard using the **Back** and **Next** buttons.

5. To build the design immediately after exiting the Wizard, on the **Execution Options** window, select **Auto-build**.

Important: Micro Focus does not recommend that you auto-deploy the design from the Wizard. There may be a delay in adding the queries to the design, so if the design is deployed but the queries have not yet loaded, deployment may fail. If this happens, reset the design, check the **Queries** tab to make sure the queries have been loaded, and deploy the design.

6. When you have entered all the information, the Wizard displays a summary of your choices. Click **Submit Design** to build your design.

Summary

Review these design choices. Click Submit Design when you finish configuring your design.

Design Name: VMart_design
Design Type: comprehensive
Optimization Objective: balanced
Schemas: public, store, online_sales
K-Safety: 1
Analyze Correlation Mode: Ignore
Propose Unsegmented Projections: true
Query File to Upload:
User Query Repository: true
Execution Options - Analyze Statistics: true
Execution Options - Auto-build: true
Execution Options - Auto-deploy: false

[Back](#) [Submit Design](#) [Cancel](#)

See Also

- [About Database Designer](#)
- [Creating a Design Manually](#)

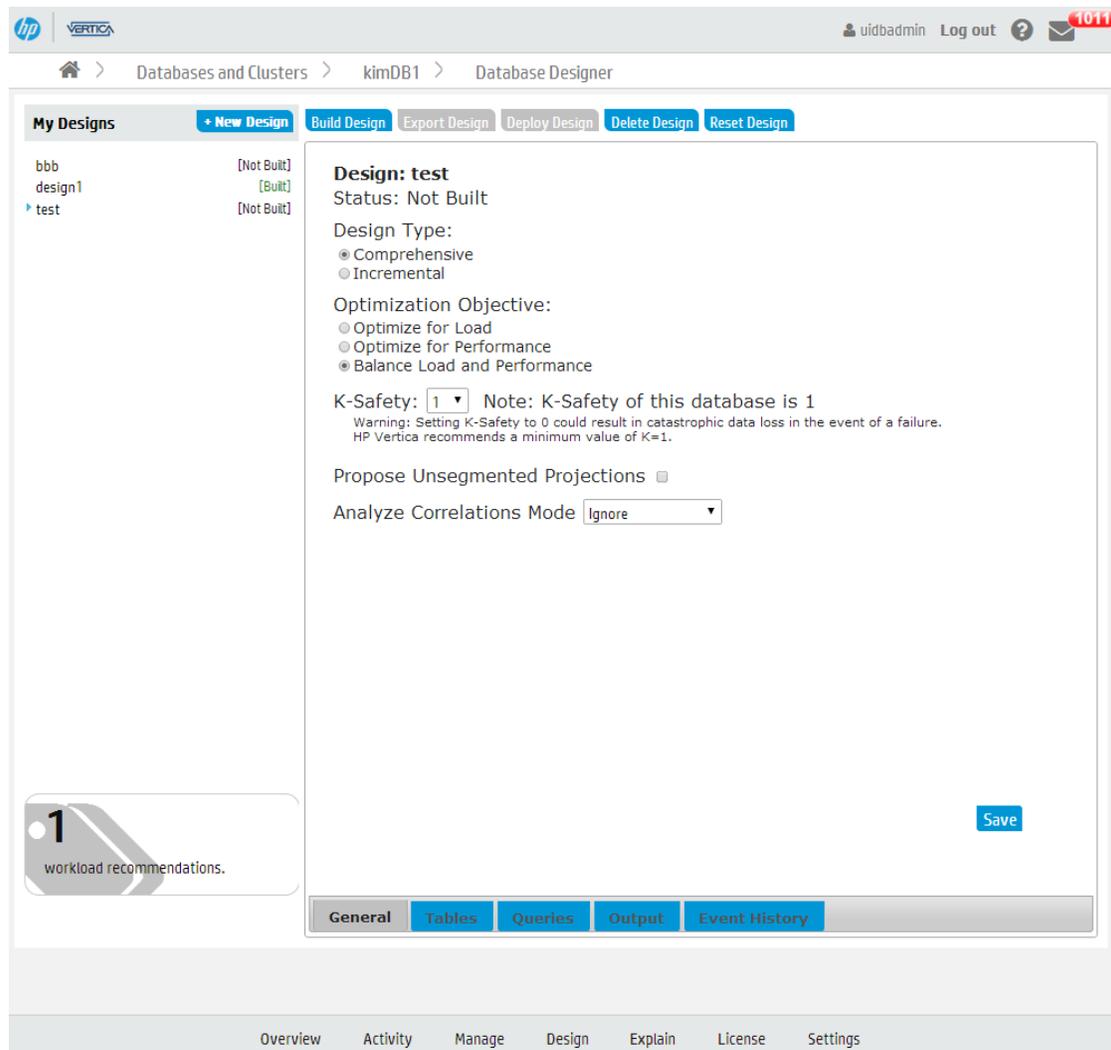

Creating a Design Manually

To create a design using Management Console and specify the configuration, take these steps.

1. On your database's dashboard, click the **Design** tab at the bottom of the page to navigate to the Database Designer page.

The left side of the Database Designer page lists the database designs you own, with the most recent design you worked on highlighted. That pane also lists the current status of the design. Details about the most recent design appear in the main pane.

The main pane contains details about the selected design.

2. To create a new design, click **New Design**.
3. Enter a name for your design and select **Manual**.

The main **Database Design** window opens, displaying the default design parameters. Vertica has created and saved a design with the name you specified, and assigned it the default parameters.

For more information, see [Design Name](#).

4. On the **General** window, modify the design type, optimization objectives, K-safety, Analyze Correlations Mode, and the setting that allows Database Designer to create unsegmented projections.

If you choose **Incremental**, the design automatically optimizes for the desired queries, and the K-safety defaults to the value of the cluster K-safety; you cannot change these values for an incremental design.

Analyze Correlations Mode determines if Database Designer analyzes and considers column correlations when creating the design. For more information, see [DESIGNER_SET_ANALYZE_CORRELATIONS_MODE](#).

5. Click the **Tables** tab. You must submit tables to your design.
6. To add tables of sample data to your design, click **Add Tables**. A list of available tables appears; select the tables you want and click **Save**. If you want to remove tables from your design, click the tables you want to remove, and click **Remove Selected**.

If a design table has been dropped from the database, a red circle with a white exclamation point appears next to the table name. Before you can build or deploy the design, you must remove any dropped tables from the design. To do this, select the dropped tables and click **Remove Selected**. You cannot build or deploy a design if any of the design tables have been dropped.

7. Click the **Queries** tab. To add queries to your design, do one of the following:
 - To add queries from the [QUERY_REQUESTS](#) system table, click **Query Repository**. In the Queries Repository dialog that appears, you can sort queries by most recent, most frequently executed, and longest running. Select the desired queries and click **Save**. All valid queries that you selected appear in the **Queries** window.
 - To add queries from a file, select **Upload**. All valid queries in the file that you select are added to the design and appear in the **Queries** window. (This option is only available for the [MC super administrator role](#).)

Database Designer checks the validity of the queries when you add the queries to the design and again when you build the design. If it finds invalid queries, it ignores them.

If you have a large number of queries, it may take time to load them. Make sure that all the queries you want Database Designer to consider when creating the design are listed in the **Queries** window.

8. Once you have specified all the parameters for your design, you should build the design. To do this, select your design and click **Build Design**.

9. Select **Analyze Statistics** if you want Database Designer to analyze the statistics before building the design.

For more information see [Statistics Analysis](#).

10. If you do not need to review the design before deploying it, select **Deploy Immediately**. Otherwise, leave that option unselected.
11. Click **Start**. On the left-hand pane, the status of your design displays as **Building** until it is complete.
12. To follow the progress of a build, click **Event History**. Status messages appear in this window and you can see the current phase of the build operation. The information in the Event History tab contains data from the `OUTPUT_EVENT_HISTORY` system table.
13. When the build completes, the left-hand pane displays **Built**. To view the deployment script, select your design and click **Output**.
14. After you deploy the design using Management Console, the deployment script is deleted. To keep a permanent copy of the deployment script, copy and paste the SQL commands from the **Output** window to a file.
15. Once you have reviewed your design and are ready to deploy it, select the design and click **Deploy Design**.
16. To follow the progress of the deployment, click **Event History**. Status messages appear in this window and you can see the current phase of the deployment operation.

In the Event History window, while the design is running, you can do one of the following:

- Click the blue button next to the design name to refresh the event history listing.
 - Click **Cancel Design Run** to cancel the design in progress.
 - Click **Force Delete Design** to cancel and delete the design in progress.
17. When the deployment completes, the left-hand pane displays **Deployment Completed**. To view the deployment script, select your design and click **Output**.

Your database is now optimized according to the parameters you set.

Getting Tuning Recommendations in MC

If queries perform sub-optimally, you can get tuning recommendations for them, as well as for hints about optimizing database objects, by using the Workload Analyzer (WLA).

WLA is a Vertica utility that analyzes system information in Vertica system tables. It then returns a set of tuning recommendations based on statistics, system and data collector events, and database/table/projection design. You can use these recommendations to tune query performance.

View WLA Recommendations

WLA recommendations are available through the database's **Overview** page.

1. On the right side of the Overview page in the Quick Stats bar, view the Workload Analyzer module. This module alerts you to the number of recommendations WLA has generated.

2. Click the number to view the WLA recommendations on the Database Designer page. The Workload Analyzer Results dialog displays tuning recommendations and the resource cost of running each command (Low, Medium, or High).

For additional information about tuning recommendations and cost see [Analyzing Workloads](#) in the Administrator's Guide and [ANALYZE_WORKLOAD](#) in the SQL Reference Manual.

The following image shows a list of WLA tuning recommendations for a database. In the output, WLA advises that you run the Database Designer on several tables and provides the cost estimate of running these operations.

Note that the cost of running Database Designer is high. When you see a high cost, you might want to run the recommended tuning action after hours.

Tuning recommendation	Cost
run database designer on table online_sales.call_center_dimension	HIGH
run database designer on table online_sales.online_page_dimension	HIGH
run database designer on table online_sales.online_sales_fact	HIGH
run database designer on table public.casey	HIGH
run database designer on table public.date_dimension	HIGH
run database designer on table public.employee_dimension	HIGH
run database designer on table public.helpful_button_stage	HIGH
run database designer on table public.inventory_fact	HIGH
run database designer on table public.my_table	HIGH
run database designer on table public.num_test	HIGH
run database designer on table public.num_test2	HIGH
run database designer on table public.numeric_table	HIGH
run database designer on table public.product_dimension	HIGH
run database designer on table public.promotion_dimension	HIGH
run database designer on table public.sample_table	HIGH

MC displays fifteen recommendations per page and includes a message at bottom left, which lets you know where you are within the total number of recommendations; for example, "Showing *n-nn* of *nn* entries." Depending on the total number of recommendations, you can move forward and backward through them by clicking the arrows at bottom right.

Tip: You can force the WLA task to run immediately by clicking **Update Recommendations** over the Cost column.

Set and Disable WLA Events

On MC, WLA automatically begins monitoring data one minute after the MC process starts. WLA then runs once per day, or immediately after you import a database to MC. It continually gathers data in the background as long as the database is running. If you haven't created a database yet, or if the database is down, WLA does nothing until the database is back up.

By default, WLA runs each day at 2 AM. To optimize when WLA uses resources, you can set WLA to run at a different time for any or all databases that MC monitors. You can also set MC to never run WLA automatically.

1. On the Home page, click **MC Settings**.
2. Click the **Monitoring** tab.
3. Under the **Workload Analyzer Assistant** section of the Monitoring page, select your time zone.
4. Select the radio button for one of the options:
 - **All Databases:** Select a time from the list. WLA will run at that time on all databases that MC monitors.
 - **Specific Database at Specific Time:** Select a database and a time from the list. At the time you specify, WLA will run at that time on the database you selected.
 - **Do Not Run Workload Analyzer On Any Database:** MC will never run WLA automatically on any database it monitors.
5. Click **Apply** at the top right of the page.

For additional information about tuning recommendations and their triggering event, see [Understanding WLA Triggering Conditions](#).

Monitoring Using MC

Management Console gathers and retains history of important system activities about your MC-managed database cluster, such as performance and resource utilization. You can use MC charts to locate performance bottlenecks on a particular node, to identify potential improvements to Vertica configuration, and as a reference for what actions users have taken on the MC interface.

Note: MC directly queries Data Collector tables on the MC-monitored databases themselves. See [Management Console Architecture](#) in Vertica Concepts. For how to set up MC to query an alternative database for monitoring data, see [Extended Monitoring](#).

The following list describes some of the areas you can monitor and troubleshoot through the MC interface:

- Multiple database cluster states and key performance indicators that report on the cluster's overall health
- Information on individual cluster nodes specific to resources
- Database activity in relation to CPU/memory, networking, and disk I/O usage
- Query concurrency and internal/user sessions that report on important events in time
- Cluster-wide messages
- Database and agent log entries
- MC user activity (what users are doing while logged in to MC)
- Issues related to the MC process
- Error handling and feedback

About Chart Updates

MC charts update dynamically with text, color, and messages Management Console receives from the agents on the database cluster. This information can help you quickly resolve problems.

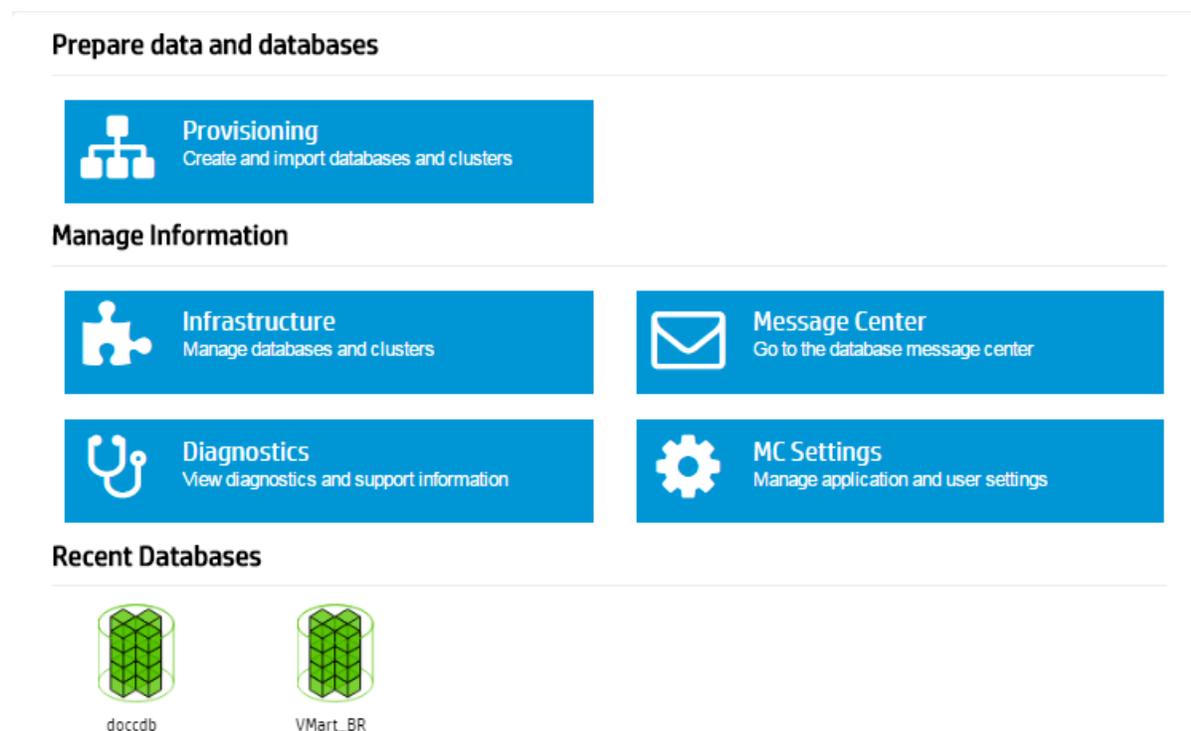

Each client session to MC uses a connection from `MaxClientSessions`, a database configuration parameter. This parameter determines the maximum number of sessions that

can run on a single database cluster node. Sometimes multiple MC users, mapped to the same database account, are concurrently monitoring the Overview and Activity pages. In such cases, graphs could be slow to update while MC waits for a connection from the pool.

Tip: You can increase the value for `MaxClientSessions` on an MC-monitored database to account for extra sessions. See [Managing Sessions](#) for details.

Viewing the Home Page

After you [connect to MC](#) and sign in, the Home page displays. This page is the entry point to all Vertica database clusters and users managed by MC. Information on this page, as well as throughout the MC interface, will appear or be hidden, based on the permissions ([access levels](#)) of the user who is logged in. The following image is what an MC super administrator sees.

Tasks

Operations you can perform in Management Console are grouped into the following task-based areas:

- **Provision Databases.** Create and import databases, and connect this includes creating new empty databases and importing existing database clusters into Management Console. You can also set up an Ambari connection to import a Vertica cluster that resides in a Hadoop environment. See [Managing Database Clusters](#).
- **Existing Infrastructure.** View all the clusters and databases monitored by MC, stop and remove databases, and view details about databases and clusters. See [Managing Database Clusters](#).
- **MC Settings.** Configure MC and user settings, as well as use the MC interface to install Vertica on a cluster of hosts. See [Managing MC Settings](#).
- **Message Center.** View, sort, and search database messages and optionally export messages to a file. See [Monitoring Database Messages in MC](#).
- **Diagnostics.** View and resolve MC-related issues, as well as browse Vertica agent and audit logs. See [Troubleshooting with MC Diagnostics](#).

Recent Databases

The **Recent Databases** section displays all databases that you created on or imported into the MC interface. You can install one or more databases, on the same cluster or on different clusters, but you can have only one database running on a single cluster at a time. UP databases appear in green and DOWN databases are red. An empty space under Recent Databases means that you have not yet created or imported a database into the MC interface, or do not have permission to view any databases managed by MC.

Monitoring Same-Name Databases on MC

If you are monitoring two databases with identical names on different clusters, you can determine which database is associated with which cluster by clicking the database icon on MC's Databases and Clusters page to view its dialog box. Information in the dialog displays the cluster on which the selected database is associated.

Viewing the Overview Page

The Overview page displays a dynamic dashboard view of your database.

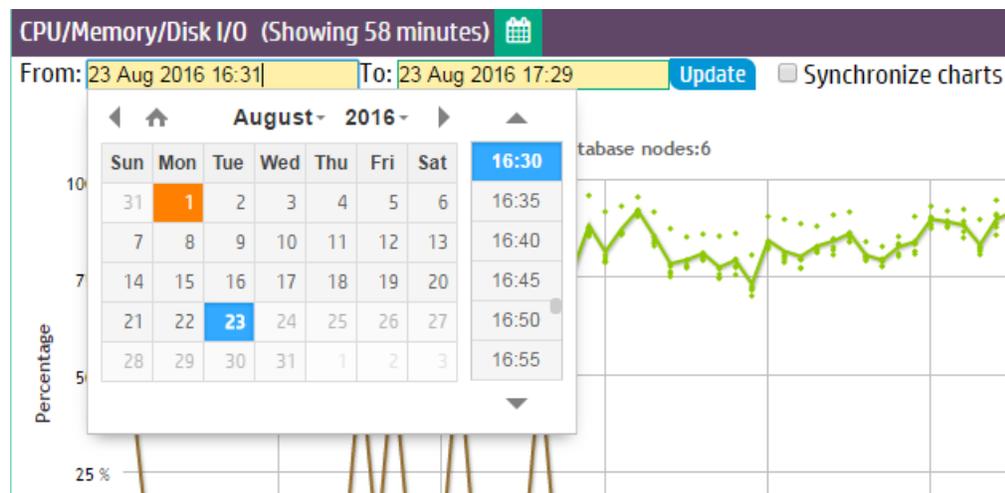

The page provides three tabs: Status Summary, System Health, and Query Synopsis. Each tab contains charts and filters displaying information about your cluster. The QuickStats widgets on the right of the page display alerts and statistics about the state of your cluster.

Information on this page updates every minute, but you can postpone updates by deselecting Auto Refresh Charts in the toolbar.

Chart Viewing Options

You can specify time frames for some charts, which display a calendar icon in their title bars. Click the calendar icon to specify the time frame for that module.

On the Status Summary tab, you can select **Synchronize charts** to simultaneously apply the specified time frame to all charts on that tab.

If you have enabled extended monitoring on your database, MC can display longer ranges of data in certain charts. See [Extended Monitoring](#). If a chart is using extended monitoring data, the rocket ship icon appears in the title bar:

You can expand some charts to view them in larger windows. Click the expand icon in the title bar to do so:

Quick Stats

The Quick Stats sidebar on the right of the page provides instant alerts and information about your cluster's status.

Database Nodes Health

	0		0		0		6	Total: 6 Version: 8.0.0-0

Unread Messages (This Week)

	6	Total Unread Messages: 411
Unread High Priority		

- **Database Nodes Health** displays which nodes are down, critical, recovering, or up. Critical and recovering nodes are included in the total nodes considered "up" by the database. Click a node value to open the Manage page.
- **Running and Queued Queries** displays current queries in the database. Click the query values to open the Query Monitoring charts.
- **Projections** displays the number of total projections, unsegmented projections, and unsafe projections for the database schema with the most projections. Click a value to open the Table Treemap chart.
- **Disk Space Usage** alerts you to the number of nodes that are low on disk space. Click the value to go to the Manage page. On the Manage page, the Storage Used KPI View is displayed.
- **Workload Analyzer (WLA)** analyzes system information retained in [SQL system tables](#) and provides tuning recommendations, along with the cost (low, medium, or high) of running the command. See [Analyzing Workloads](#) for more information.
- **I/O Wait Notices** displays the number of nodes that, in the last hour, have recorded Disk I/O waits and Network I/O waits exceeding the wait threshold (1 second for Disk and 0 seconds for Network).
- **License Consumption** displays the number of licenses your database uses, and the percentage of your Vertica Community Edition or Premium Edition license being used.
- **Unread Messages** display the number of unread messages and alerts for the database. This count differs from the number of total messages across all your databases. Click the value to open the Message Center.

Status Summary

The Status Summary tab displays four modules that provide a general overview of the status of your cluster:

- The **CPU/Memory/Disk I/O Usage** module shows cluster resource usage. The chart displays the number of nodes in the database cluster and plots average and per-node percentages for CPU, memory, and disk I/O usage. Select a resource type from the legend to remove or add it from the chart display.

Click a data point (which represents a node) to open the Manage page. See [Monitoring Cluster CPU/Memory](#).

- The **General Pool Activity** module displays GENERAL pool activity. The chart displays average query queue times, average GENERAL pool free memory, and resource rejections. Use this chart to see how much free memory there is in GENERAL pool, or if there have been high queue times. Click the expand icon in the title bar to open the chart in a bigger window.

Click a data point to open the [Resource Pools Monitoring](#) chart. See [Managing Workloads](#).

- The **Thresholds Notifications** module displays alerts generated when a threshold has been exceeded in the database. Notifications are categorized by System Health and Performance.

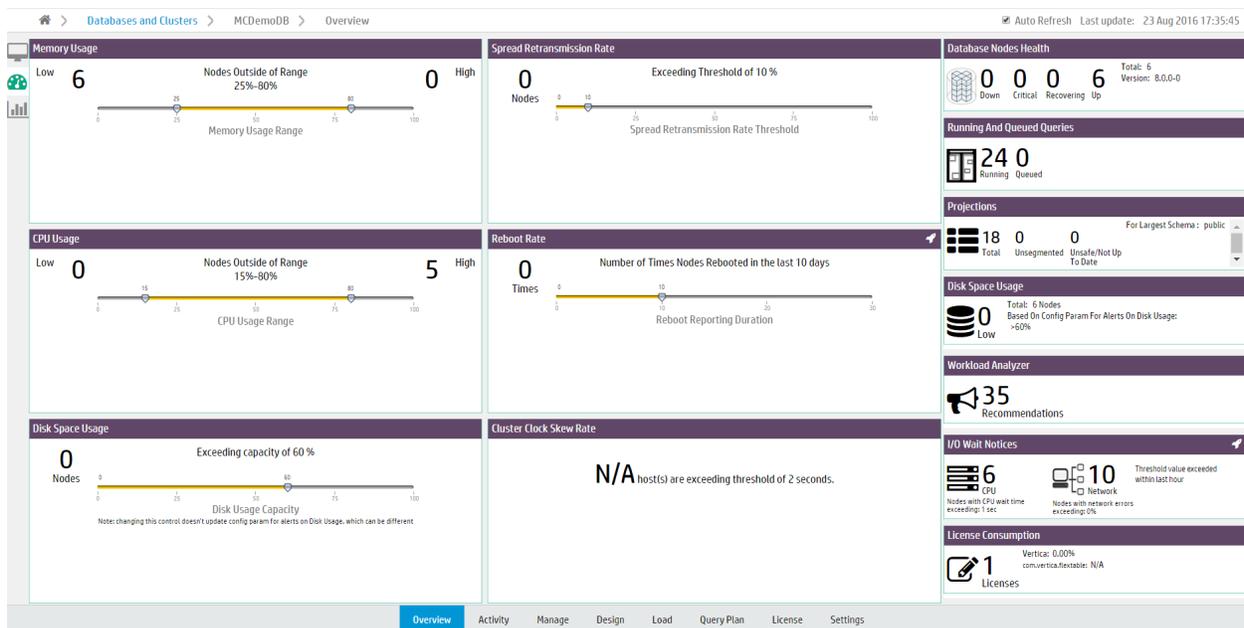

In the module, you can acknowledge an alert (which marks it as read) or click the X to stop monitoring that threshold (which stops you receiving similar alerts in the future).

Customize thresholds and alert priorities for these notifications in the Thresholds tab of the database Settings page. See [Customizing Threshold-Based Notifications](#).

- The **Queries** module displays query statistics. The first pie chart displays running and queued queries in the last 24 hours. The second chart displays completed and failed queries for the time frame you specify.

Click a query count number above the chart to open the Query Monitoring chart. See [Monitoring Running Queries](#).

System Health

The System Health tab provides a summary of your system resource usage and node information, with filters that allow you to view resource usage within the ranges you specify.

Note: Adjusting the filters on the System Health tab does not affect any database or MC settings.

- The **Memory Usage** filter displays the number of nodes with high and low memory usage. Move the sliders to adjust the memory usage range filter.

For example, if you specify a range of 25% to 75% memory usage, the filter displays how many nodes are using less than 25% of memory (Low) and how many are using more than 75% (High). Hover your cursor over the Low and High values to see lists of what nodes fall, respectively, below or above the memory usage range you specified.

Click a node value to go to the Manage page, which displays the Memory Utilization KPI View.

- The **Spread Retransmission Rate** filter displays the number of nodes with high spread retransmission rates. When a node's retransmission rate is too high, it is not communicating properly with other nodes. Move the slider to adjust the retransmission rate filter.

Hover your cursor over the Nodes value to see a list of what nodes exceeded the spread retransmission rate you specified. Click the node value to view spread retransmit rate alerts in the Message Center.

- The **CPU Usage** chart displays the number of nodes with high and low CPU usage. Move the sliders to adjust the CPU usage range filter. Hover your cursor over the Low and High values to see lists of what nodes are below or above range you specified.

Click a node value to go to the Manage page, which displays the CPU Utilization KPI View.

- The **Reboot Rate** filter displays the number of times nodes in the cluster have rebooted within the specified time frame. Use this filter to discover if nodes have gone down recently, or if there have been an unusual number of reboots. Move the slider to adjust the number of days. Hover over the Times value to see a list of the nodes that have rebooted and the times at which they did so.
- The **Disk Space Usage** filter displays the number of nodes with high disk space usage. Move the slider to adjust the disk usage filter. Hover your cursor over the Nodes value to see a list of what nodes exceed the acceptable range.

Click the nodes value to go to the Manage page, which displays the Storage Used KPI View.

- The **Cluster Clock Skew Rate** module displays the number of nodes that exceed a clock skew threshold. Nodes in a cluster whose clocks are not in sync can interfere with time-related database functions, the accuracy of database queries, and Management Console's monitoring of cluster activity.

Query Synopsis

The Query Synopsis page provides two modules that report system query activity and resource pool usage:

- The **Query Statistics** module displays four bar charts that provide an overview of running, queued queries, failed, and completed queries in the past 24 hours. Select one of the options at the top of the module to group the queries by **Resource Pools**, **Users**, or **Nodes**.

Click a bar on the chart to view details about those queries the [Query Monitoring](#) activity chart.

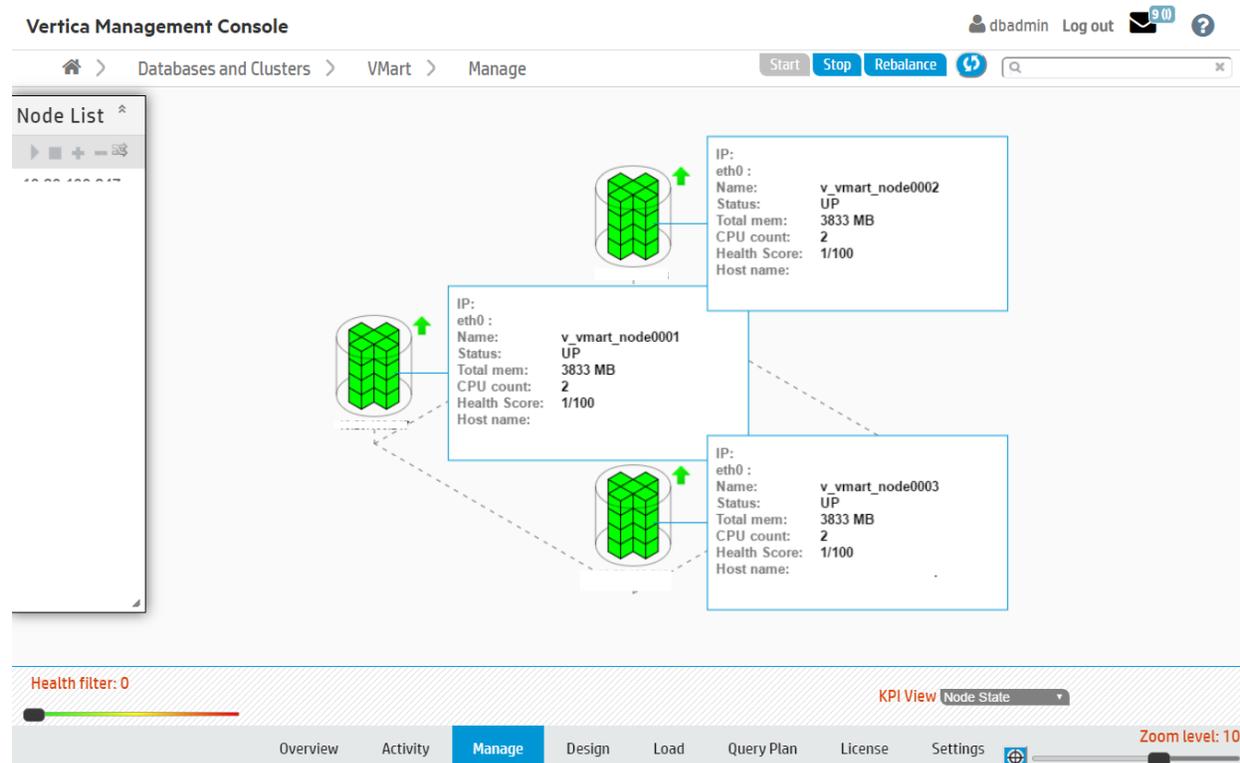

- The **User Query Type Distribution** chart provides an overview of user and system query activity. The chart reports the types of operation that ran. Hover your cursor over chart points for more details. Select a type of operation from the legend to remove or add it from the chart display. To zoom to a certain time frame, you can adjust the sliders at the bottom of the chart.

Click a bar in the graph to open the [Queries](#) chart.

Monitoring Cluster Nodes

For a visual overview of all cluster nodes, click the running database on the Databases and Clusters page and click the **Manage** tab at the bottom of the page to open the cluster status page.

The cluster status page displays the nodes in your cluster.

The appearance of the nodes indicate the following states:

- **Healthy:** The nodes appear green.
- **Up:** A small arrow to the right of the node points upward.
- **Critical:** The node appears yellow and displays a warning icon to the right.
- **Down:** The node appears red. To the right of the node, a red arrow points downwards.
- **Unplugged:** An orange outlet and plug icon appears to the right.

You can get information about a particular node by clicking it, an action that opens the [node details](#) page.

Filtering What You See

If you have a large cluster, where it might be difficult to view dozens to hundreds of nodes on the MC interface, you can filter what you see. The Zoom filter shows more or less detail on the cluster overall, and the Health Filter lets you view specific node activity; for example, you can slide the bar all the way to the right to show only nodes that are down. A message next to the health filter indicates how many nodes in the cluster are hidden from view.

On this page, you can perform the following actions on your database cluster:

- Add, remove and replace nodes
- Rebalance data across all nodes
- Stop or start (or restart) the database
- Refresh the view from information MC gathers from the production database
- View key performance indicators (KPI) on node state, CPU, memory, and storage utilization (see [Monitoring Cluster Performance](#) for details)

Note: Starting, stopping, adding, and dropping nodes and rebalancing data across nodes works with the same functionality and restrictions as those same tasks performed through the Administration Tools.

If You don't See What You Expect

If the cluster grid does not accurately reflect the current state of the database (for example if the MC interface shows a node in INITIALIZING state, but when you use the Administration Tools to View Database Cluster State, you see that all nodes are UP), click the Refresh button in the toolbar. Doing so forces MC to immediately synchronize with the agents and update MC with new data.

Don't press the F5 key, which redisplay the page using data from MC and ignores data from the agent. It can take several seconds for MC to enable all database action buttons.

Monitoring Cluster CPU/Memory

On the MC Overview page, the **CPU/Memory** subsection provides a graph-based overview of cluster resources during the last hour, which lets you quickly monitor resource distribution

across nodes.

This chart plots average and per-node percentages for both CPU and memory with updates every minute—unless you clear Auto Refresh Charts in the toolbar. You can also filter what the chart displays by clicking components in the legend at the bottom of the subsection to show/hide those components. Yellow data points represent individual nodes in the cluster at that point in time.

Investigating Areas of Concern

While viewing cluster resources, you might wonder why resources among nodes become skewed. To zoom in, use your mouse to drag around the problem area surrounding the time block of interest.

After you release the mouse, the chart refreshes to display a more detailed view of the selected area. If you hover your cursor over the node that looks like it's consuming the most resources, a dialog box summarizes that node's percent usage.

For more information, click a data point (node) on the graph to open MC's node details page. To return to the previous view, click **Reset zoom**.

- [Monitoring Node Activity](#)

Monitoring Cluster Performance

Key Performance Indicators (KPIs) are a type of performance measurement that let you quickly view the health of your database cluster through MC's **Manage** page. These metrics, which determine a node's color, make it easy for you to quickly identify problem nodes.

Metrics on the database are computed and averaged over the latest 30 seconds of activity and dynamically updated on the cluster grid.

How to Get Metrics on Your Cluster

To view metrics for a particular state, click the menu next to the **KPI View** label at the bottom of the Manage page, and select a state.

MC reports KPI scores for:

- **Node state**—(default view) shows node status (up, down, k-safety critical) by color; you can filter which nodes appear on the page by sliding the health filter from left to right
- **CPU Utilization**—average CPU utilization
- **Memory Utilization**—average percent RAM used
- **Storage Utilization**—average percent storage used

After you make a selection, there is a brief delay while MC transmits information back to the requesting client. You can also click **Sync** in the toolbar to force synchronization between MC and the client.

Node Colors and What They Mean

Nodes in the database cluster appear in color. Green is the most healthy and red is the least healthy, with varying color values in between.

Each node has an attached information dialog box that summarizes its score. It is the score's position within a range of 0 (healthiest) to 100 (least healthy) that determines the node's color *bias*. Color bias means that, depending on the value of the health score, the final color could be slightly biased; for example, a node with score 0 will be more green than a node with a score of 32, which is still within the green range but influenced by the next base color, which is yellow. Similarly, a node with a score of 80 appears as a dull shade of red, because it is influenced by orange.

MC computes scores for each node's color bias as follows:

- 0-33: green and shades of green
- 34-66: yellow and shades of yellow
- 67-100: red and shades of red shades

If the unhealthy node were to consume additional resources, its color would change from a dull orange-red to a brighter red.

Filtering Nodes From the View

The health filter is the slider in the lower left area of page. You can slide it left to right to show or hide nodes; for example, you might want to hide nodes with a score smaller than a certain value so the UI displays only the unhealthy nodes that require immediate attention. Wherever

you land on the health filter, an informational message appears to the right of the filter, indicating how many nodes are hidden from view.

Filtering is useful if you have many nodes and want to see only the ones that need attention, so you can quickly resolve issues on them.

Monitoring System Resources

MC's **Activity** page provides immediate visual insight into potential problem areas in your database's health by giving you graph-based views of query and user activity, hardware and memory impact, table and projection usage, system bottlenecks, and resource pool usage.

Select one of the following charts in the toolbar menu:

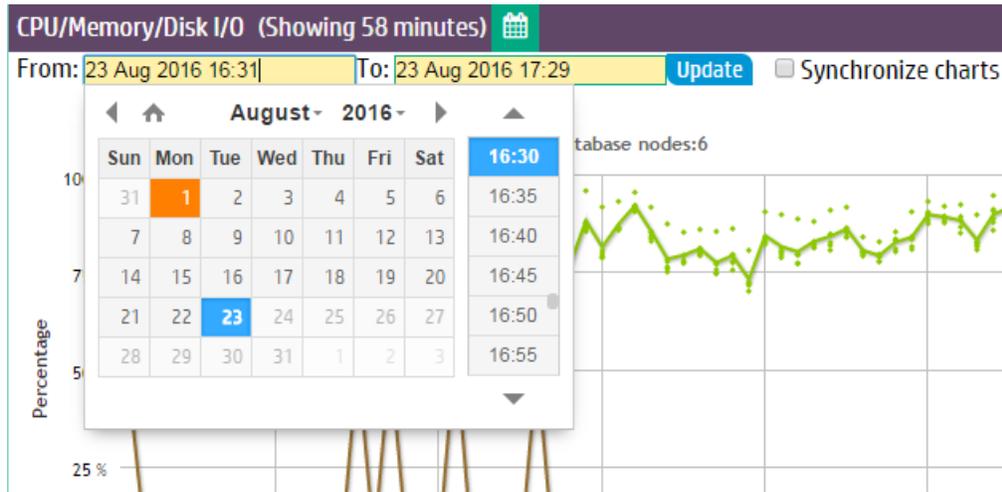

- [Queries](#)
- [Internal Sessions](#)
- [User Sessions](#)
- [Memory Usage](#)
- [System Bottlenecks](#)
- [User Query Phases](#)
- [Monitoring Table Utilization and Projections](#)
- [Query Monitoring](#)
- [Resource Pool Monitoring](#)
- [Monitoring Catalog Memory](#)

How up to date is the information?

System-level activity charts automatically update every five minutes, unless you clear Auto Refresh in the toolbar. Depending on your system, it could take several moments for the charts to display when you first access the page or change the kind of resource you want to view.

Chart Viewing Options

You can specify time frames for some charts, which display a calendar icon in their title bars. Click the calendar icon to specify the time frame for that module.

If you have enabled extended monitoring on your database, MC can display longer ranges of data in certain charts. See [Extended Monitoring](#). If a chart is using extended monitoring data, the rocket ship icon appears in the title bar:

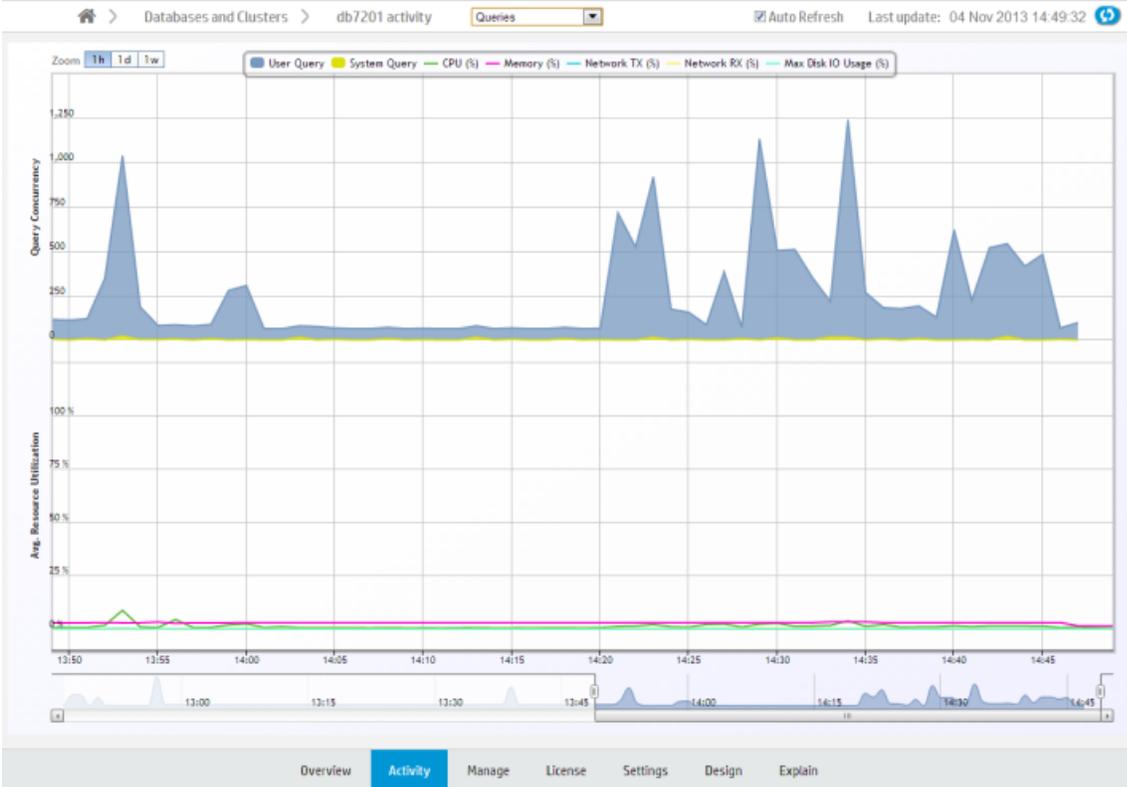

You can expand some charts to view them in larger windows. Click the expand icon in the title bar to do so:

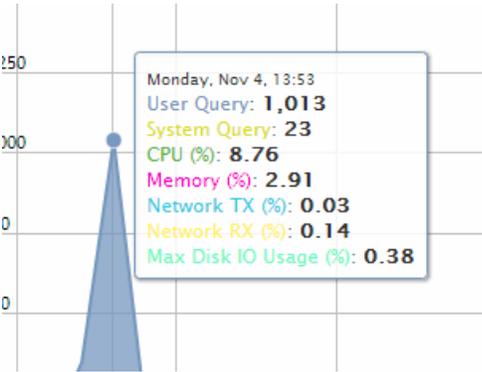

Monitoring Query Activity

The Queries chart displays information about query concurrency and average resource usage for CPU/memory, network activity, and disk I/O percent based on maximum rated bandwidth.

Hover over a data point for more information about percent usage for each of the resource types.

If you click a data point, MC opens a details page for that point in time, summarizing the number of user queries and system queries. This page can help you identify long-running queries, along with the query type. You can sort table columns and export the report to a file.

Monitoring Key Events

On the main Queries page, MC reports when a key event occurred, such as a Workload Analyzer or rebalance operation, by posting a **WLA** (Workload Analyzer) and/or **RBL** (rebalance) label on the resource section of the chart.

Filtering Chart Results

The default query concurrency is over the last hour. The chart automatically refreshes every five minutes, unless you clear the Auto Refresh option in the toolbar. You can filter results for 1 hour, 1 day, or up to 1 week, along with corresponding average resource usage. You can also click different resources in the legend to show or hide those resources.

To return to the main Queries page, use the slider bar or click the 1h button.

Viewing More Detail

To zoom in for detail, click-drag the mouse around a section or use the sliding selector bar at the bottom of the chart. After the detailed area displays, hover your cursor over a data point to view the resources anchored to that point in time.

For more detail about user or system queries, click a data point on one of the peaks. A **Detail** page opens to provide information about the queries in tabular format, including the query type, session ID, node name, query type, date, time, and the actual query that ran.

The bottom of the page indicates the number of queries it is showing on the current page, with Previous and Next buttons to navigate through the pages. You can sort the columns and export contents of the table to a file.

To return to the main Queries page, click **<database name> Activity** in the navigation bar.

Monitoring Internal Sessions

The Internal Sessions chart provides information about Vertica system activities, such as Tuple Mover and rebalance cluster operations, along with their corresponding resources, such as CPU/memory, networking, and disk I/O percent used.

Hover your cursor over a bar for more information. A dialog box appears and provides details.

Filtering Chart Results

You can filter what the chart displays by selecting options for the following components. As you filter, the **Records Requested** number changes:

- **Category**—Filter which internal session types (moveout, mergeout, rebalance cluster) appear in the graph. The number in parentheses indicates how many sessions are running on that operation.
- **Session duration**—Lists time, in milliseconds, for all sessions that appear on the graph. The minimum/maximum values on which you can filter (0 ms to *n* ms) represent the minimum/maximum elapsed times within all sessions currently displayed on the graph. After you choose a value, the chart refreshes to show only the internal sessions that were greater than or equal to the value you select.
- **Records requested**—Represents the total combined sessions for the Category and Session Duration filters.

Monitoring User Sessions

The User Sessions charts provide information about Vertica user activities for all user connections open to MC.

Choose **User Sessions** from the menu at the top of your database's Activity page to view these charts.

View Open Sessions

The Open Sessions tab displays a table of currently open sessions for each user. You can close a session or cancel a query on this tab by selecting that option from the **Actions** column.

Navigation: Overview | Activity | Manage | Design | Load | Query Plan | License | Settings

View All User Sessions

The All Sessions tab displays a history of all user sessions in a swim lane chart.

What Chart Colors Mean

Bars outlined with a dotted line are currently running sessions.

Sessions are divided into two colors, yellow and blue.

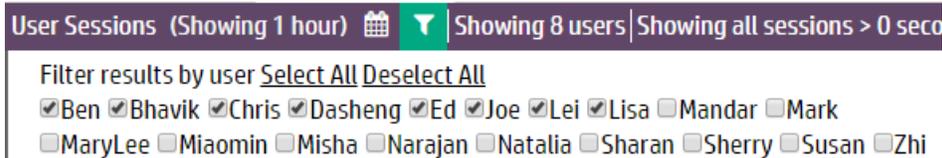

- Yellow bars represent user (system) sessions. If you click a yellow bar, MC opens a Detail page that shows all queries that ran or are still running within that session.
- Blue bars represent user requests (transactions within the session). If you click a blue bar in the graph, MC opens a Detail page that includes information for that query request only.

When you hover your mouse over a transaction bar, a dialog box provides summary information about that request, such as which user ran the query, how long the transaction took to complete, or whether the transaction is still running.

Filter Chart Results

Extremely busy systems will show a lot of activity on the interface, perhaps more than you can interpret at a glance. You can filter chart results in several ways:

- **Zoom.** The context chart at the bottom of the page highlights in blue which section of the All Sessions chart you are viewing. Click and drag the blue box left or right to view earlier or later user sessions. Click and drag the edges of the blue box to zoom in or out.
- **Select fewer users.** Click the filter icon () at the top of the page. A menu of a menu of all available users appears below. Deselect users to exclude from the chart.

- **Change the session duration (how long a session took to run).** Click the Filter icon () at the top of the page. The **Filter sessions and queries by duration** field appears below. Enter the minimum session length (in seconds) to display on the chart and click **Update**.

- **Specify a time frame.** Click the Calendar icon () at the top of the page to display the From and To fields. Using the fields, select the time frame to display in the chart and click **Update**.

Monitoring System Memory Usage

The Memory Usage chart shows how system memory is used on individual nodes over time. Information the chart displays is stored based on Data Collector retention policies, which a superuser can configure. See [Configuring Data Retention Policies](#).

The first time you access the Memory Usage chart, MC displays the first node in the cluster. MC remembers the node you last viewed and displays that node when you access the Activity page again. To choose a different node, select one from the Nodes drop-down list at the bottom of the chart. The chart automatically refreshes every five minutes unless you disable the Auto Refresh option.

Tip: On busy systems, the Node list might cover part of the graph you want to see. You can move the list out of the way by dragging it to another area on the page.

Types of System Memory

The Memory Usage chart displays a stacking area for the following memory types:

- swap
- free
- fcache (file cache)
- buffer
- other (memory in use by all other processes running on the system besides the main Vertica process, such as the MC process or agents)
- Vertica
- rcache (Vertica ROS cache)
- catalog

When you hover over a data point, a dialog box displays percentage of memory used during that time period for the selected node.

Monitoring System Bottlenecks

The System Bottlenecks chart helps you quickly locate performance bottlenecks on a particular node. The first time you access the Activity page, MC displays the first node in the cluster. To choose a different node, select one from the Nodes drop-down list at the bottom of the chart.

The System Bottlenecks chart reports what MC identifies as the most problematic resource during a given time interval. You can use this chart as a starting point for investigation.

How MC Gathers System Bottleneck Data

Every 15 minutes, MC takes the maximum percent values from various system resources and plots a single line with a data point for the component that used the highest resources at that point in time. When a different component uses the highest resources, MC displays a new data point and changes the line color to make the change in resources obvious. Very busy databases can cause frequent changes in the top resources consumed, so you might notice heavy chart activity.

In the following example, at 08:24 the maximum resources used changed from Disk I/O to CPU. The System Bottlenecks charts denotes this with a change in line color from brown to green.

The Components MC Reports on

MC reports maximum percent values for the following system components:

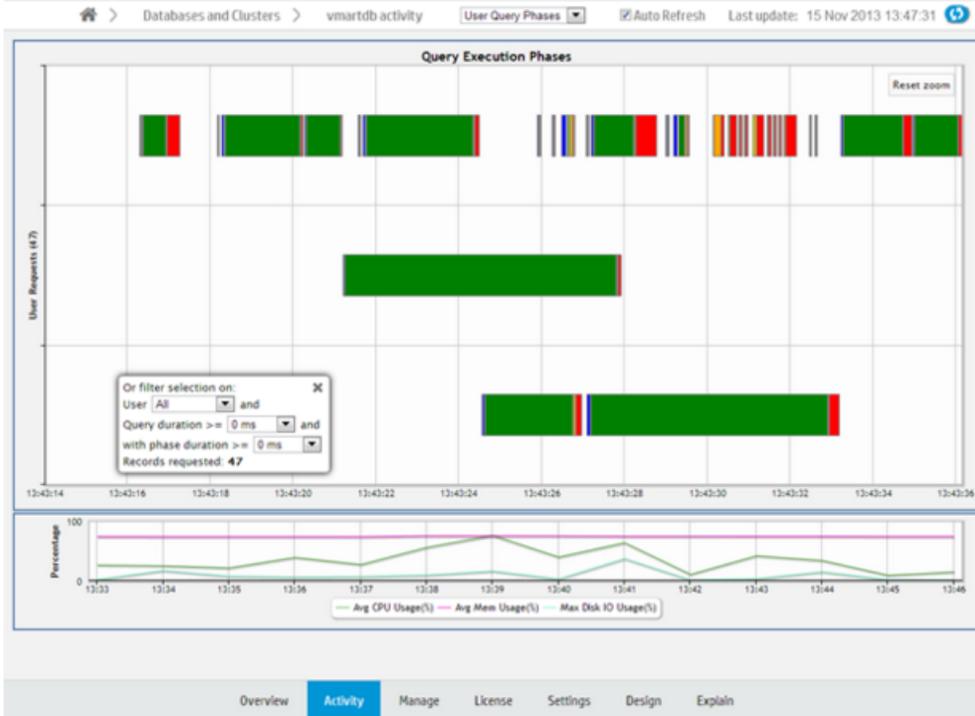

- Average percent CPU usage
- Average percent memory usage
- Maximum percent disk I/O usage
- Percent data sent over the network (TX)
- Percent data received over the network (RX)

How MC Handles Conflicts in Resources

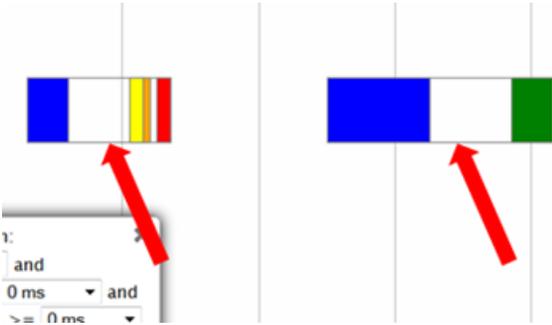

If MC encounters two metrics with the same maximum percent value, it displays one at random. If two metrics are very close in value, MC displays the higher of the two.

Monitoring User Query Phases

The User Query Phases chart provides information about the query execution phases that a query goes through before completion. Viewing this chart helps you identify at a glance queries possibly delayed because of resource contention.

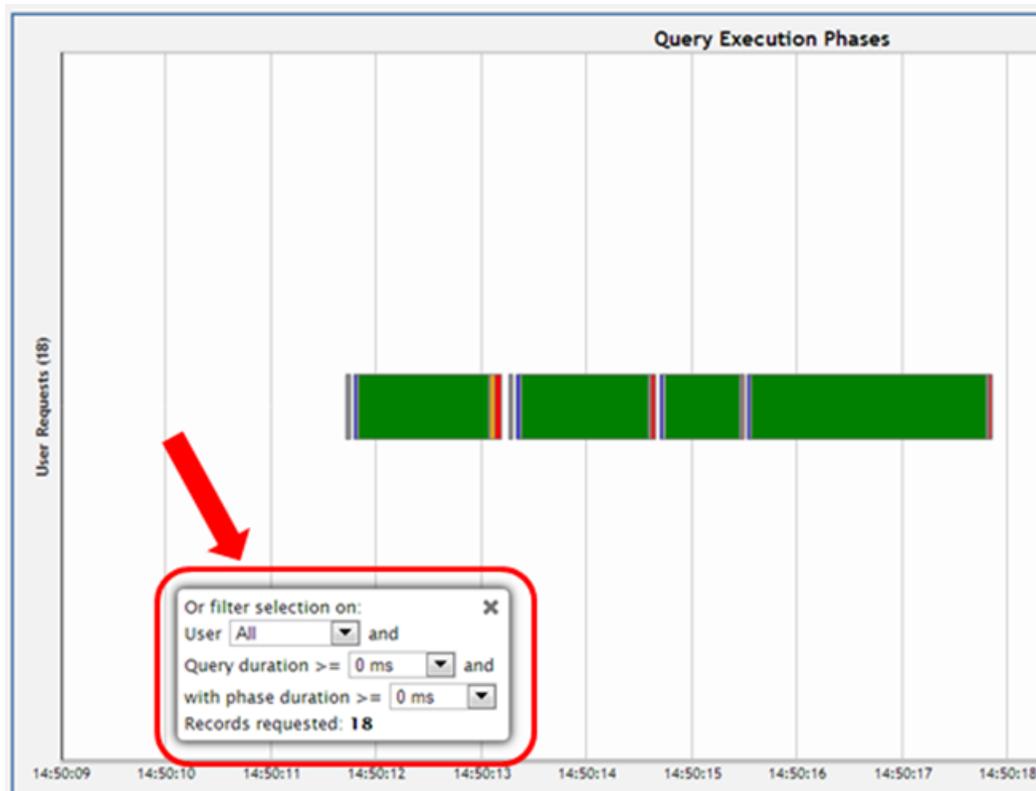

Each bar, bound by a gray box, represents an individual query. Within a query, a different color represents each query phase. The chart does not show phases for queries with durations of less than 4 seconds. Blank spaces within a query represent waiting times, as in the image below.

Hover over a phase in the query for information on the phase type and duration. The chart shows queries run over the last 15 minutes. The chart automatically refreshes every five minutes, unless you clear the Auto Refresh option in the toolbar.

Filtering Chart Results

You can filter what the chart displays by selecting options for the user running the query, minimum query duration, and minimum phase duration.

Viewing More Detail

To zoom in for detail, click-drag the mouse around a section of the chart. Click Reset Zoom, located at the top right corner of the chart, to restore the chart to its original view.

For more detail, click a query bar. The Detail page opens to provide information about the queries in tabular format, including the query type, session ID, node name, query type, date, time, the actual query that ran, and an option to run Explain Plan or profile the query. Click a table column header to sort the queries by that category.

To export the contents of the table to a file, click Export, located at the upper right of the page.

To return to the main Queries page, click Activity in the navigation bar.

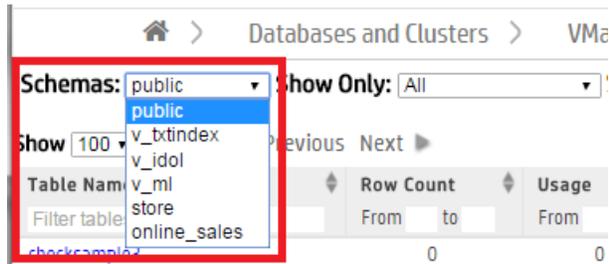

Monitoring Table Utilization and Projections

The Table Utilization activity page helps you monitor tables and projections in your database by schema.

You can use the table utilization charts on this page to identify outliers among your tables, such as those that are large or overused. The projections summary can help identify if projections are evenly distributed across nodes.

Table Visualizations

To specify a schema to view, choose one from the Schemas menu at the top of the activity page. The summary of tables and projections in that schema appear on the page.

MC visualizes your available tables by schema in a table chart or as a treemap chart.

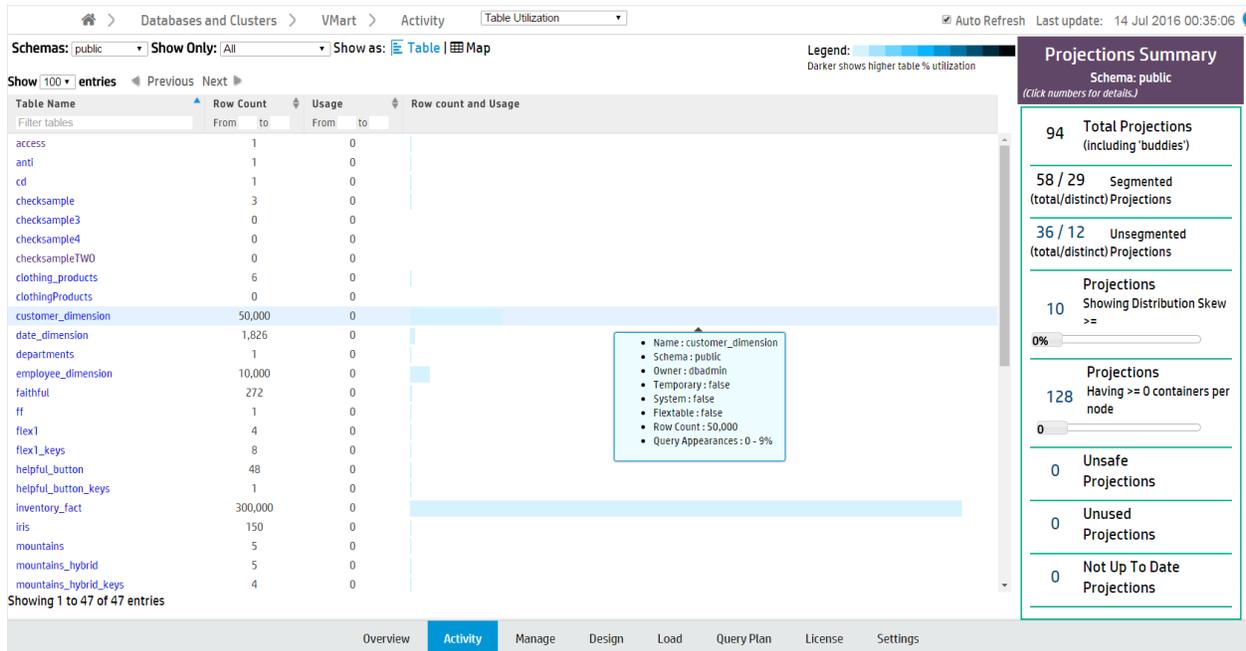

The Table chart provides flexible sorting to help you find tables you are interested in, especially if you have a large number of tables. You can use the Treemap chart for an at-a-glance graphical visualization of the relative size of your tables.

To choose how to visualize your table data, click **Table** or **Map** from the Show As menu. By default, MC displays the Table visualization. The current visualization is highlighted in blue in the Show As menu.

Show as:  **Table** |  Map

The Table chart, shown below, displays each table's row count, usage (percentage of time the table is queried), and a bar representing both row count and usage. The length of the bar indicates row count; a darker color indicates higher usage.

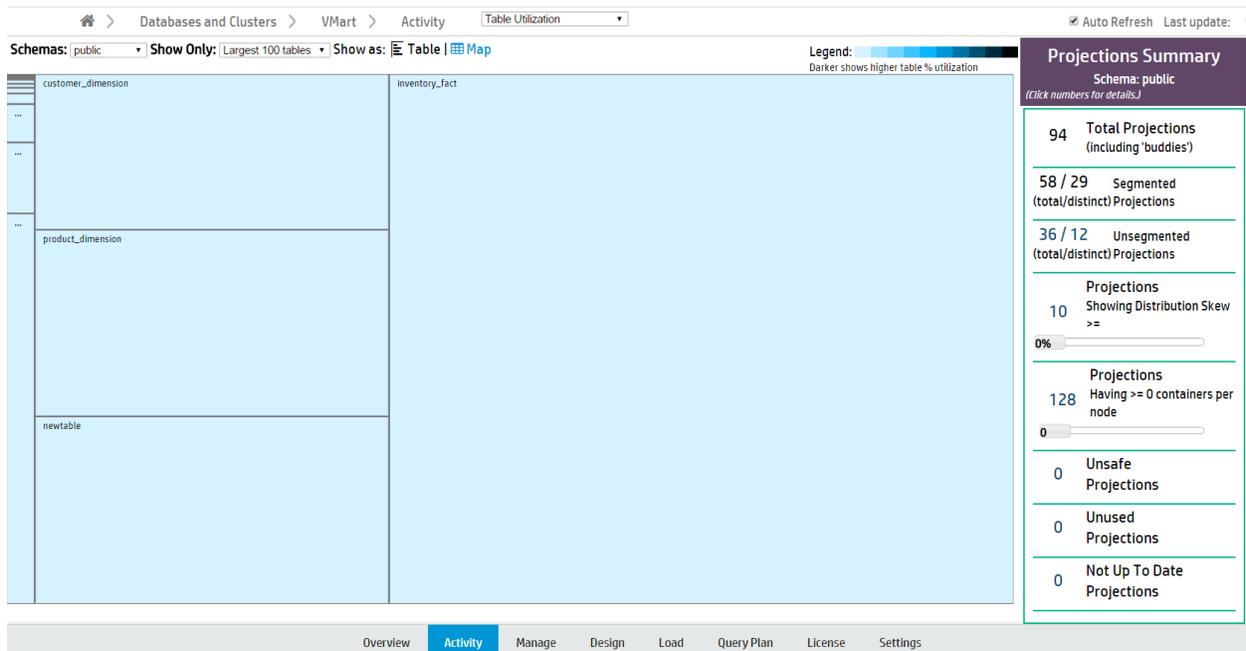

Hover over a bar in the chart to view details about that table, or click the table name to view its Table Details page.

In the Treemap visualization, tables are represented by boxes nested by size and colored by usage. Darker colors indicate higher table usage.

Depending on the number of tables in your database, the chart may be crowded. Use the Show Only filter at the top of the page to display only the largest or smallest 100 tables.

Hover over a table to view more details, or click to view its Table Details page.

The Table Details page displays information on the table's properties and columns, and about projections for the table. To the right, bar charts provide information, by node, on the amount of storage, number of deleted rows, and number of deleted vectors.

The screenshot displays the 'Table Properties For Public.Customer_dimension' section with the following data:

Property	Value
avg_bytes_per_row	43.38 bytes
is_flextable	
is_system_table	
is_temp_table	
owner_name	dbadmin
row_count	50000
table_name	customer_dimension

The 'Projections' section shows a table with the following columns:

Column Name	Data Type	Minimum	Maximum	Cardinality
annual_income	int	N/A	N/A	-1
customer_address	varchar(256)	N/A	N/A	-1
customer_age	int	N/A	N/A	-1
customer_city	varchar(64)	N/A	N/A	-1
customer_gender	varchar(8)	N/A	N/A	-1
customer_key	int	N/A	N/A	-1
customer_name	varchar(256)	N/A	N/A	-1
customer_region	varchar(64)	N/A	N/A	-1
customer_since	date	N/A	N/A	-1
customer_state	char(2)	N/A	N/A	-1
customer_type	varchar(16)	N/A	N/A	-1
deal_size	int	N/A	N/A	-1
deal_stage	varchar(32)	N/A	N/A	-1

The 'Storage By Node' chart shows three bars representing storage usage per node. The '# Deleted Rows By Node' and '# Delete Vectors By Node' charts show zero values for deleted rows and vectors.

Note: If you have deleted table rows recently, Management Console may not display the most recent row count. MC updates the row count when mergeout occurs. See [Mergeout](#).

Projections Summary

The projections summary displays information about projections by schema:

- Total projections.
- Segmented projections, the number of projections segmented across multiple nodes.
- Unsegmented projections, the number of projections that are not segmented across multiple nodes.
- Projections Showing Distribution Skew, the number of projections unevenly distributed across nodes. Tables with fewer than 1000 rows are not counted. Move the slider to configure filter by distribution skew percentage.
- The number of projections with more than the specified number of containers per node. Move the slider to configure the minimum number of containers.

- Unsafe projections, the number of projections with a K-safety less than the database's K-safety.
- Unused projections.

Click a projections number to view a list of the specified projections and their details.

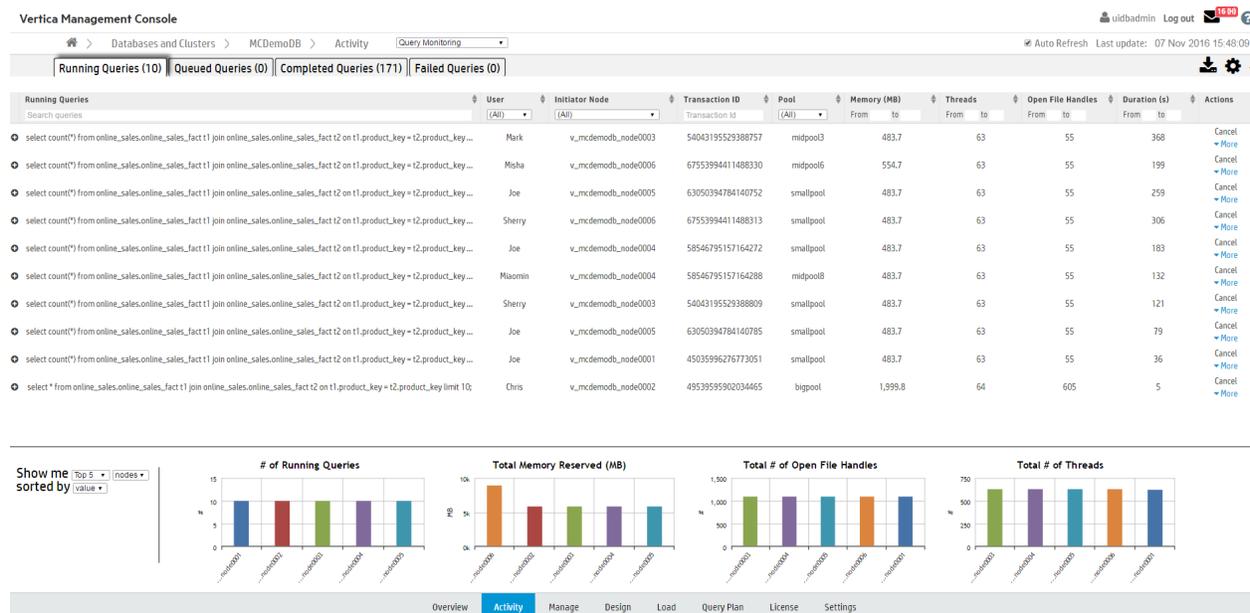

Monitoring Running Queries

The Query Monitoring activity page displays the status of recent and currently running queries, and resource information by node and user. From this page, you can profile a query or cancel a running query.

Use this page to check the status of your queries, and to quickly cancel running or queued queries to free up system resources. This page can help you identify where resources are being used, and which queries, users, or nodes are using the most resources.

The Query Monitoring page includes four tables, displayed as tabs:

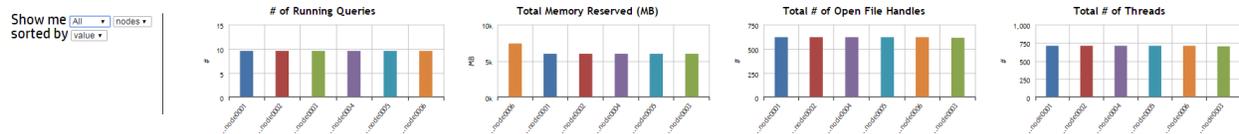

- Running queries
- Queued queries
- Completed queries
- Failed queries

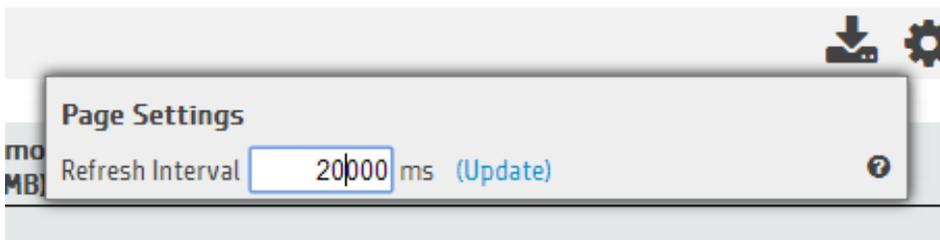

From the **Actions** column you can:

- **Cancel.** Cancel a running or queued query.
- **Close session.** Close a session for a running or queued query.
- **Explain.** Open the Query Plan page for any query.
- **Profile.** Profile any query on the Query Plan page.

The four bar charts at the bottom of the page display aggregate query usage by node or user. Hover over a bar with your cursor to see its value. When sorted by value, the left-most bar in each chart represents the node or user with the highest value.

The Query Monitoring page refreshes every 20 seconds by default. To change the refresh interval, click the Page Settings button in the upper-right corner of the page. A dialog appears. Type the new refresh interval, in milliseconds, in the text box.

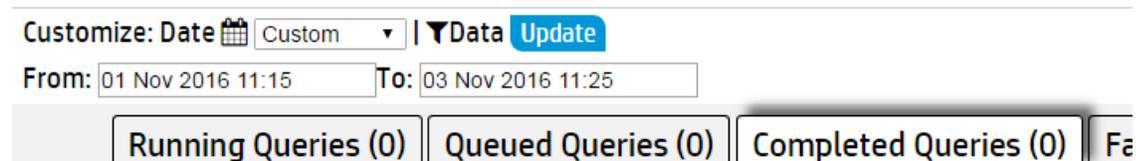

Filtering Chart Results

Use the search field below each column title to narrow down your chart results. (For example, if you enter the text *SELECT product_description* in the **Search Queries** field and select a specific node in the **Initiator Node** column, the chart returns only queries which both contain that text and were initiated on the node you specified.)

Click a column title to sort the order of the queries by that category.

There may be a large number of results for Completed and Failed Queries. Use the **Customize** section at the top of these two tabs to further filter your chart results. For either tab, you can select a custom date and time range for your results.

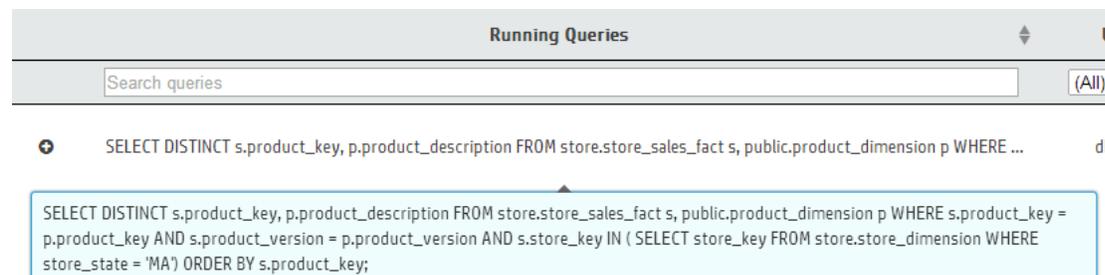

In the Completed Queries tab, click **Data** to enter additional query information to filter based on any of the following fields:

- User
- Request
- Request Duration
- Node
- Request label

Viewing More Details

Click a query to view the entire query.

In the Failed Queries chart, click the **plus (+)** icon next to a failed query to see the failure details for each node involved in the query's execution.

To export the data in one of the Query Monitoring tables, click the table's tab, then click the **Export** () button in the upper-right corner of the page. The browser downloads the data for that chart in a .dat file. The data exported includes columns that may not be visible in the MC, including the minimum and maximum values for Memory, Thread Count, and Open File Handles.

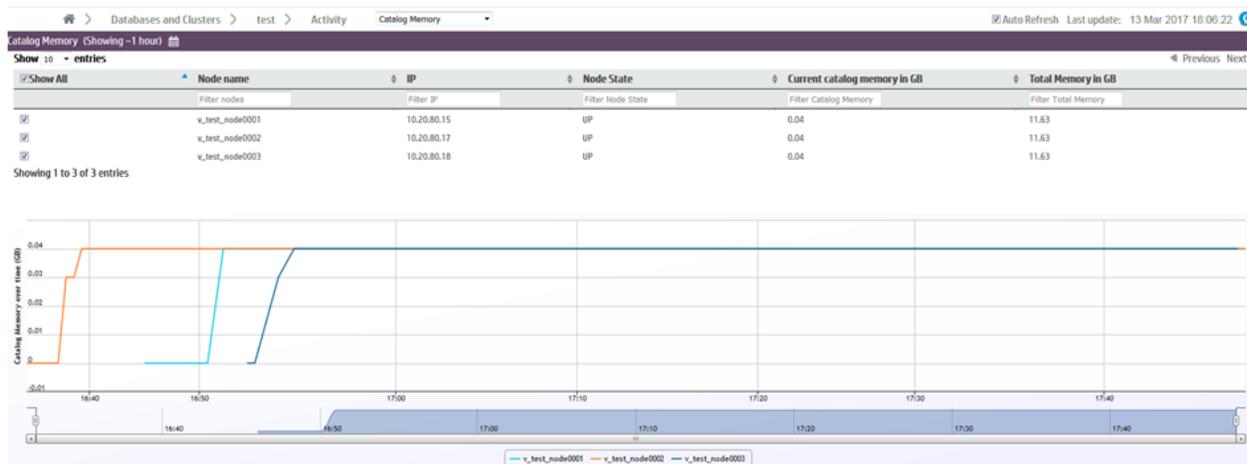

Monitoring Catalog Memory

The Catalog Memory activity page displays the catalog memory for each node. Use this page to check for sudden changes in catalog memory, or discrepancies in memory distribution across your nodes.

The Catalog Memory page displays:

- **A node details table.** The table lists the details of each node in the database, including their current catalog memory and total memory usage.
- **A catalog memory chart.** A line graph visualization of each node's catalog memory usage over time. Each line represents a node. The color legend at the bottom of the chart indicates the color of each node's line.

In the image below, catalog memory begins at 0GB for all three nodes. Over the next twenty minutes, catalog memory increases to 0.04GB in the second node (orange), then the first node (cyan), and finally in the third node (dark blue). Starting at 16:55, note that the three overlapping node lines appear as one line when all three nodes have the same catalog memory.

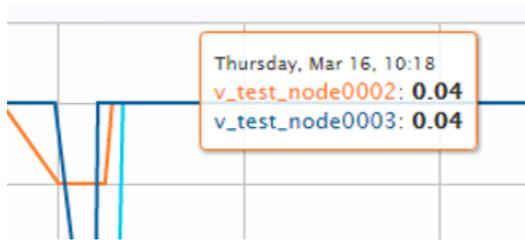

Filtering Chart Results

If you have many nodes in your database, you may want to display only certain nodes in the catalog memory chart. You can remove nodes from the chart in two ways:

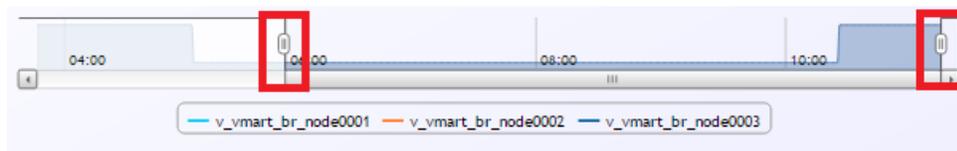

- Deselect the node's check box in the node details table.
- Deselect the node in the color legend below the chart.

Viewing More Details

Hover over any line in the chart to view the time, node name, and catalog size.

At the bottom of the chart is a summary bar that shows a quick overview of the catalog memory over time. Move the sliders on either side of the chart to zoom in on a specific time frame in the chart. When zoomed in, you can use the scrollbar to move forward or backward in time.

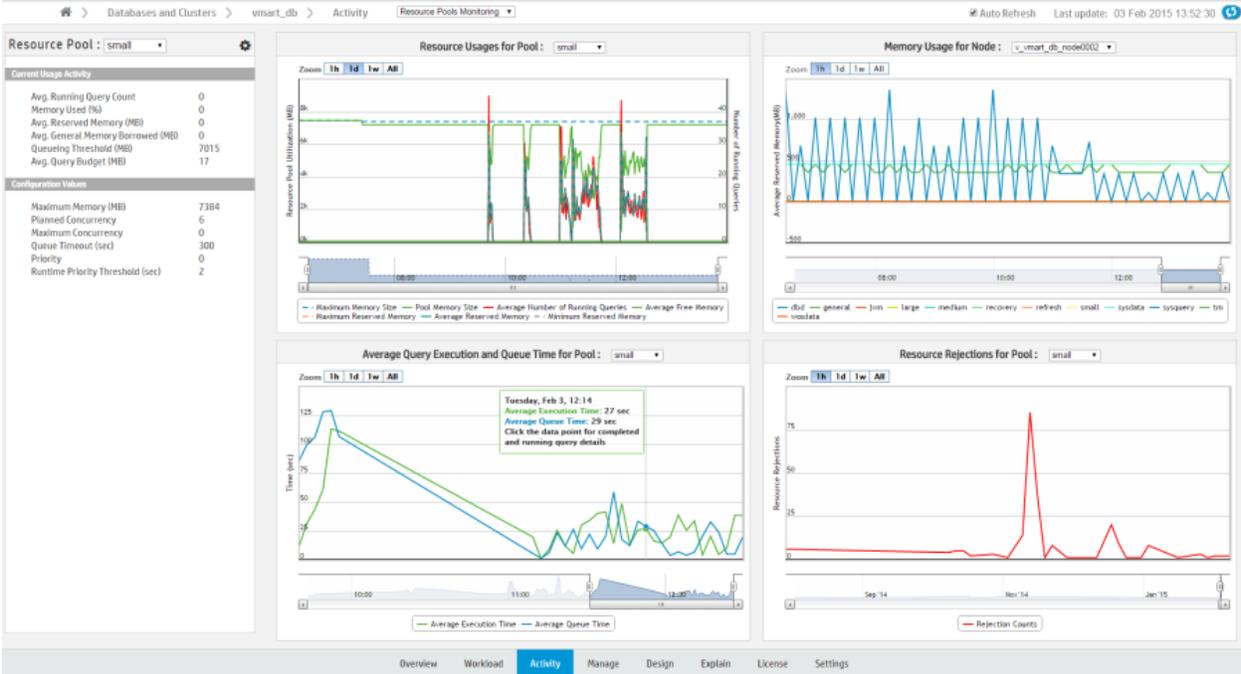

Monitoring Resource Pools

Management Console allows database administrators to monitor and configure resource pools through the Activity and Configuration pages. These pages help you manage workloads by providing visual representations of resource usage as well as resource pool configuration options.

Monitoring Resource Pools Charts

You can monitor your resource pools using the Resource Pools Monitoring charts, accessible through the Management Console Activity page.

Select a resource pool to view using the Resource Pool menu, located in the leftmost sidebar. In the sidebar, Current Usage Activity displays the pool's real-time statistics.

Monitor the selected resource pool using the following charts, which display the pool's historic data:

- **Resource Usages in Pool:** Shows the historically averaged acquired memory usage by each pool across all nodes. The graph uses two y-axes, one that shows memory size, and a second that shows the total number of running queries. Data is collected every hour. Hover over a data point for a summary of the memory usage at that specific point.
- **Memory Usage in Node:** Shows the historically acquired memory usages by all pools across all nodes. Data is collected every hour. Hover over a data point for a summary of the memory usage at that specific point
- **Average Query Execution and Query Time in Pool:** Shows the averaged query queue time plotted against the query execution time by each pool across all nodes. Data is collected every minute. Hover over data to get the average query execution and queue time in the specified pool. Click a data point to show detailed individual query information.
- **Resource Rejections in Pool:** Shows the historical total number of resource requests that were rejected in each pool across all nodes. Data is collected every hour. Click a data point to show rejection details and reasons in a pop-up window.

Configuring Resource Pools in MC

Database administrators can view information about resource pool parameters and make changes to existing parameters through the Management Console Configuration page. You can also create and remove new resource pools, assign resource pool users, and assign cascading pools.

See [Configuring Resource Pools in Management Console](#)

Permissions

Only the database administrator can monitor and configure resource pools in Management Console.

See Also

- [Configuring Resource Pools in Management Console](#)
- [Using Queries to Monitor Resource Pool Size and Usage](#)

Configuring Resource Pools in Management Console

Database administrators can view information about resource pool parameters and make changes to existing parameters in MC through the Resource Pools Configuration page. You can also create and remove new resource pools, assign resource pool users, and assign cascading pools.

Access the Resource Pools Configuration page from the Settings page by selecting the Resource Pools tab.

You can also access the Configuration page from the Resource Pools Monitoring chart, accessible through the Management Console Activity page. Click the tools icon on the top of the leftmost sidebar.

Permissions for Monitoring and Configuring Resource Pools

Only the database administrator can monitor and configure resource pools in Management Console.

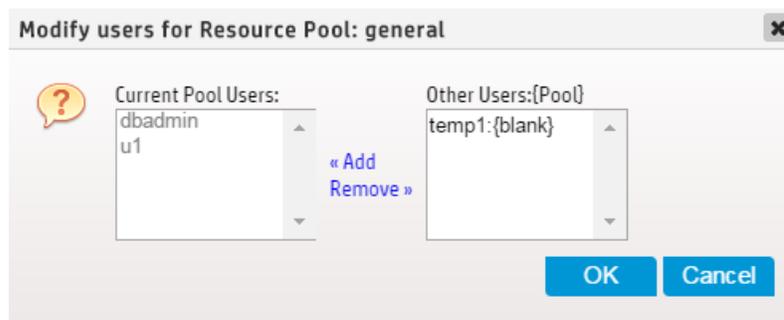

Modify Resource Pool Parameters

1. On the Resource Pools Configuration page, choose a resource pool from the Resource Pools field. Parameter fields for that resource pool appear.
2. Use the parameter fields to view and modify parameters for the resource pool. Hover your cursor in the parameter field to display information about that parameter.
3. Click **Apply** to save your changes. A success message appears

Modify Resource Pool Users

To add or remove resource pool users:

1. On the Resource Pools Configuration page, select a resource pool from the Resource Pools field.
2. Next to the Pool Users field, click **Add/Remove Pool Users**. The Modify Users for Resource Pool dialog appears.

3. The dialog displays users assigned to the resource pool in the Current Pool Users list. The Other Users list displays all other resource pool users are displayed, along with the pool to which they are currently assigned.

- a. To add users to the resource pool: Select the desired users from Other Users list and click **Add**.
 - b. To remove users from the resource pool: Select the users to be removed from the Current Pool Users list and click **Remove**.
4. Click **Apply** to save your changes. A success message appears.

Create and Remove Resource Pools

Database administrators can use MC to create resource pools and assign resource pool users, and remove user-generated resource pools.

To create a resource pool:

1. On the Resource Pools Configuration page, click **Create Pool**. Fields pre-populated with pool parameter default values appear.
2. Enter the new resource pool's parameters in the fields.
3. Click **Create Pool**. A success message appears.

To remove a resource pool:

1. First, remove all users from the resource pool to be deleted. This can be done on the Resource Pool Configuration Page.
2. When all users have been removed from the resource pool, choose the resource pool from the Resource Pools field on the Resource Pool Configuration Page. Parameter fields for that resource pool appear.
3. Click **Remove Pool**. A Confirm dialog appears.
4. Click **OK** in the Confirm dialog. A success message appears.

Monitoring Node Activity

If a node fails on an MC-managed cluster or you notice one node is using higher resources than other cluster nodes—which you might observe when monitoring the [Overview page](#)—open the [Manage](#) page and click the node you want to investigate.

The Node Details page opens and provides summary information for the node (state, name, total memory, and so on), as well as resources the selected node has been consuming for the last three hours, such as average CPU, memory, disk I/O percent usage, network consumption in kilobytes, and the percentage of disk storage the running queries have been using. You can also browse and export log-level data from AgentTools and Vertica log files. MC retains a maximum of 2000 log records.

For a more detailed view of node activity, use the mouse to drag-select around a problem area in one of the graphs, such as the large spike in network traffic in the above image. Then hover over the high data point for a summary.

Monitoring Database Messages in MC

As Management Console monitors your database, it periodically checks your system's health and performance. MC then generates messages to alert you about the state of your system. You can view and manage these messages in the Message Center.

Getting New Message Notifications

The Messages icon appears in the top-right of any database-specific page on MC (such as the Overview page or Activity page). The icon displays a new messages badge. The badge displays how many highest priority messages you have received recently.

The messages badge displays the color and letter of that priority:

- Red (H): High Priority
- Orange (N): Needs Attention
- Blue (I): Informational

In addition, the Thresholds Notification widget on the Overview page displays a summary of alerts about exceeded thresholds. Only high-priority threshold alerts appear in the Thresholds Notification widget. You can set the priority of alerts for different thresholds in the Thresholds tab on your database's Settings page.

Viewing Message Center

You can look at a preview of your most recent messages without navigating away from your current page. Click the Message Center icon in the top-right corner of Management Console to view the notification menu. The menu appears as a drop-down preview of your inbox. From this menu, you can delete, archive, or mark your messages as read.

Info	VMart	Feb 29 09:17:11	Agent status is UP on IP 10.20.100.247	

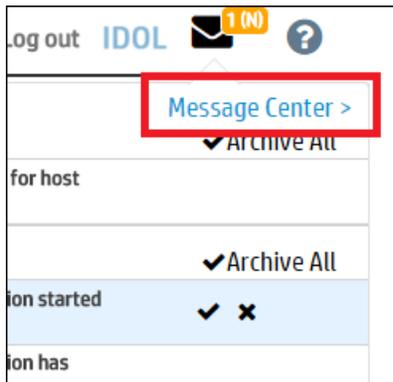

You can access the Message Center in three ways:

- Click the **Message Center** button on the MC Home Page. The Message Center displays messages about the most recent database you have viewed.

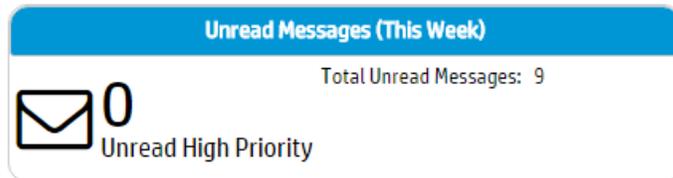

Manage Information

 Existing Infrastructure Manage databases and clusters	 Message Center Go to the database message center
 Diagnostics View diagnostics and support information	 MC Settings Manage application and user settings

- Click the **Messages** icon in the top-right of any database-specific page on MC. (For example, the icon appears on the Overview and Activity pages). A menu of your recent messages appears. Click **Message Center** in the top-right of the menu to reach the Message Center for the database you most recently viewed.

- Click the **Messages** widget on the right side of the Overview page.

Filtering Recent Messages

By default, Message Center displays up to 600 of a database's most recent messages from the past week.

To see more messages:

1. Click **Retrieve Older Messages** in the top-right of the page.
2. Use the drop-down **From** and **To** calendars to select a time range from which to retrieve older messages. You can specify days, hours, and minutes.
3. Click **Search** to display the messages from the specified time frame.

Depending on your database, you may have received hundreds of recent messages in the past seven days. To help you find the messages most relevant to you, Message Center provides several ways to filter recent messages:

- **By search term:** Use the search field at the top of the page to filter messages by any search term, such as description or date.
- **By database:** View a specific database's messages by choosing it from the Showing: [database] drop-down list at the top of the page. Message Center's default view lists up to 600 of the most recent messages for each database MC monitors.
- **By time period:** Message Center groups your recent messages by Today, Yesterday, and This Week. Click any of these headings to collapse that section of messages.
- **By message priority:** Messages are categorized as High Priority, Needs Attention, or Informational. The number of messages of each priority level appears at the top-right of the page. By default, all priority levels are displayed in the inbox. To filter messages of one priority level out of your current view, click a message count value at the top of the inbox to deselect it.
- **By threshold messages:** MC generates messages indicating when certain thresholds are exceeded in your database. To view only messages related to exceeded thresholds, click the

Thresholds Messages tab on the left hand side of the page. To modify these alert thresholds, go to the Thresholds tab, which appears in your database's Settings page.

By default, Message Center displays up to 600 recent entries per database. You can adjust the maximum limit of messages the Message Center displays in the `/opt/vconsole/config/console.properties` file. To adjust the limit, change the number in the following line:

```
messageCenter.maxEntries=600
```

Managing and Archiving Messages

Message Center archives all messages you mark as read. To mark messages as read or unread, select a message or multiple messages in the Message Center and click **Mark Read** or **Mark Unread**.

You can also perform the following tasks:

- See an archived message—Click **Archived Messages** on the right side of the Message Center. Then, use the **From** and **To** fields at the top of the page to select a date range from which to display archived messages.
- Sort archived messages by Type, Database Name, Description, or Date—Click any filter at the top of the Message Center.
- Delete messages permanently—If you prefer to delete messages, rather than archiving them, select the messages to delete. Then, click **Delete Msgs**.

Viewing Message Details

Within the Message Center, click the plus (+) symbol next to a message to get more information about the issue. You can also query the [V_MONITOR.EVENT_CONFIGURATIONS](#) table to get information about events. See the [SQL Reference Manual](#) for details.

Message Priority Levels

MC sorts messages by priority level and prioritizes them with color codes:

- High Priority (Red)
- Needs Attention (Orange)
- Informational (Blue)

At the top of your inbox, the Message Center displays the number of messages that fall within each level of priority.

Click any of the values to deselect them. This filters that type of message out of your current inbox view. For example, suppose you want to view the High Priority messages in your inbox. To remove lower-priority messages, you can click the message count values for the categories labeled Needs Attention and Informational. Doing so removes them from your current view.

Messages in the inbox are additionally labeled with one of seven subcategories, according to priority:

- High Priority: Emergency (0), Alert (1)
- Need Attention: Critical (2), Error (3)
- Informational: Warning (4), Info (5), Notice (6)

- [Customizing Threshold-Based Notifications](#)
- [Exporting MC-managed Database Messages and Logs](#)

Message Types

MC generates both default notifications and customizable threshold notifications.

Threshold Notifications

MC generates threshold-based notifications when the database exceeds specified limits on the following thresholds.

- License Status
 - License Usage
- System Health
 - Node Health
 - Node CPU
 - Node Memory
 - Node Disk Usage
 - Node Disk I/O
 - Node CPU I/O Wait
 - Node Reboot Rate
 - Node Catalog Memory
 - Node State Change
 - Network Health
 - Network I/O Error
- System Performance
 - Query
 - Queued Query Number
 - Failed Query Number
 - Spilled Query Number
 - Retried Query Number
 - Query Running Time
 - Resource Pool
 - Queries Reaching the Max Allowed Execution Time
 - Queries With Resource Rejections
 - Ended Query With Queue Time Exceeding Limit
 - Ended Query With Run Time Exceeding Limit

MC provides default settings for these notifications. You can customize threshold notification settings in the Thresholds tab in the database Settings page. Threshold notifications appear in the Message Center. High-priority threshold alerts also appear on the Overview Page. See [Customizing Threshold-Based Notifications](#) for how to prioritize alerts.

Default Notifications

By default, MC also generates messages about the database that appear only in the Message Center. You might receive messages about the following database-related conditions:

- Low disk space
- Read-only file system
- Loss of K-safety
- Current fault tolerance at critical level
- Too many ROS containers
- WOS overflow
- Change in node state
- Recovery error
- Recovery failure
- Recovery lock error
- Recovery projection retrieval error
- Refresh error
- Refresh lock error
- Workload Analyzer operations
- Tuple Mover error
- Timer service task error
- Last Good Epoch (LGE) lag

- License size compliance
- License term compliance

Customizing Threshold-Based Notifications

Management Console can generate notifications when your database exceeds threshold limits that you specify. You can configure threshold notifications per database in the Thresholds tab, which appears on your database's Settings page.

You can enable and modify message thresholds for each database that MC monitors. MC then generates a message indicating when a threshold is exceeded. For example, you can set the threshold for node disk usage to a 20% minimum and 80% maximum. As MC monitors node disk usage, it notifies you when any nodes exceed those minimum or maximum thresholds.

MC categorizes customizable message thresholds by license use, system health, and system performance. See [Message Types](#) for a list of the customizable thresholds available in MC.

The default threshold notification settings for Resource Pool Monitoring apply to the GENERAL pool. To customize messages for custom pools, click **Add New Threshold for Custom Resource Pools**.

Configuring Settings for Thresholds

Message thresholds have the following configurable settings:

- Enabling and disabling threshold-specific messages
- Threshold values
- Check time interval
- Alert Priority
- Email Destination
- Email Interval

Configure your notification settings, and click **Apply** to save your changes. If a message threshold has not been set previously, MC displays the default threshold for that setting.

Setting Priorities

You can set a notification to one of three priorities. If a threshold value is exceeded, MC:

- Priority 1 — Sends you an email notification, displays a message in the Overview page, and creates a message in the Message Center.
- Priority 2 — Displays a message in the Overview page, and creates a message in the Message Center.
- Priority 3 — Creates a message in the Message Center.

Setting Email Notifications

In order for MC to send email notifications, you must first provide MC with SMTP server settings. See [Set Up Email](#) .

When you set a threshold to Priority 1, MC can send email notifications to subscribed users.

To subscribe users to a threshold email message:

1. Set the threshold's Alert Priority field to **Priority 1: Overview and Email**. The Email Destination and Email Interval fields appear.
2. Click the browsing icon next to the Email Destination field. The Subscriber List dialog box opens.
3. You can add emails in one of two ways:
 - Select from the list of existing MC users with associated email addresses. (See [Managing MC Users](#) for how to add email addresses to user profiles.)
 - Provide an additional email address in the Entering New Email field. Click the plus (+) icon next to the field to add the address.
4. Click **OK**.
5. Select an option from the **Email Interval** field to choose how frequently users receive email notifications about the threshold if it is exceeded.
6. Click **Apply** at the top-right of the page to save your email subscriber settings.

See Also

- [Message Types](#)
- [Set Up Email](#)
- [Managing MC Users](#)

Set Up Email

Management Console can generate email alerts about high-priority database thresholds. To receive email alerts, you must first configure your SMTP settings in MC.

You must be an administrator to provide SMTP settings.

To set up MC to send email:

1. Select the **Email Gateway** tab on the MC Settings page.
2. Provide the following information about your SMTP server:
 - SMTP Server (Hostname). Maximum length is 255 characters. You can enter either the hostname or IP address.
 - SMTP server port.
 - Session Type (SSL or TLS).
 - SMTP Username.
 - SMTP Password.
 - Originating Email Alias. MC sends alerts from the email address you provide.
3. Click **Test** at the top of the page. MC validates your SMTP settings and sends a test email to the inbox of the email alias you provided.
4. Verify that you successfully received the test email.
5. Click **Apply** at the top-right of the page to save the settings.

With email settings completed, you can configure MC to send high-priority threshold alerts through email. See [Customizing Threshold-Based Notifications](#).

Searching Database Messages Managed by MC

The Management Console Message Center displays the 10,000 most recent database messages, starting with the most recent record.

If more than 600 recent messages exist for a database, MC returns a message letting you know that only the most recent 600 entries are shown, so you have the option to filter.

Changing Message Search Criteria

You can use the search field at the top right of the Message Center to filter your messages by any search term, such as database name, description, or date.

Additionally, click on any filter at the top of the Message Center to sort message by Type, Database Name, Description, or Date. To further filter messages, you can select a database from the Database Name drop down list, type a keyword in the Description filter, or enter a range of dates in the Date filter.

Retrieving Additional Messages

If more than 10,000 messages exist, older messages that occurred before the 10,000 messages do not appear in the Message Center by default. You can click **Retrieve Additional Alerts** to filter for these older messages.

To specify which messages to retrieve, click **Retrieve Additional Alerts**. The Search for Messages dialog appears. Choose a date range, one or more message types, or one or more message types within a specific date range. Click **OK** to view the messages in that range.

Search for messages [X]

Search by date range:
from: to:

Select message types to include:

Emergency Alert Critical
 Error Warning Notice
 Info

OK Cancel

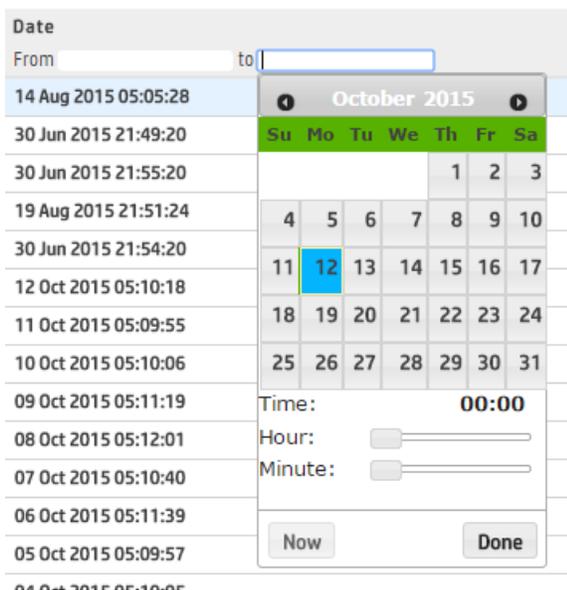

You can adjust the maximum limit of recent messages the Message Center displays in the `/opt/vconsole/config/console.properties` file. To adjust the limit, change the number in the following line:

```
messageCenter.maxEntries=5000
```

Specifying Date Range Searches

For date range searches, MC starts at the beginning of the time range and either returns all messages up to the specified end time or 10,000 messages, whichever comes first. You can filter message searches on the following date ranges:

- Any date-to-date period, including hour and minute
- Any time period up to now (forward searches)
- Any time period before now (backward searches)

After you specify a date range, click **Done** to close the calendar, and then click **OK** to see the results in the Message Center.

Exporting MC-managed Database Messages and Logs

You can export the contents of database messages, log details, query details, and MC user activity to a file.

Information comes directly from the MC interface. This means that if the last five minutes of `vertica.log` information displays on the interface, you can save that five minutes of data to a file, not the entire log. When you filter messages or logs, MC exports only the filtered results.

Depending on how you set your browser preferences, when you export messages you can view the output immediately or specify a location to save the file. System-generated file names include a timestamp for uniqueness.

The following table shows, by record type, the MC pages that contain content you can export, the name of the system-generated file, and what that file's output contains:

Message type	Where you can export on MC	System-generated filename	Contents of exported file
All db-related message types	Message Center page	<code>vertica-alerts-<timestamp>.csv</code>	Exports messages in the Message Center to a <code>.csv</code> file. Message contents are saved under the following headings: <ul style="list-style-type: none"> • Create time • Severity • Database • Summary (of message) • Description (more details)

			<ul style="list-style-type: none">• Activity

Monitoring MC User Activity Using Audit Log

When an MC user makes changes on the MC interface, whether to an MC-managed database or to the MC itself, their action generates a log entry that records a timestamp, the MC user name, the database and client host (if applicable), and the operation the user performed. You monitor user activity on the **Diagnostics > Audit Log** page.

MC records the following types of user operations:

- User log-on/log-off activities
- Database creation
- Database connection through the console interface
- Start/stop a database
- Remove a database from the console view
- Drop a database
- Database rebalance across the cluster
- License activity views on a database, as well as new license uploads
- Workload Analyzer views on a database
- Database password changes
- Database settings changes (individual settings are tracked in the audit record)
- Syncing the database with the cluster (who clicked Sync on grid view)
- Query detail viewings of a database
- Closing sessions

- Node changes (add, start, stop, replace)
- User management (add, edit, enable, disable, delete)
- LDAP authentication (enable/disable)
- Management Console setting changes (individual settings are tracked in the audit record)
- SSL certificate uploads
- Message deletion and number deleted
- Console restart from the browser interface
- Factory reset from the browser interface

Background Cleanup of Audit Records

An internal MC job starts every day and, if required, clears audit records that exceed a specified timeframe and size. The default is 90 days and 2K in log size. MC clears whichever limit is first reached.

You can adjust the time and size limits by editing the following lines in the `/opt/vconsole/config/console.properties` file:

```
vertica.audit.maxDays=90vertica.audit.maxRecords=2000
```

Filter and Export Results

You can manipulate the output of the audit log by sorting column headings, scrolling through the log, refining your search to a specific date/time and you can export audit contents to a file.

If you want to export the log, see [Exporting the User Audit Log](#).

If You Perform a Factory Reset

If you perform a factory reset on MC's Diagnostics page (restore it to its pre-configured state), MC prompts you to export audit records before the reset occurs.

Monitoring External Data Sources in Management Console

By default, Management Console monitors a database using information from that database's Data Collector (DC) tables. MC can also monitor DC tables you have copied into Vertica tables, locally or remotely.

MC administrators provide mappings to local schemas or to an external database containing the corresponding DC data. MC can then render its charts and graphs from the new repository instead of from local DC tables. This offers the benefit of loading larger sets of data faster in MC, and retaining historical data long term.

Note: MC also offers [External Monitoring](#), which allows you to set up a Vertica storage database through the MC interface, then use Kafka to stream your data to the storage database. You can use the Data Source mapping process below if you prefer to set up your own alternative data source, or do not plan to use Kafka streaming.

Map an Alternative Data Source

1. On the MC Settings page, navigate to the Data Source tab.
2. Select the database for which you are creating the data source mapping.
3. Choose the database user for which you want to create the mapping.
4. Set Repository Location to Local or Remote.
5. If Remote is selected, provide JDBC connection parameters for the remote database repository. Click **Validate Connection Properties** to confirm a successful connection.
6. Enter the schema mappings for v_internal and v_catalog. MC does not support mapping the v_monitor schema.
7. Input your table mappings in one of the following ways:
 - Click **Auto Discover**. MC retrieves the table mappings based on the database and schema mappings you provided.
 - Click **Manual Entry**. Manually input table mappings.

- Click **Load Configurations**. If you previously saved a data source configuration for the database in a file, import the file to use that configuration for the currently selected user.
8. Optionally, click **Save Configurations** to export this configuration file. You can create a mapping for another database user with this configuration file later.
 9. Click **Apply** to save and apply your configuration settings.

Reports Using Unmapped Schemas

If a report in MC needs to access a locally stored schema or table that is unmapped, MC includes information from the local DC tables for that schema to complete the report.

For remote configurations, if a report depends on an unmapped schema or table, the entire report is run against the local DC tables. If the remote database is down when MC attempts to run a report against it, MC reruns the report against the local database.

When the MC runs a report, it records missing mappings in the MC log under the INFO severity level.

Loading Data Using MC

You can use the Data Load Activity page in Management Console to import data from Amazon S3 storage to an existing table in Vertica.

MC uses the Vertica library for Amazon Web Services (AWS) to import data directly from Amazon S3 storage to Vertica. You do not need to use any third-party scripts or programs. When you run a loading job, Vertica appends rows to the target table you provide. If the job fails, or you cancel the job, Vertica commits no rows to the target table.

When you view your load history on the Instance tab, loading jobs initiated in Management Console using Amazon S3 have the name MC_S3_Load in the Stream Name column.

For more information about loading data from Amazon S3 storage to Vertica, see [Bulk Loading and Exporting Data From Amazon S3](#).

Prerequisites

To use the Load feature in Management Console, you must first have:

- Access to an Amazon S3 storage account.
- An installed version of Vertica 7.2.2 or later, which includes the Vertica library for Amazon Web Services.
- An existing table in your Vertica database to which you can copy your data. You must be the owner of the table.

Create a Loading Job

To load data from an Amazon S3 bucket to an existing table in your target database:

1. On your target database's Management Console (MC) dashboard, click the **Load** tab at the bottom of the page to view the Data Load Activity page.
2. Click the **Instance** tab.
3. Click **New S3 Data Load** at the top-right of the tab. The **Create New Amazon S3 Loading Job** dialog box opens.

4. Enter your AWS account credentials and your target location information in the required fields, which are indicated by asterisks (*).
5. (Optional) Specify additional options by completing the following fields:
 - Direct
 - COPY Parameters
 - Capture rejected data in a table
 - Reject max

For more about using these fields, see [About Configuring a Data Load from S3](#).

Cancel an Initiated Loading Job

If a loading job is in progress, you can cancel it using the **Cancel** option in the Load History tab's Cancel column. Click **Cancel** to cancel the loading job. When you cancel a job, Vertica rolls back all rows and does not commit any data to the target table.

Status	Time Started	User	Schema Name	Table Name	Execution Time (ms)	Accepted Rows	Rejected Rows	Stream Name	Cancel
Running	Mar 28, 2016 1:...	uidbadadmin	v_dbd_foo	vs_designs	0	0	N/A		Cancel
Success	Mar 28, 2016 1:...	natalia	store	store_orders_fact	10707	299994	Details	MC_S3_Load	
Failure	Mar 28, 2016 1:...	natalia	store	store_orders_fact	581	0	Details	MC_S3_Load	
Success	Mar 28, 2016 12:...	natalia	store	store_orders_fact	1299	11	N/A	S3_Data_load	
Failure	Mar 28, 2016 12:...	natalia			2	0	N/A	S3_Data_load	
Success	Mar 25, 2016 3:...	uidbadadmin	store	store_orders_fact	17990	300000	Details	MC_S3_Load

- [Loading Data From Amazon S3](#)

- [COPY](#)
- [COPY Parameters](#)

About Configuring a Data Load from S3

When you create a new S3 Data Load using MC, you have the option of further configuring the job. You can optionally specify the following:

Load Data into ROS or WOS

You can use the **Direct** field to specify whether to load the data directly into [ROS \(Read Optimized Store\)](#) containers. This is the default setting, and best for large loads of 100MB or more. For smaller loads, deselect this option to load the data into [WOS \(Write Optimized Store\)](#).

Add COPY Parameters

MC performs the loading job using a COPY statement. You can use the COPY Parameters field to further configure the COPY statement, or leave it blank. Only parameters used after the SOURCE parameter in a COPY statement are valid in this field.

Note that if you use the FILTER and PARSER parameters, they must appear in that order and precede any other parameters you use in the COPY Parameters field.

Specify EXCEPTIONS only if you set the **Capture rejected data in a table** field to No.

In the following example, you could use the DELIMITER and SKIP parameters in the COPY parameters field to separate columns with a comma and skip 1 record of input data.

```
DELIMITER ',' SKIP 1
```

To add comments in the COPY statement using this field, begin your comment with a forward slash followed by an asterisk (/*) and end it with an asterisk followed by a forward slash (*). Using a double hyphen (--) does not work in this field.

If COPY rejects the maximum number of rows, Vertica rolls back the target table rows without committing any data.

Capture Rejected Data in a Table

Use the **Capture rejected data in a table** field to create a rejected data table. A rejected data table allows you to view details about rejections through MC. If you set this field to Yes, you will be able to view rejected row data in the Load History tab.

You must have CREATE privilege on the schema if the table doesn't already exist. When you invoke multiple load processes for the same target table, MC appends all rejections data to the same table. MC generates a table using the following naming convention: *schema.s3_load_rejections_target-table-name*.

For more information about capturing rejected data, see [Saving Rejected Data To a Table](#).

Capturing Rejected Data in a Table

Use the **Capture rejected data in a table** field to create a rejected data table. A rejected data table allows you to view details about rejections through MC.

You must have CREATE privilege on the schema if the table doesn't already exist. When you invoke multiple load processes for the same target table, MC appends all rejections data to the same table. MC generates a table using the following naming convention: *schema.s3_load_rejections_target-table-name*.

For more information about capturing rejected data, see [Saving Rejected Data To a Table](#).

Set a Rejected Records Maximum

Use the Reject Max field to specify the maximum number of records that can be rejected before the load fails. If COPY rejects the maximum number of rows, Vertica rolls back the target table rows without committing any data.

Configuration Options

To further configure the loading job, you can use the following optional fields.

Field	Details
Direct	Use the Direct option to indicate whether to load the data into WOS or ROS.

Field	Details
	<ul style="list-style-type: none"> • Selected (Default): The data loads directly into ROS (Read Optimized Store) containers. Use this for large bulk loads (100MB or more). • Deselected: Data loads into WOS (Write Optimized Store). Use this for smaller bulk loads.
COPY Parameters	<p>Use the COPY Parameters field to further configure the COPY statement that will load your data.</p> <p>Valid values:</p> <ul style="list-style-type: none"> • FILTER • PARSER • DELIMITER • TRAILING NULLCOLS • NULL • ESCAPE (NO ESCAPE) • ENCLOSED • RECORD TERMINATOR • SKIP, SKIP BYTES • TRIM 'byte' • EXCEPTIONS 'path' • ENFORCELENGTH • ABORT ON ERROR • STORAGE <p>For more information about COPY syntax, see COPY and COPY Parameters.</p>
Capture rejected data in a table	<p>Use this field to create a rejected data table.</p> <ul style="list-style-type: none"> • Yes: MC generates a rejected data table.

Field	Details
	<ul style="list-style-type: none">• No: MC does not save rejected rows to a table. <p>For more information, see Saving Rejected Data To a Table.</p>
Reject max	Use this field to specify the maximum number of records that can be rejected before the load fails.

Viewing Load History

You can view a history of all your continuous and instance loading jobs in Vertica on the Data Load Activity page.

- **Continuous jobs:** Loading jobs that continuously monitor a source and stream data from the source.
- **Instance jobs:** Loading jobs that batch load from a source. Instance jobs are of a fixed length and shorter-term than continuous loads.

View Continuous Loads

The Continuous tab on the Data Load Activity page displays history of your database's continuous loading jobs. For example, you can see loading jobs you create using the Vertica integration with Kafka (see [Integrating with Apache Kafka](#)). Additionally, if you enable the MC extended monitoring feature, the Continuous tab displays the continuous jobs that stream data from your monitored database to a storage database. (See [Extended Monitoring](#) for more on how MC can use Kafka to monitor databases externally.)

Use the Continuous tab to view details about continuous jobs, such as their source, target tables, and other microbatch configuration details.

If extended monitoring is enabled, jobs streaming to the MC storage database show mc_dc_kafka_config as the scheduler name. Deselect **Show MC data collector monitoring streams** at the top of the tab to remove these jobs from the display.

In the Continuous tab, click the labels in the **Scheduler**, **Microbatch**, and **Errors Last Hour** to view additional details about those loading jobs.

Vertica Management Console dbadmin Log out

For more on continuous data streaming terminology, see [Data Streaming Integration Terms](#).

View Load Instances

In the Instance tab, you can see a history of your database's one-time loading jobs. For example, you can view instance jobs you created using the COPY command in vsql (see [COPY](#)), or instance jobs you created in MC to copy data from an Amazon S3 bucket. (For more about initiating loading jobs in MC, see [Loading Data Using MC](#).)

In the Instance tab, click the labels in the Status column and Rejected Rows column to view more details about completed jobs. For more about rejected rows, see [Capturing Load Rejections and Exceptions](#).

Continuous **Instance**

Load history for the past: 1 hour New S3 Data Load

Status	Source File	Time Started	User	Schema Name	Table Name	Execution Time (ms)	Accepted Rows	Rejected Rows	Stream Name	Cancel
Success	mcqabucket/cs...	Nov 4, 2016 5:34:05 PM	fred	public	townsfile	277	234	4	MC_S3_Load	
Success	mcqabucket/cs...	Nov 4, 2016 5:31:43 PM	fred	public	townsfile	2286	238	0	MC_S3_Load	

The number of load history results on the Instance tab depends on the [Data Collector](#) retention policy for Requests Issued and Requests Completed. To change the retention policy, see [Configuring Data Retention Policies](#).

Viewing Profile Data in MC

Management Console allows you to view profile data about a single query. You can:

- Review the profile data in multiple views
- View details about projection metadata, execution events, and optimizer events
- Identify how much time was spent in each phase of query execution and which phases took the most amount of time

After you select the database you want to use, you can view the profile data using Management Console in either of two ways:

- Focus on specific areas of database activity, such as spikes in CPU usage
- Review the profile data for a specific query

To focus on specific areas of database activity:

1. At the bottom of the Management Console window, click the **Activity** tab.
2. From the list at the top of the page, select **Queries**.
3. On the activity graph, click the data point that corresponds to the query you want to view.
4. In the **View Plan** column, click **Profile** next to the command for which you want to view the query plan. Only certain queries, like SELECT, INSERT, UPDATE, and DELETE, have profile data.
5. In The **Explain Plan** window, Vertica profiles the query.
6. You can view the output in Path Information view, Query Plan Drilldown view, Tree Path view, or Profile Analysis view. To do so, click the respective buttons on the left of the output box.

To review the profile data for a specific query:

1. In the **Explain** window, type or paste the query text into the text box. Additionally, you can monitor queries that are currently running. To do so, perform one of the following. In the **Find a Query By ID** input window:
 - Enter the query statement and transaction ID
 - Click the **Browse Running Queries** link

Caution: If you enter more than one query, Management Console profiles only the first query.

2. To receive periodic updates about the query's progress and resources used, select the **Enable Monitoring** check box. As a best practice, avoid specifying an interval time of less than 60 seconds because doing so may slow your query's progress.
3. Click the **Profile** button.

While Vertica is profiling the query, a **Cancel Query** button is enabled briefly, allowing you to cancel the query and profiling task. If the **Cancel Query** button is disabled, that means Management Console does not have the proper information to cancel the query or the query is no longer running in the database.

When processing completes, the profile data and metrics display below the text box. You can view the output in Path Information view, Query Plan Drilldown view, Tree Path view, or Profile Analysis view. To do so, click the respective view buttons on the left of the output box.

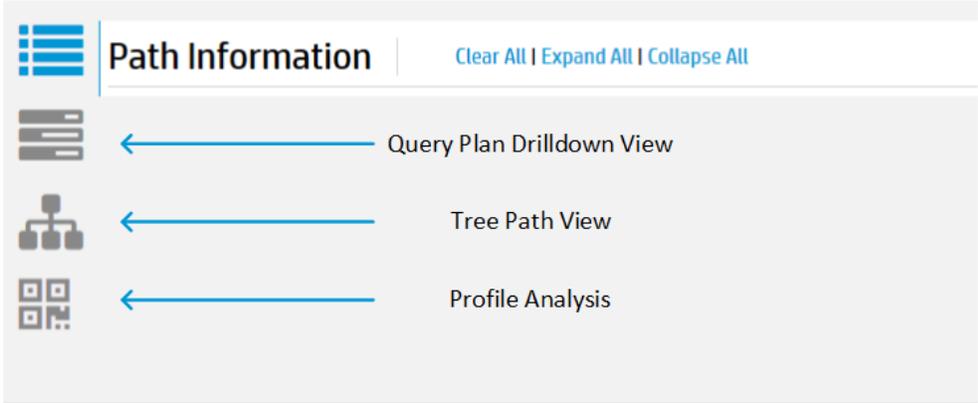

Viewing Different Profile Outputs

Vertica Management Console allows you to examine the results of your query profile in multiple views. You can view your profile in the following formats:

- Path Information view
- Query Drilldown view

- Tree Path view
- Profile Analysis view

You can change the query profile output using the icons on the bottom portion of the **Explain** page.

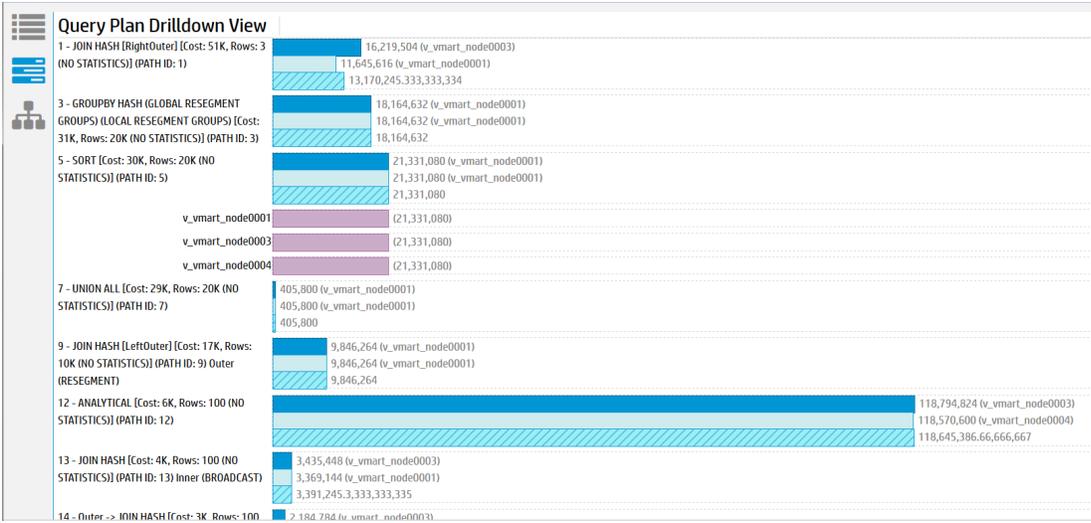

The **Path Information** view displays the query plan path along with metric data. If you enable profile monitoring, the data will update at the specified interval. To view metadata for a projection or a column, click the object name in the path output. A pop-up window displays the metadata if it is available.

The screenshot shows a detailed view of the 'Path Information' section. On the left, a tree view shows the query plan structure with nodes like JOIN HASH, GROUPBY HASH, SORT, UNION ALL, and ANALYTICAL. On the right, a table displays performance metrics for each node. The table has columns for Disk, Memory, Sent, Received, and Time, each with a progress bar. The ANALYTICAL node shows significant activity in the Sent, Received, and Time columns.

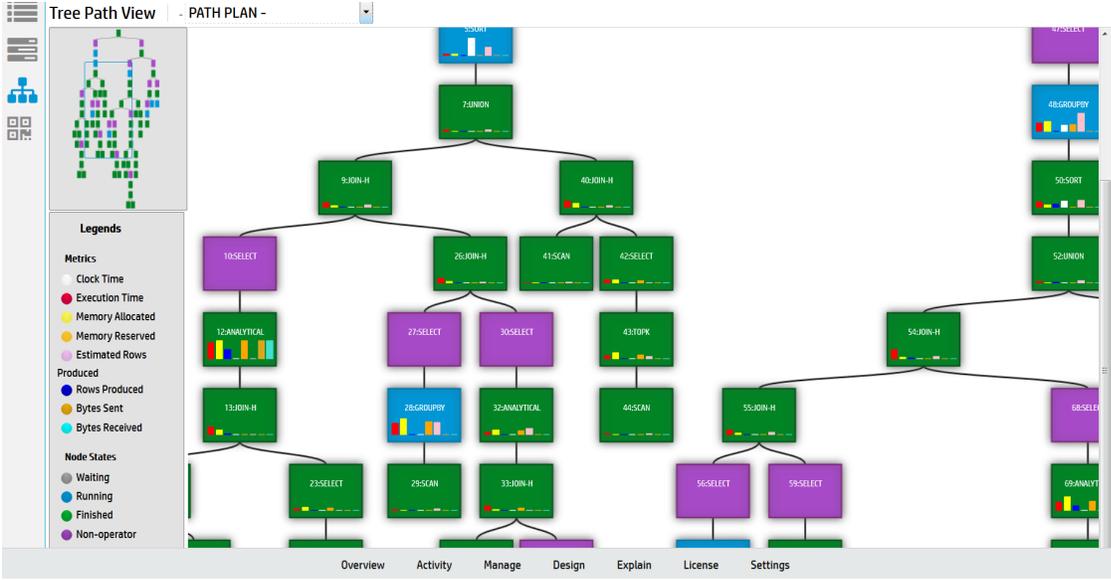

Node / Operator	Disk	Memory	Sent	Received	Time
+ JOIN HASH [RightOuter] [Cost: 51K, Rows: 3 (NO STATISTICS)] (PATH ID: 1)	Progress bar				
+----> GROUPBY HASH (GLOBAL RESEGMENT GROUPS) (LOCAL RESEGMENT GROUPS) [Cost: 31K, Rows: 20K (NO STATISTICS)] (PATH ID: 3)	Progress bar				
+----> SORT [Cost: 30K, Rows: 20K (NO STATISTICS)] (PATH ID: 5)	Progress bar				
+----> UNION ALL [Cost: 29K, Rows: 20K (NO STATISTICS)] (PATH ID: 7)	Progress bar				
+----> JOIN HASH [LeftOuter] [Cost: 17K, Rows: 10K (NO STATISTICS)] (PATH ID: 9) Outer (RESEGMENT)	Progress bar				
+----> ANALYTICAL [Cost: 6K, Rows: 100 (NO STATISTICS)] (PATH ID: 12)	Progress bar				

The **Query Plan Drilldown** view shows detailed counter information at the node and operator level.

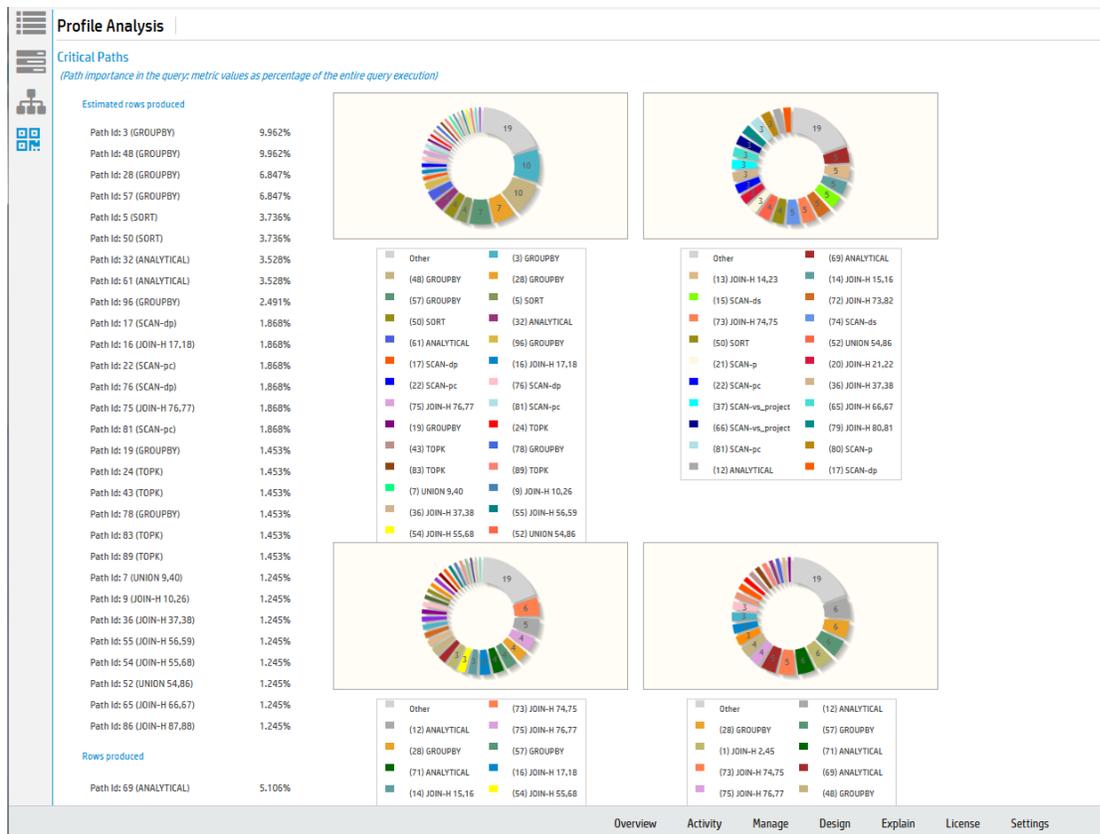

For each path, the path number is listed along with statistical information on the node and operator level. This view allows you to see which nodes are acting as outliers. Click on any of the bars to expand details for that node.

The **Tree Path** details the query plan in the form of a tree. If you enable monitoring, the state of the path blocks will change depending on whether the path is running, done, or has not started. Metric information is displayed in each path block for the counters you specified in the Profile Settings.

The **Profile Analysis** view allows you to identify any resource outliers. You can compare the estimated rows produced count with the actual rows produced count, view execution time per path, and identify memory usage per path.

When you profile a query, you will also see a pie chart detailing the query phase duration. You can also view projection metadata, execution events, and optimizer events by clicking on the respective buttons next to the pie chart.

Monitoring Profiling Progress

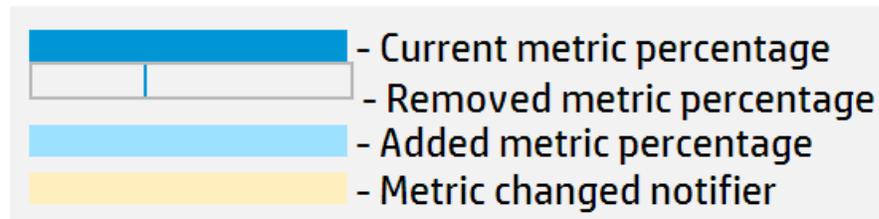

While loading profile data for a query, Management Console can provide updates about the query's progress and resources used.

To enable profiling progress updates, select the Enable Monitoring check box when profiling a query. See [Viewing Profile Data in Management Console](#).

The default interval time is 60 seconds. At the specified interval, Management Console displays an updated view of the query's progress. Note that interval times of less than 60 seconds may slow down your query.

Viewing Updated Profile Metrics

At every interval, Management Console displays a new set of profile metrics. You can view these metrics in Path Information view, Query Plan Drilldown view, or Tree view by clicking the respective view buttons on the left of the output box.

- A dark blue bar indicates the current metric percentage.
- When a metric bar has decreased, a dark blue line indicates the previous metric percentage.
- When a metric bar has increased, a light blue bar indicates the added percentage. The previous percentage appears as a dark blue bar.
- A metric bar highlighted in yellow indicates it has changed since the last interval.
- A metric bar highlighted in red indicates the absolute value of the metric has decreased. This typically means Vertica reported the previous value incorrectly, and has readjusted. (For example, if Vertica previously reported path's Time value as 75 seconds, then reports it as 50 seconds at the next interval, the metric bar turns red to indicate the decrease in absolute Time value.)

Expanding and Collapsing Query Path Profile Data

When you have a query on the EXPLAIN window, the profile data displays in the right-hand side of the lower half of the window. The query path information can be lengthy, so you can collapse path information that is uninteresting, or expand paths that you want to focus on.

- To collapse all the query paths, click **Collapse All**.
- To expand all the query paths, click **Expand All**.
- To expand an individual query path so you can see details about that step in processing the query, click the first line of the path information. Click the first line again to collapse the path data.

For information about what the profile data means, see [About Profile Data in Management Console](#).

About Profile Data in Management Console

After you profile a specific query, the Management Console Explain page displays profile data like query duration, projection metadata, execution events, optimizer events, and metrics in a pie chart.

See the following links for more information on the kinds of profile data you can review on the Management Console Explain page:

- [Projection Metadata](#)
- [Query Phase Duration](#)
- [Profile Metrics](#)
- [Execution Events](#)
- [Optimizer Events](#)

Projection Metadata

To view projection metadata for a specific projection, click the projection name in the EXPLAIN output. Metadata for that projection opens in a pop-up window.

To view projection data for all projections accessed by that query, click the **View Projection Metadata** button at the top of the **Explain** page. The metadata for all projections opens in a new browser window.

Note: If the **View Projection Metadata** button is not enabled, click **Profile** to retrieve the profile data, including the projection metadata.

The projection metadata includes the following information:

- Projection ID
- Schema name
- Whether or not it is a superprojection
- Sort columns
- IDs of the nodes the projection is stored on
- Whether or not it is segmented
- Whether or not it is up to date
- Whether or not it has statistics
- Owner name
- Anchor table name

To display a SQL script that can recreate the projection on a different cluster, click **Click to get export data**. This script is identical to the output of the [EXPORT_OBJECTS](#) function. The SQL script opens in a pop-up window.

Copy and paste the command from this window, and click **Close**.

Query Phase Duration

This pie chart appears in the upper-right corner of the Query Plan window. It shows what percentage of total query processing was spent in each phase of processing the query.

The phases included in the pie chart (when applicable) are:

- Plan
- InitPlan
- SerializePlan
- PopulateVirtualProjection
- PreparePlan
- CompilePlan

- ExecutePlan
- AbandonPlan

Hover over the slices on the pie chart or over the names of the phases in the box to get additional information. You can see the approximate number of milliseconds (ms) and percentage used during each phase.

Note: The time data in the profile metrics might not match the times in the query phase duration. These times can differ because the query phase duration graph uses the longest execution time for a given phase from all the nodes. Network latency can add more data, which is not taken into account in these calculations.

Profile Metrics

In the **Path Information** view, the area to the right of each query path contains profile metrics for that path.

- **Disk**—Bytes of data accessed from disk by each query path. If none of the query paths accessed the disk data, all the values are 0.
- **Memory**—Bytes of data accessed from memory by each query path.
- **Sent**—Bytes of data sent across the cluster by each query path.
- **Received**—Bytes of data received across the cluster by each query path.
- **Time**—Number of milliseconds (ms) that the query path took to process on a given node, shown on progress bars. The sum of this data does not match the total time required to execute the query. This mismatch occurs because many tasks are executed in parallel on different nodes.

Hover over the progress bars to get more information, such as total bytes and percentages.

Note: The time data in the profile metrics might not match the times in the [Query Phase Duration](#) chart. These times can differ because the query phase duration graph uses the longest execution time for a given phase from all the nodes. Network latency can add more data, which is not taken into account in these calculations.

Execution Events

To help you monitor your database system, Vertica logs significant events that affect database performance and functionality. Click **View Execution Events** to see information about the events that took place while the query was executing.

If the **View Execution Events** button is not enabled, click **Profile** to retrieve the profile data, including the execution events.

The arrows on the header of each column allow you to sort the table in ascending or descending order of that column.

The execution events are described in the following table.

Event Characteristic	Details
Time	Clock time when the event took place.
Node Name	Name of the node for which information is listed.
Session ID	Identifier of the session for which profile information is captured.
User ID	Identifier of the user who initiated the query.
Request ID	Unique identifier of the query request in the user session.
Event Type	Type of event processed by the execution engine. For a list of events and their descriptions, see Initial Process for Improving Query Performance .
Event Description	Generic description of the event.
Operator Name	Name of the Execution Engine component that generated the event. Examples include but are not limited to: <ul style="list-style-type: none">• DataSource• DataTarget• NetworkSend• NetworkRecv• StorageUnion

	Values from the Operator name and Path ID columns let you tie a query event back to a particular operator in the query plan. If the event did not come from a specific operator, then this column is NULL.
Path ID	Unique identifier that Vertica assigns to a query operation or a path in a query plan. If the event did not come from a specific operator, this column is NULL.
Event OID	A unique ID that identifies the specific event.
Event Details	A brief description of the event and details pertinent to the specific situation.
Suggested Action	Recommended actions (if any) to improve query processing.

Optimizer Events

To help you monitor your database system, Vertica logs significant events that affect database performance and functionality. Click **View Optimizer Events** to see a table of the events that took place while the optimizer was planning the query.

If the **View Optimizer Events** button is not enabled, click **Profile** to retrieve the profile data, including the optimizer events.

The arrows on the header of each column allow you to sort the table in ascending or descending order of that column.

The following types of optimizer events may appear in the table:

Event characteristic	Details
Time	Clock time when the event took place.
Node Name	Name of the node for which information is listed.
Session ID	Identifier of the session for which profile information is captured.
User ID	Identifier of the user who initiated the query.
Request ID	Unique identifier of the query request in the user session.
Event Type	Type of event processed by the optimizer.

Event Description	Generic description of the event.
Event OID	A unique ID that identifies the specific event.
Event Details	A brief description of the event and details pertinent to the specific situation.
Suggested Action	Recommended actions (if any) to improve query processing.

Clearing Query Data

After you finish reviewing the current query data, click **Clear All** to clear the query text and data. Alternatively, to display information about another query, enter the query text and click **Explain** or **Profile**.

Extended Monitoring

Enabling extended monitoring allows you to monitor a longer range of data through MC. This can offer insight into long-term trends in your database's health. MC can also continue to display your monitored database's dashboard while it is down.

Extended monitoring uses Kafka to stream monitoring data from your monitored databases to a single MC storage database. MC can query the storage database instead of your monitored database to render some of its charts, reducing impact on your monitored database's performance.

How Extended Monitoring Works

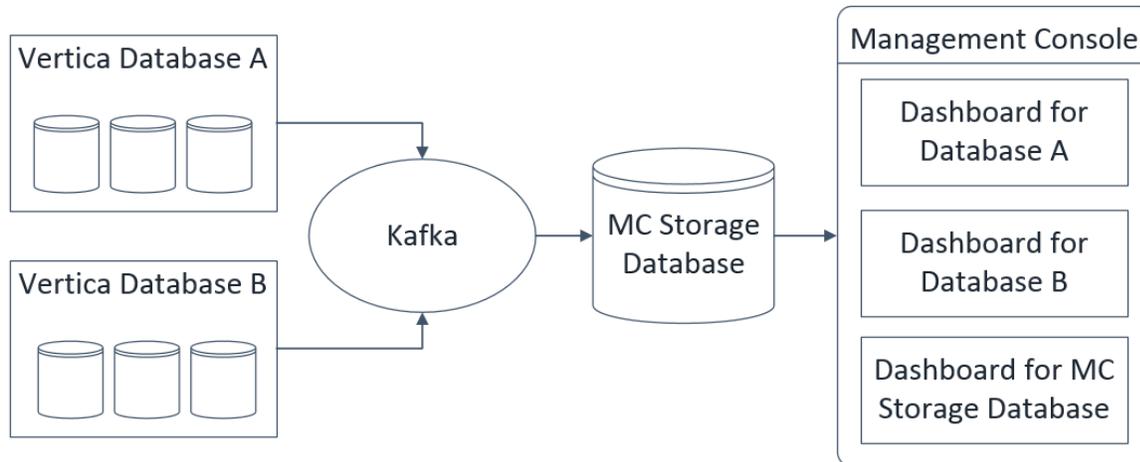

By default, MC monitors your database by querying it directly for monitoring data about system activities, performance, and resource utilization. Typically, the [Data Collector](#) stores all monitoring data in data collector (DC) tables. However, DC tables have limited retention periods. See [Retaining Monitoring Information](#).

Extended monitoring stores your database's monitoring data in a dedicated storage database. Vertica streams data from your database's DC tables through Kafka servers to the storage database. To use extended monitoring, you must have access to a running Kafka server. For more how Vertica integrates with Kafka, see [Integrating with Apache Kafka](#).

After you set up and enable extended monitoring for a monitored database, MC renders several of your database's charts and graphs by querying the MC storage database instead of directly querying the database you are monitoring.

You can enable extended monitoring for any, or all, of your monitored databases. The MC storage database provides a single repository for monitoring data from every database that uses enabled extended monitoring.

In the following example, Kafka streams system data from two monitored databases to the storage database. MC uses the storage database to render individual dashboards for each monitored database. Be aware that MC always creates a dashboard that monitors the MC storage database.

Use Extended Monitoring

Important: To use extended monitoring, Micro Focus recommends installing Management Console on a host without any other Vertica databases.

When a database has extended monitoring enabled, the MC charts that use the feature display a rocket ship icon in the corner. You can use these charts to access longer-term data about your database's health or performance.

To view historical information in these charts, click the calendar icon to specify the timeframe to display. For example, if your database has been down for several hours, your charts do not display recent activity in your database. You could use the timeframe filter in the System Bottlenecks chart to see unusual resource usage occurred in your database in the hour it went down.

You can view a history of the Kafka streaming jobs loading data into the storage database. MC displays these jobs on the Load tab of your storage database's dashboard. See [Viewing Load History](#).

Set Up Extended Monitoring

To set up extended monitoring, see [Managing the Storage Database](#) and [Managing Extended Monitoring on a Database](#).

See Also

- [Managing the Storage Database](#)
- [Managing Extended Monitoring on a Database](#)
- [Viewing Load History](#)
- [Integrating with Apache Kafka](#)
- [Retaining Monitoring Information](#)

Managing the Storage Database

Extended Monitoring stores your Vertica database's monitoring data in a dedicated MC storage database.

To use Extended Monitoring, you must first set up the storage database and configure it for Kafka streaming. Then, turn on Extended Monitoring for any or all monitored databases.

MC automatically configures a schema for the storage database, named `dcschema`, which is synced with DC tables on your monitored databases.

Caution: Do not alter `dcschema` after MC has configured it. Altering it could cause the storage database to lose data or supply incorrect monitoring information to MC.

MC Preparation

First verify that MC is not installed on the same host as a Vertica database. When Extended Monitoring is enabled, MC sharing a host with a production database can affect performance.

You must also increase the allocation of memory for the MC application server. See [Modify Memory Allocation](#). Tune these options based on:

- The demands of your database
- The amount of monitoring data you plan to view in MC charts at once.

For example, MC requires more memory to display a week of data in a chart.

Modify Memory Allocation

To modify memory allocation:

1. In Management Console, select the **Configuration** tab on the MC Settings page.
2. Modify the following fields under **Application Server JVM Settings** to increase the allocation of memory for the JVM:
 - **Initial Heap Size:** For Extended Monitoring, a minimum value of 2GB is recommended. (The default value is 1GB.)
 - **Maximum Heap Size:** For Extended Monitoring, a minimum value of 4GB is recommended. (The default value is 2GB.)
3. Click **Apply** at the top right of the page. A prompt appears to restart MC.
4. Click **OK** to restart MC and save your changes.

Storage Database Requirements

To set up storage for Extended Monitoring, your system must meet the following prerequisites:

- Vertica 8.x
- An available host, or available database whose Vertica version corresponds to the version of the database you plan to monitor. (eg. To use Extended Monitoring for a Vertica 8.1.0 database, its storage database should also be on Vertica 8.1.0.)
- Configured MC for Extended Monitoring (See [MC Preparation](#))
- Access to a deployed Kafka server (For details on installing Kafka, see the [Apache Kafka site](#))

Set Up the Storage Database

To set up the storage database for Extended Monitoring:

1. On the MC Settings page, select the MC Storage DB Setup tab.
2. In the Server field in the Kafka Broker section, enter the host name or IP addresses and ports for one or more of your deployed Kafka servers.
3. Designate the storage database in the MC External Storage Database section. You can create a new database, or use an existing database.
 - **Create a new database:** Choose this option to create a new single node cluster on an available host using a Community Edition license of Vertica. This choice does not affect your normal Vertica license usage.
 - **Use an existing database known to MC:** Choose this option to designate a database you have already imported to MC. If the schema 'dcschema' exists in the database, a dialog appears:
 - Click **Append** to keep the existing schema's data. For example, if you have already used this database for Extended Monitoring storage and are re-importing it, you can use this option to retain its historical data for continued use.
 - Click **Remove** to clear the existing schema from the database, and creates a fresh version of dcschema configured for Extended Monitoring storage.
4. Click **Enable Streaming** to enable data streaming from the Kafka server to the MC storage database.
5. Turn on Extended Monitoring for your databases on the Extended Monitoring tab. See [Managing Extended Monitoring on a Database](#) for more information.

Restart the Storage Database

If you stop the storage database while streaming is enabled, streaming to the storage database stops automatically. You must re-enable streaming on the MC Storage DB Setup tab after you restart the storage database.

If streaming to the MC storage database is disabled while Extended Monitoring on your database is on, the Kafka retention policy determines how long streaming can remain disabled without data loss. See [Managing Streaming Services for Extended Monitoring](#).

Discontinue the Storage Database

1. Select the Extended Monitoring tab in MC Settings.
2. Set Extended Monitoring for all databases to **OFF**.
3. Select the MC Storage DB Setup tab in MC Settings.
4. Click **Disable Streaming** in the MC External Storage Database section to de-activate your storage database.
5. Click **Remove** in the MC External Storage Database section to remove the MC Storage Database from MC.
6. Choose whether to keep or remove the data your storage database has collected:
 - **Keep Data:** Existing data will not be removed. If you re-use this database for Extended Monitoring storage, you can choose to append new collected monitoring data to this existing data.
 - **Remove Data:** MC deletes its customized storage schema from the database.

Configure Storage Database Memory Usage

On the Resource Pools tab of the storage database, you can optionally increase the memory size of `SYSQUERY` and `KAFKA_DEFAULT_POOL`. For setting resource pool parameters in MC, see [Configuring Resource Pools in Management Console](#).

- **SYSQUERY:** Reserved for temporary storage of intermediate results of queries against system monitoring and catalog tables. Default setting is 64M. For best performance for MC, set to 2G or higher.
- **KAFKA_DEFAULT_POOL:** Reserved for all queries executed by the Kafka scheduler. Default setting is 30%, which is the recommended setting. By default, queries spill to the general pool when they exceed the 30% memory size.

Manage Disk Space

The storage database uses a customized schema, named `dcschema`. You can monitor these tables on MC, using the Table Utilization chart on the storage database's Activity tab. The Table

Utilization chart lists all the tables in dcschema and their details, such as row counts and column properties. You can sort by row count to determine if certain tables use more disk space on your storage database. See [Monitoring Table Utilization and Projections](#).

You should regularly drop partitions from dcschema if you have limited disk space for the MC storage database. MC does not automatically drop partitions from the storage database. For more information on dropping partitions, see [Dropping Partitions](#).

The table dc_execution_engine_profiles is partitioned by day. Because this table typically contains the most rows, as a best practice you should drop partitions from this table more often. The following example shows how you can specify the partition key 2016-08-22 to drop a partition from dc_execution_engine_profiles.

```
SELECT DROP_PARTITION('dcschema.dc_execution_engine_profiles',  
2016-08-22);
```

Other than dc_execution_engine_profiles, all other tables in dcschema are partitioned by week. The next example shows you how you can drop a partition from the table dc_cpu_aggregate_by_minute, specifying the thirty-fourth week of 2016.

```
SELECT DROP_PARTITION('dcschema.dc_cpu_aggregate_by_minute',  
201634);
```

Manage Client Sessions

By default Vertica allows 50 client sessions and an additional five administrator sessions per node. If you reach the limit on the storage database, MC switches back to default monitoring, and does not use Extended Monitoring data from the storage database.

You can optionally configure the maximum number of client sessions that can run on a single database cluster node on your MC storage database's Settings page:

1. On the storage database dashboard, click the **Settings** page.
2. Choose the **General** tab.
3. Input a value in the **Maximum client sessions** field. Valid values for the parameter are 0 to 1000.

For more details about managing client connections in MC, see [Managing Client Connections](#).

See Also

- [Extended Monitoring](#)
- [Managing Extended Monitoring on a Database](#)
- [Viewing Load History](#)

Managing Extended Monitoring on a Database

When you enable extended monitoring on your Vertica database, monitoring data from your database streams through Kafka servers to the MC storage database.

You can enable streaming for any or all databases that MC monitors.

Extended Monitoring Prerequisites

Before you can enable extended monitoring, your system must meet these prerequisites:

- Vertica 8.x
- Deployed Kafka server(s)
- Configured MC for extended monitoring (See [Managing the Storage Database](#))
- Deployed MC storage database (See [Managing the Storage Database](#))

Enable Extended Monitoring

1. Select the Extended Monitoring tab on MC Settings.

The Extended Monitoring page displays all databases monitored by MC.

2. In the Memory Limit field for the database of your choice, set the maximum amount of memory the database can use for streaming monitoring data. For more about the memory limit, see [Managing Streaming Services for Extended Monitoring](#).

3. In the Extended Monitoring column, select **ON** to enable streaming for the database of your choice.

The database begins streaming its monitoring data to the Kafka server.

User Access

When you change user permissions for a database using extended monitoring, the user access policy on the storage database does not automatically update. On the Extended Monitoring page, in the user access column for your database, click Refresh to sync the policy.

If you rename a Vertica user, you must re-map the user in MC Settings before refreshing the user access policy.

- [Viewing Load History](#)
- [Integrating with Apache Kafka](#)

Managing Streaming Services for Extended Monitoring

When extended monitoring is enabled, Vertica streams data from your database through Kafka servers to the storage database.

For additional parameters that optimize the performance of Kafka with Vertica, see [Configuring Kafka for Vertica](#).

View Streaming Details in MC

Click the Load tab on your database's MC dashboard to see the Data Load Activity page. On this page, the Continuous tab displays details about all continuous loading jobs for extended monitoring. You can use this page to monitor whether your extended monitoring data is streaming successfully to the MC storage database.

See [Viewing Load History](#) for more about the Data Load Activity page.

Tip: If you do not see loading jobs for extended monitoring, verify that you have selected **Show MC data collector monitoring streams** at the top of the Continuous tab.

Prevent Data Loss

The Memory Limit buffer allows you to restart the Kafka server without data loss. Vertica queues the streamed data until you restart the Kafka server. When the Kafka server remains down for an extended period of time, data loss occurs when the queue of streamed data exceeds the buffer. You set the buffer size on the Extended Monitoring tab when you enable extended monitoring for a database. See [Managing Extended Monitoring on a Database](#).

The Kafka retention policy determines when data loss occurs during the following scenarios:

- Restarting the MC storage database (see [Managing the Storage Database](#))
- Disabling streaming on the MC storage database (see [Managing the Storage Database](#))
- Restart a micro-batch (see [Loading Data Using MC](#))

The Kafka retention policy can allow you to restart these extended monitoring components without data loss. The Kafka server retains the data while the listed components are disabled. Data loss occurs when the streamed data exceeds the Kafka retention policy's log size or retention time limits. See the [Apache Kafka documentation](#) for how to configure the retention policy.

Changing the Kafka Server

Be aware that when you change Kafka servers for extended monitoring on the MC Storage DB Setup page, you must disable all extended monitoring processes and re-configure the

MC storage database. For storage database setup instructions, see [Managing the Storage Database](#).

SQL Reference Manual

Welcome to the Vertica SQL Reference Manual. This guide provides an overview of Vertica Structured Query Language (SQL). It defines system limits, describes SQL Language elements and system tables. This guide also provides reference descriptions of SQL Data Types, SQL Functions, and SQL Statements.

This document assumes that you are familiar with the basic concepts and terminology of the SQL language and relational database management systems.

SQL in Vertica

Vertica offers a robust set of SQL elements that allow you to manage and analyze massive volumes of data quickly and reliably. Vertica uses the following:

[SQL language elements](#), including:

- Keywords and Reserved Words
- Identifiers
- Literals
- Operators
- Expressions
- Predicates
- Hints

[SQL data types](#), including:

- Binary
- Boolean
- Character
- Date/Time
- Long
- Numeric

[SQL functions](#) including Vertica-specific functions that take advantage of Vertica's unique column-store architecture. For example, call [ANALYZE_STATISTICS](#) to collect and aggregate a variable amount of sample data for statistical analysis.

[SQL statements](#) that let you write robust queries to quickly return large volumes of data.

System Limits

This section describes the system limits on the size and number of objects in a Vertica database. In most cases, computer memory and disk drive are the limiting factors.

Item	Limit
Number of nodes	Maximum 128 (without Vertica assistance)
Database size	Approximates the number of files times the file size on a platform, depending on the maximum disk configuration
Table size	The smaller of: <ul style="list-style-type: none"> • 2^{64} rows per node • 2^{63} bytes per column
Row size	32,768,000 bytes Row size is approximately the sum of its maximum column sizes, where, for example, a VARCHAR(80) has a maximum size of 80 bytes.
Key size	Limited only by row size
Number of tables/projections per database	Limited by physical RAM, as the catalog must fit in memory.
Number of concurrent connections per node	Default of 50, limited by physical RAM (or threads per process), typically 1024
Number of concurrent connections per cluster	Limited by physical RAM of a single node (or threads per process), typically 1024
Number of columns per table	1600
Number of rows per load	2^{63}
Number of partitions	1024

Item	Limit
	For details, see Partitioning Best Practices in the Administrator's Guide.
Length for a fixed-length column	65000 bytes
Length for a variable-length column	32000000 bytes
Length of basic names	128 bytes. Basic names include table names, column names, etc.
Query length	No limit
Depth of nesting subqueries	Unlimited in FROM, WHERE, and HAVING clauses

SQL Language Elements

This chapter presents detailed descriptions of the language elements and conventions of Vertica SQL.

Keywords

Keywords are words that have a specific meaning in the SQL language. Every SQL statement contains one or more keywords. Although SQL is not case-sensitive with respect to keywords, they are generally shown in uppercase letters throughout this documentation for readability purposes.

Note: If you use a keyword as the name of an identifier or an alias in your SQL statements, you may have to qualify the keyword with AS or double-quotes. Vertica requires AS or double-quotes for certain reserved and non-reserved words to prevent confusion with expression syntax, or where the use of a word would be ambiguous.

Reserved Words and Keywords

Many keywords are also reserved words.

Vertica recommends that you not use reserved words as names for objects, or as identifiers. Including reserved words can make your SQL statements confusing. Where you need to use reserved words as names for objects or as identifiers, you need to double-quote them. An example of where you might need to do this is where Vertica has added a reserved word that you already use throughout your existing SQL scripts.

Note: All reserved words are also keywords, but Vertica can add reserved words that are not keywords. A reserved word can simply be a word that is reserved for future use.

Non-reserved Keywords

Non-reserved keywords have a special meaning in some contexts, but can be used as identifiers in others. You can use non-reserved keywords as aliases—for example, SOURCE:

```
=> SELECT my_node AS SOURCE FROM nodes;
```

Note: Vertica uses several non-reserved keywords in [directed queries](#) to specify special join types. You can use these keywords as table aliases only if they are double-quoted; otherwise, double-quotes can be omitted:

- ANTI
- NULLAWARE
- SEMI
- SEMIALL
- UNI

Viewing the List of Reserved and Non-reserved Keywords

To view the current list of Vertica reserved and non-reserved words, query the [KEYWORDS](#) system table.

```
VMart=> select * from keywords;
```

The output lists keywords alphabetically and identifies them as reserved (R) or non-reserved (N).

Identifiers

Identifiers (names) of objects such as schema, table, projection, column names, and so on, can be up to 128 bytes in length.

Unquoted Identifiers

Unquoted SQL identifiers must begin with one of the following:

- Letters (use A–Z or a-z only; behavior for Unicode is undefined)
- Underscore (`_`)

Subsequent characters in an identifier can be:

- Letters (as above)
- Unicode letters (letters with diacriticals or not in the Latin alphabet)
- Underscore (_)
- Digits(0–9)
- Dollar sign (\$)

Caution: The SQL standard does not support dollar sign in identifiers so usage can cause application portability problems.

Quoted Identifiers

Identifiers enclosed in double quote (") characters can contain any character. If you want to include a double quote, you need a pair of them; for example """". You can use names that would otherwise be invalid, such as names that include only numeric characters ("123") or contain space characters, punctuation marks, keywords, and so on; for example:

```
CREATE SEQUENCE "my sequence!";
```

Double quotes are required for non-alphanumerics and SQL keywords such as "1time", "Next week" and "Select".

Note: Identifiers are not case-sensitive. Thus, identifiers "ABC", "ABc", and "aBc" are synonymous, as are ABC, ABc, and aBc.

Non-ASCII Characters

Vertica accepts non-ASCII UTF-8 Unicode characters for table names, column names, and other [Identifiers](#), extending the cases in which upper/lower case distinctions are ignored (case-folded) to all alphabets, including Latin, Cyrillic, and Greek.

For example, the following CREATE TABLE statement uses the ß (German eszett) in the table name:

```
=> CREATE TABLE straÙe(x int, y int);  
CREATE TABLE
```

Identifiers Are Stored As Created

SQL identifiers, such as table and column names, are no longer converted to lowercase. They are stored as created, and references to them are resolved using case-insensitive compares. It is not necessary to double quote mixed-case identifiers. For example, the following statement creates table ALLCAPS.

```
=> CREATE TABLE ALLCAPS(c1 varchar(30));  
=> INSERT INTO ALLCAPS values('upper case');
```

The following statements are variations of the same query and all return identical results:

```
=> SELECT * FROM ALLCAPS;  
=> SELECT * FROM allcaps;  
=> SELECT * FROM "allcaps";
```

All three commands return the same result:

```
      c1  
-----  
upper case  
(1 row)
```

Note that the system returns an error if you try to create table AllCaps:

```
=> CREATE TABLE AllCaps(c1 varchar(30));  
ROLLBACK: table "AllCaps" already exists
```

See [QUOTE_IDENT](#) for additional information.

Literals

Literals are numbers or strings used in SQL as constants. Literals are included in the select-list, along with expressions and built-in functions and can also be constants.

Vertica provides support for number-type literals (integers and numerics), string literals, VARBINARY string literals, and date/time literals. The various string literal formats are discussed in this section.

Number-Type Literals

Vertica supports three types of numbers: integers, numerics, and floats.

- **Integers** are whole numbers less than 2^{63} and must be digits.
- **Numerics** are whole numbers larger than 2^{63} or that include a decimal point with a precision and a scale. Numerics can contain exponents. Numbers that begin with 0x are hexadecimal numerics.

Numeric-type values can also be generated using casts from character strings. This is a more general syntax. See the Examples section below, as well as [Data Type Coercion Operators \(CAST\)](#).

Syntax

```
digits  
digits.[digits] | [digits].digits  
digits e[+/-]digits | [digits].digits e[+/-]digits | digits.[digits] e[+/-]digits
```

Parameters

<i>digits</i>	One or more numeric characters, 0 through 9
<i>e</i>	Exponent marker

Notes

- At least one digit must follow the exponent marker (e), if e is present.
- There cannot be any spaces or other characters embedded in the constant.
- Leading plus (+) or minus (–) signs are not considered part of the constant; they are unary operators applied to the constant.
- In most cases a numeric-type constant is automatically coerced to the most appropriate type depending on context. When necessary, you can force a numeric value to be interpreted as a specific data type by casting it as described in [Data Type Coercion Operators \(CAST\)](#).
- Floating point literals are not supported. If you specifically need to specify a float, you can cast as described in [Data Type Coercion Operators \(CAST\)](#).
- Vertica follows the IEEE specification for floating point, including NaN (not a number) and Infinity (Inf).
- A NaN is not greater than and at the same time not less than anything, even itself. In other words, comparisons always return false whenever a NaN is involved.
- Dividing INTEGERS (x / y) yields a NUMERIC result. You can use the // operator to truncate the result to a whole number.

Examples

The following are examples of number-type literals:

```
42
3.5
4.
.001
5e2
1.925e-3
```

Scientific notation :

```
=> SELECT NUMERIC '1e10';
?column?
-----
10000000000
(1 row)
```

BINARY scaling:

```
=> SELECT NUMERIC '1p10';  
?column?  
-----  
      1024  
(1 row)  
=> SELECT FLOAT 'Infinity';  
?column?  
-----  
Infinity  
(1 row)
```

The following examples illustrated using the / and // operators to divide integers:

```
=> SELECT 40/25;  
?column?  
-----  
1.6000000000000000  
(1 row)  
=> SELECT 40//25;  
?column?  
-----  
      1  
(1 row)
```

See Also

[Data Type Coercion](#)

String Literals

String literals are string values surrounded by single or double quotes. Double-quoted strings are subject to the backslash, but single-quoted strings do not require a backslash, except for `\` and `\\`.

You can embed single quotes and backslashes into single-quoted strings.

To include other backslash (escape) sequences, such as `\t` (tab), you must use the double-quoted form.

Precede single-quoted strings with a space between the string and its preceding word, since single quotes are allowed in identifiers.

See Also

- [SET STANDARD_CONFORMING_STRINGS](#)
- [SET ESCAPE_STRING_WARNING](#)
- [Internationalization Parameters](#)
- [Implement Locales for International Data Sets](#)

Character String Literals

Character string literals are a sequence of characters from a predefined character set and are enclosed by single quotes. If the single quote is part of the sequence, it must be doubled as `''`.

Syntax

`'characters'`

Parameters

<code>characters</code>	Arbitrary sequence of characters bounded by single quotes ('')
-------------------------	--

Single Quotes in a String

The SQL standard way of writing a single-quote character within a string literal is to write two adjacent single quotes. For example:

```
=> SELECT 'Chester''s gorilla';
   ?column?
-----
Chester's gorilla
(1 row)
```

Standard Conforming Strings and Escape Characters

Vertica uses standard conforming strings as specified in the SQL standard, which means that backslashes are treated as string literals, not escape characters.

Note: Earlier versions of Vertica did not use standard conforming strings, and backslashes were always considered escape sequences. To revert to this older behavior, set the `StandardConformingStrings` parameter to '0', as described in [Configuration Parameters](#) in the Administrator's Guide.

Examples

```
=> SELECT 'This is a string';
   ?column?
-----
This is a string
(1 row)
=> SELECT 'This \is a string';
      WARNING: nonstandard use of escape in a string literal at character 8
      HINT: Use the escape string syntax for escapes, e.g., E'\r\n'.
   ?column?
-----
This is a string
(1 row)
vmartdb=> SELECT E'This \is a string';
   ?column?
-----
This is a string
=> SELECT E'This is a \n new line';
   ?column?
-----
This is a
new line
(1 row)
=> SELECT 'String''s characters';
   ?column?
-----
```

```
String's characters  
(1 row)
```

See Also

- [SET STANDARD_CONFORMING_STRINGS](#)
- [SET ESCAPE_STRING_WARNING](#)
- [Internationalization Parameters](#)
- [Implement Locales for International Data Sets](#)

Dollar-Quoted String Literals

Dollar-quoted string literals are rarely used, but are provided here for your convenience.

The standard syntax for specifying string literals can be difficult to understand. To allow more readable queries in such situations, Vertica SQL provides dollar quoting. Dollar quoting is not part of the SQL standard, but it is often a more convenient way to write complicated string literals than the standard-compliant single quote syntax.

Syntax

```
$$characters$$
```

Parameters

<i>characters</i>	Arbitrary sequence of characters bounded by paired dollar signs (\$\$)
-------------------	--

Dollar-quoted string content is treated as a literal. Single quote, backslash, and dollar sign characters have no special meaning within a dollar-quoted string.

Notes

A dollar-quoted string that follows a keyword or identifier must be separated from the preceding word by whitespace; otherwise, the dollar-quoting delimiter is taken as part of the preceding identifier.

Examples

```
=> SELECT $$Fred's\n car$$;
      ?column?
-----
Fred's\n car
(1 row)

=> SELECT 'SELECT 'fact'';
ERROR: syntax error at or near "';'" at character 21
LINE 1: SELECT 'SELECT 'fact'';

=> SELECT 'SELECT $$fact'$$;
      ?column?
-----
SELECT $$fact
(1 row)

=> SELECT 'SELECT ''fact''';
      ?column?
-----
SELECT 'fact';
(1 row)
```

Unicode String Literals

Syntax

U&'characters' [UESCAPE '<Unicode escape character>']

Parameters

<i>characters</i>	Arbitrary sequence of UTF-8 characters bounded by single quotes (')
<i>Unicode escape character</i>	A single character from the source language character set other than a hexit, plus sign (+), quote ('), double quote ("), or white space

Using Standard Conforming Strings

With `StandardConformingStrings` enabled, Vertica supports SQL standard Unicode character string literals (the character set is UTF-8 only).

Before you enter a Unicode character string literal, enable standard conforming strings in one of the following ways.

- To enable for all sessions, update the `StandardConformingStrings` configuration parameter. See [Configuration Parameters](#) in the Administrator's Guide.
- To treat backslashes as escape characters for the current session, use the [SET STANDARD_CONFORMING_STRINGS](#) statement.

See also [Extended String Literals](#).

Examples

To enter a Unicode character in hexadecimal, such as the Russian phrase for "thank you, use the following syntax:

```
=> SET STANDARD_CONFORMING_STRINGS TO ON;
=> SELECT U&' \0441\043F\0430\0441\0438\0431\043E' as 'thank you';
  thank you
-----
  спасибо
(1 row)
```

To enter the German word `müde` (where `u` is really `u-umlaut`) in hexadecimal:

```
=> SELECT U&'m\00fcde';
?column?
-----
müde
(1 row)
=> SELECT 'ü';
?column?
-----
ü
(1 row)
```

To enter the `LINEAR B IDEOGRAM B240 WHEELED CHARIOT` in hexadecimal:

```
=> SELECT E'\xF0\x90\x83\x8C';
?column?
-----
(wheeled chariot character)
(1 row)
```

Note: Not all fonts support the wheeled chariot character.

See Also

- [SET STANDARD_CONFORMING_STRINGS](#)
- [SET ESCAPE_STRING_WARNING](#)
- [Internationalization Parameters](#)
- [Implement Locales for International Data Sets](#)

VARBINARY String Literals

VARBINARY string literals allow you to specify hexadecimal or binary digits in a string literal.

Syntax

```
X'<hexadecimal digits>'
B'<binary digits>'
```

Parameters

X or x	Specifies hexadecimal digits. The <hexadecimal digits> string must be enclosed in single quotes (').
B or b	Specifies binary digits. The <binary digits> string must be enclosed in single quotes (').

Examples

```
=> SELECT X'abcd';
?column?
-----
\253\315
(1 row)

=> SELECT B'101100';
?column?
-----
'
(1 row)
```

Extended String Literals

Syntax

`E'characters'`

Parameters

<code>characters</code>	Arbitrary sequence of characters bounded by single quotes ('')
-------------------------	--

You can use C-style backslash sequence in extended string literals, which are an extension to the SQL standard. You specify an extended string literal by writing the letter E as a prefix (before the opening single quote); for example:

```
E'extended character string\n'
```

Within an extended string, the backslash character (\) starts a C-style backslash sequence, in which the combination of backslash and following character or numbers represent a special byte value, as shown in the following list. Any other character following a backslash is taken literally; for example, to include a backslash character, write two backslashes (\\).

- \\ is a backslash
- \b is a backspace
- \f is a form feed
- \n is a newline
- \r is a carriage return
- \t is a tab
- \x##, where ## is a 1 or 2-digit hexadecimal number; for example \x07 is a tab
- \###, where ### is a 1, 2, or 3-digit octal number representing a byte with the corresponding code.

When an extended string literal is concatenated across lines, write only E before the first opening quote:

```
=> SELECT E'first part o'  
       'f a long line';  
       ?column?  
-----  
first part of a long line  
(1 row)
```

Two adjacent single quotes are used as one single quote:

```
=> SELECT 'Aren''t string literals fun?';  
       ?column?  
-----  
Aren't string literals fun?  
(1 row)
```

Standard Conforming Strings and Escape Characters

When interpreting commands, such as those entered in `vsq` or in queries passed via JDBC or ODBC, Vertica uses standard conforming strings as specified in the SQL standard. In standard conforming strings, backslashes are treated as string literals (ordinary characters), not escape characters.

Note: Text read in from files or streams (such as the data inserted using the [COPY](#) statement) are not treated as literal strings. The `COPY` command defines its own escape characters for the data it reads. See the [COPY](#) statement documentation for details.

The following options are available, but Micro Focus recommends that you migrate your application to use standard conforming strings at your earliest convenience, after warnings have been addressed.

- To revert to pre 4.0 behavior, set the `StandardConformingStrings` parameter to '0', as described in [Configuration Parameters](#) in the Administrator's Guide.
- To enable standard conforming strings permanently, set the `StandardConformingStrings` parameter to '1', as described in the procedure in the section, "Identifying Strings that are not Standard Conforming," below.
- To enable standard conforming strings per session, use [SET STANDARD_CONFORMING_STRING TO ON](#), which treats backslashes as escape characters for the current session only.

The two sections that follow help you identify issues between Vertica 3.5 and 4.0.

Identifying Strings That Are Not Standard Conforming

The following procedure can be used to identify nonstandard conforming strings in your application so that you can convert them into standard conforming strings:

1. Be sure the `StandardConformingStrings` parameter is off, as described in [Internationalization Parameters](#) in the Administrator's Guide.

```
=> ALTER DATABASE mydb SET StandardConformingStrings = 0;
```

Note: Micro Focus recommends that you migrate your application to use Standard Conforming Strings at your earliest convenience.

2. Turn on the `EscapeStringWarning` parameter. (ON is the default in Vertica Version 4.0 and later.)

```
=> ALTER DATABASE mydb SET EscapeStringWarning = 1;
```

Vertica now returns a warning each time it encounters an escape string within a string literal. For example, Vertica interprets the `\n` in the following example as a new line:

```
=> SELECT 'a\nb';
WARNING: nonstandard use of escape in a string literal at character 8
HINT: Use the escape string syntax for escapes, e.g., E'\r\n'.
?column?
-----
a
b
(1 row)
```

When `StandardConformingStrings` is ON, the string is interpreted as four characters: `a \ n b`.

Modify each string that Vertica flags by extending it as in the following example:

```
E'a\nb'
```

Or if the string has quoted single quotes, double them; for example, `'one'' double'`.

3. Turn on the `StandardConformingStrings` parameter for all sessions:

```
=> ALTER DATABASE mydb SET StandardConformingStrings = 1;
```

Doubled Single Quotes

This section discusses vsql inputs that are not passed on to the server.

Vertica recognizes two consecutive single quotes within a string literal as one single quote character. For example, the following inputs, 'You 're here!' ignored the second consecutive quote and returns the following:

```
=> SELECT 'You're here!';
      ?column?
-----
You're here!
(1 row)
```

This is the SQL standard representation and is preferred over the form, 'You\'re here!', because backslashes are not parsed as before. You need to escape the backslash:

```
=> SELECT (E'You\'re here!');
      ?column?
-----
You're here!
(1 row)
```

This behavior change introduces a potential incompatibility in the use of the vsql [\set](#) command, which automatically concatenates its arguments. For example, the following works in both Vertica 3.5 and 4.0:

```
\set file '\'' `pwd` '/file.txt' '\''\echo :file
```

vsql takes the four arguments and outputs the following:

```
'/home/vertica/file.txt'
```

In Vertica 3.5 the above `\set file` command could be written all with the arguments run together, but in 4.0 the adjacent single quotes are now parsed differently:

```
\set file '\''`pwd`'/file.txt'\'\echo :file
'/home/vertica/file.txt''
```

Note the extra single quote at the end. This is due to the pair of adjacent single quotes together with the backslash-quoted single quote.

The extra quote can be resolved either as in the first example above, or by combining the literals as follows:

```
\set file '\''`pwd`'/file.txt'\'\echo :file
'/home/vertica/file.txt'
```

In either case the backslash-quoted single quotes should be changed to doubled single quotes as follows:

```
\set file '''' `pwd` '/file.txt''''
```

Additional Examples

```
=> SELECT 'This \is a string';
      ?column?
-----
This \is a string
(1 row)

=> SELECT E'This \is a string';
      ?column?
-----
This is a string

=> SELECT E'This is a \n new line';
      ?column?
-----
This is a
new line
(1 row)

=> SELECT 'String''s characters';
      ?column?
-----
String's characters
(1 row)
```

Date/Time Literals

Date or time literal input must be enclosed in single quotes. Input is accepted in almost any reasonable format, including ISO 8601, SQL-compatible, traditional POSTGRES, and others.

Vertica handles date/time input more flexibly than the SQL standard requires. The exact parsing rules of date/time input and for the recognized text fields including months, days of the week, and time zones are described in [Date/Time Expressions](#).

Time Zone Values

Vertica attempts to be compatible with the SQL standard definitions for time zones. However, the SQL standard has an odd mix of date and time types and capabilities. Obvious problems are:

- Although the [DATE](#) type does not have an associated time zone, the [TIME/TIMETZ](#) type can. Time zones in the real world have little meaning unless associated with a date as well as a time, since the offset can vary through the year with daylight-saving time boundaries.
- Vertica assumes your local time zone for any data type containing only date or time.
- The default time zone is specified as a constant numeric offset from UTC. It is therefore not possible to adapt to daylight-saving time when doing date/time arithmetic across DST boundaries.

To address these difficulties, Micro Focus recommends using Date/Time types that contain both date and time when you use time zones. Micro Focus recommends that you do *not* use the type `TIME WITH TIME ZONE`, even though it is supported it for legacy applications and for compliance with the SQL standard.

Time zones and time-zone conventions are influenced by political decisions, not just earth geometry. Time zones around the world became somewhat standardized during the 1900's, but continue to be prone to arbitrary changes, particularly with respect to daylight-savings rules.

Vertica currently supports daylight-savings rules over the time period 1902 through 2038, corresponding to the full range of conventional UNIX system time. Times outside that range are taken to be in "standard time" for the selected time zone, no matter what part of the year in which they occur.

Example	Description
PST	Pacific Standard Time
-8:00	ISO-8601 offset for PST
-800	ISO-8601 offset for PST
-8	ISO-8601 offset for PST
zulu	Military abbreviation for UTC
z	Short form of zulu

Day of the Week Names

The following tokens are recognized as names of days of the week:

Day	Abbreviations
SUNDAY	SUN
MONDAY	MON
TUESDAY	TUE, TUES
WEDNESDAY	WED, WEDS
THURSDAY	THU, THUR, THURS
FRIDAY	FRI
SATURDAY	SAT

Month Names

The following tokens are recognized as names of months:

Month	Abbreviations
JANUARY	JAN
FEBRUARY	FEB

Month	Abbreviations
MARCH	MAR
APRIL	APR
MAY	MAY
JUNE	JUN
JULY	JUL
AUGUST	AUG
SEPTEMBER	SEP, SEPT
OCTOBER	OCT
NOVEMBER	NOV
DECEMBER	DEC

Interval Literal

A literal that represents a time span.

Syntax

```
[ @ ] [-] { quantity subtype-unit }[...] [ AGO ]
```

Parameters

@	Ignored
- (minus)	Specifies a negative interval value.
<i>quantity</i>	Integer numeric constant
<i>subtype-unit</i>	See Interval Subtype Units for valid values. Subtype units must be specified for year-month intervals; they are optional for day-time intervals.
AGO	Specifies a negative interval value. AGO and - (minus) are synonymous.

Notes

- The amounts of different units are implicitly added up with appropriate sign accounting.
- The boundaries of an interval constant are:
 - 9223372036854775807 usec to -9223372036854775807 usec
 - 296533 years 3 mons 21 days 04:00:54.775807 to -296533 years -3 mons -21 days -04:00:54.775807
- The range of an interval constant is $\pm 2^{63} - 1$ (plus or minus two to the sixty-third minus one) microseconds.
- In Vertica, interval fields are additive and accept large floating-point numbers.

Examples

See [Specifying Interval Input.Interval Literal](#)

Interval Subtype Units

The following tables lists subtype units that can be specified in an interval literal, divided into major categories:

- [Year-month subtype units](#)
- [Day-time subtype units](#)

Year-month subtype units

Subtypes	Units	Notes
Millennium	mil millennium	
	millennia mils	
Century	c cent century	
	centuries	
Decade	dec decade	
	decades decs	
Year	a	Julian year: 365.25 days
	ka	Julian kilo-year: 365250 days
	y year yr	Calendar year: 365 days
	years yrs	
Quarter	q qtr quarter	
	qtrs quarters	
Month	mon month m	Vertica can interpret m as minute or month, depending on context. See Processing m Input below.
	mons months	
Week	w week	
	weeks	

Day-time subtype units

Subtypes	Units	Notes	
Day	d day		
	days		
Hour	h hour hr		
	hours hrs		
Minute	min minute mm m		Vertica can interpret input unit m as minute or month, depending on context. See Processing m Input below.
	mins minutes		
Second	s sec second		
	seconds secs		
Millisecond	millisecond ms		
	milliseconds mseconds msec		
Microsecond	microsecond us usec		
	microseconds useconds usecs		

Processing m Input

Vertica uses context to interpret the input unit `m` as months or minutes. For example, the following command creates a one-column table with an interval value:

```
=> CREATE TABLE int_test(i INTERVAL YEAR TO MONTH);
```

Given the following `INSERT` statement, Vertica interprets the interval literal `1y 6m` as 1 year 6 months:

```
=> INSERT INTO int_test VALUES('1y 6m');
OUTPUT
-----
      1
(1 row)

=> SET INTERVALSTYLE TO UNITS;
=> SELECT * FROM int_test;
      i
-----
1 year 6 months
(1 row)
```

The following `ALTER TABLE` statement adds a `DAY TO MINUTE` interval column to table `int_test`:

```
=> ALTER TABLE int_test ADD COLUMN x INTERVAL DAY TO MINUTE;
ALTER TABLE
```

The next `INSERT` statement sets the first and second columns to `3y 20m` and `1y 6m`, respectively. In this case, Vertica interprets the `m` input literals in two ways:

- For column `i`, Vertica interprets the `m` input as months, and displays 4 years 8 months.
- For column `x`, Vertica interprets the `m` input as minutes. Because the interval is defined as `DAY TO MINUTE`, it converts the inserted input value `1y 6m` to 365 days 6 minutes:

```
=> INSERT INTO int_test VALUES ('3y 20m', '1y 6m');
OUTPUT
-----
      1
(1 row)

=> SELECT * FROM int_test;
      i          |          x
-----+-----
1 year 6 months |
4 years 8 months | 365 days 6 mins
(2 rows)
```

Interval Qualifier

Specifies how to interpret and format an [interval literal](#) for output, and, optionally, sets precision. Interval qualifiers are composed of one or two units:

```
unit[p] [ TO unit[p] ]
```

where:

- *unit* specifies a day-time or year-month [subtype](#).
- *p* specifies precision, an integer between 0 and 6. In general, precision only applies to SECOND units. The default precision for SECOND is 6. For details, see [Specifying Interval Precision](#).

If an interval omits an interval qualifier, the default is DAY TO SECOND(6).

Interval qualifiers are divided into two categories: [day-time](#) and [year-month](#), as shown in the tables below.

Day-time interval qualifiers

Qualifier	Description
DAY	Unconstrained
DAY TO HOUR	Span of days and hours
DAY TO MINUTE	Span of days and minutes
DAY TO SECOND	Span of days, hours, minutes, seconds, and fractions of a second.
HOUR	Hours within days
HOUR TO MINUTE	Span of hours and minutes
HOUR TO SECOND	Span of hours and seconds
MINUTE	Minutes within hours
MINUTE TO SECOND	Span of minutes and seconds
SECOND	Seconds within minutes

Note: The SECOND field can have an interval fractional seconds precision, which indicates the number of decimal digits maintained following the decimal point in the SECONDS

Day-time interval qualifiers, continued

Qualifier	Description
	value. When SECOND is not the first field, it has a precision of 2 places before the decimal point.

Year-month interval qualifiers

YEAR	Unconstrained
MONTH	Months within year
YEAR TO MONTH	Span of years and months

Note: Vertica also supports INTERVALYM, which is an alias for INTERVAL YEAR TO MONTH. Thus, the following two statements are equivalent:

```
=> SELECT INTERVALYM '1 2';  
?column?  
-----  
1 year 2 months  
  
=> SELECT INTERVAL '1 2' YEAR TO MONTH;  
?column?  
-----  
1 year 2 months  
(1 row)
```

Examples

See [Controlling Interval Format](#).

Operators

Operators are logical, mathematical, and equality symbols used in SQL to evaluate, compare, or calculate values.

Binary Operators

Each of the functions in the following table works with BINARY and VARBINARY data types.

Operator	Function	Description
'='	binary_eq	Equal to
'<>'	binary_ne	Not equal to
'<'	binary_lt	Less than
'<='	binary_le	Less than or equal to
'>'	binary_gt	Greater than
'>='	binary_ge	Greater than or equal to
'&'	binary_and	And
'~'	binary_not	Not
' '	binary_or	Or
'#'	binary_xor	Either or
' '	binary_cat	Concatenate

Notes

- If the arguments vary in length binary operators treat the values as though they are all equal in length by right-extending the smaller values with the zero byte to the full width of the column (except when using the `binary_cat` function). For example, given the values 'ff' and 'f', the value 'f' is treated as 'f0'.

- Operators are strict with respect to nulls. The result is null if any argument is null. For example, `null <> 'a'::binary` returns null.
- To apply the OR (`'|'`) operator to a `VARBINARY` type, explicitly cast the arguments; for example:

```
=> SELECT '1'::VARBINARY | '2'::VARBINARY;
?column?
-----
      3
(1 row)
```

Similarly, to apply the [LENGTH](#), [REPEAT](#), [TO_HEX](#), and [SUBSTRING](#) functions to a `BINARY` type, explicitly cast the argument; for example:

```
=> SELECT LENGTH('\001\002\003\004'::varbinary(4));
LENGTH
-----
      4
(1 row)
```

When applying an operator or function to a column, the operator's or function's argument type is derived from the column type.

Examples

In the following example, the zero byte is not removed from column `cat1` when values are concatenated:

```
=> SELECT 'ab'::BINARY(3) || 'cd'::BINARY(2) AS cat1,
'ab'::VARBINARY(3) ||
'cd'::VARBINARY(2) AS cat2;
cat1 | cat2
-----+-----
ab\000cd | abcd
(1 row)
```

When the binary value `'ab'::binary(3)` is translated to varbinary, the result is equivalent to `'ab\000'::varbinary(3)`; for example:

```
=> SELECT 'ab'::binary(3); binary
-----
ab\000
(1 row)
```

The following example performs a bitwise AND operation on the two input values (see also [BIT_AND](#)):

```
=> SELECT '10001' & '011' as AND;  
AND  
-----  
1  
(1 row)
```

The following example performs a bitwise OR operation on the two input values (see also [BIT_OR](#)):

```
=> SELECT '10001' | '011' as OR;  
OR  
-----  
10011  
(1 row)
```

The following example concatenates the two input values:

```
=> SELECT '10001' || '011' as CAT;  
CAT  
-----  
10001011  
(1 row)
```

Boolean Operators

Syntax

[AND | OR | NOT]

Parameters

SQL uses a three-valued Boolean logic where the null value represents "unknown."

a	b	a AND b	a OR b
TRUE	TRUE	TRUE	TRUE
TRUE	FALSE	FALSE	TRUE
TRUE	NULL	NULL	TRUE
FALSE	FALSE	FALSE	FALSE
FALSE	NULL	FALSE	NULL

a	b	a AND b	a OR b
NULL	NULL	NULL	NULL

a	NOT a
TRUE	FALSE
FALSE	TRUE
NULL	NULL

Notes

- The operators AND and OR are commutative, that is, you can switch the left and right operand without affecting the result. However, the order of evaluation of subexpressions is not defined. When it is essential to force evaluation order, use a [CASE](#) construct.
- Do not confuse Boolean operators with the [Boolean-Predicate](#) or the [Boolean](#) data type, which can have only two values: true and false.

Comparison Operators

Comparison operators are available for all data types where comparison makes sense. All comparison operators are binary operators that return values of True, False, or NULL.

Syntax and Parameters

<	less than
>	greater than
<=	less than or equal to
>=	greater than or equal to
= or <=>	equal
<> or !=	not equal

Notes

- The comparison operators return NULL (signifying "unknown") when either operand is null.
- The <=> operator performs an equality comparison like the = operator, but it returns true, instead of NULL, if both operands are NULL, and false, instead of NULL, if one operand is NULL.

Data Type Coercion Operators (CAST)

Data type coercion (casting) passes an expression value to an input conversion routine for a specified data type, resulting in a constant of the indicated type.

Syntax

```
SELECT CAST ( expression AS data_type )
```

```
SELECT expression::data_type
```

```
SELECT data_type 'string'
```

Parameters

<i>expression</i>	An expression of any type
<i>data_type</i>	Converts the value of <i>expression</i> to one of the following data types: <ul style="list-style-type: none">• BINARY• BOOLEAN• CHARACTER• DATE/TIME• NUMERIC

Notes

- In Vertica, data type coercion (casting) can be invoked by an explicit cast request. It must use one of the following constructs:

```
=> SELECT CAST ( expression AS data_type )  
=> SELECT expression::data_type  
=> SELECT data_type 'string'
```

- The explicit type cast can be omitted if there is no ambiguity as to the type the constant must be. For example, when a constant is assigned directly to a column, it is automatically coerced to the column's data type.
- If a binary value is cast (implicitly or explicitly) to a binary type with a smaller length, the value is silently truncated. For example:

```
=> SELECT 'abcd'::BINARY(2);  
?column?  
-----  
ab  
(1 row)
```

- Similarly, if a character value is cast (implicitly or explicitly) to a character value with a smaller length, the value is silently truncated. For example:

```
=> SELECT 'abcd'::CHAR(3);  
?column?  
-----  
abc
```

- Vertica supports only casts and resize operations as follows:
 - BINARY to and from VARBINARY
 - VARBINARY to and from LONG VARBINARY
 - BINARY to and from LONG VARBINARY
- On binary data that contains a value with fewer bytes than the target column, values are right-extended with the zero byte '\0' to the full width of the column. Trailing zeros on variable-length binary values are not right-extended:

```
=> SELECT 'ab'::BINARY(4), 'ab'::VARBINARY(4), 'ab'::LONG VARBINARY(4);
?column? | ?column? | ?column?
-----+-----+-----
ab\000\000 | ab      | ab
(1 row)
```

Examples

```
=> SELECT CAST((2 + 2) AS VARCHAR);
?column?
-----
4
(1 row)

=> SELECT (2 + 2)::VARCHAR;
?column?
-----
4
(1 row)

=> SELECT INTEGER '123';
?column?
-----
123
(1 row)

=> SELECT (2 + 2)::LONG VARCHAR
?column?
-----
4
(1 row)

=> SELECT '2.2' + 2;
ERROR:  invalid input syntax for integer: "2.2"

=> SELECT FLOAT '2.2' + 2;
?column?
-----
4.2
(1 row)
```

See Also

- [Data Type Conversions](#)
- [Data Type Coercion Chart](#)
- [CAST Failures](#)

Cast Failures

When you invoke data type coercion (casting) by an explicit cast and the cast fails, the result returns either an error or NULL. Cast failures commonly occur when you attempt to cast conflicting conversions, such as trying to convert a varchar expression that contains letters to an int.

When a cast fails, the result returned depends on the data type.

Data Type	Cast Failure Default
Date/Time	NULL
Literal	Error
All Other Types	Error

Enabling Strict Time Casts

You can enable all cast failures to result in an error, including those for Date/Time data types. Doing so allows you to see the reason why some or all of the cast failed. To return an error instead of NULL, use the [ALTER SESSION](#) statement with the SET parameter:

```
ALTER SESSION SET EnableStrictTimeCasts=1;
```

The following example shows a Date/Time cast failure that returns NULL:

```
=> CREATE TABLE mytable (a VARCHAR);
CREATE TABLE
=> INSERT INTO mytable VALUES('string');
OUTPUT
-----
1
(1 row)
=> INSERT INTO mytable VALUES('1');
OUTPUT
-----
1
(1 row)
=> SELECT a::time FROM mytable;
a
---
(2 rows)
```

When you specify `EnableStrictTimeCasts`, the cast failure returns an error:

```
=> ALTER SESSION SET EnableStrictTimeCasts=1;
ALTER SESSION
=> SELECT a::time FROM mytable;
ERROR 2005: Invalid input syntax for time: "1"
```

Returning All Cast Failures as NULL

To explicitly cast an expression to a requested data type, use the following construct:

```
SELECT expression::data_type
```

Using this command to cast any values to a conflicting data type returns the following error:

```
ERROR 2827: Could not convert "string" from column table.a to an int8
```

In addition to the `::` cast, Vertica supports the use of `::!`. Use `::!` instead of `::`, *if you want to return:*

- NULL instead of an error for any non-Date/Time data types
- NULL instead of an error after setting `EnableStrictTimeCasts`

Returning all cast failures as NULL allows those expressions that succeeded during the cast to appear in the result. Those expressions which failed during the cast, however, have a NULL value.

The following example shows a cast failure that returns an error:

```
=> CREATE TABLE mytable (a VARCHAR);
CREATE TABLE
=> INSERT INTO mytable VALUES('string');
OUTPUT
-----
1
(1 row)
=> INSERT INTO mytable VALUES('1');
OUTPUT
-----
1
(1 row)
=> SELECT a::int FROM mytable;
ERROR 2827: Could not convert "string" from column mytable.a to an int8
```

When you use `::!`, the cast fails for the "string" value and returns NULL. However, it succeeds for the "1" value and returns 1:

```
=> SELECT a::!int FROM mytable;
a
---
1
```

(2 rows)

Date/Time Operators

Syntax

[+ | - | * | /]

Parameters

+ Addition
- Subtraction
* Multiplication
/ Division

Notes

- The operators described below that take TIME or TIMESTAMP inputs actually come in two variants: one that takes TIME WITH TIME ZONE or TIMESTAMP WITH TIME ZONE, and one that takes TIME WITHOUT TIME ZONE or TIMESTAMP WITHOUT TIME ZONE. For brevity, these variants are not shown separately.
- The + and * operators come in commutative pairs (for example both DATE + INTEGER and INTEGER + DATE); only one of each such pair is shown.

Example	Result Type	Result
DATE '2001-09-28' + INTEGER '7'	DATE	'2001-10-05'
DATE '2001-09-28' + INTERVAL '1 HOUR'	TIMESTAMP	'2001-09-28 01:00:00'
DATE '2001-09-28' + TIME '03:00'	TIMESTAMP	'2001-09-28 03:00:00'
INTERVAL '1 DAY' + INTERVAL '1 HOUR'	INTERVAL	'1 DAY 01:00:00'
TIMESTAMP '2001-09-28 01:00' + INTERVAL '23 HOURS'	TIMESTAMP	'2001-09-29 00:00:00'
TIME '01:00' + INTERVAL '3 HOURS'	TIME	'04:00:00'

Example	Result Type	Result
- INTERVAL '23 HOURS'	INTERVAL	'-23:00:00'
DATE '2001-10-01' - DATE '2001-09-28'	INTEGER	'3'
DATE '2001-10-01' - INTEGER '7'	DATE	'2001-09-24'
DATE '2001-09-28' - INTERVAL '1 HOUR'	TIMESTAMP	'2001-09-27 23:00:00'
TIME '05:00' - TIME '03:00'	INTERVAL	'02:00:00'
TIME '05:00' INTERVAL '2 HOURS'	TIME	'03:00:00'
TIMESTAMP '2001-09-28 23:00' - INTERVAL '23 HOURS'	TIMESTAMP	'2001-09-28 00:00:00'
INTERVAL '1 DAY' - INTERVAL '1 HOUR'	INTERVAL	'1 DAY -01:00:00'
TIMESTAMP '2001-09-29 03:00' - TIMESTAMP '2001-09-27 12:00'	INTERVAL	'1 DAY 15:00:00'
900 * INTERVAL '1 SECOND'	INTERVAL	'00:15:00'
21 * INTERVAL '1 DAY'	INTERVAL	'21 DAYS'
DOUBLE PRECISION '3.5' * INTERVAL '1 HOUR'	INTERVAL	'03:30:00'
INTERVAL '1 HOUR' / DOUBLE PRECISION '1.5'	INTERVAL	'00:40:00'

Mathematical Operators

Mathematical operators are provided for many data types.

Operator	Description	Example	Result
!	Factorial	5 !	120
+	Addition	2 + 3	5
-	Subtraction	2 - 3	-1
*	Multiplication	2 * 3	6
/	Division (integer division produces NUMERIC results).	4 / 2	2.00...

Operator	Description	Example	Result
//	With integer division, returns an INTEGER rather than a NUMERIC.	117.32 // 2.5	46
%	Modulo (remainder)	5 % 4	1
^	Exponentiation	2.0 ^ 3.0	8
/	Square root	/ 25.0	5
/	Cube root	/ 27.0	3
!!	Factorial (prefix operator)	!! 5	120
@	Absolute value	@ -5.0	5
&	Bitwise AND	91 & 15	11
	Bitwise OR	32 3	35
#	Bitwise XOR	17 # 5	20
~	Bitwise NOT	~1	-2
<<	Bitwise shift left	1 << 4	16
>>	Bitwise shift right	8 >> 2	2

Notes

- The bitwise operators work only on integer data types, whereas the others are available for all numeric data types.
- Vertica supports the use of the factorial operators on positive and negative floating point (DOUBLE PRECISION) numbers as well as integers. For example:

```
=> SELECT 4.98!;
   ?column?
-----
 115.978600750905
(1 row)
```

- Factorial is defined in term of the gamma function, where $(-1) = \text{Infinity}$ and the other negative integers are undefined. For example:

$$(-4)! = \text{NaN}$$

$$-(4!) = -24$$

- Factorial is defined as $z! = \text{gamma}(z+1)$ for all complex numbers z . See the [Handbook of Mathematical Functions](#) (1964) Section 6.1.5.
- See `MOD()` for details about the behavior of `%`.

NULL Operators

To check whether a value is or is not NULL, use the constructs:

```
[expression IS NULL | expression IS NOT NULL]
```

Alternatively, use equivalent, but nonstandard, constructs:

```
[expression ISNULL | expression NOTNULL]
```

Do not write `expression = NULL` because NULL represents an unknown value, and two unknown values are not necessarily equal. This behavior conforms to the SQL standard.

Note: Some applications might expect that `expression = NULL` returns true if `expression` evaluates to null. Vertica strongly recommends that these applications be modified to comply with the SQL standard.

String Concatenation Operators

To concatenate two strings on a single line, use the concatenation operator (two consecutive vertical bars).

Syntax

```
string || string
```

Parameters

<i>string</i>	Is an expression of type CHAR or VARCHAR
---------------	--

Notes

- `||` is used to concatenate expressions and constants. The expressions are cast to VARCHAR if possible, otherwise to VARBINARY, and must both be one or the other.
- Two consecutive strings within a single SQL statement on separate lines are automatically concatenated

Examples

The following example is a single string written on two lines:

```
=> SELECT E'xx'-> '\\';  
?column?  
-----  
xx\  
(1 row)
```

The following examples show two strings concatenated:

```
=> SELECT E'xx' ||-> '\\';  
?column?  
-----  
xx\  
(1 row)  
  
=> SELECT 'auto' || 'mobile';  
?column?  
-----  
automobile  
(1 row)  
  
=> SELECT 'auto'-> 'mobile';  
?column?  
-----  
automobile  
(1 row)  
  
=> SELECT 1 || 2;  
?column?  
-----  
12  
(1 row)
```

```
=> SELECT '1' || '2';  
?column?  
-----  
12  
(1 row)  
  
=> SELECT '1'-> '2';  
?column?  
-----  
12  
(1 row)
```

Expressions

SQL expressions are the components of a query that compare a value or values against other values. They can also perform calculations. Expressions found inside any SQL command are usually in the form of a conditional statement.

Operator Precedence

The following table shows operator precedence in decreasing (high to low) order.

Note: When an expression includes more than one operator, Micro Focus recommends that you specify the order of operation using parentheses, rather than relying on operator precedence.

Operator/Element	Associativity	Description
.	left	table/column name separator
::	left	typecast
[]	left	array element selection
-	right	unary minus
^	left	exponentiation
* / %	left	multiplication, division, modulo
+ -	left	addition, subtraction
IS		IS TRUE, IS FALSE, IS UNKNOWN, IS NULL
IN		set membership
BETWEEN		range containment
OVERLAPS		time interval overlap
LIKE		string pattern matching
< >		less than, greater than

Operator/Element	Associativity	Description
=	right	equality, assignment
NOT	right	logical negation
AND	left	logical conjunction
OR	left	logical disjunction

Expression Evaluation Rules

The order of evaluation of subexpressions is not defined. In particular, the inputs of an operator or function are not necessarily evaluated left-to-right or in any other fixed order. To force evaluation in a specific order, use a CASE construct. For example, this is an untrustworthy way of trying to avoid division by zero in a WHERE clause:

```
=> SELECT x, y WHERE x <> 0 AND y/x > 1.5;
```

But this is safe:

```
=> SELECT x, y
WHERE
  CASE
    WHEN x <> 0 THEN y/x > 1.5
    ELSE false
  END;
```

A CASE construct used in this fashion defeats optimization attempts, so use it only when necessary. (In this particular example, it would be best to avoid the issue by writing $y > 1.5 * x$ instead.)

Limits to SQL Expressions

There are some limits on the number of modifiers and recursions that you can make in an expression. There are two limits that you should be aware of:

- The first limit is based on the stack available to the expression. VERTICA requires at least 100kb of free stack. If this limit is exceeded then the error "The query contains an expression that is too complex to analyze" may be thrown. Adding additional physical memory and/or increasing the value of `ulimit -s` max increase the available stack and prevent the error.

- The second limit is the number of recursions possible in an analytic expression. The limit is 2000. If this limit is exceeded then the error "The query contains an expression that is too complex to analyze" may be thrown. This limit cannot be increased.

Aggregate Expressions

An aggregate expression applies an aggregate function across the rows or groups of rows selected by a query.

An aggregate expression only can appear in the select list or HAVING clause of a SELECT statement. It is invalid in other clauses such as WHERE, because those clauses are evaluated before the results of aggregates are formed.

Syntax

An aggregate expression has the following format:

```
aggregate-function ( [ * ] [ ALL | DISTINCT ] expression )
```

Parameters

<i>aggregate-function</i>	A Vertica function that aggregates data over groups of rows from a query result set.
ALL DISTINCT	Specifies which input rows to process: <ul style="list-style-type: none">• ALL (default): Invokes <i>aggregate-function</i> across all input rows where <i>expression</i> evaluates to a non-null value.• DISTINCT: Invokes <i>aggregate-function</i> across all input rows where <i>expression</i> evaluates to a unique non-null value.
<i>expression</i>	A value expression that does not itself contain an aggregate expression.

CASE Expressions

The CASE expression is a generic conditional expression that can be used wherever an expression is valid. It is similar to case and if/then/else statements in other languages.

Syntax (form 1)

```
CASE
  WHEN condition THEN result
  [ WHEN condition THEN result ]
  ...
  [ ELSE result ]
END
```

Parameters

<i>condition</i>	Is an expression that returns a boolean (true/false) result. If the result is false, subsequent WHEN clauses are evaluated in the same manner.
<i>result</i>	Specifies the value to return when the associated <i>condition</i> is true.
ELSE <i>result</i>	If no <i>condition</i> is true then the value of the CASE expression is the result in the ELSE clause. If the ELSE clause is omitted and no condition matches, the result is null.

Syntax (form 2)

```
CASE expression
  WHEN value THEN result
  [ WHEN value THEN result ]
  ...
  [ ELSE result ]
END
```

Parameters

<i>expression</i>	An expression that is evaluated and compared to all the <i>value</i> specifications in the WHEN clauses until one is found that is equal.
<i>value</i>	Specifies a value to compare to the <i>expression</i> .

<i>result</i>	Specifies the value to return when the <i>expression</i> is equal to the specified <i>value</i> .
ELSE <i>result</i>	Specifies the value to return when the <i>expression</i> is not equal to any <i>value</i> ; if no ELSE clause is specified, the value returned is null.

Notes

The data types of all the result expressions must be convertible to a single output type.

Examples

The following examples show two uses of the CASE statement.

```
=> SELECT * FROM test;
 a
 ---
 1
 2
 3

=> SELECT a,
        CASE WHEN a=1 THEN 'one'
             WHEN a=2 THEN 'two'
             ELSE 'other'
        END
FROM test;
 a | case
 ---+-----
 1 | one
 2 | two
 3 | other

=> SELECT a,
        CASE a WHEN 1 THEN 'one'
             WHEN 2 THEN 'two'
             ELSE 'other'
        END
FROM test;
 a | case
 ---+-----
 1 | one
 2 | two
 3 | other
```

Special Example

A CASE expression does not evaluate subexpressions that are not needed to determine the result. You can use this behavior to avoid division-by-zero errors:

```
=> SELECT x FROM T1 WHERE
      CASE WHEN x <> 0 THEN y/x > 1.5
      ELSE false
      END;
```

Column References

Syntax

`[schema.]table-name].column-name`

Parameters

<i>schema</i>	<p>Specifies a schema. If multiple schemas are defined in the database, include the schema name. For example:</p> <pre>myschema.thisDBObject</pre>
<i>table-name</i>	<p>One of the following:</p> <ul style="list-style-type: none">• The name of a table• A table alias defined in the query's FROM clause
<i>column-name</i>	<p>A column name that is unique among all queried tables.</p>

Restrictions

A column reference cannot contain any spaces.

Comments

A comment is an arbitrary sequence of characters beginning with two consecutive hyphen characters and extending to the end of the line. For example:

```
-- This is a standard SQL comment
```

A comment is removed from the input stream before further syntax analysis and is effectively replaced by white space.

Alternatively, C-style block comments can be used where the comment begins with `/*` and extends to the matching occurrence of `*/`.

```
/* multiline comment
 * with nesting: /* nested block comment */
 */
```

These block comments nest, as specified in the SQL standard. Unlike C, you can comment out larger blocks of code that might contain existing block comments.

Date/Time Expressions

Vertica uses an internal heuristic parser for all date/time input support. Dates and times are input as strings, and are broken up into distinct fields with a preliminary determination of what kind of information might be in the field. Each field is interpreted and either assigned a numeric value, ignored, or rejected. The parser contains internal lookup tables for all textual fields, including months, days of the week, and time zones.

Vertica parses date/time type inputs as follows:

1. Break the input string into tokens and categorize each token as a string, time, time zone, or number.
2. Numeric token contains:
 - colon (:) — Parse as a time string, include all subsequent digits and colons.
 - dash (-), slash (/), or two or more dots (.) — Parse as a date string which might have a text month.
 - Numeric only — Parse as a single field or an ISO 8601 concatenated date (19990113 for January 13, 1999) or time (141516 for 14:15:16).
3. Token starts with a plus (+) or minus (-): Parse as a time zone or a special field.
4. Token is a text string: match up with possible strings.
 - Perform a binary-search table lookup for the token as either a special string (for example, today), day (for example, Thursday), month (for example, January), or noise word (for example, at, on).
 - Set field values and bit mask for fields. For example, set year, month, day for today, and additionally hour, minute, second for now.

- If not found, do a similar binary-search table lookup to match the token with a time zone.
 - If still not found, throw an error.
5. Token is a number or number field:
- If eight or six digits, and if no other date fields were previously read, interpret as a "concatenated date" (19990118 or 990118). The interpretation is YYYYMMDD or YYMMDD.
 - If token is three digits and a year was already read, interpret as day of year.
 - If four or six digits and a year was already read, interpret as a time (HHMM or HHMMSS).
 - If three or more digits and no date fields were found yet, interpret as a year (this forces yy-mm-dd ordering of the remaining date fields).
 - Otherwise the date field ordering is assumed to follow the `DateStyle` setting: mm-dd-yy, dd-mm-yy, or yy-mm-dd. Throw an error if a month or day field is found to be out of range.
6. If BC is specified: negate the year and add one for internal storage. (In the Vertica implementation, 1 BC = year zero.)
7. If BC is not specified, and year field is two digits in length: adjust the year to four digits. If field is less than 70, add 2000, otherwise add 1900.

Tip: Gregorian years AD 1–99 can be entered as 4 digits with leading zeros— for example, 0099 = AD 99.

Month Day Year Ordering

For some formats, ordering of month, day, and year in date input is ambiguous and there is support for specifying the expected ordering of these fields.

Special Date/Time Values

Vertica supports several special date/time values for convenience, as shown below. All of these values need to be written in single quotes when used as constants in SQL statements.

The values `INFINITY` and `-INFINITY` are specially represented inside the system and are displayed the same way. The others are simply notational shorthands that are converted to

ordinary date/time values when read. (In particular, NOW and related strings are converted to a specific time value as soon as they are read.)

String	Valid Data Types	Description
epoch	DATE, TIMESTAMP	1970-01-01 00:00:00+00 (UNIX SYSTEM TIME ZERO)
INFINITY	TIMESTAMP	Later than all other time stamps
-INFINITY	TIMESTAMP	Earlier than all other time stamps
NOW	DATE, TIME, TIMESTAMP	Current transaction's start time Note: NOW is not the same as the NOW function.
TODAY	DATE, TIMESTAMP	Midnight today
TOMORROW	DATE, TIMESTAMP	Midnight tomorrow
YESTERDAY	DATE, TIMESTAMP	Midnight yesterday
ALLBALLS	TIME	00:00:00.00 UTC

The following SQL-compatible functions can also be used to obtain the current time value for the corresponding data type:

- [CURRENT_DATE](#)
- [CURRENT_TIME](#)
- [CURRENT_TIMESTAMP](#)
- [LOCALTIME](#)
- [LOCALTIMESTAMP](#)

The latter four accept an optional precision specification. (See [Date/Time Functions](#).) However, these functions are SQL functions and are not recognized as data input strings.

NULL Value

NULL is a reserved keyword used to indicate that a data value is unknown.

Be very careful when using NULL in expressions. NULL is not greater than, less than, equal to, or not equal to any other expression. Use the [Boolean-Predicate](#) for determining whether an expression value is NULL.

Notes

- Vertica stores data in projections, which are sorted in a specific way. All columns are stored in ASC (ascending) order. For columns of data type NUMERIC, INTEGER, DATE, TIME, TIMESTAMP, and INTERVAL, NULL values are placed at the beginning of sorted projections (NULLS FIRST), while for columns of data type FLOAT, STRING, and BOOLEAN, NULL values are placed at the end (NULLS LAST). For details, see [NULL Sort Order](#) and [Runtime Sorting of NULL Values in Analytic Functions](#) in Analyzing Data.
- Vertica also accepts NULL characters ('\0') in constant strings and no longer removes null characters from VARCHAR fields on input or output. NULL is the ASCII abbreviation for the NULL character.
- You can write queries with expressions that contain the <=> operator for NULL=NULL joins. See [Equi-Joins and Non Equi-Joins](#) in Analyzing Data.

[NULL-handling Functions](#)

Predicates

Predicates are truth-tests. If the predicate test is true, it returns a value. Each predicate is evaluated per row, so that when the predicate is part of an entire table `SELECT` statement, the statement can return multiple results.

Predicates consist of a set of parameters and arguments. For example, in the following example `WHERE` clause:

```
WHERE name = 'Smith';
```

- `name = 'Smith'` is the predicate
- `'Smith'` is an expression

BETWEEN-predicate

The special `BETWEEN` predicate is available as a convenience.

Syntax

```
WHERE a BETWEEN x AND y
```

Examples

```
WHERE a BETWEEN x AND y
```

is equivalent to:

```
WHERE a >= x AND a <= y
```

Similarly:

```
WHERE a NOT BETWEEN x AND y
```

is equivalent to:

```
WHERE a < x OR a > y
```

You can use the `BETWEEN` predicate for date ranges:

```
=> CREATE TABLE t1 (c1 INT, c2 INT, c3 DATE);
=> COPY t1 FROM stdin DELIMITER '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1 | 2 | 2014-07-26
>> 2 | 3 | 2014-07-27
>> 3 | 4 | 2014-07-28
>> 4 | 5 | 2014-07-29
>> 5 | 6 | 2014-07-30
>> 6 | 7 | 2014-07-31
>> 7 | 8 | 2014-08-01
>> 8 | 9 | 2014-08-02
>> \.

=> SELECT* FROM t1 WHERE c3 BETWEEN DATE('2014-07-26') AND DATE('2014-07-30');
c1 | c2 | c3
-----+-----
 1 |  2 | 2014-07-26
 2 |  3 | 2014-07-27
 3 |  4 | 2014-07-28
 4 |  5 | 2014-07-29
 5 |  6 | 2014-07-30
(5 rows)
```

You can also use the NOW and INTERVAL keywords to select from a date range:

```
=> SELECT * FROM t1 WHERE c3 BETWEEN NOW()-INTERVAL '1 week' AND NOW();
c1 | c2 | c3
-----+-----
 7 |  8 | 2014-08-01
 1 |  2 | 2014-07-26
 2 |  3 | 2014-07-27
 3 |  4 | 2014-07-28
 4 |  5 | 2014-07-29
 5 |  6 | 2014-07-30
 6 |  7 | 2014-07-31
(7 rows)
```

Boolean-Predicate

Retrieves rows where the value of an expression is true, false, or unknown (null).

Syntax

```
expression IS [NOT] TRUE
expression IS [NOT] FALSE
expression IS [NOT] UNKNOWN
```

Notes

- A null input is treated as the value UNKNOWN.
- IS UNKNOWN and IS NOT UNKNOWN are effectively the same as the [NULL-predicate](#), except that the input expression does not have to be a single column value. To check a single column value for NULL, use the NULL-predicate.
- Do not confuse the boolean-predicate with [Boolean Operators](#) or the [Boolean](#) data type, which can have only two values: true and false.

Column-Value-Predicate

Syntax

column-name comparison-op constant-expression

Parameters

<i>column-name</i>	A single column of one the tables specified in the FROM Clause .
<i>comparison-op</i>	A Comparison Operators .
<i>constant-expression</i>	A constant value of the same data type as the <i>column-name</i> .

Notes

To check a column value for NULL, use the [NULL-predicate](#).

Examples

```
table.column1 = 2  
table.column2 = 'Seafood'  
table.column3 IS NULL
```

IN-predicate

Syntax

```
(column-list) [ NOT ] IN ( values-list )
```

Parameters

<i>column-list</i>	One or more comma-delimited columns in the queried tables.
<i>values-list</i>	Comma-delimited list of constant values to find in the <i>column-list</i> columns. Each <i>values-list</i> value maps to a <i>column-list</i> column according to their order in <i>values-list</i> and <i>column-list</i> , respectively. Column/value pairs must have compatible data types. You can specify multiple sets of values as follows: ((<i>values-list</i>), (<i>values-list</i>)[,...])

Examples

The following SELECT statement queries all data in table `t11`.

```
=> SELECT * FROM t11 ORDER BY pk;
pk | col1 | col2 | SKIP_ME_FLAG
-----+-----+-----+-----
 1 |  2 |  3 | t
 2 |  3 |  4 | t
 3 |  4 |  5 | f
 4 |  5 |  6 | f
 5 |  6 |  7 | t
 6 |    |  8 | f
 7 |  8 |    | t
(7 rows)
```

The following query specifies an IN predicate, to find all rows in `t11` where columns `col1` and `col2` contain values of `(2,3)` or `(6,7)`:

```
=> SELECT * FROM t11 WHERE (col1, col2) IN ((2,3), (6,7)) ORDER BY pk;
pk | col1 | col2 | SKIP_ME_FLAG
```

```
-----+-----+-----+-----  
 1 | 2 | 3 | t  
 5 | 6 | 7 | t  
(2 rows)
```

INTERPOLATE

Used to join two event series together using some ordered attribute, event series joins let you compare values from two series directly, rather than having to normalize the series to the same measurement interval.

Syntax

```
expression1 INTERPOLATE PREVIOUS VALUE expression2
```

Parameters

<i>expression1</i> <i>expression2</i>	A column reference from one the tables specified in the FROM Clause . The referenced columns are typically a DATE/TIME data type, often TIMESTAMP, inasmuch as you are joining data that represents an event series; however, the referenced columns can be of any type.
PREVIOUS VALUE	Pads the non-preserved side with the previous values from relation when there is no match. Input rows are sorted in ascending logical order of the join column. Note: An ORDER BY clause, if used, does not determine the input order but only determines query output order.

Description

- An event series join is an extension of a regular [outer join](#). Instead of padding the non-preserved side with null values when there is no match, the event series join pads the non-preserved side with the previous values from the table.

- The difference between expressing a regular outer join and an event series join is the INTERPOLATE predicate, which is used in the ON clause. See the **Examples** section below Notes and Restrictions. See also [Event Series Joins](#) in Analyzing Data.
- Data is logically partitioned on the table in which it resides, based on other ON clause equality predicates.
- Interpolated values come from the table that contains the null, not from the other table.
- Vertica does not guarantee that there will be no null values in the output. If there is no previous value for a mismatched row, that row will be padded with nulls.
- Event series join requires that both tables be sorted on columns in equality predicates, in any order, followed by the INTERPOLATED column. If data is already sorted in this order, then an explicit sort is avoided, which can improve query performance. For example, given the following tables:

```
ask: exchange, stock, ts, pricebid: exchange,  
stock, ts, price
```

In the query that follows

- ask is sorted on exchange, stock (or the reverse), ts
- bid is sorted on exchange, stock (or the reverse), ts

```
SELECT ask.price - bid.price, ask.ts, ask.stock, ask.exchange  
FROM ask FULL OUTER JOIN bid  
ON ask.stock = bid.stock AND ask.exchange =  
bid.exchange AND ask.ts INTERPOLATE PREVIOUS  
VALUE bid.ts;
```

Restrictions

- Only one INTERPOLATE expression is allowed per join.
- INTERPOLATE expressions are used only with ANSI SQL-99 syntax (the ON clause), which is already true for full outer joins.
- INTERPOLATE can be used with equality predicates only.
- The AND operator is supported but not the OR and NOT operators.
- Expressions and implicit or explicit casts are not supported, but subqueries are allowed.

Example

The examples that follow use this simple schema.

```
CREATE TABLE t(x TIME);
CREATE TABLE t1(y TIME);
INSERT INTO t VALUES('12:40:23');
INSERT INTO t VALUES('14:40:25');
INSERT INTO t VALUES('14:45:00');
INSERT INTO t VALUES('14:49:55');
INSERT INTO t1 VALUES('12:40:23');
INSERT INTO t1 VALUES('14:00:00');
COMMIT;
```

Normal Full Outer Join

```
=> SELECT * FROM t FULL OUTER JOIN t1 ON t.x = t1.y;
```

Notice the null rows from the non-preserved table:

x		y
12:40:23		12:40:23
14:40:25		
14:45:00		
14:49:55		
		14:00:00

(5 rows)

Full Outer Join with Interpolation

```
=> SELECT * FROM t FULL OUTER JOIN t1 ON t.x INTERPOLATE
PREVIOUS VALUE t1.y;
```

In this case, the rows with no entry point are padded with values from the previous row.

x		y
12:40:23		12:40:23
12:40:23		14:00:00
14:40:25		14:00:00
14:45:00		14:00:00
14:49:55		14:00:00

(5 rows)

Normal Left Outer Join

```
=> SELECT * FROM t LEFT OUTER JOIN t1 ON t.x = t1.y;
```

Again, there are nulls in the non-preserved table

x	y
12:40:23	12:40:23
14:40:25	
14:45:00	
14:49:55	

(4 rows)

Left Outer Join with Interpolation

```
=> SELECT * FROM t LEFT OUTER JOIN t1 ON t.x INTERPOLATE  
PREVIOUS VALUE t1.y;
```

Nulls padded with interpolated values.

x	y
12:40:23	12:40:23
14:40:25	14:00:00
14:45:00	14:00:00
14:49:55	14:00:00

(4 rows)

Inner Joins

For inner joins, there is no difference between a regular inner join and an event series inner join. Since null values are eliminated from the result set, there is nothing to interpolate.

A regular inner join returns only the single matching row at 12:40:23:

```
=> SELECT * FROM t INNER JOIN t1 ON t.x = t1.y;  
x      | y  
-----+-----  
12:40:23 | 12:40:23  
(1 row)
```

An event series inner join finds the same single-matching row at 12:40:23:

```
=> SELECT * FROM t INNER JOIN t1 ON t.x INTERPOLATE  
PREVIOUS VALUE t1.y;  
      x      |      y  
-----+-----  
12:40:23 | 12:40:23  
(1 row)
```

Semantics

When you write an event series join in place of normal join, values are evaluated as follows (using the schema in the above examples):

- `t` is the outer, preserved table
- `t1` is the inner, non-preserved table
- For each row in outer table `t`, the ON clause predicates are evaluated for each combination of each row in the inner table `t1`.
- If the ON clause predicates evaluate to true for any combination of rows, those combination rows are produced at the output.
- If the ON clause is false for all combinations, a single output row is produced with the values of the row from `t` along with the columns of `t1` chosen from the row in `t1` with the greatest `t1.y` value such that `t1.y < t.x`; If no such row is found, pad with nulls.

Note: `t LEFT OUTER JOIN t1` is equivalent to `t1 RIGHT OUTER JOIN t`.

In the case of a full outer join, all values from both tables are preserved.

See Also

- [Event Series Joins](#)

Join-Predicate

Specifies the columns on which records from two or more tables are joined. You can connect multiple join predicates with logical operators AND, OR, and NOT.

Syntax

`ON column-ref = column-ref [{AND | OR | NOT } column-ref = column-ref]...`

Parameters

<i>column-ref</i>	Specifies a column in a queried table. For best performance, do not join on LONG VARBINARY and LONG VARCHAR columns.
-------------------	--

LIKE-predicate

Retrieves rows where the string value of a column matches a specified pattern. The pattern can contain one or more wildcard characters.

Syntax

`string-expression [NOT] { LIKE | ILIKE | LIKEB | ILIKEB } 'pattern' [ESCAPE 'escape-character']`

Parameters

<i>string-expression</i>	The column values to search for <i>pattern</i> .
NOT	Returns true if LIKE returns false, and the reverse; equivalent to NOT <i>string</i> LIKE <i>pattern</i> .
<i>pattern</i>	Specifies what strings to match, typically containing one or both of the following wildcard characters: <ul style="list-style-type: none"> • Underscore (<code>_</code>) matches any single character. • Percent sign (<code>%</code>) matches any string of zero or more characters.
ESCAPE <i>escape-character</i>	Specifies an escape character, used in the to escape reserved characters underscore (<code>_</code>), percent (<code>%</code>), and the escape character itself. This is enforced only for non-default collations. If you omit this parameter, you can use Vertica's default escape

character, backslash (\), which is valid for CHAR and VARCHAR strings.

Note: Backslash is not valid for binary data types character. To embed an escape character for binary data types, use ESCAPE to specify a valid binary character.

Substitute Symbols

You can substitute the following symbols for LIKE and its variants:

~#	LIKEB
~~*	ILIKE
~#*	ILIKEB
!~~	NOT LIKE
!~#	NOT LIKEB
!~~*	NOT ILIKE
!~#*	NOT ILIKEB

Note: ESCAPE is not valid for the above symbols.

Pattern Matching

LIKE requires that the entire string expression match the pattern. To match a sequence of characters anywhere within a string, the pattern must start and end with a percent sign.

LIKE does not ignore trailing white space characters. If the data values to match end with an indeterminate amount of white space, append the wildcard character % to *pattern*.

LIKE Variants Compared

The LIKE predicate is compliant with the SQL standard. Vertica also supports several non-standard variants, notably ILIKE, which is equivalent to LIKE except it performs case-insensitive searches. The following differences pertain to LIKE and its variants:

- LIKE operates on UTF-8 character strings. Exact behavior depends on collation parameters such as strength. In particular, ILIKE works by setting S=2 (ignore case) in the current session locale.
- LIKE and ILIKE are stable for character strings, but immutable for binary strings, while LIKEB and ILIKEB are immutable for both cases.
- LIKEB and ILIKEB predicates do byte-at-a-time ASCII comparisons.

Locale Dependencies

In the default locale, LIKE and ILIKE handle UTF-8 character-at-a-time, locale-insensitive comparisons. ILIKE handles language-independent case-folding.

In non-default locales, LIKE and ILIKE perform locale-sensitive string comparisons, including some automatic normalization, using the same algorithm as the "=" operator on VARCHAR types.

ESCAPE expressions evaluate to exactly one octet—or one UTF-8 character for non-default locales.

Examples

The following example illustrates pattern matching in locales.

```
\locale default=> CREATE TABLE src(c1 VARCHAR(100));  
=> INSERT INTO src VALUES (U&'\00DF'); --The sharp s (ß)  
=> INSERT INTO src VALUES ('ss');  
=> COMMIT;
```

Querying the src table in the default locale returns both ss and sharp s.

```
=> SELECT * FROM src;  
c1  
----  
ß  
ss  
(2 rows)
```

The following query combines pattern-matching predicates to return the results from column c1:

```
=> SELECT c1, c1 = 'ss' AS equality, c1 LIKE 'ss'  
AS LIKE, c1 ILIKE 'ss' AS ILIKE FROM src;  
c1 | equality | LIKE | ILIKE
```

```

-----+-----+-----+-----
ß | f      | f      | f
ss | t      | t      | t
(2 rows)

```

The next query specifies unicode format for c1:

```

=> SELECT c1, c1 = U&'\00DF' AS equality,
      c1 LIKE U&'\00DF' AS LIKE,
      c1 ILIKE U&'\00DF' AS ILIKE from src;
c1 | equality | LIKE | ILIKE
-----+-----+-----+-----
ß | t      | t      | t
ss | f      | f      | f
(2 rows)

```

Now change the locale to German with a strength of 1 (ignore case and accents):

```

\locale LDE_S1
=> SELECT c1, c1 = 'ss' AS equality,
      c1 LIKE 'ss' as LIKE, c1 ILIKE 'ss' AS ILIKE from src;
c1 | equality | LIKE | ILIKE
-----+-----+-----+-----
ß | t      | t      | t
ss | t      | t      | t
(2 rows)

```

This example illustrates binary data types with pattern-matching predicates:

```

=> CREATE TABLE t (c BINARY(1));
=> INSERT INTO t values(HEX_TO_BINARY('0x00'));
=> INSERT INTO t values(HEX_TO_BINARY('0xFF'));
=> SELECT TO_HEX(c) from t;
TO_HEX
-----
00
ff
(2 rows)
select * from t;
c
-----
\000
\377
(2 rows)
=> SELECT c, c = '\000', c LIKE '\000', c ILIKE '\000' from t;
c | ?column? | ?column? | ?column?
-----+-----+-----+-----
\000 | t      | t      | t
\377 | f      | f      | f
(2 rows)
=> SELECT c, c = '\377', c LIKE '\377', c ILIKE '\377' from t;
c | ?column? | ?column? | ?column?
-----+-----+-----+-----
\000 | f      | f      | f
\377 | t      | t      | t
(2 rows)

```

NULL-predicate

Tests for null values.

Syntax

```
value_expression IS [ NOT ] NULL
```

Parameters

<i>value_expression</i>	A column name, literal, or function.
-------------------------	--------------------------------------

Examples

Column name:

```
=> SELECT date_key FROM date_dimension WHERE date_key IS NOT NULL;
date_key
-----
      1
     366
    1462
    1097
       2
       3
       6
       7
       8
...

```

Function:

```
=> SELECT MAX(household_id) IS NULL FROM customer_dimension;
?column?
-----
f
(1 row)

```

Literal:

```
=> SELECT 'a' IS NOT NULL;
?column?
-----
t

```

(1 row)

Hints

Hints are directives that you embed within a query or directed query. They conform to the following syntax:

```
/*+ hint-name[, hint-name]... */
```

Hints are bracketed by comment characters `/*+` and `*/`, which can enclose multiple comma-delimited hints. For example:

```
/*+ DIRECT, LABEL(myLabel) */
```

Restrictions

When embedding hints, be aware of the following restrictions:

- Do not embed spaces in the comment characters `/*` and `*/`.
- In general, spaces are allowed before and after the plus (+) character and *hint-name*; however, some third-party tools do not support spaces embedded inside `/*+`.

Supported Hints

Vertica supports the following hints:

General hints	<code>ALLNODES</code>	Qualifies an <code>EXPLAIN</code> statement to request a query plan that assumes all nodes are active.
	<code>ENABLE_WITH_CLAUSE_MATERIALIZATION</code>	Enables and disables <code>WITH clause</code> materialization for a specific query.
	<code>EARLY_MATERIALIZATION</code>	Specifies early materialization of a table for the current query.
	<code>DIRECT</code>	Specifies to write data directly to disk (ROS); valid only for <code>CREATE [TEMPORARY] TABLE AS</code> ,

		INSERT , MERGE , and UPDATE operations.
	LABEL	Labels a query so you can identify it for profiling and debugging.
Join hints	SYNTACTIC_JOIN	Enforces join order and enables other join hints.
	DISTRIB	Sets the input operations for a distributed join to broadcast, resegment, local, or filter.
	GBYTYPE	Specifies which algorithm— GROUPBY HASH or GROUPBY PIPELINED —the Vertica query optimizer should use to implement a GROUP BY clause.
	JTYPE	Enforces the join type: merge or hash join.
	UTYPE	Specifies how to combine UNION ALL input.
Table hints	PROJS	Specifies one or more projections to use for a queried table.
	SKIP_PROJS	Specifies which projections to avoid using for a queried table.
Directed query hints	IGNORECONST	Maps an input query constant to one or more annotated query constants.
	VERBATIM	Enforces execution of an annotated query exactly as written.

ALLNODES

Qualifies an [EXPLAIN](#) statement to request a query plan that assumes all nodes are active. If you omit this hint, the [EXPLAIN](#) statement produces a query plan that takes into account any nodes that are currently down.

Syntax

```
EXPLAIN /*+ ALLNODES */ ...
```

Examples

In the following example, the ALLNODES hint requests a query plan that assumes all nodes are active.

```
QUERY PLAN DESCRIPTION:
-----

Opt Vertica Options
-----
PLAN_ALL_NODES_ACTIVE

EXPLAIN /*+ALLNODES*/ select * from Emp_Dimension;

Access Path:
+-STORAGE ACCESS for Emp_Dimension [Cost: 125, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
| Projection: public.Emp_Dimension_b0
| Materialize: Emp_Dimension.Employee_key, Emp_Dimension.Employee_gender, Emp_Dimension.Courtesy_
title, Emp_Dimension.Employee_first_name, Emp_Dimension.Employee_middle_initial, Emp_
Dimension.Employee_last_name, Emp_Dimension.Employee_age, Emp_Dimension.Employee_birthdate, Emp_
Dimension.Employee_street, Emp_Dimension.Employee_city, Emp_Dimension.Employee_state, Emp_
Dimension.Employee_region, Emp_Dimension.Employee_position
| Execute on: All Nodes
```

AUTO

Specifies to initially load data into WOS. This hint overrides the table's [load method](#).

The following statements support this hint:

- [INSERT](#)
- [MERGE](#)
- [UPDATE](#)
- [CREATE \[TEMPORARY\] TABLE AS](#)

For more information about data load options, see [Choosing a Load Method](#).

Syntax

```
statement-name /*+ AUTO */ ...
```

DIRECT

Specifies to bypass memory (WOS) and write table data directly to disk (ROS). This hint overrides the table's [load method](#), by default set to AUTO.

The following statements support this hint:

- **DELETE**: If used with `/*+DIRECT*/`, stores delete vectors in ROS.
- **INSERT**
- **MERGE**
- **UPDATE**
- **CREATE [TEMPORARY] TABLE AS**

For more information about data load options, see [Choosing a Load Method](#).

Syntax

```
statement-name /*+ DIRECT */ ...
```

DISTRIB

Specifies to the optimizer how to distribute join key data to implement a join.

Syntax

```
...JOIN /*+ DISTRIB(outer-join, inner-join) */
```

Arguments

<i>outer-join</i> <i>inner-join</i>	<p>Specifies how to distribute data on the outer and inner joins:</p> <ul style="list-style-type: none">• L (local): Inner and outer join keys are identically segmented on each node, join locally.• R (resegment): Inner and outer join keys are not identically segmented.
--	--

	<p>Resegment join-key data before implementing the join.</p> <ul style="list-style-type: none">• B (broadcast): Inner and outer join keys are not identically segmented. Broadcast data of this join key to other nodes before implementing the join.• F (filter): Join table is unsegmented. Filter data as needed by the other join key before implementing the join.• A (any): Let the optimizer choose the distribution method that it considers to be most cost-effective.
--	---

Description

The DISTRIB hint specifies to the optimizer how to distribute join key data in order to implement a join. If a specified distribution is not feasible, the optimizer ignores the hint and throws a warning.

The following requirements apply:

- Queries that include the DISTRIB hint must also include the SYNTACTIC_JOIN hint. Otherwise, the optimizer ignores the DISTRIB hint and throws a warning.
- Join syntax must conform with ANSI SQL-92 join conventions.

Examples

In the following query, the join is qualified with a DISTRIB hint of `/*+ DISTRIB(L,R)*/`. This hint tells the optimizer to resegment data of join key `stores.store_key` before joining it to the `sales.store_key` data:

```
SELECT /*+ SYNTACTIC_JOIN */ sales.store_key, stores.store_name, sales.product_description,  
sales.sales_quantity, sales.sale_date  
FROM (store.storeSales AS sales JOIN /*+DISTRIB(L,R),JTYPE(H)*/ store.store_dimension AS stores ON  
(sales.store_key = stores.store_key))  
WHERE (sales.sale_date = '2014-12-01'::date) ORDER BY sales.store_key, sales.sale_date;
```

EARLY_MATERIALIZATION

Specifies early materialization of a table for the current query. A query can include this hint for any number of tables. Typically, the query optimizer delays materialization until late in the query execution process. This hint overrides any choices that the optimizer otherwise would make.

This hint can be useful in cases where late materialization of join inputs precludes other optimizations—for example, pushing aggregation down the joins, or using live aggregate projections. In these cases, qualifying a join input with `EARLY_MATERIALIZATION` can enable the optimizations.

Syntax

```
table-name [ [AS] alias] /*+ EARLY_MATERIALIZATION */
```

ENABLE_WITH_CLAUSE_MATERIALIZATION

Enables and disables [WITH clause](#) materialization for a specific query. Materialization is automatically cleared when the query returns. For more information about materializing WITH clauses, see [Materialization of WITH Clause](#) in Analyzing Data.

Syntax

```
WITH /*+ENABLE_WITH_CLAUSE_MATERIALIZATION*/ with-query...
```

GBYTYPE

Specifies which algorithm—`GROUPBY HASH` or `GROUPBY PIPELINED`—the Vertica query optimizer should use to implement a [GROUP BY](#) clause. If both algorithms are valid for this query, the query optimizer chooses the specified algorithm over the algorithm that the query optimizer might otherwise choose in its query plan.

Syntax

```
...GROUP BY /*+ GBYTYPE( HASH | PIPE ) */
```

Arguments

HASH PIPE	<p>Specifies the GROUP BY algorithm to use:</p> <ul style="list-style-type: none">• HASH: GROUPBY HASH algorithm• PIPE: GROUPBY PIPELINED algorithm <p>Note: Vertica uses the GROUPBY PIPELINED algorithm only if the query and one of its projections comply with GROUP BY PIPELINED requirements. Otherwise, Vertica issues a warning and uses GROUPBY HASH.</p> <p>For more information about both algorithms, see GROUP BY Implementation Options.</p>
-------------	--

Examples

See [Controlling GROUPBY Algorithm Choice](#) in Analyzing Data.

IGNORECONST

In a directed query, maps an input query constant to one or more annotated query constants.

Syntax

```
/*+ IGNORECONST(arg) */
```

Description

IGNORECONST lets you create directed queries that support input queries with various conditions. IGNORECONST requires an integer argument. This argument matches constants in

input and annotated queries that you want the optimizer to ignore.

Examples

In the following example a directed query is created where input and annotated queries set IGNORECONST hints on Employee_city and Employee_position:

```
=> SAVE QUERY SELECT Employee_first_name, Employee_last_name FROM EMP_Dimension
WHERE Employee_city='somewhere' /*+IGNORECONST(1)*/
AND Employee_position='somejob' /*+IGNORECONST(2)*/;
SAVE QUERY

=> CREATE DIRECTED QUERY CUSTOM 'findEmployees' SELECT Employee_first_name, Employee_last_name FROM
EMP_Dimension /*+projs('public.Emp_Dimension_Unseg')*/
WHERE Employee_city='somewhere' /*+IGNORECONST(1)*/
AND Employee_position='somejob' /*+IGNORECONST(2)*/;
CREATE DIRECTED QUERY
```

IGNORECONST pairs two sets of constants:

- IGNORECONST(1) pairs input and annotated query settings for Employee_city.
- IGNORECONST(2) pairs input and annotated query settings for Employee_position.

See Also

[Ignoring Constants in Directed Queries](#)

JTYPE

Specifies the join algorithm as hash or merge.

Syntax

```
...JOIN /*+ JTYPE(join-type) */
```

Arguments

<i>join-type</i>	One of the following arguments: <ul style="list-style-type: none">• H: Hash join
------------------	--

- M: Merge join, valid only if both join inputs are already sorted on the join columns, otherwise Vertica ignores it and throws a warning.

Note: The optimizer relies upon the query or DDL to verify whether input data is sorted, rather than the actual runtime order of the data.

- FM: Forced merge join. Before performing the merge, the optimizer re-sorts the join inputs. Two restrictions apply:
 - This option is valid only for simple join conditions. For example:

```
SELECT /*+ SYNTACTIC_JOIN*/ * FROM x JOIN /*+JTYPE(FM)*/ y ON x.c1 = y.c1;
```

- Join columns must be of the same type and precision or scale. One exception applies: string columns can have different lengths

Description

Use the JTYPE hint to specify the algorithm the optimizer uses to join table data. If specified algorithm is not feasible, the optimizer ignores the hint and throws a warning.

Requirements

- Queries that include the JTYPE hint must also include the SYNTACTIC_JOIN hint. Otherwise, the optimizer ignores the JTYPE hint and throws a warning.
- Join syntax must conform with ANSI SQL-92 join conventions.

LABEL

Assigns a label to a statement in order to identify it for profiling and debugging.

LABEL hints are valid in the following statements:

- [DELETE](#)
- [INSERT](#)
- [MERGE](#)
- [SELECT](#)

- [UPDATE](#)
- [UNION](#): Valid in the UNION's first SELECT statement. Vertica ignores labels in subsequent SELECT statements.

Syntax

```
statement-name /*+ LABEL (label-string) */
```

Arguments

<i>label-string</i>	A string that is up to 128 octets long. If enclosed with single quotes, <i>label-string</i> can contain embedded spaces.
---------------------	--

Examples

```
=> SELECT /*+ LABEL(MySelectQuery)*/ COUNT(*) FROM t;  
=> INSERT /*+ LABEL('Yet Another Query')*/ INTO t VALUES(1);
```

See Also

[Labeling Queries](#) in the Administrator's Guide

PROJS

Specifies one or more projections to use for a queried table.

Syntax

```
...FROM table-name /*+ PROJS( [schema.]projection[,...] ) */
```

Arguments

<i>schema</i>	<p>Specifies a schema. If multiple schemas are defined in the database, include the schema name. For example:</p> <pre>myschema.thisDBObject</pre>
<i>projection</i>	<p>The projection to use. You can specify a list of comma-delimited projections.</p>

Description

The PROJS hint can specify multiple projections; the optimizer determines which ones are valid and uses the one that is most cost-effective for the queried table. If no hinted projection is valid, the query returns a warning and ignores projection hints.

Examples

The following query includes a PROJS hint that specifies two projections:

```
=> EXPLAIN SELECT * FROM Emp_Dimension /*+PROJS('public.Emp_Dimension_Unseg', 'public.Emp_Dimension')*/;
```

The first projection `public.Emp_Dimension_Unseg` does not include all columns in the queried table `Emp_Dimension`, so the optimizer cannot use it. The second projection includes all table columns so the optimizer uses it, as verified by the following query plan:

```
QUERY PLAN DESCRIPTION:
-----
explain SELECT * FROM Emp_Dimension /*+PROJS('public.Emp_Dimension_Unseg', 'public.Emp_Dimension')*/;
Access Path:
+-STORAGE ACCESS for Emp_Dimension [Cost: 125, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
| Projection: public.Emp_Dimension_b0
```

SKIP_PROJS

Specifies which projections to avoid using for a queried table.

Syntax

```
...FROM table-name /*+ SKIP_PROJS( [[db-name.]schema.]projection[,...] ) */
```

Arguments

<code>[<i>db-name</i>.]<i>schema</i></code>	<p>Specifies a schema. If multiple schemas are defined in the database, include the schema name. For example:</p> <pre>myschema.thisDBObject</pre>
<code><i>projection</i></code>	A projection to skip. You can specify a list of comma-delimited projections.

Description

The SKIP_PROJS specifies one or more projections that the optimizer should avoid using. If the SKIP_PROJS hint excludes all available projections that are valid for the query, the optimizer issues a warning and ignores the projection hints.

Examples

In this example, the EXPLAIN output shows that the optimizer uses the projection `public.Emp_Dimension_b0` for a given query:

```
QUERY PLAN DESCRIPTION:
-----

EXPLAIN SELECT Employee_last_name, Employee_first_name, Employee_city, Employee_position FROM Emp_
Dimension;

Access Path:
+-STORAGE ACCESS for Emp_Dimension [Cost: 59, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
| Projection: public.Emp_Dimension_b0
```

You can use the SKIP_PROJS hint to avoid using this projection. If another projection is available that is valid for this query, the optimizer uses it instead:

```
QUERY PLAN DESCRIPTION:
-----

EXPLAIN SELECT Employee_last_name, Employee_first_name, Employee_city, Employee_position FROM Emp_
Dimension /*+SKIP_PROJS('public.Emp_Dimension')*/;

Access Path:
+-STORAGE ACCESS for Emp_Dimension [Cost: 152, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
| Projection: public.Emp_Dimension_Unseg
```

SYNTACTIC_JOIN

Enforces join order and enables other join hints.

Syntax

```
/*+ SYN[TACTIC]_JOIN */
```

Description

In order to achieve optimal performance, the optimizer often overrides a query's specified join order. By including the `SYNTACTIC_JOIN` hint, you can ensure that the optimizer enforces the query's join order exactly as specified. One requirement applies: the join syntax must conform with ANSI SQL-92 conventions.

The `SYNTACTIC_JOIN` hint must immediately follow `SELECT`. If the annotated query includes another hint that must also follow `SELECT`, such as `VERBATIM`, combine the two hints together. For example:

```
SELECT /*+ syntactic_join,verbatim */ ...
```

Examples

In the following examples, the optimizer produces different plans for two queries that differ only by including or excluding the `SYNTACTIC_JOIN` hint.

Excludes `SYNTACTIC_JOIN`

```
EXPLAIN SELECT sales.store_key, stores.store_name, products.product_description, sales.sales_
quantity, sales.sale_date
FROM (store.store_sales sales JOIN products ON sales.product_key=products.product_key)
JOIN store.store_dimension stores ON sales.store_key=stores.store_key
WHERE sales.sale_date='2014-12-01' order by sales.store_key, sales.sale_date;
```

```
Access Path:
+-SORT [Cost: 14K, Rows: 100K (NO STATISTICS)] (PATH ID: 1)
| Order: sales.store_key ASC, sales.sale_date ASC
| Execute on: All Nodes
```

```

| +---> JOIN HASH [Cost: 11K, Rows: 100K (NO STATISTICS)] (PATH ID: 2) Outer (RESEGMENT)(LOCAL ROUND
ROBIN) Inner (RESEGMENT)
| |      Join Cond: (sales.product_key = products.product_key)
| |      Materialize at Input: sales.store_key, sales.product_key, sales.sale_date, sales.sales_
quantity
| |      Execute on: All Nodes
| | +-- Outer -> JOIN HASH [Cost: 1K, Rows: 100K (NO STATISTICS)] (PATH ID: 3)
| | |      Join Cond: (sales.store_key = stores.store_key)
| | |      Execute on: All Nodes
| | | +-- Outer -> STORAGE ACCESS for sales [Cost: 1K, Rows: 100K (NO STATISTICS)] (PATH ID: 4)
| | | |      Projection: store.store_sales_b0
| | | |      Materialize: sales.store_key
| | | |      Filter: (sales.sale_date = '2014-12-01'::date)
| | | |      Execute on: All Nodes
| | | |      Runtime Filter: (SIP1(HashJoin): sales.store_key)
| | | +-- Inner -> STORAGE ACCESS for stores [Cost: 34, Rows: 250] (PATH ID: 5)

| | |      Materialize: stores.store_key, stores.store_name
| | |      Execute on: All Nodes

```

TRICKLE

Specifies to load data only into WOS. This hint overrides the table's [load method](#), by default set to AUTO.

The following statements support this hint:

- [DELETE](#): If used with `/*+TRICKLE*/`, stores delete vectors in WOS.
- [INSERT](#)
- [MERGE](#)
- [UPDATE](#)
- [CREATE \[TEMPORARY\] TABLE AS](#)

For more information about data load options, see [Choosing a Load Method](#).

Syntax

```
statement-name /*+ TRICKLE */ ...
```

UTYPE

Specifies how to combine [UNION ALL](#) input.

Syntax

```
...UNION ALL /*+ UTYPE(union-type) */
```

Arguments

<i>union-type</i>	One of the following arguments: <ul style="list-style-type: none">• U: Concatenates UNION ALL input (default).• M: Merges UNION ALL input in the same sort order as the source query results. This option requires all input from the source queries to use the
-------------------	--

same sort order; otherwise, Vertica throws a warning and concatenates the UNION ALL input.

Note: The optimizer relies upon the query or DDL to verify whether input data is sorted, rather than the actual runtime order of the data.

Requirements

Queries that include the UTYPE hint must also include the SYNTACTIC_JOIN hint. Otherwise, the optimizer ignores the UTYPE hint and throws a warning.

VERBATIM

Enforces execution of an annotated query exactly as written.

VERBATIM directs the optimizer to create a query plan that incorporates all hints in a annotated query. Furthermore, it directs the optimizer not to apply its own plan development processing on query plan components that pertain to those hints.

Usage of this hint varies between [optimizer-generated](#) and [custom](#) directed queries, as described below.

Syntax

```
SELECT /*+ VERBATIM */ ...
```

Requirements

The VERBATIM hint must immediately follow SELECT. If the annotated query includes another hint that must also follow SELECT, such as SYNTACTIC_JOIN, combine the two hints together. For example:

```
SELECT /*+ syntactic_join,verbatim */ ...
```

Optimizer-Generated Directed Queries

The optimizer always includes the VERBATIM hint in the annotated queries that it [generates for directed queries](#). For example, given the following

CREATE DIRECTED QUERY OPTIMIZER statement:

```
=> CREATE DIRECTED QUERY OPTIMIZER getStoreSales SELECT sales.store_key, stores.store_name,
sales.product_description, sales.sales_quantity, sales.sale_date FROM store.storesales sales JOIN
store.store_dimension stores ON sales.store_key=stores.store_key WHERE sales.sale_date='2014-12-01'
/*+IGNORECONST(1)*/ AND stores.store_name='Store1' /*+IGNORECONST(2)*/ ORDER BY sales.store_key,
sales.sale_date;
CREATE DIRECTED QUERY
```

The optimizer generates an annotated query that includes the VERBATIM hint:

```
=> SELECT query_name, annotated_query FROM V_CATALOG.DIRECTED_QUERIES WHERE query_name =
'getStoreSales';
-[ RECORD 1 ]-----
query_name      | getStoreSales
annotated_query | SELECT /*+ syntactic_join,verbatim */ sales.store_key AS store_key, stores.store_
name AS store_name, sales.product_description AS product_description, sales.sales_quantity AS sales_
quantity, sales.sale_date AS sale_date
FROM (store.storeSales AS sales/*+projs('store.storeSales')*/ JOIN /*+Distrib(L,L),JType(H)*/
store.store_dimension AS stores/*+projs('store.store_dimension_DBD_10_rep_VMartDesign')*/ ON
(sales.store_key = stores.store_key))
WHERE (sales.sale_date = '2014-12-01'::date /*+IgnoreConst(1)*/) AND (stores.store_name =
'Store1'::varchar(6) /*+IgnoreConst(2)*/)
ORDER BY 1 ASC, 5 ASC
```

When the optimizer uses this directed query, it produces a query plan that is equivalent to the query plan that it used when it created the directed query:

```
=> ACTIVATE DIRECTED QUERY getStoreSales;
ACTIVATE DIRECTED QUERY

=> EXPLAIN SELECT sales.store_key, stores.store_name, sales.product_description, sales.sales_
quantity, sales.sale_date FROM store.storesales sales JOIN store.store_dimension stores ON
sales.store_key=stores.store_key WHERE sales.sale_date='2014-12-04' AND stores.store_name='Store14'
ORDER BY sales.store_key, sales.sale_date;

QUERY PLAN DESCRIPTION:
-----

EXPLAIN SELECT sales.store_key, stores.store_name, sales.product_description, sales.sales_quantity,
sales.sale_date FROM store.storesales sales JOIN store.store_dimension stores ON sales.store_
key=stores.store_key WHERE sales.sale_date='2014-12-04' AND stores.store_name='Store14' ORDER BY
sales.store_key, sales.sale_date;

The following active directed query(query name: getStoreSales) is being executed:
SELECT /*+syntactic_join,verbatim*/ sales.store_key, stores.store_name, sales.product_description,
sales.sales_quantity, sales.sale_date
FROM (store.storeSales sales/*+projs('store.storeSales')*/ JOIN /*+Distrib('L', 'L'), JType
('H')*/store.store_dimension stores
```

```
/*+projs('store.store_dimension_DBD_10_rep_VMartDesign')*/ ON ((sales.store_key = stores.store_key)))  
WHERE ((sales.sale_date = '2014-12-04'::date)  
AND (stores.store_name = 'Store14'::varchar(7))) ORDER BY sales.store_key, sales.sale_date
```

Access Path:

```
+--JOIN HASH [Cost: 463, Rows: 622 (NO STATISTICS)] (PATH ID: 2)  
| Join Cond: (sales.store_key = stores.store_key)  
| Materialize at Output: sales.sale_date, sales.sales_quantity, sales.product_description  
| Execute on: All Nodes  
| +-- Outer -> STORAGE ACCESS for sales [Cost: 150, Rows: 155K (NO STATISTICS)] (PATH ID: 3)  
| | Projection: store.storeSales_b0  
| | Materialize: sales.store_key  
| | Filter: (sales.sale_date = '2014-12-04'::date)  
| | Execute on: All Nodes  
| | Runtime Filter: (SIP1(HashJoin): sales.store_key)  
| +-- Inner -> STORAGE ACCESS for stores [Cost: 35, Rows: 2] (PATH ID: 4)  
| | Projection: store.store_dimension_DBD_10_rep_VMartDesign_node0001  
| | Materialize: stores.store_name, stores.store_key  
| | Filter: (stores.store_name = 'Store14')  
| | Execute on: All Nodes
```

Custom Directed Queries

The VERBATIM hint is included in a [custom directed query](#) only if you explicitly include it in the annotated query that you write for that directed query. When the optimizer uses that directed query, it respects the VERBATIM hint and creates a query plan accordingly.

If you omit the VERBATIM hint when you create a custom directed query, the hint is not stored with the annotated query. When the optimizer uses that directed query, it applies its own plan development processing on the annotated query before it generates a query plan. This query plan might not be equivalent to the query plan that the optimizer would have generated for the Vertica version in which the directed query was created.

SQL Data Types

The following table summarizes the data types that Vertica supports. It also shows the default placement of null values in projections. The Size column is listed as uncompressed bytes.

Type	Size (bytes)	Description	NULL Sorting
Binary types (For more information, see Binary Data Types .)			
BINARY	1 to 65000	Fixed-length binary string	NULLS LAST
VARBINARY	1 to 65000	Variable-length binary string	NULLS LAST
LONG VARBINARY	1 to 32,000,000	Long variable-length binary string	NULLS LAST
BYTEA	1 to 65000	Variable-length binary string (synonym for VARBINARY)	NULLS LAST
RAW	1 to 65000	Variable-length binary string (synonym for VARBINARY)	NULLS LAST
Boolean types (See Boolean Data Type .)			
BOOLEAN	1	True or False or NULL	NULLS LAST
Character types (See Character Data Types and Long Data Types .)			
CHAR	1 to 65000	Fixed-length character string	NULLS LAST
VARCHAR	1 to 65000	Variable-length character string	NULLS LAST
LONG VARCHAR	1 to 32,000,000	Long variable-length character string	NULLS LAST
Date/time types (See Date/Time Data Types .)			
DATE	8	Represents a month, day, and year	NULLS FIRST
DATETIME	8	Represents a date and time with or without timezone (synonym for TIMESTAMP)	NULLS FIRST
SMALLDATETIME	8	Represents a date and time with or	NULLS FIRST

Type	Size (bytes)	Description	NULL Sorting
		without timezone (synonym for <code>TIMESTAMP</code>)	
<code>TIME</code>	8	Represents a time of day without timezone	NULLS FIRST
<code>TIME WITH TIMEZONE</code>	8	Represents a time of day with timezone	NULLS FIRST
<code>TIMESTAMP</code>	8	Represents a date and time without timezone	NULLS FIRST
<code>TIMESTAMP WITH TIMEZONE</code>	8	Represents a date and time with timezone	NULLS FIRST
<code>INTERVAL</code>	8	Measures the difference between two points in time	NULLS FIRST
<code>INTERVAL DAY TO SECOND</code>	8	Represents an interval measured in days and seconds	NULLS FIRST
<code>INTERVAL YEAR TO MONTH</code>	8	Represents an interval measured in years and months	NULLS FIRST
Approximate numeric types (See DOUBLE PRECISION (FLOAT) .)			
<code>DOUBLE PRECISION</code>	8	Signed 64-bit IEEE floating point number, requiring 8 bytes of storage	NULLS LAST
<code>FLOAT</code>	8	Signed 64-bit IEEE floating point number, requiring 8 bytes of storage	NULLS LAST
<code>FLOAT(n)</code>	8	Signed 64-bit IEEE floating point number, requiring 8 bytes of storage	NULLS LAST
<code>FLOAT8</code>	8	Signed 64-bit IEEE floating point number, requiring 8 bytes of storage	NULLS LAST
<code>REAL</code>	8	Signed 64-bit IEEE floating point number, requiring 8 bytes of storage	NULLS LAST
Exact numeric types (See Numeric Data Types .)			

Type	Size (bytes)	Description	NULL Sorting
INTEGER	8	Signed 64-bit integer, requiring 8 bytes of storage	NULLS FIRST
INT	8	Signed 64-bit integer, requiring 8 bytes of storage	NULLS FIRST
BIGINT	8	Signed 64-bit integer, requiring 8 bytes of storage	NULLS FIRST
INT8	8	Signed 64-bit integer, requiring 8 bytes of storage	NULLS FIRST
SMALLINT	8	Signed 64-bit integer, requiring 8 bytes of storage	NULLS FIRST
TINYINT	8	Signed 64-bit integer, requiring 8 bytes of storage	NULLS FIRST
DECIMAL	8+	8 bytes for the first 18 digits of precision, plus 8 bytes for each additional 19 digits	NULLS FIRST
NUMERIC	8+	8 bytes for the first 18 digits of precision, plus 8 bytes for each additional 19 digits	NULLS FIRST
NUMBER	8+	8 bytes for the first 18 digits of precision, plus 8 bytes for each additional 19 digits	NULLS FIRST
MONEY	8+	8 bytes for the first 18 digits of precision, plus 8 bytes for each additional 19 digits	NULLS FIRST

Binary Data Types

Store raw-byte data, such as IP addresses, up to 65000 bytes.

Syntax

```
BINARY ( Length ) { VARBINARY | BINARY VARYING | BYTEA | RAW } ( max-Length )
```

Parameters

<i>Length</i> <i>max-Length</i>	Specifies the length of the string (column width, declared in bytes (octets), in CREATE TABLE statements).
-----------------------------------	--

Notes

- BYTEA and RAW are synonyms for VARBINARY.
- The data types BINARY and BINARY VARYING (VARBINARY) are collectively referred to as *binary string types* and the values of binary string types are referred to as *binary strings*.
- A binary string is a sequence of octets, or bytes. Binary strings store raw-byte data, while character strings store text.
- A binary value value of NULL appears last (largest) in ascending order.
- The binary data types, BINARY and VARBINARY, are similar to the [Character Data Types](#), CHAR and VARCHAR, respectively, except that binary data types contain byte strings, rather than character strings.
- BINARY—A fixed-width string of *length* bytes, where the number of bytes is declared as an optional specifier to the type. If length is omitted, the default is 1. Where necessary, values are right-extended to the full width of the column with the zero byte. For example:

```
=> SELECT TO_HEX('ab'::BINARY(4));  
to_hex  
-----  
61620000
```

- VARBINARY—A variable-width string up to a length of *max-length* bytes, where the maximum number of bytes is declared as an optional specifier to the type. The default is the default attribute size, which is 80, and the maximum length is 65000 bytes. VARBINARY values are not extended to the full width of the column. For example:

```
=> SELECT TO_HEX('ab'::VARBINARY(4));  
to_hex  
-----  
6162
```

- You can use several formats when working with binary values, but the hexadecimal format is generally the most straightforward and is emphasized in Vertica documentation.
- Binary operands `&`, `~`, `|` and `#` have special behavior for binary data types, as described in [Binary Operators](#).
- On input, strings are translated from:
 - Hexadecimal representation to a binary value using the [HEX_TO_BINARY](#) function
 - Bitstring representation to a binary value using the [BITSTRING_TO_BINARY](#) function.

Both functions take a `VARCHAR` argument and return a `VARBINARY` value. See the Examples section below.

- Binary values can also be represented in octal format by prefixing the value with a backslash `'\'`.

Note: If you use `vsql`, you must use the escape character (`\`) when you insert another backslash on input; for example, input `'\141'` as `'\\141'`.

You can also input values represented by printable characters. For example, the hexadecimal value `'0x61'` can also be represented by the symbol `'1'`.

See [Bulk-Loading Data](#) in the Administrator's Guide.

- Like the input format the output format is a hybrid of octal codes and printable ASCII characters. A byte in the range of printable ASCII characters (the range `[0x20, 0x7e]`) is represented by the corresponding ASCII character, with the exception of the backslash (`'\'`), which is escaped as `'\\'`. All other byte values are represented by their corresponding octal values. For example, the bytes `{97,92,98,99}`, which in ASCII are `{a, \, b, c}`, are translated to text as `'a\\bc'`.
- The following aggregate functions are supported for binary data types:
 - [BIT_AND](#)
 - [BIT_OR](#)

- [BIT_XOR](#)
- [MAX](#)
- [MIN](#)

`BIT_AND`, `BIT_OR`, and `BIT_XOR` are bitwise operations that are applied to each non-null value in a group, while `MAX` and `MIN` are bitwise comparisons of binary values.

- Like their [binary operator](#) counterparts, if the values in a group vary in length, the aggregate functions treat the values as though they are all equal in length by extending shorter values with zero bytes to the full width of the column. For example, given a group containing the values `'ff'`, `null`, and `'f'`, a binary aggregate ignores the null value and treats the value `'f'` as `'f0'`. Also, like their binary operator counterparts, these aggregate functions operate on `VARBINARY` types explicitly and operate on `BINARY` types implicitly through casts. See [Data Type Coercion Operators \(CAST\)](#).

Examples

The following example shows `VARBINARY` [HEX_TO_BINARY](#)(`VARCHAR`) and `VARCHAR` [TO_HEX](#)(`VARBINARY`) usage.

Table `t` and its projection are created with binary columns:

```
=> CREATE TABLE t (c BINARY(1));
=> CREATE PROJECTION t_p (c) AS SELECT c FROM t;
```

Insert minimum byte and maximum byte values:

```
=> INSERT INTO t values(HEX_TO_BINARY('0x00'));
=> INSERT INTO t values(HEX_TO_BINARY('0xFF'));
```

Binary values can then be formatted in hex on output using the `TO_HEX` function:

```
=> SELECT TO_HEX(c) FROM t;
to_hex
-----
00
ff
(2 rows)
```

The `BIT_AND`, `BIT_OR`, and `BIT_XOR` functions are interesting when operating on a group of values. For example, create a sample table and projections with binary columns:

The example that follows uses table `t` with a single column of `VARBINARY` data type:

```
=> CREATE TABLE t ( c VARBINARY(2) );  
=> INSERT INTO t values(HEX_TO_BINARY('0xFF00'));  
=> INSERT INTO t values(HEX_TO_BINARY('0xFFFF'));  
=> INSERT INTO t values(HEX_TO_BINARY('0xF00F'));
```

Query table t to see column c output:

```
=> SELECT TO_HEX(c) FROM t;  
TO_HEX  
-----  
ff00  
ffff  
f00f  
(3 rows)
```

Now issue the bitwise AND operation. Because these are aggregate functions, an implicit GROUP BY operation is performed on results using $(ff00 \& (ffff) \& f00f)$:

```
=> SELECT TO_HEX(BIT_AND(c)) FROM t;  
TO_HEX  
-----  
f000  
(1 row)
```

Issue the bitwise OR operation on $(ff00 | (ffff) | f00f)$:

```
=> SELECT TO_HEX(BIT_OR(c)) FROM t;  
TO_HEX  
-----  
ffff  
(1 row)
```

Issue the bitwise XOR operation on $(ff00 \# (ffff) \# f00f)$:

```
=> SELECT TO_HEX(BIT_XOR(c)) FROM t;  
TO_HEX  
-----  
f0f0  
(1 row)
```

Boolean Data Type

Vertica provides the standard SQL type `BOOLEAN`, which has two states: `true` and `false`. The third state in SQL boolean logic is `unknown`, which is represented by the `NULL` value.

Syntax

BOOLEAN

Parameters

Valid literal data values for input are:

TRUE	't'	'true'	'y'	'yes'	'1'	1
FALSE	'f'	'false'	'n'	'no'	'0'	0

Notes

- Do not confuse the BOOLEAN data type with [Boolean Operators](#) or the [Boolean-Predicate](#).
- The keywords TRUE and FALSE are preferred and are SQL-compliant.
- A Boolean value of NULL appears last (largest) in ascending order.
- All other values must be enclosed in single quotes.
- Boolean values are output using the letters t and f.

See Also

- [NULL Value](#)
- [Data Type Coercion Chart](#)

Character Data Types

Stores strings of letters, numbers, and symbols.

Character data can be stored as fixed-length or variable-length strings. Fixed-length strings are right-extended with spaces on output; variable-length strings are not extended.

Syntax

```
[ CHARACTER | CHAR ] ( octet_length ) [ VARCHAR | CHARACTER VARYING ] ( octet_length )
```

Parameters

<i>octet_length</i>	Specifies the length of the string (column width, declared in bytes (octets), in CREATE TABLE statements).
---------------------	--

Notes

- The data types CHARACTER (CHAR) and CHARACTER VARYING (VARCHAR) are collectively referred to as *character string types*, and the values of character string types are known as *character strings*.
- CHAR is conceptually a fixed-length, blank-padded string. Any trailing blanks (spaces) are removed on input, and only restored on output. The default length is 1, and the maximum length is 65000 octets (bytes).
- VARCHAR is a variable-length character data type. The default length is 80, and the maximum length is 65000 octets. For string values longer than 65000, use [Long Data Types](#). Values can include trailing spaces.
- Normally, you use VARCHAR for all of your string data. You only use CHAR when you need fixed-width string output. For example, you can use CHAR columns for data to be transferred to a legacy system that requires fixed-width strings.
- When you define character columns, specify the maximum size of any string to be stored in a column. For example, to store strings up to 24 octets in length, use either of the following definitions:

```
CHAR(24)      /* fixed-length */VARCHAR(24) /* variable-length */
```

- The maximum length parameter for VARCHAR and CHAR data type refers to the number of octets that can be stored in that field, not the number of characters (Unicode code points). When using multibyte UTF-8 characters, the fields must be sized to accommodate from 1 to

4 octets per character, depending on the data. If the data loaded into a VARCHAR/CHAR column exceeds the specified maximum size for that column, data is truncated on UTF-8 character boundaries to fit within the specified size. See COPY.

Note: Remember to include the extra octets required for multibyte characters in the column-width declaration, keeping in mind the 65000 octet column-width limit.

- String literals in SQL statements must be enclosed in single quotes.
- Due to compression in Vertica, the cost of overestimating the length of these fields is incurred primarily at load time and during sorts.
- NULL appears last (largest) in ascending order. See also [GROUP BY Clause](#) for additional information about NULL ordering.

The Difference Between NULL and NUL

NUL represents a character whose ASCII/Unicode code is 0, sometimes qualified "ASCII NUL".

NULL means no value, and is true of a field (column) or constant, not of a character.

CHAR, LONG VARCHAR, and VARCHAR string data types accept ASCII NULs.

The following example casts the input string containing NUL values to VARCHAR:

```
=> SELECT 'vert\0ica'::CHARACTER VARYING AS VARCHAR;  
VARCHAR  
-----  
vert\0ica  
(1 row)
```

The result contains 9 characters:

```
=> SELECT LENGTH('vert\0ica'::CHARACTER VARYING);  
length  
-----  
9  
(1 row)
```

If you use an [extended string literal](#), the length is 8 characters:

```
=> SELECT E'vert\0ica'::CHARACTER VARYING AS VARCHAR;  
VARCHAR  
-----  
vertica  
(1 row)  
=> SELECT LENGTH(E'vert\0ica'::CHARACTER VARYING);
```

```
LENGTH
-----
      8
(1 row)
```

Date/Time Data Types

Vertica supports the full set of SQL date and time data types. In most cases, a combination of DATE, DATETIME, SMALLDATETIME, TIME, TIMESTAMP WITHOUT TIME ZONE, and TIMESTAMP WITH TIME ZONE, and INTERVAL provides a complete range of date/time functionality required by any application.

In compliance with the SQL standard, Vertica also supports the TIME WITH TIME ZONE data type.

The following table lists the characteristics about the date/time data types. All these data types have a size of 8 bytes.

Name	Description	Low Value	High Value	Resolution
DATE	Dates only (no time of day)	~ 25e+15 BC	~ 25e+15 AD	1 day
TIME [(p)]	Time of day only (no date)	00:00:00.00	23:59:60.999999	1 μ s
TIMETZ [(p)]	Time of day only, with time zone	00:00:00.00+14	23:59:59.999999-14	1 μ s
TIMESTAMP [(p)]	Both date and time, without time zone	290279-12-22 19:59:05.224194 BC	294277-01-09 04:00:54.775806 AD	1 μ s
TIMESTAMPZ [(p)]	Both date and time, with time zone	290279-12-22 19:59:05.224194 BC UTC	294277-01-09 04:00:54.775806 AD UTC	1 μ s
INTERVAL [(p)]DAY TO SECOND	Time intervals	-106751991 days 04:00:54.775807	+106751991 days 04:00:54.775807	1 μ s
INTERVAL [(p)]YEAR TO MONTH	Time intervals	~ -768e15 yrs	~ 768e15 yrs	1 month

Time Zone Abbreviations for Input

Vertica recognizes the files in /opt/vertica/share/timezonesets as date/time input values and defines the default list of strings accepted in the AT TIME ZONE zone parameter. The names are not necessarily used for date/time output—output is driven by the official time zone abbreviations associated with the currently selected time zone parameter setting.

Notes

- In Vertica, `TIME ZONE` is a synonym for `TIMEZONE`.
- Vertica uses Julian dates for all date/time calculations, which can correctly predict and calculate any date more recent than 4713 BC to far into the future, based on the assumption that the average length of the year is 365.2425 days.
- All date/time types are stored in eight bytes.
- A date/time value of `NULL` appears first (smallest) in ascending order.
- All the date/time data types accept the special literal value `NOW` to specify the current date and time. For example:

```
=> SELECT TIMESTAMP 'NOW';
      ?column?
-----
2012-03-13 11:42:22.766989
(1 row)
```

- In Vertica, the [INTERVAL](#) data type is SQL:2008 compliant and allows modifiers, called [interval qualifiers](#), that divide the `INTERVAL` type into two primary subtypes, `DAY TO SECOND` (the default) and `YEAR TO MONTH`. You use the [SET INTERVALSTYLE](#) command to change the `intervalstyle` run-time parameter for the current session.

Intervals are represented internally as some number of microseconds and printed as up to 60 seconds, 60 minutes, 24 hours, 30 days, 12 months, and as many years as necessary. Fields can be positive or negative.

See Also

- [TZ Environment Variable](#)
- [Using Time Zones With Vertica](#)
- [Sources for Time Zone and Daylight Saving Time Data](#)

DATE

Consists of a month, day, and year.

Syntax

DATE

Parameters/Limits

Low Value	High Value	Resolution
~ 25e+15 BC	~ 25e+15 AD	1 DAY

See [SET DATESTYLE](#) for information about ordering.

Example	Description
January 8, 1999	Unambiguous in any datestyle input mode
1999-01-08	ISO 8601; January 8 in any mode (recommended format)
1/8/1999	January 8 in MDY mode; August 1 in DMY mode
1/18/1999	January 18 in MDY mode; rejected in other modes
01/02/03	January 2, 2003 in MDY mode February 1, 2003 in DMY mode February 3, 2001 in YMD mode
1999-Jan-08	January 8 in any mode
Jan-08-1999	January 8 in any mode
08-Jan-1999	January 8 in any mode
99-Jan-08	January 8 in YMD mode, else error
08-Jan-99	January 8, except error in YMD mode
Jan-08-99	January 8, except error in YMD mode

Example	Description
19990108	ISO 8601; January 8, 1999 in any mode
990108	ISO 8601; January 8, 1999 in any mode
1999.008	Year and day of year
J2451187	Julian day
January 8, 99 BC	Year 99 before the Common Era

DATETIME

DATETIME is an alias for [TIMESTAMP/TIMESTAMPTZ](#).

INTERVAL

Measures the difference between two points in time. Intervals can be positive or negative. The INTERVAL data type is divided into two major subtypes:

- [Year-month](#): Span of years and months
- [Day-time](#): Span of days, hours, minutes, seconds, and fractional seconds

Syntax

```
INTERVAL [ ( p ) ] 'interval-literal' [ interval-qualifier ]
```

Parameters

<i>p</i>	Specifies precision of the seconds field, where <i>p</i> is an integer between 0 - 6. For details, see Specifying Interval Precision . Default: 6
<i>interval-literal</i>	A character string that expresses an interval, conforms to this format: <code>[-] { <i>quantity subtype-unit</i> } [...] [AGO]</code>

	For details, see Interval Literal .
<i>interval-qualifier</i>	Optionally specifies how to interpret and format an interval literal for output, and, optionally, sets precision. If omitted, the default is DAY TO SECOND(6). For details, see Interval Qualifier .

Limits

Name	Low Value	High Value	Resolution
INTERVAL [(p)] DAY TO SECOND	-106751991 days 04:00:54.775807	+/-106751991 days 04:00:54.775807	1 microsecond
INTERVAL [(p)] YEAR TO MONTH	~/ -768e15 yrs	~ 768e15 yrs	1 month

Setting Interval Unit Display

You can control how Vertica displays interval units in a SELECT INTERVAL query, with [SET INTERVALSTYLE](#) and [SET DATESTYLE](#). These statements only affect interval output format.

Important: DATESTYLE settings supersede INTERVALSTYLE. If DATESTYLE is set to SQL, interval unit display always conforms to the SQL:2008 standard, which omits interval unit display. If DATESTYLE is set to ISO, you can use [SET INTERVALSTYLE](#) to omit or display interval unit display, as described below.

Omitting Interval Units

To omit interval units from the output, set INTERVALSTYLE to PLAIN. This is the default setting, which conforms with the SQL:2008 standard:

```
=> SET INTERVALSTYLE TO PLAIN;
SET
=> SELECT INTERVAL '3 2';
?column?
-----
3 02:00
```

When `INTERVALSTYLE` is set to `PLAIN`, units are omitted from the output, even if the query specifies input units:

```
=> SELECT INTERVAL '3 days 2 hours';  
?column?  
-----  
3 02:00
```

If `DATESTYLE` is set to `SQL`, Vertica conforms with SQL:2008 standard and always omits interval units from output:

```
=> SET DATESTYLE TO SQL;  
SET  
=> SET INTERVALSTYLE TO UNITS;  
SET  
=> SELECT INTERVAL '3 2';  
?column?  
-----  
3 02:00
```

Displaying Interval Units

To enable display of interval units, `DATESTYLE` must be set to `ISO`. You can then display interval units by setting `INTERVALSTYLE` to `UNITS`:

```
=> SET DATESTYLE TO ISO;  
SET  
=> SET INTERVALSTYLE TO UNITS;  
SET  
=> SELECT INTERVAL '3 2';  
?column?  
-----  
3 days 2 hours
```

Checking INTERVALSTYLE and DATESTYLE Settings

Use `SHOW` statements to check `INTERVALSTYLE` and `DATESTYLE` settings:

```
=> SHOW INTERVALSTYLE;  
name      | setting  
-----+-----  
intervalstyle | units  
=> SHOW DATESTYLE;  
name      | setting  
-----+-----  
datestyle  | ISO, MDY
```

Specifying Interval Input

Interval values are expressed through [interval literals](#). An interval literal is composed of one or more interval fields, where each field represents a span of days and time, or years and months, as follows:

```
[ - ] { quantity subtype-unit } [ ... ] [ AGO ]
```

Using Subtype Units

Subtype units are optional for [day-time](#) intervals; they must be specified for [year-month](#) intervals.

For example, the first statement below implicitly specifies days and time; the second statement explicitly identifies day and time units. Both statements return the same result:

```
=> SET INTERVALSTYLE TO UNITS;
=> SELECT INTERVAL '1 12:59:10:05';
      ?column?
-----
1 day 12:59:10.005
(1 row)

=> SELECT INTERVAL '1 day 12 hours 59 min 10 sec 5 milliseconds';
      ?column?
-----
1 day 12:59:10.005
(1 row)
```

The following two statements add 28 days and 4 weeks to the current date, respectively. The intervals in both cases are equal and the statements return the same result. However, in the first statement, the interval literal omits the subtype (implicitly days); in the second statement, the interval literal must include the subtype unit weeks:

```
=> SELECT CURRENT_DATE;
      ?column?
-----
2016-08-15
(1 row)

=> SELECT CURRENT_DATE + INTERVAL '28';
      ?column?
-----
2016-09-12 00:00:00
(1 row)

dbadmin=> SELECT CURRENT_DATE + INTERVAL '4 weeks';
      ?column?
-----
2016-09-12 00:00:00
```

```
(1 row)
```

An interval literal can include day-time and year-month fields. For example, the following statement adds an interval of 4 years, 4 weeks, 4 days and 14 hours to the current date. The years and weeks fields must include subtype units; the days and hours fields omit them:

```
> SELECT CURRENT_DATE + INTERVAL '4 years 4 weeks 4 14';
      ?column?
-----
2020-09-15 14:00:00
(1 row)
```

Omitting Subtype Units

You can specify quantities of days, hours, minutes, and seconds without specifying units. Vertica recognizes colons in interval literals as part of the timestamp:

```
=> SELECT INTERVAL '1 4 5 6';
      ?column?
-----
1 day 04:05:06
=> SELECT INTERVAL '1 4:5:6';
      ?column?
-----
1 day 04:05:06
=> SELECT INTERVAL '1 day 4 hour 5 min 6 sec';
      ?column?
-----
1 day 04:05:06
```

If Vertica cannot determine the units, it applies the quantity to any missing units based on the interval qualifier. In the next two examples, Vertica uses the default interval qualifier (`DAY TO SECOND(6)`) and assigns the trailing 1 to days, since it has already processed hours, minutes, and seconds in the output:

```
=> SELECT INTERVAL '4:5:6 1';
      ?column?
-----
1 day 04:05:06
=> SELECT INTERVAL '1 4:5:6';
      ?column?
-----
1 day 04:05:06
```

In the next two examples, Vertica recognizes 4:5 as hours:minutes. The remaining values in the interval literal are assigned to the missing units: 1 is assigned to days and 2 is assigned to seconds.

```
SELECT INTERVAL '4:5 1 2';
?column?
-----
1 day 04:05:02
=> SELECT INTERVAL '1 4:5 2';
?column?
-----
1 day 04:05:02
```

Specifying the interval qualifier can change how Vertica interprets 4 : 5:

```
=> SELECT INTERVAL '4:5' MINUTE TO SECOND;
?column?
-----
00:04:05
```

Controlling Interval Format

[Interval qualifiers](#) specify a range of options that Vertica uses to interpret and format an [interval literal](#). The interval qualifier can also specify precision. Each interval qualifier is composed of one or two units:

```
unit[p] [ TO unit[p] ]
```

where:

- *unit* specifies a day-time or year-month [subtype](#).
- *p* specifies precision, an integer between 0 and 6. In general, precision only applies to SECOND units. The default precision for SECOND is 6. For details, see [Specifying Interval Precision](#).

If an interval omits an interval qualifier, Vertica uses the default DAY TO SECOND(6).

Interval Qualifier Categories

Interval qualifiers belong to one of the following categories:

- Year-month: Span of years and months
- Day-time: Span of days, hours, minutes, seconds, and fractional seconds

Year-Month

Vertica supports two year-month subtypes: YEAR and MONTH.

In the following example, YEAR TO MONTH qualifies the interval literal 1 2 to indicate a span of 1 year and two months:

```
=> SELECT interval '1 2' YEAR TO MONTH;
      ?column?
-----
1 year 2 months
(1 row)
```

If you omit the qualifier, Vertica uses the default interval qualifier DAY TO SECOND and returns a different result:

```
=> SELECT interval '1 2';
      ?column?
-----
1 day 2 hours
(1 row)
```

The following example uses the interval qualifier YEAR. In this case, Vertica extracts only the year from the interval literal 1y 10m :

```
=> SELECT INTERVAL '1y 10m' YEAR;
      ?column?
-----
1 year
(1 row)
```

In the next example, the interval qualifier MONTH converts the same interval literal to months:

```
=> SELECT INTERVAL '1y 10m' MONTH;
      ?column?
-----
22 months
(1 row)
```

Day-Time

Vertica supports four day-time subtypes: DAY, HOUR, MINUTE, and SECOND.

In the following example, the interval qualifier DAY TO SECOND(4) qualifies the interval literal 1h 3m 6s 5msecs 57us. The qualifier also sets precision on seconds to 4:

```
=> SELECT INTERVAL '1h 3m 6s 5msecs 57us' DAY TO SECOND(4);
      ?column?
-----
01:03:06.0051
(1 row)
```

If no interval qualifier is specified, Vertica uses the default subtype DAY TO SECOND(6), regardless of how you specify the interval literal. For example, as an extension to SQL:2008, both of the following commands return 910 days:

```
=> SELECT INTERVAL '2-6';
      ?column?
-----
    910 days
=> SELECT INTERVAL '2 years 6 months';
      ?column?
-----
    910 days
```

An interval qualifier can extract other values from the input parameters. For example, the following command extracts the HOUR value from the interval literal `3 days 2 hours`:

```
=> SELECT INTERVAL '3 days 2 hours' HOUR;
      ?column?
-----
    74 hours
```

The primary day/time (`DAY TO SECOND`) and year/month (`YEAR TO MONTH`) subtype ranges can be restricted to more specific range of types by an interval qualifier. For example, `HOUR TO MINUTE` is a limited form of day/time interval, which can be used to express time zone offsets.

```
=> SELECT INTERVAL '1 3' HOUR to MINUTE;
      ?column?
-----
    01:03
```

`hh:mm:ss` and `hh:mm` formats are used only when at least two of the fields specified in the interval qualifier are non-zero and there are no more than 23 hours or 59 minutes:

```
=> SELECT INTERVAL '2 days 12 hours 15 mins' DAY TO MINUTE;
      ?column?
-----
    2 days 12:15
=> SELECT INTERVAL '15 mins 20 sec' MINUTE TO SECOND;
      ?column?
-----
    00:15:20
=> SELECT INTERVAL '1 hour 15 mins 20 sec' MINUTE TO SECOND;
      ?column?
-----
    75 mins 20 secs
```

Specifying Interval Precision

In general, interval precision only applies to seconds. If no precision is explicitly specified, Vertica rounds precision to a maximum of six decimal places. For example:

```
=> SELECT INTERVAL '2 hours 4 minutes 3.709384766 seconds' DAY TO SECOND;
      ?column?
-----
```

```
02:04:03.709385  
(1 row)
```

Vertica lets you specify interval precision in two ways:

- After the `INTERVAL` keyword
- After the `SECOND` unit of an interval qualifier, one of the following:
 - `DAY TO SECOND`
 - `HOUR TO SECOND`
 - `MINUTE TO SECOND`
 - `SECOND`

For example, the following statements use both methods to set precision, and return identical results:

```
=> SELECT INTERVAL(4) '2 hours 4 minutes 3.709384766 seconds' DAY TO SECOND;  
?column?  
-----  
02:04:03.7094  
(1 row)  
  
=> SELECT INTERVAL '2 hours 4 minutes 3.709384766 seconds' DAY TO SECOND(4);  
?column?  
-----  
02:04:03.7094  
(1 row)
```

If the same statement specifies precision more than once, Vertica uses the lesser precision. For example, the following statement specifies precision twice: the `INTERVAL` keyword specifies precision of 1, while the interval qualifier `SECOND` specifies precision of 2. Vertica uses the lesser precision of 1:

```
=> SELECT INTERVAL(1) '1.2467' SECOND(2);  
?column?  
-----  
1.2 secs
```

Setting Precision on Interval Table Columns

If you create a table with an interval column, the following restrictions apply to the column definition:

- You can set precision on the INTERVAL keyword only if you omit specifying an interval qualifier. If you try to set precision on the INTERVAL keyword and include an interval qualifier, Vertica returns an error.
- You can set precision only on the last unit of an interval qualifier. For example:

```
CREATE TABLE public.testint2
(
  i INTERVAL HOUR TO SECOND(3)
);
```

If you specify precision on another unit, Vertica discards it when it saves the table definition.

Fractional Seconds in Interval Units

Vertica supports intervals in milliseconds (hh:mm:ss:ms), where 01:02:03:25 represents 1 hour, 2 minutes, 3 seconds, and 025 milliseconds. Milliseconds are converted to fractional seconds as in the following example, which returns 1 day, 2 hours, 3 minutes, 4 seconds, and 25.5 milliseconds:

```
=> SELECT INTERVAL '1 02:03:04:25.5';
?column?
-----
1 day 02:03:04.0255
```

Vertica allows fractional minutes. The fractional minutes are rounded into seconds:

```
=> SELECT INTERVAL '10.5 minutes';
?column?
-----
00:10:30
=> select interval '10.659 minutes';
?column?
-----
00:10:39.54
=> select interval '10.3333333333333333 minutes';
?column?
-----
00:10:20
```

Considerations

- An INTERVAL can include only the subset of units that you need; however, year/month intervals represent calendar years and months with no fixed number of days, so year/month interval values cannot include days, hours, minutes. When year/month values are specified for day/time intervals, the intervals extension assumes 30 days per month and 365 days per

year. Since the length of a given month or year varies, day/time intervals are never output as months or years, only as days, hours, minutes, and so on.

- Day/time and year/month intervals are logically independent and cannot be combined with or compared to each other. In the following example, an interval-literal that contains DAYS cannot be combined with the YEAR TO MONTH type:

```
=> SELECT INTERVAL '1 2 3' YEAR TO MONTH;
ERROR 3679: Invalid input syntax for interval year to month: "1 2 3"
```

- Vertica accepts intervals up to $2^{63} - 1$ microseconds or months (about 18 digits).
- INTERVAL YEAR TO MONTH can be used in an analytic [RANGE window](#) when the ORDER BY column type is `TIMESTAMP/TIMESTAMP WITH TIMEZONE`, or `DATE`. Using `TIME/TIME WITH TIMEZONE` are not supported.
- You can use INTERVAL DAY TO SECOND when the ORDER BY column type is `TIMESTAMP/TIMESTAMP WITH TIMEZONE`, `DATE`, and `TIME/TIME WITH TIMEZONE`.

Examples

Examples in this section assume that INTERVALSTYLE is set to PLAIN , so results omit [subtype units](#). Interval values that omit an [interval qualifier](#) use the default to DAY TO SECOND(6).

Query	Result
SELECT INTERVAL '00:2500:00';	1 17:40
SELECT INTERVAL '2500' MINUTE TO SECOND;	2500
SELECT INTERVAL '2500' MINUTE;	2500
SELECT INTERVAL '28 days 3 hours' HOUR TO SECOND;	675:00
SELECT INTERVAL(3) '28 days 3 hours';	28 03:00
SELECT INTERVAL(3) '28 days 3 hours 1.234567';	28 03:01:14.074
SELECT INTERVAL(3) '28 days 3 hours 1.234567 sec';	28 03:00:01.235
SELECT INTERVAL(3) '28 days 3.3 hours' HOUR TO SECOND;	675:18
SELECT INTERVAL(3) '28 days 3.35 hours' HOUR TO SECOND;	675:21
SELECT INTERVAL(3) '28 days 3.37 hours' HOUR TO SECOND;	675:22:12
SELECT INTERVAL '1.234567 days' HOUR TO SECOND;	29:37:46.5888
SELECT INTERVAL '1.23456789 days' HOUR TO SECOND;	29:37:46.665696

Query	Result
SELECT INTERVAL(3) '1.23456789 days' HOUR TO SECOND;	29:37:46.666
SELECT INTERVAL(3) '1.23456789 days' HOUR TO SECOND(2);	29:37:46.67
SELECT INTERVAL(3) '01:00:01.234567' as "one hour+";	01:00:01.235
SELECT INTERVAL(3) '01:00:01.234567' = INTERVAL(3) '01:00:01.234567';	t
SELECT INTERVAL(3) '01:00:01.234567' = INTERVAL '01:00:01.234567';	f
SELECT INTERVAL(3) '01:00:01.234567' = INTERVAL '01:00:01.234567' HOUR TO SECOND(3);	t
SELECT INTERVAL(3) '01:00:01.234567' = INTERVAL '01:00:01.234567' MINUTE TO SECOND (3);	t
SELECT INTERVAL '255 1.1111' MINUTE TO SECOND(3);	255:01.111
SELECT INTERVAL '@ - 5 ago';	5
SELECT INTERVAL '@ - 5 minutes ago';	00:05
SELECT INTERVAL '@ 5 minutes ago';	-00:05
SELECT INTERVAL '@ ago -5 minutes';	00:05
SELECT DATE_PART('month', INTERVAL '2-3' YEAR TO MONTH);	3
SELECT FLOOR((TIMESTAMP '2005-01-17 10:00' - TIMESTAMP '2005-01-01') / INTERVAL '7');	2

Processing Signed Intervals

In the SQL:2008 standard, a minus sign before an interval-literal or as the first character of the interval-literal negates the entire literal, not just the first component. In Vertica, a leading minus sign negates the entire interval, not just the first component. The following commands both return the same value:

```
=> SELECT INTERVAL '-1 month - 1 second';
?column?
-----
-29 days 23:59:59

=> SELECT INTERVAL -'1 month - 1 second';
?column?
-----
-29 days 23:59:59
```

Use one of the following commands instead to return the intended result:

```
=> SELECT INTERVAL -'1 month 1 second';
?column?
```

```
-----  
-30 days 1 sec  
=> SELECT INTERVAL '-30 00:00:01';  
?column?  
-----  
-30 days 1 sec
```

Two negatives together return a positive:

```
=> SELECT INTERVAL '--1 month - 1 second';  
?column?  
-----  
29 days 23:59:59  
=> SELECT INTERVAL '--1 month 1 second';  
?column?  
-----  
30 days 1 sec
```

You can use the year-month syntax with no spaces. Vertica allows the input of negative months but requires two negatives when paired with years.

```
=> SELECT INTERVAL '3-3' YEAR TO MONTH;  
?column?  
-----  
3 years 3 months  
=> SELECT INTERVAL '3--3' YEAR TO MONTH;  
?column?  
-----  
2 years 9 months
```

When the interval-literal looks like a year/month type, but the type is day/second, or vice versa, Vertica reads the interval-literal from left to right, where number-number is years-months, and number <space> <signed number> is whatever the units specify. Vertica processes the following command as $(-)$ 1 year 1 month = $(-)$ 365 + 30 = -395 days:

```
=> SELECT INTERVAL '-1-1' DAY TO HOUR;  
?column?  
-----  
-395 days
```

If you insert a space in the interval-literal, Vertica processes it based on the subtype DAY TO HOUR: $(-)$ 1 day – 1 hour = $(-)$ 24 – 1 = -23 hours:

```
=> SELECT INTERVAL '-1 -1' DAY TO HOUR;  
?column?  
-----  
-23 hours
```

Two negatives together returns a positive, so Vertica processes the following command as $(-)$ 1 year – 1 month = $(-)$ 365 – 30 = -335 days:

```
=> SELECT INTERVAL '-1--1' DAY TO HOUR;
?column?
-----
-335 days
```

If you omit the value after the hyphen, Vertica assumes 0 months and processes the following command as 1 year 0 month –1 day = 365 + 0 – 1 = –364 days:

```
=> SELECT INTERVAL '1- -1' DAY TO HOUR;
?column?
-----
364 days
```

Casting with Intervals

You can use CAST to convert strings to intervals, and vice versa.

String to Interval

You cast a string to an interval as follows:

```
CAST( [ INTERVAL[(p)] ] [-] ] interval-Literal AS INTERVAL[(p)] interval-qualifier )
```

For example:

```
=> SELECT CAST('3700 sec' AS INTERVAL);
?column?
-----
01:01:40
```

You can cast intervals within day-time or the year-month subtypes but not between them:

```
=> SELECT CAST(INTERVAL '4440' MINUTE as INTERVAL);
?column?
-----
3 days 2 hours
=> SELECT CAST(INTERVAL -'01:15' as INTERVAL MINUTE);
?column?
-----
-75 mins
```

Interval to String

You cast an interval to a string as follows:

```
CAST( (SELECT interval ) AS VARCHAR[(n)] )
```

For example:

```
=> SELECT CONCAT(
  'Tomorrow at this time: ',
  CAST((SELECT INTERVAL '24 hours') + CURRENT_TIMESTAMP(0) AS VARCHAR));
      CONCAT
-----
Tomorrow at this time: 2016-08-17 08:41:23-04
(1 row)
```

Operations with Intervals

If you divide an interval by an interval, you get a FLOAT:

```
=> SELECT INTERVAL '28 days 3 hours' HOUR(4) / INTERVAL '27 days 3 hours' HOUR(4);
      ?column?
-----
1.036866359447
```

An INTERVAL divided by FLOAT returns an INTERVAL:

```
=> SELECT INTERVAL '3' MINUTE / 1.5;
      ?column?
-----
2 mins
```

INTERVAL MODULO (remainder) INTERVAL returns an INTERVAL:

```
=> SELECT INTERVAL '28 days 3 hours' HOUR % INTERVAL '27 days 3 hours' HOUR;
      ?column?
-----
24 hours
```

If you add INTERVAL and TIME, the result is TIME, modulo 24 hours:

```
=> SELECT INTERVAL '1' HOUR + TIME '1:30';
      ?column?
-----
02:30:00
```

SMALLDATETIME

SMALLDATETIME is an alias for [TIMESTAMP/TIMESTAMPTZ](#).

TIME/TIMETZ

Stores the specified time of day. TIMETZ is the same as TIME WITH TIME ZONE: both data types store the UTC offset of the specified time.

Syntax

TIME

```
TIME [ (p) ] [ { WITHOUT | WITH } TIME ZONE ] 'input-string' [ AT TIME ZONE zone ]
```

TIMETZ

```
TIME [ (p) ] 'input-string' [ AT TIME ZONE zone ]
```

Parameters

<i>p</i>	Optional precision value that specifies the number of fractional digits retained in the seconds field, an integer value between 0 and 6. If you omit specifying precision, Vertica returns up to 6 fractional digits.
WITHOUT TIME ZONE WITH TIME ZONE	Specifies whether to include a time zone with the stored value: <ul style="list-style-type: none"> WITHOUT TIME ZONE (default): Specifies that <i>input-string</i> does not include a time zone. If the input string contains a time zone, Vertica ignores this qualifier. Instead, it conforms to WITH TIME ZONE behavior. WITH TIME ZONE: Specifies to convert <i>input-string</i> to UTC, using the UTC offset for the specified time zone. If the input string omits a time zone, Vertica uses the UTC offset of the time zone that is configured for your system.
<i>input-string</i>	See Input String below.
AT TIME ZONE <i>zone</i>	See TIME AT TIME ZONE and TIMESTAMP AT TIME ZONE .

TIME versus TIMETZ

TIMETZ and [TIMESTAMPTZ](#) are not parallel SQL constructs. TIMESTAMPTZ records a time and date in GMT, converting from the specified TIME_ZONE. TIMETZ records the specified time and the specified time zone, in minutes, from GMT.

Limits

Name	Low Value	High Value	Resolution
TIME [p]	00:00:00.00	23:59:60.999999	1 μ s
TIME [p] WITH TIME ZONE	00:00:00.00+14	23:59:59.999999-14	1 μ s

Input String

A TIME input string can be set to any of the formats shown below:

Example	Description
04:05:06.789	ISO 8601
04:05:06	ISO 8601
04:05	ISO 8601
040506	ISO 8601
04:05 AM	Same as 04:05; AM does not affect value
04:05 PM	Same as 16:05
04:05:06.789-8	ISO 8601
04:05:06-08:00	ISO 8601
04:05-08:00	ISO 8601
040506-08	ISO 8601
04:05:06 PST	Time zone specified by name

Data Type Coercion

You can cast a TIME or TIMETZ interval to a TIMESTAMP. This returns the local date and time as follows:

```
=> SELECT (TIME '3:01am')::TIMESTAMP;
      ?column?
-----
2012-08-30 03:01:00
(1 row)

=> SELECT (TIMETZ '3:01am')::TIMESTAMP;
      ?column?
-----
2012-08-22 03:01:00
(1 row)
```

Casting the same TIME or TIMETZ interval to a TIMESTAMPTZ returns the local date and time, appended with the UTC offset—in this example, -05:

```
=> SELECT (TIME '3:01am')::TIMESTAMPTZ;
      ?column?
-----
2016-12-08 03:01:00-05
(1 row)
```

TIME AT TIME ZONE

Converts the specified TIME to the time in another time zone.

Syntax

```
TIME [WITH TIME ZONE] 'input-string' AT TIME ZONE 'zone'
```

Parameters

<code>WITH TIME ZONE</code>	Converts the input string to UTC, using the UTC offset for the specified time zone. If the input string omits a time zone, Vertica uses the UTC offset of the time zone that is configured for your system , and converts the input string accordingly
<code>zone</code>	Specifies the time zone to use in the conversion, either as a literal or

interval that specifies UTC offset:

- AT TIME ZONE INTERVAL '*utc-offset*'
- AT TIME ZONE '*time-zone-literal*'

For details, see [Specifying Time Zones](#) below.

Note: Vertica treats literals TIME ZONE and TIMEZONE as synonyms.

Specifying Time Zones

You can specify time zones in two ways:

- A string literal such as America/Chicago or PST
- An interval that specifies a UTC offset—for example, INTERVAL '-08:00'

It is generally good practice to specify time zones with literals that indicate a geographic location. Vertica makes the necessary seasonal adjustments, and thereby avoids inconsistent results. For example, the following two queries are issued when daylight time is in effect. Because the local UTC offset during daylight time is -04, both queries return the same results:

```
=> SELECT CURRENT_TIME(0) "EDT";
      EDT
-----
12:34:35-04
(1 row)

=> SELECT CURRENT_TIME(0) AT TIME ZONE 'America/Denver' "Mountain Time";
      Mountain Time
-----
10:34:35-06
(1 row)

=> SELECT CURRENT_TIME(0) AT TIME ZONE INTERVAL '-06:00' "Mountain Time";
      Mountain Time
-----
10:34:35-06
(1 row)
```

If you use the UTC offset in a similar query when standard time is in effect, you must adjust the UTC offset accordingly—for Denver time, to -07—otherwise, Vertica returns a different (and erroneous) result:

```
=> SELECT CURRENT_TIME(0) "EST";
      EST
-----
14:18:22-05
(1 row)

=> SELECT CURRENT_TIME(0) AT TIME ZONE INTERVAL '-06:00' "Mountain Time";
      Mountain Time
-----
13:18:22-06
(1 row)
```

You can show and set the session's time zone with [SHOW TIMEZONE](#) and [SET TIME ZONE](#), respectively:

```
=> SHOW TIMEZONE;
      name |      setting
-----+-----
timezone | America/New_York
(1 row)

=> SELECT CURRENT_TIME(0) "Eastern Daylight Time";
      Eastern Daylight Time
-----
12:18:24-04
(1 row)

=> SET TIMEZONE 'America/Los_Angeles';
SET

=> SELECT CURRENT_TIME(0) "Pacific Daylight Time";
      Pacific Daylight Time
-----
09:18:24-07
(1 row)
```

Time Zone Literals

To view the default list of valid literals, see the files in the following directory:

opt/vertica/share/timezonesets

For example:

```
$ cat Antarctica.txt
...
# src/timezone/tznames/Antarctica.txt
#
AWST    28800    # Australian Western Standard Time
          #      (Antarctica/Casey)
          #      (Australia/Perth)
...
```

```
NZST    43200    # New Zealand Standard Time
          #      (Antarctica/McMurdo)
          #      (Pacific/Auckland)
ROTT    -10800    # Rothera Time
          #      (Antarctica/Rothera)
SYOT    10800    # Syowa Time
          #      (Antarctica/Syowa)
VOST    21600    # Vostok time
          #      (Antarctica/Vostok)
```

Examples

The following example assumes that local time is EST (Eastern Standard Time). The query converts the specified time to MST (mountain standard time):

```
=> SELECT CURRENT_TIME(0);
      timezone
-----
10:10:56-05
(1 row)

=> SELECT TIME '10:10:56' AT TIME ZONE 'America/Denver' "Denver Time";
      Denver Time
-----
08:10:56-07
(1 row)
```

The next example adds a time zone literal to the input string—in this case, Europe/Vilnius—and converts the time to MST:

```
=> SELECT TIME '09:56:13 Europe/Vilnius' AT TIME ZONE 'America/Denver';
      Denver Time
-----
00:56:13-07
(1 row)
```

TIMESTAMP/TIMESTAMPTZ

Stores the specified date and time. `TIMESTAMPTZ` is the same as `TIMESTAMP WITH TIME ZONE`: both data types store the UTC offset of the specified time.

`TIMESTAMP` is an alias for `DATETIME` and `SMALLDATETIME`.

Syntax

TIMESTAMP

```
TIMESTAMP [ (p) ] [ { WITHOUT | WITH } TIME ZONE ] 'input-string' [ AT TIME ZONE zone ]
```

TIMESTAMPTZ

```
TIMESTAMPTZ [ (p) ] 'input-string' [ AT TIME ZONE zone ]
```

Parameters

<i>p</i>	Optional precision value that specifies the number of fractional digits retained in the seconds field, an integer value between 0 and 6. If you omit specifying precision, Vertica returns up to 6 fractional digits.
WITHOUT TIME ZONE WITH TIME ZONE	Specifies whether to include a time zone with the stored value: <ul style="list-style-type: none"> WITHOUT TIME ZONE (default): Specifies that <i>input-string</i> does not include a time zone. If the input string contains a time zone, Vertica ignores this qualifier. Instead, it conforms to WITH TIME ZONE behavior. WITH TIME ZONE: Specifies to convert <i>input-string</i> to UTC, using the UTC offset for the specified time zone. If the input string omits a time zone, Vertica uses the UTC offset of the time zone that is configured for your system.
<i>input-string</i>	See Input String below.
AT TIME ZONE <i>zone</i>	See TIMESTAMP AT TIME ZONE .

Limits

In the following table, values are rounded. See [Date/Time Data Types](#) for more detail.

Name	Low Value	High Value	Resolution
TIMESTAMP [(p)] [WITHOUT TIME ZONE]	290279 BC	294277 AD	1 μ s
TIMESTAMP [(p)] WITH TIME ZONE	290279 BC	294277 AD	1 μ s

Input String

The date/time input string concatenates a date and a time. The input string can include a time zone, specified as a literal such as *America/Chicago*, or as a UTC offset.

The following list represents typical date/time input variations:

- 1999-01-08 04:05:06
- 1999-01-08 04:05:06 -8:00
- January 8 04:05:06 1999 PST

The input string can also specify the calendar era, either AD (default) or BC. If you omit the calendar era, Vertica assumes the current calendar era (AD). The calendar era typically follows the time zone; however, the input string can include it in various locations. For example, the following queries return the same results:

```
=> SELECT TIMESTAMP WITH TIME ZONE 'March 1, 44 12:00 CET BC ' "Caesar's Time of Death EST";
Caesar's Time of Death EST
-----
0044-03-01 06:00:00-05 BC
(1 row)

=> SELECT TIMESTAMP WITH TIME ZONE 'March 1, 44 12:00 BC CET' "Caesar's Time of Death EST";
Caesar's Time of Death EST
-----
0044-03-01 06:00:00-05 BC
(1 row)
```

Examples: TIMESTAMP Computation

Statement	Returns
SELECT (TIMESTAMP '2014-01-17 10:00' - TIMESTAMP '2014-01-01');	16 10:10
SELECT (TIMESTAMP '2014-01-17 10:00' - TIMESTAMP '2014-01-01') / 7;	2 08:17:08.571429
SELECT TIMESTAMP '2009-05-29 15:21:00.456789'-TIMESTAMP '2009-05-28';	1 15:21:00.456789
SELECT (TIMESTAMP '2009-05-29 15:21:00.456789'-TIMESTAMP '2009-05-28')(3);	1 15:21:00.457
SELECT '2017-03-18 07:00'::TIMESTAMPTZ(0) + INTERVAL '1.5 day';	2017-03-19 19:00:00-04
SELECT (TIMESTAMP '2014-01-17 10:00' - TIMESTAMP '2014-01-01') day;	16
SELECT cast((TIMESTAMP '2014-01-17 10:00' - TIMESTAMP '2014-01-01') day as integer) / 7;	2
SELECT floor((TIMESTAMP '2014-01-17 10:00' - TIMESTAMP '2014-01-01') / interval '7');	2
SELECT (TIMESTAMP '2009-05-29 15:21:00.456789'-TIMESTAMP '2009-05-28')second;	141660.456789
SELECT (TIMESTAMP '2012-05-29 15:21:00.456789'-TIMESTAMP '2009-01-01') year;	3
SELECT (TIMESTAMP '2012-05-29 15:21:00.456789'-TIMESTAMP '2009-01-01') month;	40
SELECT (TIMESTAMP '2012-05-29 15:21:00.456789'-TIMESTAMP '2009-01-01') year to month;	3-4
SELECT (TIMESTAMP '2012-05-29 15:21:00.456789'-TIMESTAMP '2009-01-01') second (3);	107536860.457
SELECT (TIMESTAMP '2012-05-29 15:21:00.456789'-TIMESTAMP '2009-01-01') minute;	1792281
SELECT (TIMESTAMP '2012-05-29 15:21:00.456789'-TIMESTAMP '2009-01-01') minute to second(3);	1792281:00.457
SELECT TIMESTAMP 'infinity';	infinity

TIMESTAMP AT TIME ZONE

Converts the specified `TIMESTAMP` or `TIMESTAMPTZ` (`TIMESTAMP WITH TIMEZONE`) to another time zone. Vertica executes `AT TIME ZONE` differently, depending on whether the date input is a `TIMESTAMP` or `TIMESTAMPTZ`. See [TIMESTAMP Versus TIMESTAMPTZ Behavior](#) below.

Syntax

timestamp-clause AT TIME ZONE 'zone'

Parameters

<i>timestamp-clause</i>	<p>Specifies the timestamp to convert, either <code>TIMESTAMP</code> or <code>TIMESTAMPTZ</code>.</p> <p>For details, see TIMESTAMP/TIMESTAMPTZ.</p>
AT TIME ZONE <i>zone</i>	<p>Specifies the time zone to use in the timestamp conversion, where <i>zone</i> is a literal or interval that specifies a UTC offset:</p> <ul style="list-style-type: none"> • AT TIME ZONE INTERVAL '<i>utc-offset</i>' • AT TIME ZONE '<i>time-zone-literal</i>' <p>For details, see Specifying Time Zones below.</p> <p>Note: Vertica treats literals <code>TIME ZONE</code> and <code>TIMEZONE</code> as synonyms.</p>

TIMESTAMP Versus TIMESTAMPTZ Behavior

How Vertica interprets `AT TIME ZONE` depends on whether the date input is a `TIMESTAMP` or `TIMESTAMPTZ`:

Date input	Action
<code>TIMESTAMP</code>	<p>If the input string specifies no time zone, Vertica performs two actions:</p> <ol style="list-style-type: none"> 1. Converts the input string to the time zone of the <code>AT TIME ZONE</code> argument. 2. Returns the time for the current session's time zone. <p>If the input string includes a time zone, Vertica implicitly casts it to a <code>TIMESTAMPTZ</code> and converts it accordingly (see <code>TIMESTAMPTZ</code> below).</p> <p>For example, the following statement specifies a <code>TIMESTAMP</code> with no time</p>

Date input	Action
	<p>zone. Vertica executes the statement as follows:</p> <ol style="list-style-type: none"> 1. Converts the input string to PDT (Pacific Daylight Time). 2. Returns that time in the local time zone, which is three hours later: <pre data-bbox="431 495 1398 831"> => SHOW TIMEZONE; name setting -----+----- timezone America/New_York (1 row) SELECT TIMESTAMP '2017-3-14 5:30' AT TIME ZONE 'PDT'; timezone ----- 2017-03-14 08:30:00-04 (1 row) </pre>
TIMESTAMPTZ	<p>Vertica converts the input string to the time zone of the AT TIME ZONE argument and returns that time.</p> <p>For example, the following statement specifies a TIMESTAMPTZ data type. The input string omits any time zone expression, so Vertica assumes the input string to be in local time zone (America/New_York) and returns the time of the AT TIME ZONE argument:</p> <pre data-bbox="431 1146 1398 1503"> => SHOW TIMEZONE; name setting -----+----- timezone America/New_York (1 row) => SELECT TIMESTAMP WITH TIME ZONE '2001-02-16 20:38:40' AT TIME ZONE 'America/Denver'; timezone ----- 2001-02-16 18:38:40 (1 row) </pre> <p>The input string in the next statement explicitly specifies a time zone, so Vertica coerces the TIMESTAMP to a TIMESTAMPTZ and returns the time of the AT TIME ZONE argument:</p> <pre data-bbox="431 1671 1398 1860"> => SELECT TIMESTAMP '2001-02-16 20:38:40 America/Mexico_City' AT TIME ZONE 'Asia/Tokyo'; timezone ----- 2001-02-17 11:38:40 (1 row) </pre>

Specifying Time Zones

You can specify time zones in two ways:

- A string literal such as `America/Chicago` or `PST`
- An interval that specifies a UTC offset—for example, `INTERVAL '-08:00'`

It is generally good practice to specify time zones with literals that indicate a geographic location. Vertica makes the necessary seasonal adjustments, and thereby avoids inconsistent results. For example, the following two queries are issued when daylight time is in effect. Because the local UTC offset during daylight time is `-04`, both queries return the same results:

```
=> SELECT TIMESTAMPTZ '2017-03-16 09:56:13' AT TIME ZONE 'America/Denver' "Denver Time";
       Denver Time
-----
2017-03-16 07:56:13
(1 row)

=> SELECT TIMESTAMPTZ '2017-03-16 09:56:13' AT TIME ZONE INTERVAL '-06:00' "Denver Time";
       Denver Time
-----
2017-03-16 07:56:13
(1 row)
```

If you issue a use the UTC offset in a similar query when standard time is in effect, you must adjust the UTC offset accordingly—for Denver time, to `-07`—otherwise, Vertica returns a different (and erroneous) result:

```
=> SELECT TIMESTAMPTZ '2017-01-16 09:56:13' AT TIME ZONE 'America/Denver' "Denver Time";
       Denver Time
-----
2017-01-16 07:56:13
(1 row)

=> SELECT TIMESTAMPTZ '2017-01-16 09:56:13' AT TIME ZONE INTERVAL '-06:00' "Denver Time";
       Denver Time
-----
2017-01-16 08:56:13
(1 row)
```

You can show and set the session's time zone with [SHOW TIMEZONE](#) and [SET TIME ZONE](#), respectively:

```
=> SHOW TIMEZONE;
 name | setting
-----+-----
timezone | America/New_York
(1 row)
```

```
=> SELECT CURRENT_TIMESTAMP(0) "Eastern Daylight Time";
Eastern Daylight Time
-----
2017-03-20 12:18:24-04
(1 row)

=> SET TIMEZONE 'America/Los_Angeles';
SET

=> SELECT CURRENT_TIMESTAMP(0) "Pacific Daylight Time";
Pacific Daylight Time
-----
2017-03-20 09:18:24-07
(1 row)
```

Time Zone Literals

To view the default list of valid literals, see the files in the following directory:

`opt/vertica/share/timezonesets`

For example:

```
$ cat Antarctica.txt
...
# src/timezone/tznames/Antarctica.txt
#

AWST    28800    # Australian Western Standard Time
        #      (Antarctica/Casey)
        #      (Australia/Perth)
...

NZST    43200    # New Zealand Standard Time
        #      (Antarctica/McMurdo)
        #      (Pacific/Auckland)

ROTT    -10800    # Rothera Time
        #      (Antarctica/Rothera)

SYOT    10800    # Syowa Time
        #      (Antarctica/Syowa)

VOST    21600    # Vostok time
        #      (Antarctica/Vostok)
```

Examples

The following examples assume that the current time zone is `America/New_York`:

Convert the string `10:00` to the specified time zone:

```
=> SELECT TIME '10:00' AT TIME ZONE 'America/Chicago';
timezone
-----
```

```
09:00:00-06  
(1 row)
```

Long Data Types

Store data up to 32,000,000 bytes:

- `LONG VARBINARY`—Variable-length raw-byte data, such as spatial data. `LONG VARBINARY` values are not extended to the full width of the column.
- `LONG VARCHAR`—Variable-length strings, such as log files and unstructured data. `LONG VARCHAR` values are not extended to the full width of the column.

The maximum size for the `LONG` data types is 32,000,000 bytes. Use the `LONG` data types only when you need to store data greater than 65,000 bytes, which is the maximum size for `VARBINARY` and `VARCHAR` data types. Such data might include unstructured data, online comments or posts, or small log files.

Default length is 1048576.

Flex tables have a default `LONG VARBINARY __raw__` column, with a `NOT NULL` constraint. For more information, see [Using Flex Tables](#).

Syntax

```
LONG VARBINARY (max_Length )  
LONG VARCHAR (octet_Length )
```

Parameters

<i>max_Length</i>	Specifies the length of the byte string (column width, declared in bytes (octets)), in CREATE TABLE statements). Maximum value: 32,000,000.
<i>octet_Length</i>	Specifies the length of the string (column width, declared in bytes (octets)), in CREATE TABLE statements). Maximum value: 32,000,000.

Notes

For optimal performance of LONG data types, Vertica recommends that you:

- Use the LONG data types as *storage only* containers; Vertica supports operations on the content of LONG data types, but not all the operations that VARCHAR and VARBINARY take.
- Use the VARBINARY and VARCHAR data types, instead of their LONG counterparts, whenever possible. The VARBINARY and VARCHAR data types are more flexible and have a wider range of operations.
- Do not sort, segment, or partition projections on LONG data type columns.
- Do not add constraints, such as a primary key, to any LONG VARBINARY or LONG VARCHAR columns.
- Do not join or aggregate any LONG data type columns.

Example

The following example creates a table `user_comments` with a LONG VARCHAR column and inserts data into it:

```
=> CREATE TABLE user_comments
      (id INTEGER,
       username VARCHAR(200),
       time_posted TIMESTAMP,
       comment_text LONG VARCHAR(200000));
=> INSERT INTO user_comments VALUES
      (1,
       'User1',
       TIMESTAMP '2013-06-25 12:47:32.62',
       'The weather tomorrow will be cold and rainy and then
       on the day after, the sun will come and the temperature
       will rise dramatically.');
```

Numeric Data Types

Numeric data types are numbers stored in database columns. These data types are typically grouped by:

- **Exact** numeric types, values where the precision and scale need to be preserved. The exact numeric types are `INTEGER`, `BIGINT`, `DECIMAL`, `NUMERIC`, `NUMBER`, and `MONEY`.
- **Approximate** numeric types, values where the precision needs to be preserved and the scale can be floating. The approximate numeric types are `DOUBLE PRECISION`, `FLOAT`, and `REAL`.

Implicit casts from `INTEGER`, `FLOAT`, and `NUMERIC` to `VARCHAR` are not supported. If you need that functionality, write an explicit cast using one of the following forms:

```
CAST(x AS data-type-name) or x::data-type-name
```

The following example casts a float to an integer:

```
=> SELECT(FLOAT '123.5')::INT;
?column?
-----
      124
(1 row)
```

String-to-numeric data type conversions accept formats of quoted constants for scientific notation, binary scaling, hexadecimal, and combinations of numeric-type literals:

- **Scientific notation :**

```
=> SELECT FLOAT '1e10';
?column?
-----
10000000000
(1 row)
```

- **BINARY scaling :**

```
=> SELECT NUMERIC '1p10';
?column?
-----
      1024
(1 row)
```

- **Hexadecimal:**

```
=> SELECT NUMERIC '0x0abc';  
?column?  
-----  
2748  
(1 row)
```

DOUBLE PRECISION (FLOAT)

Vertica supports the numeric data type `DOUBLE PRECISION`, which is the IEEE-754 8-byte floating point type, along with most of the usual floating point operations.

Syntax

```
[ DOUBLE PRECISION | FLOAT | FLOAT(n) | FLOAT8 | REAL ]
```

Parameters

Note: On a machine whose floating-point arithmetic does not follow IEEE-754, these values probably do not work as expected.

Double precision is an inexact, variable-precision numeric type. In other words, some values cannot be represented exactly and are stored as approximations. Thus, input and output operations involving double precision might show slight discrepancies.

- All of the `DOUBLE PRECISION` data types are synonyms for 64-bit IEEE `FLOAT`.
- The n in `FLOAT(n)` must be between 1 and 53, inclusive, but a 53-bit fraction is always used. See the IEEE-754 standard for details.
- For exact numeric storage and calculations (money for example), use `NUMERIC`.
- Floating point calculations depend on the behavior of the underlying processor, operating system, and compiler.
- Comparing two floating-point values for equality might not work as expected.

Values

`COPY` accepts floating-point data in the following format:

- Optional leading white space
- An optional plus ("+") or minus sign ("-")
- A decimal number, a hexadecimal number, an infinity, a NAN, or a null value

Decimal Number

A decimal number consists of a non-empty sequence of decimal digits possibly containing a radix character (decimal point "."), optionally followed by a decimal exponent. A decimal exponent consists of an "E" or "e", followed by an optional plus or minus sign, followed by a non-empty sequence of decimal digits, and indicates multiplication by a power of 10.

Hexadecimal Number

A hexadecimal number consists of a "0x" or "0X" followed by a non-empty sequence of hexadecimal digits possibly containing a radix character, optionally followed by a binary exponent. A binary exponent consists of a "P" or "p", followed by an optional plus or minus sign, followed by a non-empty sequence of decimal digits, and indicates multiplication by a power of 2. At least one of radix character and binary exponent must be present.

Infinity

An infinity is either INF or INFINITY, disregarding case.

NaN (Not A Number)

A NaN is NAN (disregarding case) optionally followed by a sequence of characters enclosed in parentheses. The character string specifies the value of NAN in an implementation-dependent manner. (The Vertica internal representation of NAN is 0xfff8000000000000LL on x86 machines.)

When writing infinity or NAN values as constants in a SQL statement, enclose them in single quotes. For example:

```
=> UPDATE table SET x = 'Infinity'
```

Note: Vertica follows the IEEE definition of NaNs (IEEE 754). The SQL standards do not specify how floating point works in detail.

IEEE defines NaNs as a set of floating point values where each one is not equal to anything, even to itself. A NaN is not greater than and at the same time not less than anything, even itself. In other words, comparisons always return false whenever a NaN is involved.

However, for the purpose of sorting data, NaN values must be placed somewhere in the result. The value generated 'NaN' appears in the context of a floating point number

matches the NaN value generated by the hardware. For example, Intel hardware generates (0xffff800000000000LL), which is technically a Negative, Quiet, Non-signaling NaN.

Vertica uses a different NaN value to represent floating point NULL (0x7ffffffffffffeLL). This is a Positive, Quiet, Non-signaling NaN and is reserved by Vertica

A NaN example follows.

```
=> SELECT CBRT('NaN'); -- cube root
      CBRT
-----
      NaN
(1 row)

=> SELECT 'NaN' > 1.0;
      ?column?
-----
           f
(1 row)
```

Null Value

The load file format of a null value is user defined, as described in the COPY command. The Vertica internal representation of a null value is 0x7ffffffffffffeLL. The interactive format is controlled by the vsql printing option null. For example:

```
\pset null '(null)'
```

The default option is not to print anything.

Rules

- $-0 == +0$
- $1/0 = \text{Infinity}$
- $0/0 == \text{Nan}$
- $\text{NaN} \neq \text{anything}$ (even NaN)

To search for NaN column values, use the following predicate:

```
... WHERE column != column
```

This is necessary because WHERE *column* = 'NaN' cannot be true by definition.

Sort Order (Ascending)

- NaN
- -Inf
- numbers
- +Inf
- NULL

Notes

- NULL appears last (largest) in ascending order.
- All overflows in floats generate +/-infinity or NaN, per the IEEE floating point standard.

INTEGER

A signed 8-byte (64-bit) data type.

Syntax

```
[ INTEGER | INT | BIGINT | INT8 | SMALLINT | TINYINT ]
```

Parameters

INT, INTEGER, INT8, SMALLINT, TINYINT, and BIGINT are all synonyms for the same signed 64-bit integer data type. Automatic compression techniques are used to conserve disk space in cases where the full 64 bits are not required.

Notes

- The range of values is $-2^{63}+1$ to $2^{63}-1$.
- $2^{63} = 9,223,372,036,854,775,808$ (19 digits).

- The value -2^{63} is reserved to represent NULL.
- NULL appears first (smallest) in ascending order.
- Vertica does not have an explicit 4-byte (32-bit integer) or smaller types. Vertica's encoding and compression automatically eliminate the storage overhead of values that fit in less than 64 bits.

Restrictions

- The JDBC type INTEGER is 4 bytes and is not supported by Vertica. Use BIGINT instead.
- Vertica does not support the SQL/JDBC types NUMERIC, SMALLINT, or TINYINT.
- Vertica does not check for overflow (positive or negative) except in the aggregate function SUM(). If you encounter overflow when using SUM, use SUM_FLOAT(), which converts to floating point.

[Data Type Coercion Chart](#)

NUMERIC

Numeric data types store fixed point numeric data. For example, a money value of \$123.45 can be stored in a NUMERIC(5, 2) field.

Syntax

NUMERIC | DECIMAL | NUMBER | MONEY [(*precision* [, *scale*])]

Parameters

<i>precision</i>	The total number of significant digits that the data type stores. <i>precision</i> must be positive and ≤ 1024 . If you assign a value that exceeds the <i>precision</i> value, an error occurs.
------------------	---

<i>scale</i>	The maximum number of digits to the right of the decimal point that the data type stores. <i>scale</i> must be non-negative and less than or equal to <i>precision</i> . If you omit the <i>scale</i> parameter, the <i>scale</i> value is set to 0. If you assign a value with more decimal digits than <i>scale</i> , the value is rounded to <i>scale</i> digits.
--------------	--

Notes

- The maximum number of significant digits (digits to the left of the decimal point) is equal to precision minus scale. For example, NUMERIC(9, 6) allows three significant digits. In this case, if you insert a value that has more than three significant digits, an error occurs.
- Numeric data types that have a precision of 18 or less have similar performance characteristics as INTEGER, regardless of the scale. When possible, Vertica recommends using a precision <= 18.
- NUMERIC, DECIMAL, NUMBER, and MONEY are all synonyms that return NUMERIC data. The four numeric data types differ in their default precision and scale values:

Type	Precision	Scale
NUMERIC	37	15
DECIMAL	37	15
NUMBER	38	0
MONEY	18	4

- Numeric data types are *exact* data types that store values of a specified precision and scale, expressed with a number of digits before and after a decimal point. This contrasts with the Vertica integer and floating data types:

The **DOUBLE PRECISION (FLOAT)** type supports ~15 digits, variable exponent, and represents numeric values approximately.

The **INTEGER** type supports ~18 digits, whole numbers only.

- The *approximate* numeric data type, DOUBLE PRECISION, uses floating points and may be less precise than NUMERIC data types.
- Supported numeric operations include the following:

Basic math: +, -, *, /

Aggregation: SUM, MIN, MAX, COUNT

Comparison operators: <, <=, =, <=>, <>, >, >=

- NUMERIC divide operates directly on numeric values, without converting to floating point. The result has at least 18 decimal places and is rounded.
- NUMERIC mod (including %) operates directly on numeric values, without converting to floating point. The result has the same scale as the numerator and never needs rounding.
- NULL appears first (smallest) in ascending order.
- COPY accepts a DECIMAL data type with a decimal point ('.'), prefixed by – or +(optional).
- The NUMERIC data type is preferred for non-integer constants, because it is always exact. For example:

```
=> SELECT 1.1 + 2.2 = 3.3;
?column?
-----
t
(1 row)

=> SELECT 1.1::float + 2.2::float = 3.3::float;
?column?
-----
f
(1 row)
```

- Performance of the NUMERIC data type has been fine tuned for the common case of 18 digits of precision.
- Some of the more complex operations used with numeric data types result in an implicit cast to FLOAT. When using SQRT, STDDEV, transcendental functions such as LOG, and TO_CHAR/TO_NUMBER formatting, the result is always FLOAT.
- For valid encoding types for numeric data type columns, see [Encoding Types](#).

Examples

The following series of commands creates a table that contains a numeric data type and then performs some mathematical operations on the data:

```
=> CREATE TABLE num1 (id INTEGER, amount NUMERIC(8,2));
```

Insert some values into the table:

```
=> INSERT INTO num1 VALUES (1, 123456.78);
```

Query the table:

```
=> SELECT * FROM num1;
 id | amount
-----+-----
   1 | 123456.78
(1 row)
```

The following example returns the NUMERIC column, amount, from table num1:

```
=> SELECT amount FROM num1;
 amount
-----
123456.78
(1 row)
```

The following syntax adds one (1) to the amount:

```
=> SELECT amount+1 AS 'amount' FROM num1;
 amount
-----
123457.78
(1 row)
```

The following syntax multiplies the amount column by 2:

```
=> SELECT amount*2 AS 'amount' FROM num1;
 amount
-----
246913.56
(1 row)
```

The following syntax returns a negative number for the amount column:

```
=> SELECT -amount FROM num1;
?column?
-----
-123456.78
(1 row)
```

The following syntax returns the absolute value of the amount argument:

```
=> SELECT ABS(amount) FROM num1;
 ABS
-----
123456.78
(1 row)
```

The following syntax casts the NUMERIC amount as a FLOAT data type:

```
=> SELECT amount::float FROM num1;
   amount
-----
 123456.78
(1 row)
```

[Mathematical Functions](#)

[Encoding Types](#)

Numeric Data Type Overflow

Vertica does not check for overflow (positive or negative) except in the aggregate function `SUM()`. If you encounter overflow when using `SUM`, use `SUM_FLOAT()` which converts to floating point.

For a detailed discussion of how Vertica handles overflow when you use the functions `SUM`, `SUM_FLOAT`, and `AVG` with numeric data types, see [Numeric Data Type Overflow with SUM, SUM_FLOAT, and AVG](#). The discussion includes directives for turning off silent numeric overflow and setting precision for numeric data types.

Dividing by zero returns an error:

```
=> SELECT 0/0;
ERROR 3117:  Division by zero

=> SELECT 0.0/0;
ERROR 3117:  Division by zero

=> SELECT 0 // 0;
ERROR 3117:  Division by zero

=> SELECT 200.0/0;
ERROR 3117:  Division by zero

=> SELECT 116.43 // 0;
ERROR 3117:  Division by zero
```

Dividing zero as a `FLOAT` by zero returns `NaN`:

```
=> SELECT 0.0::float/0;
?column?
-----
      NaN
=> SELECT 0.0::float//0;
?column?
```

```
-----  
NaN
```

Dividing a non-zero FLOAT by zero returns Infinity:

```
=> SELECT 2.0::float/0;  
?column?  
-----  
Infinity  
=> SELECT 200.0::float//0;  
?column?  
-----  
Infinity
```

Add, subtract, and multiply operations ignore overflow. Sum and average operations use 128-bit arithmetic internally. `SUM()` reports an error if the final result overflows, suggesting the use of `SUM_FLOAT(INT)`, which converts the 128-bit sum to a `FLOAT8`. For example:

```
=> CREATE TEMP TABLE t (i INT);  
=> INSERT INTO t VALUES (1<<62);  
=> SELECT SUM(i) FROM t;  
ERROR: sum() overflowed  
HINT: try sum_float() instead  
=> SELECT SUM_FLOAT(i) FROM t;  
SUM_FLOAT  
-----  
2.30584300921369e+19
```

Numeric Data Type Overflow with SUM, SUM_FLOAT, and AVG

When you use the functions `SUM`, `SUM_FLOAT`, and `AVG` with a `NUMERIC` data type, be aware that overflow can occur and how Vertica responds to that overflow.

This discussion applies to both the aggregate and analytic functions.

For queries, when using the functions `SUM`, `SUM_FLOAT`, and `AVG` with a `NUMERIC` data type, Vertica allows for silent overflow if you exceed your specified precision.

Vertica also allows numeric overflow when you use the `SUM` or `SUM_FLOAT` functions with LAPs.

Default Overflow Handling

With NUMERIC data types, Vertica internally works with multiples of 18 digits. If your specified precision is less than 18 (for example, $x(12, 0)$), Vertica allows for an overflow up to and including the first multiple of 18. In some situations, if you sum a column ($SUM(x)$), you can exceed the number of digits Vertica internally reserves for the result. In this case, Vertica allows a silent overflow.

Turning Off Silent Numeric Overflow

You can turn off silent numeric overflow and instruct Vertica to implicitly include extra digit places. Specifying extra spaces allows Vertica to consistently return your expected results, even when you exceed the precision specified in your DDL.

You turn off silent numeric overflow by setting the parameter `AllowNumericOverflow` to 0 (false).

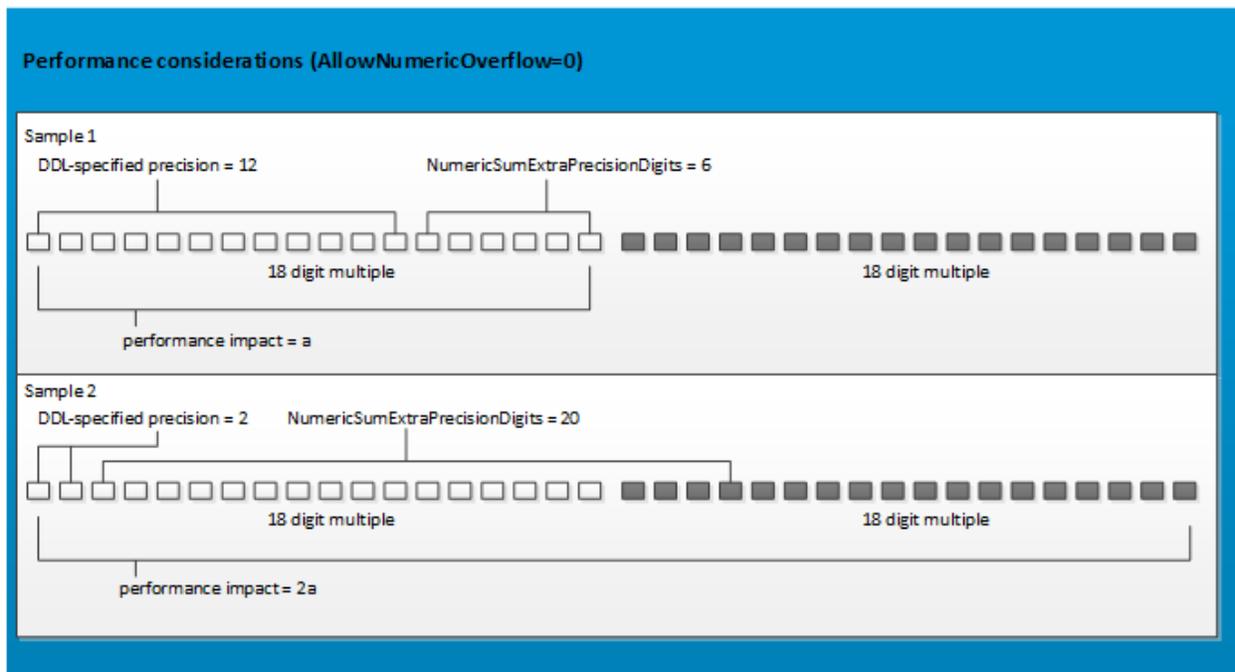

When you set the parameter to 0, Vertica considers the value of a corresponding parameter, `NumericSumExtraPrecisionDigits`.

The `NumericSumExtraPrecisionDigits` parameter defaults to 6, meaning that Vertica internally add six places beyond your DDL-specified precision. Adding extra precision digits can allow Vertica to consistently return results that overflow your DDL-specified precision. However, there can be a performance impact for crossing into the second multiple of 18 internally.

An example:

- Suppose your DDL specifies 11 (for example, $x(11, 0)$) and you accept the default of `NumericSumExtraPrecisionDigits` (6). In this case, Vertica internally stays within the first multiple of 18 digits and no additional performance impact occurs.
- Given the same example, if you set `NumericSumExtraPrecisionDigits` to 10, Vertica internally crosses a threshold into the second multiple of 18. Performance-wise, if (hypothetically) the first example is performance "a," then the second is "2a," substantially increasing the performance impact. Beyond the second multiple of 18, the performance impact continues to be "2a."

This sample representation shows how Vertica responds internally when you set `AllowNumericOverflow` to 0 (false).

Vertica recommends that you turn off silent numeric overflow and set the parameter `NumericSumExtraPrecisionDigits` if you expect to exceed the precision specified in your DDL. Crossing into the second multiple of 18 can affect performance. Therefore, consider carefully before setting `NumericSumExtraPrecisionDigits` to a number higher than what you need for returning the SUM of your numeric columns.

Be aware that, if you turn off `AllowNumericOverflow`, and you exceed the number of extra precision digits set by `NumericSumExtraPrecisionDigits`, Vertica returns an error.

Impact on Live Aggregate Projections (LAPs)

For LAPs, Vertica also allows silent numeric overflow if your LAP uses the `SUM` or `SUM_FLOAT` functions. To turn off silent numeric overflow for LAPs:

1. Set the parameter `AllowNumericOverflow` to 0.
2. Set the parameter `NumericSumExtraPrecisionDigits` to the number of implicit digits you want. Alternatively, use the default setting of 6.
3. Drop and re-create your LAPs.

If you turn off silent numeric overflow, be aware of the following scenarios where an overflow causes a roll back or error message. In these examples, `AllowNumericOverflow` is set to 0 (false), and each LAP uses the `SUM` or `SUM_FLOAT` function.

When numeric overflow is off:

- A load can roll back upon overflow.

Vertica aggregates data before loading in into a LAP. If you are inserting, copying, or merging data, and an overflow occurs during load as Vertica is aggregating the data, Vertica rolls back the load.

- An overflow can occur after load as Vertica sums existing data.

Vertica computes the sum of existing data separately from the computation that it does during data load. If your LAP selects a column using SUM or SUM_FLOAT and an overflow occurs, Vertica produces an error message. This response is similar to the way Vertica produces an error for a query using the SUM or SUM_FLOAT function.

- An overflow can occur during merge-out.

Vertica logs a message during merge-out if an overflow occurs as Vertica computes a final sum during the tuple mover operation. If an error occurs, Vertica marks the LAP as out-of-date. Vertica no longer runs tuple mover operations with the out-of-date LAP.

Data Type Coercion

Vertica supports two types of data type casting:

- *Implicit casting*—Occurs when the expression automatically converts the data from one type to another.
- *Explicit casting*—Occurs when you write a SQL statement that specifies the target data type for the conversion.

The ANSI SQL-92 standard supports implicit casting between similar data types:

- Number types
- CHAR, VARCHAR, LONG VARCHAR
- BINARY, VARBINARY, LONG VARBINARY

Vertica supports two types of nonstandard implicit casts:

- From CHAR to FLOAT, to match the one from VARCHAR to FLOAT. The following example converts the CHAR '3' to a FLOAT so it can add the number 4.33 to the FLOAT result of the second expression:

```
=> SELECT '3'::CHAR + 4.33::FLOAT;
?column?
-----
      7.33
(1 row)
```

- Between DATE and TIMESTAMP. The following example DATE to a TIMESTAMP and calculates the time 6 hours, 6 minutes, and 6 seconds back from 12:00 AM:

```
=> SELECT DATE('now') - INTERVAL '6:6:6';
?column?
-----
2013-07-30 17:53:54
(1 row)
```

When there is no ambiguity about the data type of an expression value, it is implicitly coerced to match the expected data type. In the following command, the quoted string constant '2' is implicitly coerced into an INTEGER value so that it can be the operand of an arithmetic operator (addition):

```
=> SELECT 2 + '2';
?column?
-----
      4
(1 row)
```

A concatenate operation explicitly takes arguments of any data type. In the following example, the concatenate operation implicitly coerces the arithmetic expression `2 + 2` and the INTEGER constant `2` to VARCHAR values so that they can be concatenated.

```
=> SELECT 2 + 2 || 2;
?column?
-----
      42
(1 row)
```

Another example is to first get today's date:

```
=> SELECT DATE 'now';
?column?
-----
2013-07-31
(1 row)
```

The following command converts DATE to a TIMESTAMP and adds a day and a half to the results by using INTERVAL:

```
=> SELECT DATE 'now' + INTERVAL '1 12:00:00';
       ?column?
-----
2013-07-31 12:00:00
(1 row)
```

Most implicit casts stay within their relational family and go in one direction, from less detailed to more detailed. For example:

- DATE to TIMESTAMP/TZ
- INTEGER to NUMERIC to FLOAT
- CHAR to FLOAT
- CHAR to VARCHAR
- CHAR and/or VARCHAR to FLOAT
- CHAR to LONG VARCHAR
- VARCHAR to LONG VARCHAR
- BINARY to VARBINARY
- BINARY to LONG VARBINARY
- VARBINARY to LONG VARBINARY

More specifically, data type coercion works in this manner in Vertica:

Type	Direction	Type	Notes
INT8	>	FLOAT8	Implicit, can lose significance
FLOAT8	>	INT8	Explicit, rounds
VARCHAR	<->	CHAR	Implicit, adjusts trailing spaces
VARBINARY	<->	BINARY	Implicit, adjusts trailing NULs
VARCHAR	>	LONG VARCHAR	Implicit, adjusts trailing spaces
VARBINARY	>	LONG VARBINARY	Implicit, adjusts trailing NULs

No other types cast to or from LONGVARBINARY, VARBINARY, or BINARY. In the following list, <any> means one these types: INT8, FLOAT8, DATE, TIME, TIMETZ, TIMESTAMP, TIMESTAMPTZ, INTERVAL.

- <any> -> VARCHAR—implicit
- VARCHAR -> <any>—explicit, except that VARCHAR->FLOAT is implicit
- <any> <-> CHAR—explicit
- DATE -> TIMESTAMP/TZ—implicit
- TIMESTAMP/TZ -> DATE—explicit, loses time-of-day
- TIME -> TIMETZ—implicit, adds local timezone
- TIMETZ -> TIME—explicit, loses timezone
- TIME -> INTERVAL—implicit, day to second with days=0
- INTERVAL -> TIME—explicit, truncates non-time parts
- TIMESTAMP <-> TIMESTAMPTZ—implicit, adjusts to local timezone
- TIMESTAMP/TZ -> TIME—explicit, truncates non-time parts
- TIMESTAMPTZ -> TIMETZ—explicit
- VARBINARY -> LONG VARBINARY—implicit
- LONG VARBINARY -> VARBINARY—explicit
- VARCHAR -> LONG VARCHAR—implicit
- LONG VARCHAR -> VARCHAR—explicit

Important: Implicit casts from INTEGER, FLOAT, and NUMERIC to VARCHAR are not supported. If you need that functionality, write an explicit cast:

```
CAST(x AS data-type-name)
```

or

```
x::data-type-name
```

The following example casts a FLOAT to an INTEGER:

```
=> SELECT(FLOAT '123.5')::INT;  
?column?
```

```
-----  
      124  
(1 row)
```

String-to-numeric data type conversions accept formats of quoted constants for scientific notation, binary scaling, hexadecimal, and combinations of numeric-type literals:

- Scientific notation :

```
=> SELECT FLOAT '1e10';  
      ?column?  
-----  
10000000000  
(1 row)
```

- BINARY scaling :

```
=> SELECT NUMERIC '1p10';  
      ?column?  
-----  
      1024  
(1 row)
```

- Hexadecimal:

```
=> SELECT NUMERIC '0x0abc';  
      ?column?  
-----  
      2748  
(1 row)
```

Examples

The following example casts three strings as NUMERICs:

```
=> SELECT NUMERIC '12.3e3', '12.3p10'::NUMERIC, CAST('0x12.3p-10e3' AS NUMERIC);  
?column? | ?column? |      ?column?  
-----+-----+-----  
12300 | 12595.2 | 17.76123046875000  
(1 row)
```

This example casts a VARBINARY string into a LONG VARBINARY data type:

```
=> SELECT B'101111000'::LONG VARBINARY;  
?column?  
-----  
\001x
```

Conversion Types					
Data Types	Implicit	Explicit	Assignment	Assignment without numeric meaning	Conversion without explicit casting
BOOLEAN			INTEGER LONG VARCHAR VARCHAR CHAR		
INTEGER	BOOLEAN NUMERIC FLOAT		INTERVAL DAY/SECOND INTERVAL YEAR/MONTH	LONG VARCHAR VARCHAR CHAR	
NUMERIC	FLOAT		INTEGER	LONG VARCHAR VARCHAR CHAR	NUMERIC
FLOAT			INTEGER NUMERIC	LONG VARCHAR VARCHAR CHAR	
LONG VARCHAR	FLOAT CHAR	BOOLEAN INTEGER NUMERIC VARCHAR TIMESTAMP TIMESTAMP WITH TIME ZONE DATE TIME TIME WITH TIME ZONE INTERVAL DAY/SECOND INTERVAL YEAR/MONTH LONG VARBINARY			LONG VARCHAR
VARCHAR	FLOAT LONG VARCHAR CHAR	BOOLEAN INTEGER NUMERIC TIMESTAMP TIMESTAMP WITH TIME ZONE DATE TIME TIME WITH TIME ZONE INTERVAL			VARCHAR

Conversion Types					
Data Types	Implicit	Explicit	Assignment	Assignment without numeric meaning	Conversion without explicit casting
		DAY/SECOND INTERVAL YEAR/MONTH

INTERVAL YEAR/MONTH			INTEGER LONG CHAR VARCHAR CHAR		INTERVAL YEAR/MONTH
LONG VARBINARY		VARBINARY			LONG VARBINARY
VARBINARY	LONG VARBINARY BINARY				VARBINARY
BINARY	VARBINARY				BINARY

Implicit and Explicit Conversion

Vertica supports data type conversion of values without explicit casting, such as `NUMERIC(10,6) -> NUMERIC(18,4)`. Implicit data type conversion occurs automatically when converting values of different, but compatible, types to the target column's data type. For example, when adding values, `(INT + NUMERIC)`, the result is implicitly cast to a `NUMERIC` type to accommodate the prominent type in the statement. Depending on the input data types, different precision and scale can occur.

An explicit type conversion must occur when the source data cannot be cast implicitly to the target column's data type.

Assignment Conversion

In data assignment conversion, coercion implicitly occurs when values are assigned to database columns in an `INSERT` or `UPDATE . . SET` statement. For example, in a statement that includes

INSERT ... VALUES('2.5'), where the target column data type is NUMERIC(18,5), a cast from VARCHAR to the column data type is inferred.

In an assignment without numeric meaning, the value is subject to CHAR/VARCHAR/LONG VARCHAR comparisons.

SQL Functions

Functions return information from the database. Except for [Vertica-specific functions](#), you can use a function anywhere an expression is allowed.

This chapter describes each function that Vertica supports. The Behavior Type section of these descriptions categorizes the function's return behavior as one of the following:

Immutable (invariant)

When run with a given set of arguments, immutable functions such as [AVG\(\)](#) always produce the same result, regardless of environment or session settings such as locale. Some immutable functions can take an optional stable argument; in this case they are treated as stable functions.

Stable

When run with a given set of arguments, stable functions produce the same result within a single query or scan operation. However, a stable function can produce different results when issued under different environments or at different times, such as change of locale and time zone—for example, [SYSDATE\(\)](#) and 'today'.

Volatile

Regardless of their arguments or environment, volatile functions can return a different result with each invocation—for example, [RANDOM\(\)](#).

Note: All Vertica-specific functions are volatile; thus, the descriptions of these functions omit a Behavior Type section.

Aggregate Functions

Note: All functions in this section that have an [analytic](#) function counterpart are appended with [Aggregate] to avoid confusion between the two.

Aggregate functions summarize data over groups of rows from a query result set. The groups are specified using the [GROUP BY](#) clause. They are allowed only in the select list and in the [HAVING](#) and [ORDER BY](#) clauses of a [SELECT](#) statement (as described in [Aggregate Expressions](#)).

Notes

- Except for `COUNT`, these functions return a null value when no rows are selected. In particular, `SUM` of no rows returns `NULL`, not zero.
- In some cases you can replace an expression that includes multiple aggregates with a single aggregate of an expression. For example `SUM(x) + SUM(y)` can be expressed as `SUM(x+y)` (where `x` and `y` are `NOT NULL`).
- Vertica does not support nested aggregate functions.

You can also use some of the simple aggregate functions as analytic (window) functions. See [Analytic Functions](#) for details. See also [SQL Analytics](#) in Analyzing Data.

APPROXIMATE_COUNT_DISTINCT

Returns the number of distinct non-NULL values in a data set.

Behavior Type

Immutable

Syntax

```
APPROXIMATE_COUNT_DISTINCT ( expression [, error-tolerance ] )
```

Parameters

<i>expression</i>	Value to be evaluated using any data type that supports equality comparison.
<i>error-tolerance</i>	<p>Numeric value that represents the desired percentage of error tolerance, distributed around the value returned by this function. The smaller the error tolerance, the closer the approximation</p> <p>You can set <i>error-tolerance</i> to a minimum value of 0.88, with an error than is lognormally distributed with standard deviation. Vertica imposes no maximum restriction, but any value greater than 5 is implemented with 5% error tolerance.</p> <p>If you omit this argument, Vertica uses an error tolerance of 1.75 (%).</p>

Restrictions

APPROXIMATE_COUNT_DISTINCT and DISTINCT aggregates cannot be in the same query block.

Error Tolerance

APPROXIMATE_COUNT_DISTINCT(*x*, *error-tolerance*) returns a value equal to COUNT (DISTINCT *x*), with an error that is lognormally distributed with standard deviation.

Parameter *error-tolerance* is optional. Supply this argument to specify the desired standard deviation. *error-tolerance* is defined as 2.17 standard deviations, which corresponds to a 97 percent confidence interval:

$$\text{standard-deviation} = \text{error tolerance} / 2.17$$

For example:

- ***error-tolerance* = 1**
The default setting, corresponds to a standard deviation. 97 percent of the time, APPROXIMATE_COUNT_DISTINCT(*x*, 5) returns a value between:

- `COUNT(DISTINCT x) / 1.01`
- `COUNT(DISTINCT x) * 1.01`
- ***error-tolerance* = 5**
97 percent of the time, `APPROXIMATE_COUNT_DISTINCT(x)` returns a value between:
 - `COUNT(DISTINCT x) / 1.05`
 - `COUNT(DISTINCT x) * 1.05`

A 99 percent confidence interval corresponds to 2.58 standard deviations. To set *error-tolerance* confidence level corresponding to 99 (instead of a 97) percent, multiply *error-tolerance* by $2.17 / 2.58 = 0.841$.

For example, if you specify *error-tolerance* as $5 * 0.841 = 4.2$, `APPROXIMATE_COUNT_DISTINCT(x, 4.2)` returns values 99 percent of the time between:

- `COUNT (DISTINCT x)COUNT / 1.05`
- `COUNT (DISTINCT x) * 1.05`

Examples

Count the total number of distinct values in column `product_key` from table `store.store_sales_fact`:

```
=> SELECT COUNT(DISTINCT product_key) FROM store.store_sales_fact;
COUNT
-----
19982
(1 row)
```

Count the approximate number of distinct values in `product_key` with various error tolerances. The smaller the error tolerance, the closer the approximation:

```
=> SELECT APPROXIMATE_COUNT_DISTINCT(product_key,5) AS five_pct_accuracy,
APPROXIMATE_COUNT_DISTINCT(product_key,1) AS one_pct_accuracy,
APPROXIMATE_COUNT_DISTINCT(product_key,.88) AS point_eighteight_pct_accuracy
FROM store.store_sales_fact;

five_pct_accuracy | one_pct_accuracy | point_eighteight_pct_accuracy
-----+-----+-----
19431 | 19921 | 19921
(1 row)
```

- [APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS](#)
- [COUNT \[Aggregate\]](#)

APPROXIMATE_COUNT_DISTINCT_SYNOPSIS

Summarizes the information of distinct non-NULL values and materializes the result set in a `VARBINARY` or `LONG VARBINARY` *synopsis* object. The calculated result is within a specified range of error tolerance. You save the synopsis object in a Vertica table for use by [APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS](#).

Note: If you are upgrading from a release to Vertica 8.1.1, you must drop the pre-existing synopsis object and recreate it to get the result.

Behavior Type

Immutable

Syntax

```
APPROXIMATE_COUNT_DISTINCT_SYNOPSIS ( expression [, error-tolerance] )
```

Parameters

<i>expression</i>	Value to evaluate using any data type that supports equality comparison.
<i>error-tolerance</i>	Numeric value that represents the desired percentage of error tolerance, distributed around the value returned by this function. The smaller the error tolerance, the closer the approximation You can set <i>error-tolerance</i> to a minimum value of 0.88, with an error than is lognormally distributed with standard deviation.

	<p>Vertica imposes no maximum restriction, but any value greater than 5 is implemented with 5% error tolerance.</p> <p>If you omit this argument, Vertica uses an error tolerance of 1.75 (%).</p> <p>For more details, see APPROXIMATE_COUNT_DISTINCT.</p>
--	---

Restrictions

`APPROXIMATE_COUNT_DISTINCT_SYNOPSIS` and `DISTINCT` aggregates cannot be in the same query block.

Example

See [APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS](#).

APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS

Calculates the number of distinct non-NULL values from the synopsis objects created by [APPROXIMATE_COUNT_DISTINCT_SYNOPSIS](#).

Note: If you are upgrading from a release to Vertica 8.1.1, you must drop the pre-existing synopsis object and recreate it to get the result.

Behavior Type

Immutable

Syntax

```
APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS ( synopsis-obj[, error-tolerance ] )
```

Parameters

<i>synopsis-obj</i>	A synopsis object created by APPROXIMATE_COUNT_DISTINCT_SYNOPSIS .
---------------------	--

<i>error-tolerance</i>	<p>Numeric value that represents the desired percentage of error tolerance, distributed around the value returned by this function. The smaller the error tolerance, the closer the approximation</p> <p>You can set <i>error-tolerance</i> to a minimum value of 0.88, with an error than is lognormally distributed with standard deviation. Vertica imposes no maximum restriction, but any value greater than 5 is implemented with 5% error tolerance.</p> <p>If you omit this argument, Vertica uses an error tolerance of 1.75 (%).</p> <p>For more details, see APPROXIMATE_COUNT_DISTINCT.</p>
------------------------	---

Restrictions

`APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS` and `DISTINCT` aggregates cannot be in the same query block.

Examples

The following examples review and compare different ways to obtain a count of unique values in a table column:

Return an exact count of unique values in column `product_key`, from table `store.store_sales_fact`:

```
=> \timing
Timing is on.
=> SELECT COUNT(DISTINCT product_key) from store.store_sales_fact;
count
-----
19982
(1 row)

Time: First fetch (1 row): 553.033 ms. All rows formatted: 553.075 ms
```

Return an approximate count of unique values in column `product_key`:

```
=> SELECT APPROXIMATE_COUNT_DISTINCT(product_key) as unique_product_keys
FROM store.store_sales_fact;
unique_product_keys
-----
19921
(1 row)

Time: First fetch (1 row): 394.562 ms. All rows formatted: 394.600 ms
```

Create a synopsis object that represents a set of `store.store_sales_fact` data with unique `product_key` values, store the synopsis in the new table `my_summary`:

```
=> CREATE TABLE my_summary AS SELECT APPROXIMATE_COUNT_DISTINCT_SYNOPSIS (product_key) syn
    FROM store.store_sales_fact;
CREATE TABLE
Time: First fetch (0 rows): 582.662 ms. All rows formatted: 582.682 ms
```

Return a count from the saved synopsis:

```
=> SELECT APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS(syn) FROM my_summary;
ApproxCountDistinctOfSynopsis
-----
                        19921
(1 row)

Time: First fetch (1 row): 105.295 ms. All rows formatted: 105.335 ms
```

APPROXIMATE_MEDIAN [Aggregate]

Computes the approximate median of an expression over a group of rows. The function returns a FLOAT value.

APPROXIMATE_MEDIAN is an alias of [APPROXIMATE_PERCENTILE \[Aggregate\]](#) with a parameter of 0.5.

Note: This function is best suited for large groups of data. If you have a small group of data, use the exact [MEDIAN \[Analytic\]](#) function.

Behavior Type

Immutable

Syntax

```
APPROXIMATE_MEDIAN ( expression )
```

Parameters

<i>expression</i>	Any FLOAT or INT data type. The function returns the approximate middle value or an interpolated value that would be the approximate
-------------------	--

middle value once the values are sorted. Null values are ignored in the calculation.

Examples

Tip: For optimal performance when using `GROUP BY` in your query, verify that your table is sorted on the `GROUP BY` column.

The following examples uses this table:

```
CREATE TABLE allsales(state VARCHAR(20), name VARCHAR(20), sales INT) ORDER BY state;
INSERT INTO allsales VALUES('MA', 'A', 60);
INSERT INTO allsales VALUES('NY', 'B', 20);
INSERT INTO allsales VALUES('NY', 'C', 15);
INSERT INTO allsales VALUES('MA', 'D', 20);
INSERT INTO allsales VALUES('MA', 'E', 50);
INSERT INTO allsales VALUES('NY', 'F', 40);
INSERT INTO allsales VALUES('MA', 'G', 10);
COMMIT;
```

Calculate the approximate median of all sales in this table:

```
=> SELECT APPROXIMATE_MEDIAN (sales) FROM allsales;
APROXIMATE_MEDIAN
-----
                20
(1 row)
```

Modify the query to group sales by state, and obtain the approximate median for each one:

```
=> SELECT state, APPROXIMATE_MEDIAN(sales) FROM allsales GROUP BY state;
state | APPROXIMATE_MEDIAN
-----+-----
MA    |                    35
NY    |                    20
(2 rows)
```

See Also

- [MEDIAN \[Analytic\]](#)
- [PERCENTILE_CONT \[Analytic\]](#)

- [APPROXIMATE_PERCENTILE \[Aggregate\]](#)
- [SQL Analytics](#)

APPROXIMATE_PERCENTILE [Aggregate]

Computes the approximate percentile of an expression over a group of rows. This function returns a FLOAT value. Nulls are ignored.

Note: This function is best suited for large groups of data. If you have a small group of data, use the exact [PERCENTILE_CONT \[Analytic\]](#) function.

Behavior Type

Immutable

Syntax

```
APPROXIMATE_PERCENTILE ( expression USING PARAMETERS percentile = number )
```

Parameters

<i>expression</i>	Any FLOAT or INT data type. Null values are ignored.
<i>number</i>	Percentile value, which must be a FLOAT constant ranging from 0 to 1 (inclusive).

Examples

Tip: For optimal performance when using GROUP BY in your query, verify that your table is sorted on the GROUP BY column.

The following example uses this table:

```
CREATE TABLE allsales(state VARCHAR(20), name VARCHAR(20), sales INT) ORDER BY state;
INSERT INTO allsales VALUES('MA', 'A', 60);
INSERT INTO allsales VALUES('NY', 'B', 20);
INSERT INTO allsales VALUES('NY', 'C', 15);
INSERT INTO allsales VALUES('MA', 'D', 20);
INSERT INTO allsales VALUES('MA', 'E', 50);
INSERT INTO allsales VALUES('NY', 'F', 40);
INSERT INTO allsales VALUES('MA', 'G', 10);
COMMIT;
```

Calculate the approximate percentile for sales in each state:

```
=> SELECT state, APPROXIMATE_PERCENTILE(sales USING PARAMETERS percentile=0.5) AS median FROM
allsales GROUP BY state;
state | median
-----+-----
MA    |      35
NY    |      20
(2 rows)
```

See Also

- [MEDIAN \[Analytic\]](#)
- [PERCENTILE_CONT \[Analytic\]](#)
- [SQL Analytics](#)

AVG [Aggregate]

Computes the average (arithmetic mean) of an expression over a group of rows. AVG always returns a DOUBLE PRECISION value.

The AVG aggregate function differs from the [AVG](#) analytic function, which computes the average of an expression over a group of rows within a window.

Behavior Type

Immutable

Syntax

```
AVG ( [ ALL | DISTINCT ] expression )
```

Parameters

ALL	Invokes the aggregate function for all rows in the group (default).
DISTINCT	Invokes the aggregate function for all distinct non-null values of the expression found in the group.
<i>expression</i>	The value whose average is calculated over a set of rows, any expression that can have a DOUBLE PRECISION result.

Overflow Handling

By default, Vertica allows silent numeric overflow when you call this function on numeric data types. For more information on this behavior and how to change it, see [Numeric Data Type Overflow with SUM, SUM_FLOAT, and AVG](#).

Examples

The following query returns the average income from the customer table:

```
=> SELECT AVG(annual_income) FROM customer_dimension;
      AVG
-----
2104270.6485
(1 row)
```

See Also

- [COUNT \[Aggregate\]](#)
- [SUM \[Aggregate\]](#)
- [Numeric Data Types](#)

BIT_AND

Takes the bitwise AND of all non-null input values. If the input parameter is NULL, the return value is also NULL.

Behavior Type

Immutable

Syntax

```
BIT_AND ( expression )
```

Parameters

<i>expression</i>	The BINARY or VARBINARY input value to evaluate. BIT_AND operates on VARBINARY types explicitly and on BINARY types implicitly through casts .
-------------------	--

Returns

BIT_AND returns:

- The same value as the argument data type.
- 1 for each bit compared, if all bits are 1; otherwise 0.

If the columns are different lengths, the return values are treated as though they are all equal in length and are right-extended with zero bytes. For example, given a group containing hex values ff, null, and f, BIT_AND ignores the null value and extends the value f to f0.

Example

The example that follows uses table t with a single column of VARBINARY data type:

```
=> CREATE TABLE t ( c VARBINARY(2) );  
=> INSERT INTO t values(HEX_TO_BINARY('0xFF00'));
```

```
=> INSERT INTO t values(HEX_TO_BINARY('0xFFFF'));  
=> INSERT INTO t values(HEX_TO_BINARY('0xF00F'));
```

Query table `t` to see column `c` output:

```
=> SELECT TO_HEX(c) FROM t;  
TO_HEX  
-----  
ff00  
ffff  
f00f  
(3 rows)
```

Query table `t` to get the AND value for column `c`:

```
=> SELECT TO_HEX(BIT_AND(c)) FROM t;  
TO_HEX  
-----  
f000  
(1 row)
```

The function is applied pairwise to all values in the group, resulting in `f000`, which is determined as follows:

1. `ff00` (record 1) is compared with `ffff` (record 2), which results in `ff00`.
2. The result from the previous comparison is compared with `f00f` (record 3), which results in `f000`.

See Also

[Binary Data Types](#)

BIT_OR

Takes the bitwise OR of all non-null input values. If the input parameter is NULL, the return value is also NULL.

Behavior Type

Immutable

Syntax

`BIT_OR (expression)`

Parameters

<i>expression</i>	The [BINARY VARBINARY] input value to be evaluated. BIT_OR() operates on VARBINARY types explicitly and on BINARY types implicitly through casts .
-------------------	--

Returns

BIT_OR returns:

- The same value as the argument data type.
- 1 for each bit compared, if any bit is 1; otherwise 0.

If the columns are different lengths, the return values are treated as though they are all equal in length and are right-extended with zero bytes. For example, given a group containing hex values ff, null, and f, the function ignores the null value and extends the value f to f0.

Example

The example that follows uses table t with a single column of VARBINARY data type:

```
=> CREATE TABLE t ( c VARBINARY(2) );
=> INSERT INTO t values(HEX_TO_BINARY('0xFF00'));
=> INSERT INTO t values(HEX_TO_BINARY('0xFFFF'));
=> INSERT INTO t values(HEX_TO_BINARY('0xF00F'));
```

Query table t to see column c output:

```
=> SELECT TO_HEX(c) FROM t;
TO_HEX
-----
ff00
ffff
f00f
(3 rows)
```

Query table t to get the OR value for column c:

```
=> SELECT TO_HEX(BIT_OR(c)) FROM t;  
TO_HEX  
-----  
ffff  
(1 row)
```

The function is applied pairwise to all values in the group, resulting in ffff, which is determined as follows:

1. ff00 (record 1) is compared with ffff, which results in ffff.
2. The ff00 result from the previous comparison is compared with f00f (record 3), which results in ffff.

See Also

[Binary Data Types](#)

BIT_XOR

Takes the bitwise XOR of all non-null input values. If the input parameter is NULL, the return value is also NULL.

Behavior Type

Immutable

Syntax

```
BIT_XOR ( expression )
```

Parameters

<i>expression</i>	The BINARY or VARBINARY input value to evaluate. BIT_XOR operates on VARBINARY types explicitly and on BINARY types implicitly through casts .
-------------------	--

Returns

BIT_XOR returns:

- The same value as the argument data type.
- 1 for each bit compared, if there are an odd number of arguments with set bits; otherwise 0.

If the columns are different lengths, the return values are treated as though they are all equal in length and are right-extended with zero bytes. For example, given a group containing hex values ff, null, and f, the function ignores the null value and extends the value f to f0.

Example

First create a sample table and projections with binary columns:

The example that follows uses table t with a single column of VARBINARY data type:

```
=> CREATE TABLE t ( c VARBINARY(2) );
=> INSERT INTO t values(HEX_TO_BINARY('0xFF00'));
=> INSERT INTO t values(HEX_TO_BINARY('0xFFFF'));
=> INSERT INTO t values(HEX_TO_BINARY('0xF00F'));
```

Query table t to see column c output:

```
=> SELECT TO_HEX(c) FROM t;
 TO_HEX
-----
ff00
ffff
f00f
(3 rows)
```

Query table t to get the XOR value for column c:

```
=> SELECT TO_HEX(BIT_XOR(c)) FROM t;
 TO_HEX
-----
f0f0
(1 row)
```

See Also

[Binary Data Types](#)

BOOL_AND [Aggregate]

Processes Boolean values and returns a Boolean value result. If all input values are true, BOOL_AND returns t. Otherwise it returns f (false).

Behavior Type

Immutable

Syntax

```
BOOL_AND ( expression )
```

Parameters

<i>expression</i>	A Boolean data type or any non-Boolean data type that can be implicitly coerced to a Boolean data type.
-------------------	---

Examples

The following example shows how to use aggregate functions BOOL_AND, BOOL_OR, and BOOL_XOR. The sample table mixers includes columns for models and colors.

```
=> CREATE TABLE mixers(model VARCHAR(20), colors VARCHAR(20));  
CREATE TABLE
```

Insert sample data into the table. The sample adds two color fields for each model.

```
=> INSERT INTO mixers  
SELECT 'beginner', 'green'  
UNION ALL  
SELECT 'intermediate', 'blue'  
UNION ALL  
SELECT 'intermediate', 'blue'  
UNION ALL  
SELECT 'advanced', 'green'  
UNION ALL  
SELECT 'advanced', 'blue'  
UNION ALL  
SELECT 'professional', 'blue'
```

```
UNION ALL
SELECT 'professional', 'green'
UNION ALL
SELECT 'beginner', 'green';
OUTPUT
-----
      8
(1 row)
```

Query the table. The result shows models that have two blue (BOOL_AND), one or two blue (BOOL_OR), and specifically not more than one blue (BOOL_XOR) mixer.

```
=> SELECT model,
BOOL_AND(colors= 'blue')AS two_blue,
BOOL_OR(colors= 'blue')AS one_or_two_blue,
BOOL_XOR(colors= 'blue')AS specifically_not_more_than_one_blue
FROM mixers
GROUP BY model;
```

model	two_blue	one_or_two_blue	specifically_not_more_than_one_blue
advanced	f	t	t
beginner	f	f	f
intermediate	t	t	f
professional	f	t	t

(4 rows)

BOOL_OR [Aggregate]

Processes Boolean values and returns a Boolean value result. If at least one input value is true, BOOL_OR returns t. Otherwise, it returns f.

Behavior Type

Immutable

Syntax

`BOOL_OR (expression)`

Parameters

<i>expression</i>	A Boolean data type or any non-Boolean data type that can be implicitly coerced to a Boolean data type.
-------------------	---

Examples

The following example shows how to use aggregate functions `BOOL_AND`, `BOOL_OR`, and `BOOL_XOR`. The sample table `mixers` includes columns for models and colors.

```
=> CREATE TABLE mixers(model VARCHAR(20), colors VARCHAR(20));  
CREATE TABLE
```

Insert sample data into the table. The sample adds two color fields for each model.

```
=> INSERT INTO mixers  
SELECT 'beginner', 'green'  
UNION ALL  
SELECT 'intermediate', 'blue'  
UNION ALL  
SELECT 'intermediate', 'blue'  
UNION ALL  
SELECT 'advanced', 'green'  
UNION ALL  
SELECT 'advanced', 'blue'  
UNION ALL  
SELECT 'professional', 'blue'  
UNION ALL  
SELECT 'professional', 'green'  
UNION ALL  
SELECT 'beginner', 'green';  
OUTPUT  
-----  
      8  
(1 row)
```

Query the table. The result shows models that have two blue (`BOOL_AND`), one or two blue (`BOOL_OR`), and specifically not more than one blue (`BOOL_XOR`) mixer.

```
=> SELECT model,  
       BOOL_AND(colors= 'blue')AS two_blue,  
       BOOL_OR(colors= 'blue')AS one_or_two_blue,
```

```
BOOL_XOR(colors= 'blue')AS specifically_not_more_than_one_blue  
FROM mixers  
GROUP BY model;
```

model	two_blue	one_or_two_blue	specifically_not_more_than_one_blue
advanced	f	t	t
beginner	f	f	f
intermediate	t	t	f
professional	f	t	t

BOOL_XOR [Aggregate]

Processes Boolean values and returns a Boolean value result. If specifically only one input value is true, BOOL_XOR returns t. Otherwise, it returns f.

Behavior Type

Immutable

Syntax

```
BOOL_XOR ( expression )
```

Parameters

<i>expression</i>	A Boolean data type or any non-Boolean data type that can be implicitly coerced to a Boolean data type.
-------------------	---

Examples

The following example shows how to use aggregate functions `BOOL_AND`, `BOOL_OR`, and `BOOL_XOR`. The sample table `mixers` includes columns for models and colors.

```
=> CREATE TABLE mixers(model VARCHAR(20), colors VARCHAR(20));  
CREATE TABLE
```

Insert sample data into the table. The sample adds two color fields for each model.

```
=> INSERT INTO mixers  
SELECT 'beginner', 'green'  
UNION ALL  
SELECT 'intermediate', 'blue'  
UNION ALL  
SELECT 'intermediate', 'blue'  
UNION ALL  
SELECT 'advanced', 'green'  
UNION ALL  
SELECT 'advanced', 'blue'  
UNION ALL  
SELECT 'professional', 'blue'  
UNION ALL  
SELECT 'professional', 'green'  
UNION ALL  
SELECT 'beginner', 'green';  
OUTPUT  
-----  
      8  
(1 row)
```

Query the table. The result shows models that have two blue (`BOOL_AND`), one or two blue (`BOOL_OR`), and specifically not more than one blue (`BOOL_XOR`) mixer.

```
=> SELECT model,  
BOOL_AND(colors= 'blue')AS two_blue,  
BOOL_OR(colors= 'blue')AS one_or_two_blue,  
BOOL_XOR(colors= 'blue')AS specifically_not_more_than_one_blue  
FROM mixers  
GROUP BY model;  
  
   model   | two_blue | one_or_two_blue | specifically_not_more_than_one_blue  
-----+-----+-----+-----  
advanced   | f        | t                | t  
beginner   | f        | f                | f  
intermediate | t        | t                | f  
professional | f        | t                | t  
(4 rows)
```

CORR

Returns the DOUBLE PRECISION coefficient of correlation of a set of expression pairs. CORR eliminates expression pairs where either expression in the pair is NULL. If no rows remain, the function returns NULL.

Syntax

```
CORR ( expression1, expression2 )
```

Parameters

<i>expression1</i>	The dependent DOUBLE PRECISION expression
<i>expression2</i>	The independent DOUBLE PRECISION expression

Example

```
=> SELECT CORR (Annual_salary, Employee_age) FROM employee_dimension;  
CORR  
-----  
-0.00719153413192422  
(1 row)
```

COUNT [Aggregate]

Returns as a BIGINT the number of rows in each group where the expression is not NULL. If the query has no GROUP BY clause, COUNT returns the number of table rows.

The COUNT aggregate function differs from the [COUNT](#) analytic function, which returns the number over a group of rows within a window.

Behavior Type

Immutable

Syntax

```
COUNT ( [ * ] [ ALL | DISTINCT ] expression )
```

Parameters

<code>*</code>	Specifies to count all rows in the specified table or each group.
<code>ALL DISTINCT</code>	Specifies how to count rows where <i>expression</i> has a non-null value: <ul style="list-style-type: none">• ALL (default): Counts all rows where <i>expression</i> evaluates to a non-null value.• DISTINCT: Counts all rows where <i>expression</i> evaluates to a distinct non-null value.
<i>expression</i>	The column or expression whose non-null values are counted.

Examples

The following query returns the number of distinct values in the `primary_key` column of the `date_dimension` table:

```
=> SELECT COUNT (DISTINCT date_key) FROM date_dimension;
```

```
COUNT
-----
 1826
(1 row)
```

This example returns all distinct values of evaluating the expression `x+y` for all `inventory_fact` records.

```
=> SELECT COUNT (DISTINCT date_key + product_key) FROM inventory_fact;

COUNT
-----
21560
(1 row)
```

You can create an equivalent query using the `LIMIT` keyword to restrict the number of rows returned:

```
=> SELECT COUNT(date_key + product_key) FROM inventory_fact GROUP BY date_key LIMIT 10;

COUNT
-----
 173
   31
  321
  113
  286
   84
  244
  238
  145
  202
(10 rows)
```

This query returns the number of distinct values of `date_key` in all records with the specific distinct `product_key` value.

```
=> SELECT product_key, COUNT (DISTINCT date_key) FROM inventory_fact
   GROUP BY product_key LIMIT 10;

product_key | count
-----+-----
          1 |    12
          2 |    18
          3 |    13
          4 |    17
          5 |    11
          6 |    14
          7 |    13
          8 |    17
          9 |    15
         10 |    12
(10 rows)
```

This query counts each distinct `product_key` value in `inventory_fact` table with the constant `1`.

```
=> SELECT product_key, COUNT (DISTINCT product_key) FROM inventory_fact
      GROUP BY product_key LIMIT 10;
```

product_key	count
1	1
2	1
3	1
4	1
5	1
6	1
7	1
8	1
9	1
10	1

(10 rows)

This query selects each distinct date_key value and counts the number of distinct product_key values for all records with the specific product_key value. It then sums the qty_in_stock values in all records with the specific product_key value and groups the results by date_key.

```
=> SELECT date_key, COUNT (DISTINCT product_key), SUM(qty_in_stock) FROM inventory_fact
      GROUP BY date_key LIMIT 10;
```

date_key	count	sum
1	173	88953
2	31	16315
3	318	156003
4	113	53341
5	285	148380
6	84	42421
7	241	119315
8	238	122380
9	142	70151
10	202	95274

(10 rows)

This query selects each distinct product_key value and then counts the number of distinct date_key values for all records with the specific product_key value. It also counts the number of distinct warehouse_key values in all records with the specific product_key value.

```
=> SELECT product_key, COUNT (DISTINCT date_key), COUNT (DISTINCT warehouse_key) FROM inventory_fact
      GROUP BY product_key LIMIT 15;
```

product_key	count	count
1	12	12
2	18	18
3	13	12
4	17	18
5	11	9
6	14	13
7	13	13

```

      8 |    17 |    15
      9 |    15 |    14
     10 |    12 |    12
     11 |    11 |    11
     12 |    13 |    12
     13 |     9 |     7
     14 |    13 |    13
     15 |    18 |    17
(15 rows)

```

This query selects each distinct `product_key` value, counts the number of distinct `date_key` and `warehouse_key` values for all records with the specific `product_key` value, and then sums all `qty_in_stock` values in records with the specific `product_key` value. It then returns the number of `product_version` values in records with the specific `product_key` value.

```

=> SELECT product_key, COUNT (DISTINCT date_key),
      COUNT (DISTINCT warehouse_key),
      SUM (qty_in_stock),
      COUNT (product_version)
      FROM inventory_fact GROUP BY product_key LIMIT 15;

```

```

product_key | count | count | sum | count
-----+-----+-----+-----+-----
      1 |    12 |    12 | 5530 |    12
      2 |    18 |    18 | 9605 |    18
      3 |    13 |    12 | 8404 |    13
      4 |    17 |    18 | 10006 |    18
      5 |    11 |     9 | 4794 |    11
      6 |    14 |    13 | 7359 |    14
      7 |    13 |    13 | 7828 |    13
      8 |    17 |    15 | 9074 |    17
      9 |    15 |    14 | 7032 |    15
     10 |    12 |    12 | 5359 |    12
     11 |    11 |    11 | 6049 |    11
     12 |    13 |    12 | 6075 |    13
     13 |     9 |     7 | 3470 |     9
     14 |    13 |    13 | 5125 |    13
     15 |    18 |    17 | 9277 |    18
(15 rows)

```

The following example returns the number of warehouses from the `warehouse_dimension` table:

```

=> SELECT COUNT(warehouse_name) FROM warehouse_dimension;

COUNT
-----
     100
(1 row)

```

This next example returns the total number of vendors:

```

=> SELECT COUNT(*) FROM vendor_dimension;

```

```
COUNT
-----
      50
(1 row)
```

COVAR_POP

Returns the population covariance for a set of expression pairs. The return value is of type `DOUBLE PRECISION`. `COVAR_POP` eliminates expression pairs where either expression in the pair is `NULL`. If no rows remain, the function returns `NULL`.

Syntax

```
SELECT COVAR_POP ( expression1, expression2 )
```

Parameters

<i>expression1</i>	The dependent <code>DOUBLE PRECISION</code> expression
<i>expression2</i>	The independent <code>DOUBLE PRECISION</code> expression

Example

```
=> SELECT COVAR_POP (Annual_salary, Employee_age)
      FROM employee_dimension;
      COVAR_POP
-----
-9032.34810730019
(1 row)
```

COVAR_SAMP

Returns the sample covariance for a set of expression pairs. The return value is of type DOUBLE PRECISION. COVAR_SAMP eliminates expression pairs where either expression in the pair is NULL. If no rows remain, the function returns NULL.

Syntax

```
SELECT COVAR_SAMP ( expression1, expression2 )
```

Parameters

<i>expression1</i>	The dependent DOUBLE PRECISION expression
<i>expression2</i>	The independent DOUBLE PRECISION expression

Example

```
=> SELECT COVAR_SAMP (Annual_salary, Employee_age)
      FROM employee_dimension;
      COVAR_SAMP
-----
-9033.25143244343
(1 row)
```

GROUP_ID

Uniquely identifies duplicate sets for GROUP BY queries that return duplicate grouping sets. This function returns one or more integers, starting with zero (0), as identifiers.

For the number of duplicates n for a particular grouping, GROUP_ID returns a range of sequential numbers, 0 to $n-1$. For the first each unique group it encounters, GROUP_ID returns the value 0. If GROUP_ID finds the same grouping again, the function returns 1, then returns 2 for the next found grouping, and so on.

Note: Use GROUP_ID only in SELECT statements that contain a **GROUP BY** aggregate: **CUBE**, **GROUPING SETS**, and **ROLLUP**.

Behavior Type

Immutable

Syntax

GROUP_ID ()

Examples

This example shows how GROUP_ID creates unique identifiers when a query produces duplicate groupings. For an expenses table, the following query groups the results by category of expense and year and rolls up the sum for those two columns. The results have duplicate groupings for category and NULL. The first grouping has a GROUP_ID of 0, and the second grouping has a GROUP_ID of 1.

```
=> SELECT Category, Year, SUM(Amount), GROUPING_ID(Category, Year),
      GROUP_ID() FROM expenses GROUP BY Category, ROLLUP(Category,Year)
      ORDER BY Category, Year, GROUPING_ID();
```

Category	Year	SUM	GROUPING_ID	GROUP_ID
Books	2005	39.98	0	0
Books	2007	29.99	0	0
Books	2008	29.99	0	0
Books		99.96	1	0
Books		99.96	1	1
Electricity	2005	109.99	0	0
Electricity	2006	109.99	0	0

Electricity	2007	229.98	0	0
Electricity		449.96	1	1
Electricity		449.96	1	0

- [GROUPING_ID](#)
- [GROUPING SETS Aggregate](#)
- [GROUP BY Clause](#)
- [ROLLUP Aggregate](#)

GROUPING

Disambiguates the use of NULL values when GROUP BY queries with multilevel aggregates generate NULL values to identify subtotals in grouping columns. Such NULL values from the original data can also occur in rows. GROUPING returns 1, if the value of *expression* is:

- NULL, representing an aggregated value
- 0 for any other value, including NULL values in rows

Note: Use GROUPING only in SELECT statements that contain a [GROUP BY](#) aggregate: [CUBE](#), [GROUPING SETS](#), and [ROLLUP](#).

Behavior Type

Immutable

Syntax

```
GROUPING ( expression )
```

Parameters

<i>expression</i>	An expression in the GROUP BY clause
-------------------	--------------------------------------

Examples

The following query uses the GROUPING function, taking one of the GROUP BY expressions as an argument. For each row, GROUPING returns one of the following:

- 0: The column is part of the group for that row
- 1: The column is not part of the group for that row

The 1 in the GROUPING(Year) column for electricity and books indicates that these values are subtotals. The right-most column values for both GROUPING(Category) and GROUPING(Year) are 1. This value indicates that neither column contributed to the GROUP BY. The final row represents the total sales.

```
=> SELECT Category, Year, SUM(Amount),  
       GROUPING(Category), GROUPING(Year) FROM expenses  
       GROUP BY ROLLUP(Category, Year) ORDER BY Category, Year, GROUPING_ID();
```

Category	Year	SUM	GROUPING	GROUPING
Books	2005	39.98	0	0
Books	2007	29.99	0	0
Books	2008	29.99	0	0
Books		99.96	0	1
Electricity	2005	109.99	0	0
Electricity	2006	109.99	0	0
Electricity	2007	229.98	0	0
Electricity		449.96	0	1
		549.92	1	1

See Also

- [GROUPING_ID](#)
- [GROUPING SETS Aggregate](#)

- [GROUP BY Clause](#)
- [ROLLUP Aggregate](#)

GROUPING_ID

Concatenates the set of Boolean values generated by the [GROUPING](#) function into a bit vector. `GROUPING_ID` treats the bit vector as a binary number and returns it as a base-10 value that identifies the grouping set combination.

By using `GROUPING_ID` you avoid the need for multiple, individual `GROUPING` functions. `GROUPING_ID` simplifies row-filtering conditions, because rows of interest are identified using a single return from `GROUPING_ID = n`. Use `GROUPING_ID` to identify grouping combinations.

Note: Use `GROUPING_ID` only in `SELECT` statements that contain a [GROUP BY](#) aggregate: [CUBE](#), [GROUPING SETS](#), and [ROLLUP](#).

Behavior Type

Immutable

Syntax

```
GROUPING_ID ( [expression[,...]] )
```

<i>expression</i>	An expression that matches one of the expressions in the <code>GROUP BY</code> clause. If the <code>GROUP BY</code> clause includes a list of expressions, <code>GROUPING_ID</code> returns a number corresponding to the <code>GROUPING</code> bit vector associated with a row.
-------------------	--

Examples

This example shows how calling `GROUPING_ID` without an expression returns the `GROUPING` bit vector associated with a full set of multilevel aggregate expressions. The `GROUPING_ID`

value is comparable to `GROUPING_ID(a,b)` because `GROUPING_ID()` includes all columns in the `GROUP BY ROLLUP`:

```
=> SELECT a,b,COUNT(*), GROUPING_ID() FROM T GROUP BY ROLLUP(a,b);
```

In the following query, the `GROUPING(Category)` and `GROUPING(Year)` columns have three combinations:

- 0,0
- 0,1
- 1,1

```
=> SELECT Category, Year, SUM(Amount),
       GROUPING(Category), GROUPING(Year) FROM expenses
       GROUP BY ROLLUP(Category, Year) ORDER BY Category, Year, GROUPING_ID();
```

Category	Year	SUM	GROUPING	GROUPING
Books	2005	39.98	0	0
Books	2007	29.99	0	0
Books	2008	29.99	0	0
Books		99.96	0	1
Electricity	2005	109.99	0	0
Electricity	2006	109.99	0	0
Electricity	2007	229.98	0	0
Electricity		449.96	0	1
		549.92	1	1

`GROUPING_ID` converts these values as follows:

Binary Set Values	Decimal Equivalents
00	0
01	1
11	3
0	Category, Year

The following query returns the single number for each `GROUP BY` level that appears in the `gr_id` column:

```
=> SELECT Category, Year, SUM(Amount),
       GROUPING(Category),GROUPING(Year),GROUPING_ID(Category,Year) AS gr_id
       FROM expenses GROUP BY ROLLUP(Category, Year);
```

Category	Year	SUM	GROUPING	GROUPING	gr_id
Books	2008	29.99	0	0	0
Books	2005	39.98	0	0	0

Electricity	2007	229.98	0	0	0
Books	2007	29.99	0	0	0
Electricity	2005	109.99	0	0	0
Electricity		449.96	0	1	1
		549.92	1	1	3
Electricity	2006	109.99	0	0	0
Books		99.96	0	1	1

The `gr_id` value determines the GROUP BY level for each row:

GROUP BY Level	GROUP BY Row Level
3	Total sum
1	Category
0	Category, year

You can also use the [DECODE](#) function to give the values more meaning by comparing each search value individually:

```
=> SELECT Category, Year, SUM(AMOUNT), DECODE(GROUPING_ID(Category, Year),
      3, 'Total',
      1, 'Category',
      0, 'Category,Year')
      AS GROUP_NAME FROM expenses GROUP BY ROLLUP(Category, Year);
Category | Year | SUM | GROUP_NAME
-----+-----+-----+-----
Electricity | 2006 | 109.99 | Category,Year
Books | | 99.96 | Category
Electricity | 2007 | 229.98 | Category,Year
Books | 2007 | 29.99 | Category,Year
Electricity | 2005 | 109.99 | Category,Year
Electricity | | 449.96 | Category
| | 549.92 | Total
Books | 2005 | 39.98 | Category,Year
Books | 2008 | 29.99 | Category,Year
```

MAX [Aggregate]

Returns the greatest value of an expression over a group of rows. The return value has the same type as the expression data type.

The MAX [analytic function](#) differs from the aggregate function, in that it returns the maximum value of an expression over a group of rows within a window.

Aggregate functions MIN and MAX can operate with Boolean values. MAX can act upon a [Boolean data type](#) or a value that can be implicitly converted to a Boolean. If at least one input value is true, MAX returns t (true). Otherwise, it returns f (false). In the same scenario, MIN returns t (true) if all input values are true. Otherwise it returns f.

Behavior Type

Immutable

Syntax

```
MAX ( expression )
```

Parameters

<i>expression</i>	Any expression for which the maximum value is calculated, typically a column reference .
-------------------	--

Examples

The following query returns the largest value in column `sales_dollar_amount`.

```
=> SELECT MAX(sales_dollar_amount) AS highest_sale FROM store.store_sales_fact;
highest_sale
-----
           600
(1 row)
```

The following example shows you the difference between the MIN and MAX aggregate functions when you use them with a Boolean value. The sample creates a table, adds two rows of data, and shows sample output for MIN and MAX.

```
=> CREATE TABLE min_max_functions (torf BOOL);

=> INSERT INTO min_max_functions VALUES (1);
=> INSERT INTO min_max_functions VALUES (0);

=> SELECT * FROM min_max_functions;
  torf
-----
  t
  f
(2 rows)

=> SELECT min(torf) FROM min_max_functions;
  min
-----
  f
(1 row)

=> SELECT max(torf) FROM min_max_functions;
  max
-----
  t
(1 row)
```

See Also

[Data Aggregation](#)

MIN [Aggregate]

Returns the smallest value of an expression over a group of rows. The return value has the same type as the expression data type.

The MIN [analytic function](#) differs from the aggregate function, in that it returns the minimum value of an expression over a group of rows within a window.

Aggregate functions MIN and MAX can operate with Boolean values. MAX can act upon a [Boolean data type](#) or a value that can be implicitly converted to a Boolean. If at least one input value is true, MAX returns t (true). Otherwise, it returns f (false). In the same scenario, MIN returns t (true) if all input values are true. Otherwise it returns f.

Behavior Type

Immutable

Syntax

`MIN (expression)`

Parameters

<i>expression</i>	Any expression for which the minimum value is calculated, typically a column reference .
-------------------	--

Examples

The following query returns the lowest salary from the `employee_dimension` table.

This example shows how you can query to return the lowest salary from the `employee_dimension` table.

```
=> SELECT MIN(annual_salary) AS lowest_paid FROM employee_dimension;
lowest_paid
-----
          1200
(1 row)
```

The following example shows you the difference between the `MIN` and `MAX` aggregate functions when you use them with a Boolean value. The sample creates a table, adds two rows of data, and shows sample output for `MIN` and `MAX`.

```
=> CREATE TABLE min_max_functions (torf BOOL);

=> INSERT INTO min_max_functions VALUES (1);
=> INSERT INTO min_max_functions VALUES (0);

=> SELECT * FROM min_max_functions;
torf
-----
t
f
(2 rows)

=> SELECT min(torf) FROM min_max_functions;
min
-----
f
(1 row)

=> SELECT max(torf) FROM min_max_functions;
max
-----
```

```
t  
(1 row)
```

[Data Aggregation](#)

REGR_AVGX

Returns the `DOUBLE PRECISION` average of the independent expression in an expression pair. `REGR_AVGX` eliminates expression pairs where either expression in the pair is `NULL`. If no rows remain, `REGR_AVGX` returns `NULL`.

Syntax

```
SELECT REGR_AVGX ( expression1, expression2 )
```

Parameters

<i>expression1</i>	The dependent <code>DOUBLE PRECISION</code> expression
<i>expression2</i>	The independent <code>DOUBLE PRECISION</code> expression

Example

```
=> SELECT REGR_AVGX (Annual_salary, Employee_age)  
      FROM employee_dimension;  
      REGR_AVGX  
-----  
      39.321  
(1 row)
```

REGR_AVGY

Returns the `DOUBLE PRECISION` average of the dependent expression in an expression pair. The function eliminates expression pairs where either expression in the pair is `NULL`. If no rows remain, the function returns `NULL`.

Syntax

```
REGR_AVGY ( expression1, expression2 )
```

Parameters

<i>expression1</i>	The dependent DOUBLE PRECISION expression
<i>expression2</i>	The independent DOUBLE PRECISION expression

Example

```
=> SELECT REGR_AVGY (Annual_salary, Employee_age)
      FROM employee_dimension;
REGR_AVGY
-----
58354.4913
(1 row)
```

REGR_COUNT

Returns the count of all rows in an expression pair. The function eliminates expression pairs where either expression in the pair is NULL. If no rows remain, the function returns 0.

Syntax

```
SELECT REGR_COUNT ( expression1, expression2 )
```

Parameters

<i>expression1</i>	The dependent DOUBLE PRECISION expression
<i>expression2</i>	The independent DOUBLE PRECISION expression

Example

```
=> SELECT REGR_COUNT (Annual_salary, Employee_age) FROM employee_dimension;
REGR_COUNT
-----
          10000
(1 row)
```

REGR_INTERCEPT

Returns the y-intercept of the regression line determined by a set of expression pairs. The return value is of type `DOUBLE PRECISION`. `REGR_INTERCEPT` eliminates expression pairs where either expression in the pair is `NULL`. If no rows remain, `REGR_INTERCEPT` returns `NULL`.

Syntax

```
SELECT REGR_INTERCEPT ( expression1, expression2 )
```

Parameters

<i>expression1</i>	The dependent <code>DOUBLE PRECISION</code> expression
<i>expression2</i>	The independent <code>DOUBLE PRECISION</code> expression

Example

```
=> SELECT REGR_INTERCEPT (Annual_salary, Employee_age) FROM employee_dimension;
REGR_INTERCEPT
-----
59929.5490163437
(1 row)
```

REGR_R2

Returns the square of the correlation coefficient of a set of expression pairs. The return value is of type `DOUBLE PRECISION`. `REGR_R2` eliminates expression pairs where either expression in

the pair is NULL. If no rows remain, REGR_R2 returns NULL.

Syntax

```
SELECT REGR_R2 ( expression1, expression2 )
```

Parameters

<i>expression1</i>	The dependent DOUBLE PRECISION expression
<i>expression2</i>	The independent DOUBLE PRECISION expression

Example

```
=> SELECT REGR_R2 (Annual_salary, Employee_age) FROM employee_dimension;
      REGR_R2
-----
5.17181631706311e-05
(1 row)
```

REGR_SLOPE

Returns the slope of the regression line, determined by a set of expression pairs. The return value is of type DOUBLE PRECISION. REGR_SLOPE eliminates expression pairs where either expression in the pair is NULL. If no rows remain, REGR_SLOPE returns NULL.

Syntax

```
SELECT REGR_SLOPE ( expression1, expression2 )
```

Parameters

<i>expression1</i>	The dependent DOUBLE PRECISION expression
<i>expression2</i>	The independent DOUBLE PRECISION expression

Example

```
=> SELECT REGR_SLOPE (Annual_salary, Employee_age) FROM employee_dimension;
      REGR_SLOPE
-----
-40.056400303749
(1 row)
```

REGR_SXX

Returns the sum of squares of the difference between the independent expression (*expression2*) and its average.

That is, REGR_SXX returns: $\sum[(expression2 - average(expression2))(expression2 - average(expression2))]$

The return value is of type DOUBLE PRECISION. REGR_SXX eliminates expression pairs where either expression in the pair is NULL. If no rows remain, REGR_SXX returns NULL.

Syntax

```
SELECT REGR_SXX ( expression1, expression2 )
```

Parameters

<i>expression1</i>	The dependent DOUBLE PRECISION expression
<i>expression2</i>	The independent DOUBLE PRECISION expression

Example

```
=> SELECT REGR_SXX (Annual_salary, Employee_age) FROM employee_dimension;
      REGR_SXX
-----
2254907.59
(1 row)
```

REGR_SXY

Returns the sum of products of the difference between the dependent expression (*expression1*) and its average and the difference between the independent expression (*expression2*) and its average.

That is, REGR_SXY returns: $\sum[(expression1 - average(expression1))(expression2 - average(expression2))]$

The return value is of type DOUBLE PRECISION. REGR_SXY eliminates expression pairs where either expression in the pair is NULL. If no rows remain, REGR_SXY returns NULL.

Syntax

```
SELECT REGR_SXY ( expression1, expression2 )
```

Parameters

<i>expression1</i>	The dependent DOUBLE PRECISION expression
<i>expression2</i>	The independent DOUBLE PRECISION expression

Example

```
=> SELECT REGR_SXY (Annual_salary, Employee_age) FROM employee_dimension;
      REGR_SXY
-----
-90323481.0730019
(1 row)
```

REGR_SYY

Returns the sum of squares of the difference between the dependent expression (*expression1*) and its average.

That is, REGR_SYY returns: $\sum[(expression1 - average(expression1))(expression1 - average(expression1))]$

The return value is of type `DOUBLE PRECISION`. `REGR_SYY` eliminates expression pairs where either expression in the pair is `NULL`. If no rows remain, `REGR_SYY` returns `NULL`.

Syntax

```
SELECT REGR_SYY ( expression1, expression2 )
```

Parameters

<i>expression1</i>	The dependent <code>DOUBLE PRECISION</code> expression
<i>expression2</i>	The independent <code>DOUBLE PRECISION</code> expression

Example

```
=> SELECT REGR_SYY (Annual_salary, Employee_age) FROM employee_dimension;  
      REGR_SYY  
-----  
69956728794707.2  
(1 row)
```

STDDEV [Aggregate]

Evaluates the statistical sample standard deviation for each member of the group. The return value is the same as the square root of [VAR_SAMP](#):

```
STDDEV(expression) = SQRT(VAR_SAMP(expression))
```

Behavior Type

Immutable

Syntax

```
STDDEV ( expression )
```

Parameters

<i>expression</i>	Any NUMERIC data type or any non-numeric data type that can be implicitly converted to a numeric data type. STDDEV returns the same data type as <i>expression</i> .
-------------------	--

Related Functions

- Nonstandard function STDDEV is provided for compatibility with other databases. It is semantically identical to [STDDEV_SAMP](#).
- This aggregate function differs from analytic function [STDDEV](#), which computes the statistical sample standard deviation of the current row with respect to the group of rows within a window.
- When [VAR_SAMP](#) returns NULL, STDDEV returns NULL.

Examples

The following example returns the statistical sample standard deviation for each household ID from the `customer_dimension` table of the VMart example database:

```
=> SELECT STDDEV(household_id) FROM customer_dimension;  
      STDDEV  
-----  
8651.5084240071
```

STDDEV_POP [Aggregate]

Evaluates the statistical population standard deviation for each member of the group.

Behavior Type

Immutable

Syntax

`STDDEV_POP (expression)`

Parameters

<i>expression</i>	Any NUMERIC data type or any non-numeric data type that can be implicitly converted to a numeric data type. <code>STDDEV_POP</code> returns the same data type as <i>expression</i> .
-------------------	---

Related Functions

- This function differs from the analytic function [STDDEV_POP](#), which evaluates the statistical population standard deviation for each member of the group of rows within a window.
- `STDDEV_POP` returns the same value as the square root of [VAR_POP](#):

`STDDEV_POP(expression) = SQRT(VAR_POP(expression))`

- When [VAR_SAMP](#) returns NULL, this function returns NULL.

Examples

The following example returns the statistical population standard deviation for each household ID in the customer table.

```
=> SELECT STDDEV_POP(household_id) FROM customer_dimension;
   STDDEV_POP
-----
 8651.41895973367
(1 row)
```

See Also

- [Analytic Functions](#)
- [SQL Analytics](#)

STDDEV_SAMP [Aggregate]

Evaluates the statistical sample standard deviation for each member of the group. The return value is the same as the square root of [VAR_SAMP](#):

```
STDDEV_SAMP(expression) = SQRT(VAR_SAMP(expression))
```

Behavior Type

Immutable

Syntax

```
STDDEV_SAMP ( expression )
```

Parameters

<i>expression</i>	Any NUMERIC data type or any non-numeric data type that can be implicitly converted to a numeric data type. STDDEV_SAMP returns the same data type as <i>expression</i> .
-------------------	---

Related Functions

- STDDEV_SAMP is semantically identical to nonstandard function [STDDEV](#), which is provided for compatibility with other databases.
- This aggregate function differs from analytic function [STDDEV_SAMP](#), which computes the statistical sample standard deviation of the current row with respect to the group of rows within a window.
- When [VAR_SAMP](#) returns NULL, STDDEV_SAMP returns NULL.

Examples

The following example returns the statistical sample standard deviation for each household ID from the customer dimension table.

```
=> SELECT STDDEV_SAMP(household_id) FROM customer_dimension;
      stddev_samp
-----
8651.50842400771
(1 row)
```

SUM [Aggregate]

Computes the sum of an expression over a group of rows. SUM returns a `DOUBLE PRECISION` value for a floating-point expression. Otherwise, the return value is the same as the expression data type.

The SUM aggregate function differs from the [SUM](#) analytic function, which computes the sum of an expression over a group of rows within a window.

Behavior Type

Immutable

Syntax

```
SUM ( [ ALL | DISTINCT ] expression )
```

Parameters

ALL	Invokes the aggregate function for all rows in the group (default)
DISTINCT	Invokes the aggregate function for all distinct non-null values of the expression found in the group
<i>expression</i>	Any NUMERIC data type or any non-numeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument.

Overflow Handling

If you encounter data overflow when using `SUM()`, use [SUM_FLOAT](#) which converts the data to a floating point. By default, Vertica allows silent numeric overflow when you call this function

on numeric data types. For more information on this behavior and how to change it, see [Numeric Data Type Overflow with SUM, SUM_FLOAT, and AVG](#).

Example

The following query returns the total sum of the `product_cost` column.

```
=> SELECT SUM(product_cost) AS cost FROM product_dimension;
      cost
-----
  9042850
(1 row)
```

See Also

- [AVG \[Aggregate\]](#)
- [COUNT \[Aggregate\]](#)

SUM_FLOAT [Aggregate]

Computes the sum of an expression over a group of rows and returns a `DOUBLE PRECISION` value.

Behavior Type

Immutable

Syntax

```
SUM_FLOAT ( [ ALL | DISTINCT ] expression )
```

Parameters

ALL	Invokes the aggregate function for all rows in the group (default).
DISTINCT	Invokes the aggregate function for all distinct non-null values of the expression found in the group.

<i>expression</i>	Any expression whose result is type DOUBLE PRECISION.
-------------------	---

Overflow Handling

By default, Vertica allows silent numeric overflow when you call this function on numeric data types. For more information on this behavior and how to change it, see [Numeric Data Type Overflow with SUM, SUM_FLOAT, and AVG](#).

Example

The following query returns the floating-point sum of the average price from the product table:

```
=> SELECT SUM_FLOAT(average_competitor_price) AS cost FROM product_dimension;
      cost
-----
 18181102
(1 row)
```

VAR_POP [Aggregate]

Evaluates the population variance for each member of the group. This is defined as the sum of squares of the difference of *expression* from the mean of *expression*, divided by the number of remaining rows:

$$\frac{(\text{SUM}(\text{expression} * \text{expression}) - \text{SUM}(\text{expression}) * \text{SUM}(\text{expression}) / \text{COUNT}(\text{expression}))}{\text{COUNT}(\text{expression})}$$

Behavior Type

Immutable

Syntax

```
VAR_POP ( expression )
```

Parameters

<i>expression</i>	Any NUMERIC data type or any non-numeric data type that can be implicitly converted to a numeric data type. VAR_POP returns the same
-------------------	--

	data type as <i>expression</i> .
--	----------------------------------

Related Functions

This aggregate function differs from analytic function [VAR_POP](#), which computes the population variance of the current row with respect to the group of rows within a window.

Examples

The following example returns the population variance for each household ID in the customer table.

```
=> SELECT VAR_POP(household_id) FROM customer_dimension;
      var_pop
-----
74847050.0168393
(1 row)
```

VAR_SAMP [Aggregate]

Evaluates the sample variance for each row of the group. This is defined as the sum of squares of the difference of *expression* from the mean of *expression* divided by the number of remaining rows minus 1:

$$\frac{(\text{SUM}(\textit{expression} * \textit{expression}) - \text{SUM}(\textit{expression}) * \text{SUM}(\textit{expression}) / \text{COUNT}(\textit{expression}))}{(\text{COUNT}(\textit{expression}) - 1)}$$

Behavior Type

Immutable

Syntax

```
VAR_SAMP ( expression )
```

Parameters

<i>expression</i>	Any NUMERIC data type or any non-numeric data type that can be
-------------------	--

implicitly converted to a numeric data type. VAR_SAMP returns the same data type as *expression*.

Related Functions

- VAR_SAMP is semantically identical to nonstandard function [VARIANCE](#), which is provided for compatibility with other databases.
- This aggregate function differs from analytic function [VAR_SAMP](#), which computes the sample variance of the current row with respect to the group of rows within a window.

Examples

The following example returns the sample variance for each household ID in the customer table.

```
=> SELECT VAR_SAMP(household_id) FROM customer_dimension;
      var_samp
-----
74848598.0106764
(1 row)
```

See Also

[VARIANCE \[Aggregate\]](#)

VARIANCE [Aggregate]

Evaluates the sample variance for each row of the group. This is defined as the sum of squares of the difference of *expression* from the mean of *expression* divided by the number of remaining rows minus 1.

```
(SUM(expression*expression) - SUM(expression) *SUM(expression) /COUNT(expression)) / (COUNT(expression) -1)
```

Behavior Type

Immutable

Syntax

VARIANCE (*expression*)

Parameters

<i>expression</i>	Any NUMERIC data type or any non-numeric data type that can be implicitly converted to a numeric data type. VARIANCE returns the same data type as <i>expression</i> .
-------------------	--

Related Functions

The nonstandard function VARIANCE is provided for compatibility with other databases. It is semantically identical to [VAR_SAMP](#).

This aggregate function differs from analytic function [VARIANCE](#), which computes the sample variance of the current row with respect to the group of rows within a window.

Examples

The following example returns the sample variance for each household ID in the customer table.

```
=> SELECT VARIANCE(household_id) FROM customer_dimension;
      variance
-----
74848598.0106764
(1 row)
```

Analytic Functions

Note: All analytic functions in this section with an aggregate counterpart are appended with [Analytics] in the heading to avoid confusion between the two function types.

Vertica analytics are SQL functions based on the ANSI 99 standard. These functions handle complex analysis and reporting tasks—for example:

- Rank the longest-standing customers in a particular state.
- Calculate the moving average of retail volume over a specified time.
- Find the highest score among all students in the same grade.
- Compare the current sales bonus that salespersons received against their previous bonus.

Analytic functions return aggregate results but they do not group the result set. They return the group value multiple times, once per record. You can sort group values, or partitions, using a window `ORDER BY` clause, but the order affects only the function result set, not the entire query result set.

Syntax

General

```
analytic-function ( arguments ) OVER(  
...[ window-partition-clause ]  
...[ window-order-clause [ window-frame-clause ] ]  
)
```

With named window

```
analytic-function ( arguments ) OVER(  
...[ named-window [ window-frame-clause ] ]  
)
```

Parameters

<i>analytic-function</i> (<i>arguments</i>)	A Vertica analytic function and its arguments.
--	--

OVER	<p>Specifies how to partition, sort, and window frame function input with respect to the current row. The input data is the result set that the query returns after it evaluates FROM, WHERE, GROUP BY, and HAVING clauses.</p> <p>An empty OVER clause provides the best performance for single threaded queries on a single node.</p>
<i>window-partition-clause</i>	<p>Groups input rows according to one or more columns or expressions.</p> <p>If you omit this clause, no grouping occurs and the analytic function processes all input rows as a single partition.</p>
<i>window-order-clause</i>	<p>Optionally specifies how to sort rows that are supplied to the analytic function. If the OVER clause also includes a partition clause, rows are sorted within each partition.</p>
<i>window-frame-clause</i>	<p>Only valid for some analytic functions, specifies as input a set of rows relative to the row that is currently being evaluated by the analytic function. After the function processes that row and its window, Vertica advances the current row and adjusts the window boundaries accordingly.</p>
<i>named-window</i>	<p>The name of a window that you define in the same query with a window name clause. This definition encapsulates window partitioning and sorting. Named windows are useful when the query invokes multiple analytic functions with similar OVER clauses.</p> <p>A window name clause cannot specify a window frame clause. However, you can qualify the named window in an OVER clause with a window frame clause.</p>

Requirements

The following requirements apply to analytic functions:

- All require an OVER clause. Each function has its own OVER clause requirements. For example, you can supply an empty OVER clause for some analytic aggregate functions such as [SUM](#). For other functions, window frame and order clauses might be required, or might be invalid.
- Analytic functions can be invoked only in a query's SELECT and ORDER BY clauses.
- Analytic functions cannot be nested. For example, the following query is not allowed:

```
=> SELECT MEDIAN(RANK() OVER(ORDER BY sal) OVER()).
```

- WHERE, GROUP BY and HAVING operators are technically not part of the analytic function. However, they determine input to that function.

See Also

- [SQL Analytics](#)
- [GROUP BY Queries](#)

Window Partition Clause

When specified, a window partition clause divides the rows of the function input based on user-provided expressions. If no expression is provided, the partition clause can improve query performance by using parallelism.

Window partitioning is similar to the GROUP BY clause except that it returns only one result row per input row. If you omit specifying a window partition clause, all input rows are treated as a single partition.

When used with analytic functions, results are computed per partition and start over again (reset) at the beginning of each subsequent partition.

Syntax

```
{ PARTITION BY expression[,...] | PARTITION BEST | PARTITION NODES }
```

Parameters

<code>PARTITION BY <i>expression</i></code>	Expression on which to sort the partition, where <i>expression</i> can be a column, constant, or an arbitrary expression formed on columns. Use <code>PARTITION BY</code> for analytic functions with specific partitioning requirements.
<code>PARTITION BEST</code>	<p>Use parallelism to improve performance for multi-threaded queries across multiple nodes.</p> <p><code>OVER(PARTITION BEST)</code> provides the best performance on multi-threaded queries across multiple nodes.</p> <p>The following considerations apply to using <code>PARTITION BEST</code>:</p> <ul style="list-style-type: none">• Use <code>PARTITION BEST</code> for analytic functions that have no partitioning requirements and are thread safe—for example, a one-to-many transform.• Do not use <code>PARTITION BEST</code> on user-defined transform functions (UDTFs) that are not thread-safe. Doing so can produce an error or incorrect results. If a UDTF is not thread safe, use <code>PARTITION NODES</code>.
<code>PARTITION NODES</code>	<p>Use parallelism to improve performance for single-threaded queries across multiple nodes.</p> <p><code>OVER(PARTITION NODES)</code> provides the best performance on single-threaded queries across multiple nodes.</p>

Examples

See [Window Partitioning](#) in Analyzing Data.

Window Order Cause

Specifies how to sort rows that are supplied to the analytic function. If the `OVER` clause also includes a [window partition clause](#), rows are sorted within each partition.

The window order clause only specifies order within a window result set. The query can have its own **ORDER BY** clause outside the OVER clause. This has precedence over the window order clause and orders the final result set.

An window order clause also creates a default **window frame** if none is explicitly specified.

Syntax

```
ORDER BY { expression[ sort-qualifiers ] } [,...]
```

sort-qualifiers =

```
[ ASC | DESC ]  
[ NULLS { FIRST | LAST | AUTO } ]
```

Parameters

<i>expression</i>	A column, constant, or arbitrary expression formed on columns, on which to sort input rows.
ASC DESC	Specifies the ordering sequence as ascending (default) or descending.
NULLS {FIRST LAST AUTO}	<p>Specifies whether to position null values first or last. Default positioning depends on whether the sort order is ascending or descending:</p> <ul style="list-style-type: none">• Ascending default: NULLS LAST• Descending default: NULLS FIRST <p>If you specify NULLS AUTO, Vertica chooses the positioning that is most efficient for this query, either either NULLS FIRST or NULLS LAST.</p> <p>If you omit all sort qualifiers, Vertica uses ASC NULLS LAST.</p> <p>For more information, see:</p> <ul style="list-style-type: none">• NULL Sort Order• Runtime Sorting of NULL Values in Analytic Functions

Examples

See [Window Ordering](#) in Analyzing Data.

Window Frame Clause

Specifies a window frame, which comprises a set of rows relative to the row that is currently being evaluated by the analytic function. After the function processes that row and its window, Vertica advances the current row and adjusts the window boundaries accordingly. If the OVER clause also specifies a [partition](#), Vertica also checks that window boundaries do not cross partition boundaries. This process repeats until the function evaluates the last row of the last partition.

Syntax

```
{ ROWS | RANGE }  
  { BETWEEN start-point AND end-point } | start-point  
  
start-point / end-point =  
{ UNBOUNDED {PRECEDING | FOLLOWING}  
  | CURRENT ROW  
  | constant-value {PRECEDING | FOLLOWING}  
}
```

Parameters

ROWS RANGE	Specifies whether Vertica determines window frame dimensions as physical or logical offsets from the current row. See ROWS versus RANGE below for details.
BETWEEN <i>start-point</i> AND <i>end-point</i>	Specifies the window's first and last rows, where <i>start-point</i> and <i>end-point</i> can be one of the following (discussed in detail below): <ul style="list-style-type: none">• UNBOUNDED {PRECEDING FOLLOWING}• CURRENT ROW

	<ul style="list-style-type: none"> • <i>constant-value</i> {PRECEDING FOLLOWING} <p><i>start-point</i> must resolve to a row or value that is less than or equal to <i>end-point</i>.</p>
UNBOUNDED PRECEDING	Specifies that the window frame extends to the current partition's first row.
<i>start-point</i>	If ROWS or RANGE specifies only a start point, Vertica uses the current row as the end point and creates the window frame accordingly. In this case, <i>start-point</i> must resolve to a row that is less than or equal to the current row.
UNBOUNDED FOLLOWING	Specifies that the window frame extends to the current partition's last row.
CURRENT ROW	Specifies the current row or value as the window's start or end point.
<i>constant-value</i> {PRECEDING FOLLOWING}	<p>Specifies a constant value or expression that evaluates to a constant value. The value specifies a physical or logical offset from the current row, depending on whether you specify ROWS or RANGE.</p> <p>Other dependencies also pertain, depending whether you specify ROWS and RANGE. See ROWS versus RANGE below for details.</p>

Requirements

In order to specify a window frame, the OVER must also specify a [window order](#) (ORDER BY) [clause](#). If the OVER clause omits specifying a window frame, the function creates a default window that extends from the current row to the first row in the current partition. This is equivalent to the following clause:

```
RANGE UNBOUNDED PRECEDING AND CURRENT ROW
```

ROWS versus RANGE

The window frame's offset from the current row can be physical or logical:

- ROWS specifies the window's *start-point* and *end-point* as a number of rows relative to the current row. If *start-point* and *end-point* are expressed as constant values, the value must evaluate to a positive integer.
- RANGE specifies the window as a logical offset such as time. The range value must match the [window order](#) (ORDER BY) [clause](#) data type: NUMERIC, DATE/TIME, FLOAT or INTEGER.

Use of ROWS or RANGE imposes specific requirements on setting the window's start and end points as constant values:

Setting constant values for ROWS

The constant must evaluate to a positive INTEGER.

Setting constant values for RANGE

The following requirements apply:

- The constant must evaluate to a positive numeric value or INTERVAL literal.
- If the constant evaluates to a NUMERIC value, the ORDER BY column type must be a NUMERIC data type.
- If the constant evaluates to an INTERVAL DAY TO SECOND subtype, the ORDER BY column type must be one of the following: TIMESTAMP, TIME, DATE, or INTERVAL DAY TO SECOND.
- If the constant evaluates to an INTERVAL YEAR TO MONTH, the ORDER BY column type must be one of the following: TIMESTAMP, DATE, or INTERVAL YEAR TO MONTH.
- The [window order clause](#) can specify only one expression.

Examples

See [Window Framing](#) in Analyzing Data

Window Name Clause

Defines a named window that specifies window partition and order clauses for an analytic function. This window is specified in the function's OVER clause. Named windows can be useful when you write queries that invoke multiple analytic functions with similar OVER clauses—for example, they use the same partition (PARTITION BY) clauses.

Syntax

WINDOW *window-name* AS (*window-partition-clause* [*window-order-clause*])

Parameters

WINDOW <i>window-name</i>	Specifies the window name. All window names must be unique within the same query.
<i>window-partition-clause</i> [<i>window-order-clause</i>]	Clauses to invoke when an OVER clause references this window. If the window definition omits a window order clause , the OVER clause can specify its own order clause.

Requirements

- A WINDOW clause cannot include a [window frame clause](#).
- Each WINDOW clause within the same query must have a unique name.
- A WINDOW clause can reference another window that is already named. For example, the following query names window w1 before w2. Thus, the WINDOW clause that defines w2 can reference w1:

```
=> SELECT RANK() OVER(w1 ORDER BY sal DESC), RANK() OVER w2  
FROM EMP WINDOW w1 AS (PARTITION BY deptno), w2 AS (w1 ORDER BY sal);
```

Examples

See [Named Windows](#) in Analyzing Data.

See Also

[Analytic Functions](#)

AVG [Analytic]

Computes an average of an expression in a group within a window. AVG returns the same data type as the expression's numeric data type.

The AVG analytic function differs from the [AVG](#) aggregate function, which computes the average of an expression over a group of rows.

Behavior Type

Immutable

Syntax

```
AVG ( expression ) OVER (
... [ window-partition-clause ]
... [ window-order-clause ]
... [ window-frame-clause ] )
```

Parameters

<i>expression</i>	Any data that can be implicitly converted to a numeric data type.
OVER()	See Analytic Functions .

Overflow Handling

By default, Vertica allows silent numeric overflow when you call this function on numeric data types. For more information on this behavior and how to change it, see [Numeric Data Type Overflow with SUM, SUM_FLOAT, and AVG](#).

Examples

The following query finds the sales for that calendar month and returns a running/cumulative average (sometimes called a moving average) using the default window of RANGE UNBOUNDED PRECEDING AND CURRENT ROW:

```
=> SELECT calendar_month_number_in_year Mo, SUM(product_price) Sales,
        AVG(SUM(product_price)) OVER (ORDER BY calendar_month_number_in_year)::INTEGER Average
        FROM product_dimension pd, date_dimension dm, inventory_fact if
        WHERE dm.date_key = if.date_key AND pd.product_key = if.product_key GROUP BY Mo;
```

Mo	Sales	Average
1	23869547	23869547
2	19604661	21737104
3	22877913	22117374
4	22901263	22313346
5	23670676	22584812
6	22507600	22571943
7	21514089	22420821
8	24860684	22725804
9	21687795	22610470
10	23648921	22714315
11	21115910	22569005
12	24708317	22747281

(12 rows)

To return a moving average that is not a running (cumulative) average, the window can specify **ROWS BETWEEN 2 PRECEDING AND 2 FOLLOWING**:

```
=> SELECT calendar_month_number_in_year Mo, SUM(product_price) Sales,
        AVG(SUM(product_price)) OVER (ORDER BY calendar_month_number_in_year
        ROWS BETWEEN 2 PRECEDING AND 2 FOLLOWING)::INTEGER Average
        FROM product_dimension pd, date_dimension dm, inventory_fact if
        WHERE dm.date_key = if.date_key AND pd.product_key = if.product_key GROUP BY Mo;
```

Mo	Sales	Average
1	23869547	22117374
2	19604661	22313346
3	22877913	22584812
4	22901263	22312423
5	23670676	22694308
6	22507600	23090862
7	21514089	22848169
8	24860684	22843818
9	21687795	22565480
10	23648921	23204325
11	21115910	22790236
12	24708317	23157716

(12 rows)

BOOL_AND [Analytic]

Returns the Boolean value of an expression within a window. If all input values are true, BOOL_AND returns t. Otherwise, it returns f.

Behavior Type

Immutable

Syntax

```
BOOL_AND ( expression ) OVER (
... [ window-partition-clause ]
... [ window-order-clause ]
... [ window-frame-clause ] )
```

Parameters

<i>expression</i>	A Boolean Data Type or any non-Boolean data type that can be implicitly converted to a Boolean data type. The function returns a Boolean value.
OVER()	See Analytic Functions .

Examples

The following example illustrates how you can use the BOOL_AND, BOOL_OR, and BOOL_XOR analytic functions. The sample table, employee, includes a column for type of employee and years paid.

```
=> CREATE TABLE employee(emptytype VARCHAR, yearspaid VARCHAR);
CREATE TABLE
```

Insert sample data into the table to show years paid. In more than one case, an employee could be paid more than once within one year.

```
=> INSERT INTO employee
SELECT 'contractor1', '2014'
UNION ALL
SELECT 'contractor2', '2015'
```

```
UNION ALL
SELECT 'contractor3', '2014'
UNION ALL
SELECT 'contractor1', '2014'
UNION ALL
SELECT 'contractor2', '2014'
UNION ALL
SELECT 'contractor3', '2015'
UNION ALL
SELECT 'contractor4', '2014'
UNION ALL
SELECT 'contractor4', '2014'
UNION ALL
SELECT 'contractor5', '2015'
UNION ALL
SELECT 'contractor5', '2016';
OUTPUT
-----
      10
(1 row)
```

Query the table. The result shows employees that were paid twice in 2014 (BOOL_AND), once or twice in 2014 (BOOL_OR), and specifically not more than once in 2014 (BOOL_XOR).

```
=> SELECT DISTINCT emptype,
BOOL_AND(yearspaid='2014') OVER (PARTITION BY emptype) AS paidtwicein2014,
BOOL_OR(yearspaid='2014') OVER (PARTITION BY emptype) AS paidonceortwicein2014,
BOOL_XOR(yearspaid='2014') OVER (PARTITION BY emptype) AS paidjustoncein2014
FROM employee;
```

emptype	paidtwicein2014	paidonceortwicein2014	paidjustoncein2014
contractor1	t	t	f
contractor2	f	t	t
contractor3	f	t	t
contractor4	t	t	f
contractor5	f	f	f

(5 rows)

BOOL_OR [Analytic]

Returns the Boolean value of an expression within a window. If at least one input value is true, BOOL_OR returns t. Otherwise, it returns f.

Behavior Type

Immutable

Syntax

```
BOOL_OR ( expression ) OVER (  
... [ window-partition-clause ]  
... [ window-order-clause ]  
... [ window-frame-clause ] )
```

Parameters

<i>expression</i>	A Boolean Data Type or any non-Boolean data type that can be implicitly converted to a Boolean data type. The function returns a Boolean value.
OVER()	See Analytic Functions .

Examples

The following example illustrates how you can use the BOOL_AND, BOOL_OR, and BOOL_XOR analytic functions. The sample table, employee, includes a column for type of employee and years paid.

```
=> CREATE TABLE employee(emptytype VARCHAR, yearspaid VARCHAR);  
CREATE TABLE
```

Insert sample data into the table to show years paid. In more than one case, an employee could be paid more than once within one year.

```
=> INSERT INTO employee  
SELECT 'contractor1', '2014'  
UNION ALL  
SELECT 'contractor2', '2015'
```

```
UNION ALL
SELECT 'contractor3', '2014'
UNION ALL
SELECT 'contractor1', '2014'
UNION ALL
SELECT 'contractor2', '2014'
UNION ALL
SELECT 'contractor3', '2015'
UNION ALL
SELECT 'contractor4', '2014'
UNION ALL
SELECT 'contractor4', '2014'
UNION ALL
SELECT 'contractor5', '2015'
UNION ALL
SELECT 'contractor5', '2016';
OUTPUT
-----
      10
(1 row)
```

Query the table. The result shows employees that were paid twice in 2014 (BOOL_AND), once or twice in 2014 (BOOL_OR), and specifically not more than once in 2014 (BOOL_XOR).

```
=> SELECT DISTINCT emptype,
BOOL_AND(yearspaid='2014') OVER (PARTITION BY emptype) AS paidtwicein2014,
BOOL_OR(yearspaid='2014') OVER (PARTITION BY emptype) AS paidonceortwicein2014,
BOOL_XOR(yearspaid='2014') OVER (PARTITION BY emptype) AS paidjustoncein2014
FROM employee;
```

emptype	paidtwicein2014	paidonceortwicein2014	paidjustoncein2014
contractor1	t	t	f
contractor2	f	t	t
contractor3	f	t	t
contractor4	t	t	f
contractor5	f	f	f

(5 rows)

BOOL_XOR [Analytic]

Returns the Boolean value of an expression within a window. If only one input value is true, BOOL_XOR returns t. Otherwise, it returns f.

Behavior Type

Immutable

Syntax

```
BOOL_XOR ( expression ) OVER (
... [ window-partition-clause ]
... [ window-order-clause ]
... [ window-frame-clause ] )
```

Parameters

<i>expression</i>	A Boolean Data Type or any non-Boolean data type that can be implicitly converted to a Boolean data type. The function returns a Boolean value.
OVER()	See Analytic Functions .

Examples

The following example illustrates how you can use the BOOL_AND, BOOL_OR, and BOOL_XOR analytic functions. The sample table, employee, includes a column for type of employee and years paid.

```
=> CREATE TABLE employee(emptytype VARCHAR, yearspaid VARCHAR);
CREATE TABLE
```

Insert sample data into the table to show years paid. In more than one case, an employee could be paid more than once within one year.

```
=> INSERT INTO employee
SELECT 'contractor1', '2014'
UNION ALL
SELECT 'contractor2', '2015'
```

```
UNION ALL
SELECT 'contractor3', '2014'
UNION ALL
SELECT 'contractor1', '2014'
UNION ALL
SELECT 'contractor2', '2014'
UNION ALL
SELECT 'contractor3', '2015'
UNION ALL
SELECT 'contractor4', '2014'
UNION ALL
SELECT 'contractor4', '2014'
UNION ALL
SELECT 'contractor5', '2015'
UNION ALL
SELECT 'contractor5', '2016';
OUTPUT
-----
      10
(1 row)
```

Query the table. The result shows employees that were paid twice in 2014 (BOOL_AND), once or twice in 2014 (BOOL_OR), and specifically not more than once in 2014 (BOOL_XOR).

```
=> SELECT DISTINCT emptype,
BOOL_AND(yearspaid='2014') OVER (PARTITION BY emptype) AS paidtwicein2014,
BOOL_OR(yearspaid='2014') OVER (PARTITION BY emptype) AS paidonceortwicein2014,
BOOL_XOR(yearspaid='2014') OVER (PARTITION BY emptype) AS paidjustoncein2014
FROM employee;
```

emptype	paidtwicein2014	paidonceortwicein2014	paidjustoncein2014
contractor1	t	t	f
contractor2	f	t	t
contractor3	f	t	t
contractor4	t	t	f
contractor5	f	f	f

CONDITIONAL_CHANGE_EVENT [Analytic]

Assigns an event window number to each row, starting from 0, and increments by 1 when the result of evaluating the argument expression on the current row differs from that on the previous row.

Behavior Type

Immutable

Syntax

```
CONDITIONAL_CHANGE_EVENT ( expression ) OVER (
... [ window-partition-clause ]
... window-order-clause )
```

Parameters

<i>expression</i>	SQL scalar expression that is evaluated on an input record. The result of <i>expression</i> can be of any data type.
OVER()	See Analytic Functions .

Notes

The analytic *window-order-clause* is required but the *window-partition-clause* is optional.

Example

```
=> SELECT CONDITIONAL_CHANGE_EVENT(bid)
      OVER (PARTITION BY symbol ORDER BY ts) AS cce
FROM TickStore;
```

The system returns an error when no ORDER BY clause is present:

```
=> SELECT CONDITIONAL_CHANGE_EVENT(bid)
      OVER (PARTITION BY symbol) AS cce
   FROM TickStore;

ERROR: conditional_change_event must contain an
ORDER BY clause within its analytic clause
```

For more examples, see [Event-Based Windows](#) in Analyzing Data.

See Also

- [CONDITIONAL_TRUE_EVENT \[Analytic\]](#)
- [ROW_NUMBER \[Analytic\]](#)
- [Time Series Analytics](#)
- [Event-Based Windows](#)

CONDITIONAL_TRUE_EVENT [Analytic]

Assigns an event window number to each row, starting from 0, and increments the number by 1 when the result of the boolean argument expression evaluates true. For example, given a sequence of values for column *a*, as follows:

```
( 1, 2, 3, 4, 5, 6 )
```

`CONDITIONAL_TRUE_EVENT(a > 3)` returns 0, 0, 0, 1, 2, 3.

Behavior Type:

Immutable

Syntax

```
CONDITIONAL_TRUE_EVENT ( boolean-expression ) OVER
... ( [ window-partition-clause ]
... window-order-clause )
```

Parameters

<i>boolean-expression</i>	SQL scalar expression that is evaluated on an input record, type BOOLEAN.
OVER()	See Analytic Functions .

Notes

The analytic *window-order-clause* is required but the *window-partition-clause* is optional.

Example

```
> SELECT CONDITIONAL_TRUE_EVENT(bid > 10.6)
   OVER(PARTITION BY bid ORDER BY ts) AS cte
FROM Tickstore;
```

The system returns an error if the ORDER BY clause is omitted:

```
> SELECT CONDITIONAL_TRUE_EVENT(bid > 10.6)
   OVER(PARTITION BY bid) AS cte
FROM Tickstore;

ERROR: conditional_true_event must contain an ORDER BY
clause within its analytic clause
```

For more examples, see [Event-Based Windows](#) in Analyzing Data.

See Also

- [CONDITIONAL_CHANGE_EVENT \[Analytic\]](#)
- [Time Series Analytics](#)
- [Event-Based Windows](#)

COUNT [Analytic]

Counts occurrences within a group within a window. If you specify * or some non-null constant, COUNT() counts all rows.

Behavior Type

Immutable

Syntax

```
COUNT ( expression ) OVER (
... [ window-partition-clause ]
... [ window-order-clause ]
... [ window-frame-clause ] )
```

Parameters

<i>expression</i>	Returns the number of rows in each group for which the <i>expression</i> is not null. Can be any expression resulting in BIGINT.
OVER()	See Analytic Functions .

Example

Using the schema defined in [Window Framing](#) in Analyzing Data, the following COUNT function omits window order and window frame clauses; otherwise Vertica would treat it as a window aggregate. Think of the window of reporting aggregates as UNBOUNDED PRECEDING and UNBOUNDED FOLLOWING.

```
=> SELECT deptno, sal, empno, COUNT(sal)
      OVER (PARTITION BY deptno) AS count FROM emp;
```

```
deptno | sal | empno | count
-----+-----+-----+-----
    10 | 101 |     1 |     2
    10 | 104 |     4 |     2
    20 | 110 |    10 |     6
    20 | 110 |     9 |     6
    20 | 109 |     7 |     6
```

20	109	6	6
20	109	8	6
20	109	11	6
30	105	5	3
30	103	3	3
30	102	2	3

Using `ORDER BY sal` creates a moving window query with default window: `RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW`.

```
=> SELECT deptno, sal, empno, COUNT(sal)
      OVER (PARTITION BY deptno ORDER BY sal) AS count
      FROM emp;
```

deptno	sal	empno	count
10	101	1	1
10	104	4	2
20	100	11	1
20	109	7	4
20	109	6	4
20	109	8	4
20	110	10	6
20	110	9	6
30	102	2	1
30	103	3	2
30	105	5	3

Using the VMart schema, the following query finds the number of employees who make less than or equivalent to the hourly rate of the current employee. The query returns a running/cumulative average (sometimes called a moving average) using the default window of `RANGE UNBOUNDED PRECEDING AND CURRENT ROW`:

```
=> SELECT employee_last_name AS "last_name", hourly_rate, COUNT(*)
      OVER (ORDER BY hourly_rate) AS moving_count from employee_dimension;
```

last_name	hourly_rate	moving_count
Gauthier	6	4
Taylor	6	4
Jefferson	6	4
Nielson	6	4
McNulty	6.01	11
Robinson	6.01	11
Dobisz	6.01	11
Williams	6.01	11
Kramer	6.01	11
Miller	6.01	11
Wilson	6.01	11
Vogel	6.02	14
Moore	6.02	14
Vogel	6.02	14
Carcetti	6.03	19
...		

To return a moving average that is not also a running (cumulative) average, the window should specify `ROWS BETWEEN 2 PRECEDING AND 2 FOLLOWING`:

```
=> SELECT employee_last_name AS "last_name", hourly_rate, COUNT(*)  
       OVER (ORDER BY hourly_rate ROWS BETWEEN 2 PRECEDING AND 2 FOLLOWING)  
       AS moving_count from employee_dimension;
```

See Also

- [COUNT \[Aggregate\]](#)
- [AVG \[Analytic\]](#)
- [SUM \[Analytic\]](#)
- [SQL Analytics](#)

CUME_DIST [Analytic]

Calculates the cumulative distribution, or relative rank, of the current row with regard to other rows in the same partition within a window.

`CUME_DIST()` returns a number greater than 0 and less than or equal to 1, where the number represents the relative position of the specified row within a group of n rows. For a row x (assuming `ASC` ordering), the `CUME_DIST` of x is the number of rows with values lower than or equal to the value of x , divided by the number of rows in the partition. For example, in a group of three rows, the cumulative distribution values returned would be $1/3$, $2/3$, and $3/3$.

Note: Because the result for a given row depends on the number of rows preceding that row in the same partition, you should always specify a *window-order-clause* when you call this function.

Behavior Type

Immutable

Syntax

```
CUME_DIST ( ) OVER (  
... [ window-partition-clause ]  
... window-order-clause )
```

Parameters

OVER()	See Analytic Functions .
--------	--

Examples

The following example returns the cumulative distribution of sales for different transaction types within each month of the first quarter.

```
=> SELECT calendar_month_name AS month, tender_type, SUM(sales_quantity),
        CUME_DIST()
        OVER (PARTITION BY calendar_month_name ORDER BY SUM(sales_quantity)) AS
CUME_DIST
FROM store.store_sales_fact JOIN date_dimension
USING(date_key) WHERE calendar_month_name IN ('January','February','March')
AND tender_type NOT LIKE 'Other'
GROUP BY calendar_month_name, tender_type;
```

month	tender_type	SUM	CUME_DIST
March	Credit	469858	0.25
March	Cash	470449	0.5
March	Check	473033	0.75
March	Debit	475103	1
January	Cash	441730	0.25
January	Debit	443922	0.5
January	Check	446297	0.75
January	Credit	450994	1
February	Check	425665	0.25
February	Debit	426726	0.5
February	Credit	430010	0.75
February	Cash	430767	1

(12 rows)

- [PERCENT_RANK \[Analytic\]](#)
- [PERCENTILE_DISC \[Analytic\]](#)
- [SQL Analytics](#)

DENSE_RANK [Analytic]

Within each window partition, ranks all rows in the query results set according to the order specified by the window's `ORDER BY` clause. A `DENSE_RANK` function returns a sequence of ranking numbers without any gaps.

`DENSE_RANK` executes as follows:

1. Sorts partition rows as specified by the `ORDER BY` clause.
 2. Compares the `ORDER BY` values of the preceding row and current row and ranks the current row as follows:
 - If `ORDER BY` values are the same, the current row gets the same ranking as the preceding row.
- Note:** Null values are considered equal. For detailed information on how null values are sorted, see [NULL Sort Order](#).
- If the `ORDER BY` values are different, `DENSE_RANK` increments or decrements the current row's ranking by 1, depending whether sort order is ascending or descending.

`DENSE_RANK` always changes the ranking by 1, so no gaps appear in the ranking sequence. The largest rank value is the number of unique `ORDER BY` values returned by the query.

Behavior Type

Immutable

Syntax

```
DENSE_RANK() OVER(  
... [ window-partition-clause ]  
... window-order-clause )
```

Parameters

OVER()	See Analytic Functions .
--------	--

See [Analytic Functions](#)

Compared with RANK

RANK leaves gaps in the ranking sequence, while **DENSE_RANK** does not. The example below compares the behavior of the two functions.

Example

The following query invokes **RANK** and **DENSE_RANK** to rank customers by annual income. The two functions return different rankings, as follows:

- If `annual_salary` contains duplicate values, **RANK()** inserts duplicate rankings and then skips one or more values—for example, from 4 to 6 and 7 to 9.
- In the parallel column `Dense Rank`, **DENSE_RANK()** also inserts duplicate rankings, but leaves no gaps in the rankings sequence:

```
=> SELECT employee_region region, employee_key, annual_salary,
       RANK() OVER (PARTITION BY employee_region ORDER BY annual_salary) Rank,
       DENSE_RANK() OVER (PARTITION BY employee_region ORDER BY annual_salary) "Dense Rank"
FROM employee_dimension;
```

region	employee_key	annual_salary	Rank	Dense Rank
West	5248	1200	1	1
West	6880	1204	2	2
West	5700	1214	3	3
West	9857	1218	4	4
West	6014	1218	4	4
West	9221	1220	6	5
West	7646	1222	7	6
West	6621	1222	7	6
West	6488	1224	9	7
West	7659	1226	10	8
West	7432	1226	10	8

EXPONENTIAL_MOVING_AVERAGE [Analytic]

Calculates the exponential moving average (EMA) of expression E with smoothing factor X . An EMA differs from a simple moving average in that it provides a more stable picture of changes to data over time.

The EMA is calculated by adding the previous EMA value to the current data point scaled by the smoothing factor, as in the following formula:

$$EMA = EMA\theta + (X * (E - EMA\theta))$$

where:

- E is the current data point
- $EMA\theta$ is the previous row's EMA value.
- X is the smoothing factor.

This function also works at the row level. For example, EMA assumes the data in a given column is sampled at uniform intervals. If the users' data points are sampled at non-uniform intervals, they should run the time series [gap filling and interpolation \(GFI\)](#) operations before `EMA()`

Behavior Type

Immutable

Syntax

```
EXPONENTIAL_MOVING_AVERAGE (  $E$ ,  $X$  ) OVER (
... [ window-partition-clause ]
... window-order-clause )
```

Parameters

<i>E</i>	The value whose average is calculated over a set of rows. Can be INTEGER, FLOAT or NUMERIC type and must be a constant.
<i>X</i>	A positive FLOAT value between 0 and 1 that is used as the smoothing factor.
OVER ()	See Analytic Functions .

Examples

The following example uses time series [gap filling and interpolation](#) (GFI) first in a subquery, and then performs an EXPONENTIAL_MOVING_AVERAGE operation on the subquery result.

Create a simple four-column table:

```
=> CREATE TABLE ticker(  
    time TIMESTAMP,  
    symbol VARCHAR(8),  
    bid1 FLOAT,  
    bid2 FLOAT );
```

Insert some data, including nulls, so GFI can do its interpolation and gap filling:

```
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:00', 'ABC', 60.45, 60.44);  
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:01', 'ABC', 60.49, 65.12);  
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:02', 'ABC', 57.78, 59.25);  
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:03', 'ABC', null, 65.12);  
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:04', 'ABC', 67.88, null);  
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:00', 'XYZ', 47.55, 40.15);  
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:01', 'XYZ', 44.35, 46.78);  
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:02', 'XYZ', 71.56, 75.78);  
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:03', 'XYZ', 85.55, 70.21);  
=> INSERT INTO ticker VALUES ('2009-07-12 03:00:04', 'XYZ', 45.55, 58.65);  
=> COMMIT;
```

Note: During gap filling and interpolation, Vertica takes the closest non null value on either side of the time slice and uses that value. For example, if you use a linear interpolation scheme and you do not specify IGNORE NULLS, and your data has one real value and one null, the result is null. If the value on either side is null, the result is null. See [When Time Series Data Contains Nulls](#) in Analyzing Data for details.

Query the table that you just created to you can see the output:

```
=> SELECT * FROM ticker;
      time          | symbol | bid1 | bid2
-----+-----+-----+-----
2009-07-12 03:00:00 | ABC    | 60.45 | 60.44
2009-07-12 03:00:01 | ABC    | 60.49 | 65.12
2009-07-12 03:00:02 | ABC    | 57.78 | 59.25
2009-07-12 03:00:03 | ABC    |      | 65.12
2009-07-12 03:00:04 | ABC    | 67.88 |
2009-07-12 03:00:00 | XYZ    | 47.55 | 40.15
2009-07-12 03:00:01 | XYZ    | 44.35 | 46.78
2009-07-12 03:00:02 | XYZ    | 71.56 | 75.78
2009-07-12 03:00:03 | XYZ    | 85.55 | 70.21
2009-07-12 03:00:04 | XYZ    | 45.55 | 58.65
(10 rows)
```

The following query processes the first and last values that belong to each 2-second time slice in table `trades'` column `a`. The query then calculates the exponential moving average of expression `fv` and `lv` with a smoothing factor of 50%:

```
=> SELECT symbol, slice_time, fv, lv,
      EXPONENTIAL_MOVING_AVERAGE(fv, 0.5)
      OVER (PARTITION BY symbol ORDER BY slice_time) AS ema_first,
      EXPONENTIAL_MOVING_AVERAGE(lv, 0.5)
      OVER (PARTITION BY symbol ORDER BY slice_time) AS ema_last
FROM (
  SELECT symbol, slice_time,
         TS_FIRST_VALUE(bid1 IGNORE NULLS) as fv,
         TS_LAST_VALUE(bid2 IGNORE NULLS) AS lv
  FROM ticker TIMESERIES slice_time AS '2 seconds'
  OVER (PARTITION BY symbol ORDER BY time) ) AS sq;
```

```
symbol | slice_time          | fv   | lv   | ema_first | ema_last
-----+-----+-----+-----+-----+-----
ABC    | 2009-07-12 03:00:00 | 60.45 | 65.12 | 60.45    | 65.12
ABC    | 2009-07-12 03:00:02 | 57.78 | 65.12 | 59.115   | 65.12
ABC    | 2009-07-12 03:00:04 | 67.88 | 65.12 | 63.4975  | 65.12
XYZ    | 2009-07-12 03:00:00 | 47.55 | 46.78 | 47.55    | 46.78
XYZ    | 2009-07-12 03:00:02 | 71.56 | 70.21 | 59.555   | 58.495
XYZ    | 2009-07-12 03:00:04 | 45.55 | 58.65 | 52.5525  | 58.5725
(6 rows)
```

FIRST_VALUE [Analytic]

Lets you select the first value of a table or partition (determined by the *window-order-clause*) without having to use a self join. This function is useful when you want to use the first value as a baseline in calculations.

Use `FIRST_VALUE()` with the *window-order-clause* to produce deterministic results. If no window is specified for the current row, the default window is `UNBOUNDED PRECEDING AND CURRENT ROW`.

Behavior Type

Immutable

Syntax

```
FIRST_VALUE ( expression [ IGNORE NULLS ] ) OVER (
... [ window-partition-clause ]
... [ window-order-clause ]
... [ window-frame-clause ] )
```

Parameters

<i>expression</i>	Expression to evaluate—or example, a constant, column, nonanalytic function, function expression, or expressions involving any of these.
IGNORE NULLS	Specifies to return the first non-null value in the set, or NULL if all values are NULL. If you omit this option and the first value in the set is null, the function returns NULL.
OVER()	See Analytic Functions .

Examples

The following query asks for the first value in the partitioned day of week, and illustrates the potential nondeterministic nature of `FIRST_VALUE()`:

```
=> SELECT calendar_year, date_key, day_of_week, full_date_description,
       FIRST_VALUE(full_date_description)
       OVER(PARTITION BY calendar_month_number_in_year ORDER BY day_of_week)
       AS "first_value"
FROM date_dimension
WHERE calendar_year=2003 AND calendar_month_number_in_year=1;
```

The first value returned is January 31, 2003; however, the next time the same query is run, the first value might be January 24 or January 3, or the 10th or 17th. This is because the analytic `ORDER BY` column `day_of_week` returns rows that contain ties (multiple Fridays). These repeated values make the `ORDER BY` evaluation result nondeterministic, because rows that contain ties can be ordered in any way, and any one of those rows qualifies as being the first value of `day_of_week`.

calendar_year	date_key	day_of_week	full_date_description	first_value
2003	31	Friday	January 31, 2003	January 31, 2003
2003	24	Friday	January 24, 2003	January 31, 2003
2003	3	Friday	January 3, 2003	January 31, 2003
2003	10	Friday	January 10, 2003	January 31, 2003
2003	17	Friday	January 17, 2003	January 31, 2003
2003	6	Monday	January 6, 2003	January 31, 2003
2003	27	Monday	January 27, 2003	January 31, 2003
2003	13	Monday	January 13, 2003	January 31, 2003
2003	20	Monday	January 20, 2003	January 31, 2003
2003	11	Saturday	January 11, 2003	January 31, 2003
2003	18	Saturday	January 18, 2003	January 31, 2003
2003	25	Saturday	January 25, 2003	January 31, 2003
2003	4	Saturday	January 4, 2003	January 31, 2003
2003	12	Sunday	January 12, 2003	January 31, 2003
2003	26	Sunday	January 26, 2003	January 31, 2003
2003	5	Sunday	January 5, 2003	January 31, 2003
2003	19	Sunday	January 19, 2003	January 31, 2003
2003	23	Thursday	January 23, 2003	January 31, 2003
2003	2	Thursday	January 2, 2003	January 31, 2003
2003	9	Thursday	January 9, 2003	January 31, 2003
2003	16	Thursday	January 16, 2003	January 31, 2003
2003	30	Thursday	January 30, 2003	January 31, 2003
2003	21	Tuesday	January 21, 2003	January 31, 2003
2003	14	Tuesday	January 14, 2003	January 31, 2003
2003	7	Tuesday	January 7, 2003	January 31, 2003
2003	28	Tuesday	January 28, 2003	January 31, 2003
2003	22	Wednesday	January 22, 2003	January 31, 2003
2003	29	Wednesday	January 29, 2003	January 31, 2003
2003	15	Wednesday	January 15, 2003	January 31, 2003
2003	1	Wednesday	January 1, 2003	January 31, 2003
2003	8	Wednesday	January 8, 2003	January 31, 2003

(31 rows)

Note: The `day_of_week` results are returned in alphabetical order because of lexical rules. The fact that each day does not appear ordered by the 7-day week cycle (for example, starting with Sunday followed by Monday, Tuesday, and so on) has no affect on results.

To return deterministic results, modify the query so that it performs its analytic ORDER BY operations on a **unique** field, such as `date_key`:

```
=> SELECT calendar_year, date_key, day_of_week, full_date_description,
FIRST_VALUE(full_date_description) OVER
(PARTITION BY calendar_month_number_in_year ORDER BY date_key) AS "first_value"
FROM date_dimension WHERE calendar_year=2003;
```

`FIRST_VALUE()` returns a first value of January 1 for the January partition and the first value of February 1 for the February partition. Also, the `full_date_description` column contains no ties:

calendar_year	date_key	day_of_week	full_date_description	first_value
2003	1	Wednesday	January 1, 2003	January 1, 2003
2003	2	Thursday	January 2, 2003	January 1, 2003
2003	3	Friday	January 3, 2003	January 1, 2003
2003	4	Saturday	January 4, 2003	January 1, 2003
2003	5	Sunday	January 5, 2003	January 1, 2003
2003	6	Monday	January 6, 2003	January 1, 2003
2003	7	Tuesday	January 7, 2003	January 1, 2003
2003	8	Wednesday	January 8, 2003	January 1, 2003
2003	9	Thursday	January 9, 2003	January 1, 2003
2003	10	Friday	January 10, 2003	January 1, 2003

LAG [Analytic]

Returns the value of the input expression at the given offset before the current row within a window. This function lets you access more than one row in a table at the same time. This is useful for comparing values when the relative positions of rows can be reliably known. It also lets you avoid the more costly self join, which enhances query processing speed.

For information on getting the rows that follow, see [LEAD](#).

Behavior Type

Immutable

Syntax

```
LAG ( expression [, offset ] [, default ] ) OVER (
... [ window-partition-clause ]
... window-order-clause )
```

Parameters

<i>expression</i>	The expression to evaluate—for example, a constant, column, non-analytic function, function expression, or expressions involving any of these.
<i>offset</i>	Indicates how great is the lag. The default value is 1 (the previous row). This parameter must evaluate to a constant positive integer.
<i>default</i>	The value returned if <i>offset</i> falls outside the bounds of the table or partition. This value must be a constant value or an expression that can be evaluated to a constant; its data type is coercible to that of the first

	argument.
OVER()	See Analytic Functions

Examples

This example sums the current balance by date in a table and also sums the previous balance from the last day. Given the inputs that follow, the data satisfies the following conditions:

- For each `some_id`, there is exactly 1 row for each date represented by `month_date`.
- For each `some_id`, the set of dates is consecutive; that is, if there is a row for February 24 and a row for February 26, there would also be a row for February 25.
- Each `some_id` has the same set of dates.

```
=> CREATE TABLE balances (
    month_date DATE,
    current_bal INT,
    some_id INT);

=> INSERT INTO balances values ('2009-02-24', 10, 1);
=> INSERT INTO balances values ('2009-02-25', 10, 1);
=> INSERT INTO balances values ('2009-02-26', 10, 1);
=> INSERT INTO balances values ('2009-02-24', 20, 2);
=> INSERT INTO balances values ('2009-02-25', 20, 2);
=> INSERT INTO balances values ('2009-02-26', 20, 2);
=> INSERT INTO balances values ('2009-02-24', 30, 3);
=> INSERT INTO balances values ('2009-02-25', 20, 3);
=> INSERT INTO balances values ('2009-02-26', 30, 3);
```

Now run the `LAG()` function to sum the current balance for each date and sum the previous balance from the last day:

```
=> SELECT month_date,
    SUM(current_bal) as current_bal_sum,
    SUM(previous_bal) as previous_bal_sum FROM
    (SELECT month_date, current_bal,
    LAG(current_bal, 1, 0) OVER
    (PARTITION BY some_id ORDER BY month_date)
    AS previous_bal FROM balances) AS subQ
    GROUP BY month_date ORDER BY month_date;
month_date | current_bal_sum | previous_bal_sum
-----+-----+-----
2009-02-24 |          60 |           0
2009-02-25 |          50 |          60
2009-02-26 |          60 |          50
(3 rows)
```

Using the same example data, the following query would not be allowed because `LAG()` is nested inside an aggregate function:

```
=> SELECT month_date,
       SUM(current_bal) as current_bal_sum,
       SUM(LAG(current_bal, 1, 0) OVER
          (PARTITION BY some_id ORDER BY month_date)) AS previous_bal_sum
FROM some_table GROUP BY month_date ORDER BY month_date;
```

The following example uses the [VMart database](#). LAG first returns the annual income from the previous row, and then it calculates the difference between the income in the current row from the income in the previous row:

```
=> SELECT occupation, customer_key, customer_name, annual_income,
       LAG(annual_income, 1, 0) OVER (PARTITION BY occupation
          ORDER BY annual_income) AS prev_income, annual_income -
       LAG(annual_income, 1, 0) OVER (PARTITION BY occupation
          ORDER BY annual_income) AS difference
FROM customer_dimension ORDER BY occupation, customer_key LIMIT 20;
```

occupation	customer_key	customer_name	annual_income	prev_income	difference

LAST_VALUE [Analytic]

Lets you select the last value of a table or partition (determined by the *window-order-clause*) without having to use a self join. LAST_VALUE takes the last record from the partition after the window order clause. The function then computes the expression against the last record, and returns the results. This function is useful when you want to use the last value as a baseline in calculations.

Use LAST_VALUE () with the *window-order-clause* to produce deterministic results. If no window is specified for the current row, the default window is UNBOUNDED PRECEDING AND CURRENT ROW.

Tip: Due to default window semantics, LAST_VALUE does not always return the last value of a partition. If you omit *Window Frame Clause* from the analytic clause, LAST_VALUE operates on this default window. Although results can seem non-intuitive by not returning the bottom of the current partition, it returns the bottom of the window, which continues to change along with the current input row being processed. If you want to return the last value of a partition, use UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING. See examples below.

Behavior Type

Immutable

Syntax

```
LAST_VALUE ( expression [ IGNORE NULLS ] ) OVER (
... [ window-partition-clause ]
```

... [[window-order-clause](#)]
... [[window-frame-clause](#)])

Parameters

<i>expression</i>	Expression to evaluate—for example, a constant, column, nonanalytic function, function expression, or expressions involving any of these.
IGNORE NULLS	Specifies to return the last non-null value in the set, or NULL if all values are NULL. If you omit this option and the last value in the set is null, the function returns NULL.
OVER()	See Analytic Functions .

Example

Using the schema defined in [Window Framing](#) in Analyzing Data, the following query does not show the highest salary value by department; instead it shows the highest salary value by department by salary.

```
=> SELECT deptno, sal, empno, LAST_VALUE(sal)
      OVER (PARTITION BY deptno ORDER BY sal) AS lv
FROM emp;
deptno | sal | empno | lv
-----+-----+-----+-----
    10 | 101 |     1 | 101
    10 | 104 |     4 | 104
    20 | 100 |    11 | 100
    20 | 109 |     7 | 109
    20 | 109 |     6 | 109
    20 | 109 |     8 | 109
    20 | 110 |    10 | 110
    20 | 110 |     9 | 110
    30 | 102 |     2 | 102
    30 | 103 |     3 | 103
    30 | 105 |     5 | 105
```

If you include the window frame clause `ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING`, `LAST_VALUE()` returns the highest salary by department, an accurate representation of the information:

```
=> SELECT deptno, sal, empno, LAST_VALUE(sal)
      OVER (PARTITION BY deptno ORDER BY sal
            ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING) AS lv
FROM emp;
deptno | sal | empno | lv
-----+-----+-----+-----
```

10		101		1		104
10		104		4		104
20		100		11		110
20		109		7		110
20		109		6		110
20		109		8		110
20		110		10		110
20		110		9		110
30		102		2		105
30		103		3		105
30		105		5		105

For more examples, see [FIRST_VALUE\(\)](#).

- [TIME_SLICE](#)
- [SQL Analytics](#)

LEAD [Analytic]

Returns values from the row after the current row within a window, letting you access more than one row in a table at the same time. This is useful for comparing values when the relative positions of rows can be reliably known. It also lets you avoid the more costly self join, which enhances query processing speed.

Behavior Type

Immutable

Syntax

```
LEAD ( expression [, offset ] [, default ] ) OVER (
... [ window-partition-clause ]
... window-order-clause )
```

Parameters

<i>expression</i>	The expression to evaluate—for example, a constant, column, non-analytic function, function expression, or expressions involving any of these.
<i>offset</i>	Is an optional parameter that defaults to 1 (the next row). This parameter must evaluate to a constant positive integer.
<i>default</i>	The value returned if <i>offset</i> falls outside the bounds of the table or partition. This value must be a constant value or an expression that can be evaluated to a constant; its data type is coercible to that of the first argument.
OVER()	See Analytic Functions

Examples

LEAD finds the hire date of the employee hired just after the current row:

```
=> SELECT employee_region, hire_date, employee_key, employee_last_name,
       LEAD(hire_date, 1) OVER (PARTITION BY employee_region ORDER BY hire_date) AS "next_hired"
       FROM employee_dimension ORDER BY employee_region, hire_date, employee_key;
employee_region | hire_date | employee_key | employee_last_name | next_hired
-----+-----+-----+-----+-----
East            | 1956-04-08 | 9218 | Harris            | 1957-02-06
East            | 1957-02-06 | 7799 | Stein             | 1957-05-25
East            | 1957-05-25 | 3687 | Farmer            | 1957-06-26
East            | 1957-06-26 | 9474 | Bauer             | 1957-08-18
East            | 1957-08-18 | 570  | Jefferson         | 1957-08-24
East            | 1957-08-24 | 4363 | Wilson            | 1958-02-17
East            | 1958-02-17 | 6457 | McCabe            | 1958-06-26
East            | 1958-06-26 | 6196 | Li                 | 1958-07-16
East            | 1958-07-16 | 7749 | Harris            | 1958-09-18
East            | 1958-09-18 | 9678 | Sanchez           | 1958-11-10
(10 rows)
```

The next example uses LEAD and LAG to return the third row after the salary in the current row and fifth salary before the salary in the current row.

```
=> SELECT hire_date, employee_key, employee_last_name,
       LEAD(hire_date, 1) OVER (ORDER BY hire_date) AS "next_hired" ,
       LAG(hire_date, 1) OVER (ORDER BY hire_date) AS "last_hired"
       FROM employee_dimension ORDER BY hire_date, employee_key;
hire_date | employee_key | employee_last_name | next_hired | last_hired
-----+-----+-----+-----+-----
1956-04-11 | 2694 | Farmer            | 1956-05-12 |
1956-05-12 | 5486 | Winkler           | 1956-09-18 | 1956-04-11
```

```

1956-09-18 |      5525 | McCabe           | 1957-01-15 | 1956-05-12
1957-01-15 |       560 | Greenwood       | 1957-02-06 | 1956-09-18

1957-05-25 |      9506 | Webber          | 1957-07-04 | 1957-02-06
1957-07-04 |      6723 | Kramer          | 1957-07-07 | 1957-05-25
1957-07-07 |      5827 | Garnett         | 1957-11-11 | 1957-07-04
1957-11-11 |       373 | Reyes           | 1957-11-21 | 1957-07-07
1957-11-21 |      3874 | Martin          | 1958-02-06 | 1957-11-11
(10 rows)

```

The following example returns employee name and salary, along with the next highest and lowest salaries.

```

=> SELECT employee_last_name, annual_salary,
       NVL(LEAD(annual_salary) OVER (ORDER BY annual_salary),
          MIN(annual_salary) OVER()) "Next Highest",
       NVL(LAG(annual_salary) OVER (ORDER BY annual_salary),
          MAX(annual_salary) OVER()) "Next Lowest"
  FROM employee_dimension;
employee_last_name | annual_salary | Next Highest | Next Lowest
-----+-----+-----+-----
Nielson            |          1200 |          1200 |      995533
Lewis              |          1200 |          1200 |          1200
Harris             |          1200 |          1202 |          1200
Robinson           |          1202 |          1202 |          1200
Garnett            |          1202 |          1202 |          1202
Weaver             |          1202 |          1202 |          1202
Nielson            |          1202 |          1202 |          1202
McNulty            |          1202 |          1204 |          1202
Farmer             |          1204 |          1204 |          1202
Martin             |          1204 |          1204 |          1204
(10 rows)

```

The next example returns, for each assistant director in the employees table, the hire date of the director hired just after the director on the current row. For example, Jackson was hired on 2016-12-28, and the next director hired was Bauer:

```

=> SELECT employee_last_name, hire_date,
       LEAD(hire_date, 1) OVER (ORDER BY hire_date DESC) as "NextHired"
  FROM employee_dimension WHERE job_title = 'Assistant Director';
employee_last_name | hire_date | NextHired
-----+-----+-----
Jackson            | 2016-12-28 | 2016-12-26
Bauer              | 2016-12-26 | 2016-12-11
Miller             | 2016-12-11 | 2016-12-07
Fortin             | 2016-12-07 | 2016-11-27
Harris             | 2016-11-27 | 2016-11-15
Goldberg           | 2016-11-15 |
(5 rows)

```

- [LAG \[Analytic\]](#)
- [SQL Analytics](#)

MAX [Analytic]

Returns the maximum value of an expression within a window. The return value has the same type as the expression data type.

The analytic functions `MIN()` and `MAX()` can operate with Boolean values. The `MAX()` function acts upon a [Boolean Data Type](#) or a value that can be implicitly converted to a Boolean value. If at least one input value is true, `MAX()` returns `t` (true). Otherwise, it returns `f` (false). In the same scenario, the `MIN()` function returns `t` (true) if all input values are true. Otherwise, it returns `f`.

Behavior Type

Immutable

Syntax

```
MAX ( expression ) OVER (
... [ window-partition-clause ]
... [ window-order-clause ]
... [ window-frame-clause ] )
```

Parameters

<i>expression</i>	Any expression for which the maximum value is calculated, typically a column reference .
OVER()	See Analytic Functions .

Examples

The following query computes the deviation between the employees' annual salary and the maximum annual salary in Massachusetts:

```
=> SELECT employee_state, annual_salary,
       MAX(annual_salary)
       OVER(PARTITION BY employee_state ORDER BY employee_key) max,
       annual_salary- MAX(annual_salary)
       OVER(PARTITION BY employee_state ORDER BY employee_key) diff
FROM employee_dimension
WHERE employee_state = 'MA';
```

employee_state	annual_salary	max	diff
MA	1918	995533	-993615
MA	2058	995533	-993475
MA	2586	995533	-992947
MA	2500	995533	-993033
MA	1318	995533	-994215
MA	2072	995533	-993461
MA	2656	995533	-992877
MA	2148	995533	-993385
MA	2366	995533	-993167
MA	2664	995533	-992869

(10 rows)

The following example shows you the difference between the MIN and MAX analytic functions when you use them with a Boolean value. The sample creates a table with two columns, adds two rows of data, and shows sample output for MIN and MAX.

```
CREATE TABLE min_max_functions (emp VARCHAR, torf BOOL);

INSERT INTO min_max_functions VALUES ('emp1', 1);
INSERT INTO min_max_functions VALUES ('emp1', 0);

SELECT DISTINCT emp,
min(torf) OVER (PARTITION BY emp) AS worksasbooleanand,
Max(torf) OVER (PARTITION BY emp) AS worksasbooleanor
FROM min_max_functions;
```

emp	worksasbooleanand	worksasbooleanor
emp1	f	t

(1 row)

See Also

- [SQL Analytics](#)
- [MAX \[Aggregate\]](#)
- [MIN \[Analytic\]](#)

MEDIAN [Analytic]

For each row, returns the median value of a value set within each partition. MEDIAN determines the argument with the highest numeric precedence, implicitly converts the remaining arguments to that data type, and returns that data type.

MEDIAN is an alias of [PERCENTILE_CONT \[Analytic\]](#) with an argument of 0.5 (50%).

Behavior Type

Immutable

Syntax

```
MEDIAN ( expression ) OVER ( [ window-partition-clause ] )
```

Parameters

<i>expression</i>	Any NUMERIC data type or any non-numeric data type that can be implicitly converted to a numeric data type. The function returns the middle value or an interpolated value that would be the middle value once the values are sorted. Null values are ignored in the calculation.
OVER()	If the OVER clause specifies <i>window-partition-clause</i> , MEDIAN groups input rows according to one or more columns or expressions. If this clause is omitted, no grouping occurs and MEDIAN processes all input rows as a single partition.

Examples

See [Calculating a Median Value](#)

See Also

- [PERCENTILE_CONT \[Analytic\]](#)
- [SQL Analytics](#)

MIN [Analytic]

Returns the minimum value of an expression within a window. The return value has the same type as the expression data type.

The analytic functions `MIN()` and `MAX()` can operate with Boolean values. The `MAX()` function acts upon a [Boolean Data Type](#) or a value that can be implicitly converted to a Boolean value. If at least one input value is true, `MAX()` returns t (true). Otherwise, it returns f (false). In the same scenario, the `MIN()` function returns t (true) if all input values are true. Otherwise, it returns f.

Behavior Type

Immutable

Syntax

```
MAX ( expression ) OVER (
... [ window-partition-clause ]
... [ window-order-clause ]
... [ window-frame-clause ] )
```

Parameters

<i>expression</i>	Any expression for which the minimum value is calculated, typically a column reference .
OVER()	See Analytic Functions .

Examples

The following example shows how you can query to determine the deviation between the employees' annual salary and the minimum annual salary in Massachusetts:

```
=> SELECT employee_state, annual_salary,
        MIN(annual_salary)
        OVER(PARTITION BY employee_state ORDER BY employee_key) min,
        annual_salary - MIN(annual_salary)
        OVER(PARTITION BY employee_state ORDER BY employee_key) diff
FROM employee_dimension
WHERE employee_state = 'MA';
```

employee_state	annual_salary	min	diff
MA	1918	1204	714
MA	2058	1204	854
MA	2586	1204	1382
MA	2500	1204	1296
MA	1318	1204	114
MA	2072	1204	868
MA	2656	1204	1452
MA	2148	1204	944
MA	2366	1204	1162
MA	2664	1204	1460

(10 rows)

The following example shows you the difference between the MIN and MAX analytic functions when you use them with a Boolean value. The sample creates a table with two columns, adds two rows of data, and shows sample output for MIN and MAX.

```
CREATE TABLE min_max_functions (emp VARCHAR, torf BOOL);

INSERT INTO min_max_functions VALUES ('emp1', 1);
INSERT INTO min_max_functions VALUES ('emp1', 0);

SELECT DISTINCT emp,
min(torf) OVER (PARTITION BY emp) AS worksasbooleanand,
Max(torf) OVER (PARTITION BY emp) AS worksasbooleanor
FROM min_max_functions;
```

emp	worksasbooleanand	worksasbooleanor
emp1	f	t

(1 row)

- [MAX \[Analytic\]](#)

NTILE [Analytic]

Equally divides an ordered data set (partition) into a *{value}* number of subsets within a window, where the subsets are numbered 1 through the value in parameter *constant-value*. For example, if *constant-value*= 4 and the partition contains 20 rows, NTILE divides the partition rows into four equal subsets of five rows. NTILE assigns each row to a subset by giving row a number from 1 to 4. The rows in the first subset are assigned 1, the next five are assigned 2, and so on.

If the number of partition rows is not evenly divisible by the number of subsets, the rows are distributed so no subset is more than one row larger than any other subset, and the lowest subsets have extra rows. For example, if *constant-value*= 4 and the number of rows = 21, the first subset has six rows, the second subset has five rows, and so on.

If the number of subsets is greater than the number of rows, then a number of subsets equal to the number of rows is filled, and the remaining subsets are empty.

Behavior Type

Immutable

Syntax

```
NTILE ( constant-value ) OVER (
... [ window-partition-clause ]
... window-order-clause )
```

Parameters

<i>constant-value</i>	Specifies the number of subsets , where <i>constant-value</i> must
-----------------------	--

	resolve to a positive constant for each partition.
OVER()	See Analytic Functions .

Examples

The following query assigns each month's sales total into one of four subsets:

```
=> SELECT calendar_month_name AS MONTH, SUM(sales_quantity),
        NTILE(4) OVER (ORDER BY SUM(sales_quantity)) AS NTILE
FROM store.store_sales_fact JOIN date_dimension
USING(date_key)
GROUP BY calendar_month_name
ORDER BY NTILE;
MONTH | SUM | NTILE
-----+-----+-----
November | 2040726 | 1
June | 2088528 | 1
February | 2134708 | 1
April | 2181767 | 2
January | 2229220 | 2
October | 2316363 | 2
September | 2323914 | 3
March | 2354409 | 3
August | 2387017 | 3
July | 2417239 | 4
May | 2492182 | 4
December | 2531842 | 4
(12 rows)
```

See Also

- [PERCENTILE_CONT \[Analytic\]](#)
- [WIDTH_BUCKET](#)
- [SQL Analytics](#)

NTH_VALUE [Analytic]

Returns the value evaluated at the row that is the *n*th row of the window (counting from 1). If the specified row does not exist, NTH_VALUE returns NULL.

Behavior Type

Immutable

Syntax

```
NTH_VALUE ( expression, row-number [ IGNORE NULLS ] ) OVER (
... [ window-frame-clause ]
... [ Window Order Cause ]
... [ window-frame-clause ] )
```

Parameters

<i>expression</i>	Expression to evaluate. The expression can be a constant, column name, nonanalytic function, function expression, or expressions that include any of these.
<i>row-number</i>	Specifies the row to evaluate, where <i>row-number</i> evaluates to an integer ≥ 1 .
IGNORE NULLS	Specifies to return the first non-NULL value in the set, or NULL if all values are NULL.
OVER()	See Analytic Functions .

Example

In the following example, for each tuple (current row) in table t1, the window frame clause defines the window as follows:

```
ORDER BY b ROWS BETWEEN 3 PRECEDING AND CURRENT ROW
```

For each window, n for n th value is $a+1$. a is the value of column a in the tuple.

NTH_VALUE returns the result of the expression $b+1$, where b is the value of column b in the n th row, which is the $a+1$ row within the window.

```
=> SELECT * FROM t1 ORDER BY a;
 a | b
---+---
 1 | 10
 2 | 20
```

```
2 | 21
3 | 30
4 | 40
5 | 50
6 | 60
(7 rows)

=> SELECT NTH_VALUE(b+1, a+1) OVER
      (ORDER BY b ROWS BETWEEN 3 PRECEDING AND CURRENT ROW) FROM t1;
?column?
-----
      22
      31

(7 rows)
```

PERCENT_RANK [Analytic]

Calculates the relative rank of a row for a given row in a group within a window by dividing that row's rank less 1 by the number of rows in the partition, also less 1. `PERCENT_RANK` always returns values from 0 to 1 inclusive. The first row in any set has a `PERCENT_RANK` of 0. The return value is `NUMBER`.

$$(\text{rank} - 1) / ([\text{rows}] - 1)$$

In the preceding formula, `rank` is the rank position of a row in the group and `rows` is the total number of rows in the partition defined by the `OVER()` clause.

Behavior Type

Immutable

Syntax

```
PERCENT_RANK ( ) OVER (
... [ window-partition-clause ]
... window-order-clause )
```

Parameters

OVER()	See Analytic Functions
--------	--

Examples

The following example finds the percent rank of gross profit for different states within each month of the first quarter:

```
=> SELECT calendar_month_name AS MONTH, store_state,
        SUM(gross_profit_dollar_amount),
        PERCENT_RANK() OVER (PARTITION BY calendar_month_name
        ORDER BY SUM(gross_profit_dollar_amount)) AS PERCENT_RANK
FROM store.store_sales_fact JOIN date_dimension
USING(date_key)
JOIN store.store_dimension
USING (store_key)
WHERE calendar_month_name IN ('January','February','March')
AND store_state IN ('OR','IA','DC','NV','WI')
GROUP BY calendar_month_name, store_state
ORDER BY calendar_month_name, PERCENT_RANK;
```

MONTH	store_state	SUM	PERCENT_RANK
February	IA	418490	0
February	OR	460588	0.25
February	DC	616553	0.5
February	WI	619204	0.75
February	NV	838039	1
January	OR	446528	0
January	IA	474501	0.25
January	DC	628496	0.5
January	WI	679382	0.75
January	NV	871824	1
March	IA	460282	0
March	OR	481935	0.25
March	DC	716063	0.5
March	WI	771575	0.75
March	NV	970878	1

(15 rows)

The following example calculates, for each employee, the percent rank of the employee's salary by their job title:

```
=> SELECT job_title, employee_last_name, annual_salary,
        PERCENT_RANK()
        OVER (PARTITION BY job_title ORDER BY annual_salary DESC) AS percent_rank
FROM employee_dimension
ORDER BY percent_rank, annual_salary;
```

job_title	employee_last_name	annual_salary	percent_rank
-----------	--------------------	---------------	--------------

PERCENTILE_CONT [Analytic]

An inverse distribution function where, for each row, PERCENTILE_CONT returns the value that would fall into the specified percentile among a set of values in each partition within a window. For example, if the argument to the function is 0.5, the result of the function is the median of the data set (50th percentile). PERCENTILE_CONT assumes a continuous distribution data model. NULL values are ignored.

PERCENTILE_CONT computes the percentile by first computing the row number where the percentile row would exist. For example:

$$row-number = 1 + percentile-value * (num-partition-rows - 1)$$

If *row-number* is a whole number (within an error of 0.00001), the percentile is the value of row *row-number*.

Otherwise, Vertica interpolates the percentile value between the value of the CEILING (*row-number*) row and the value of the FLOOR(*row-number*) row. In other words, the percentile is calculated as follows:

$$\begin{aligned} & (\text{CEILING}(row-number) - row-number) * (\text{Value of FLOOR}(row-number) row) \\ & + (row-number - \text{FLOOR}(row-number)) * (\text{Value of CEILING}(row-number) row) \end{aligned}$$

Note: If the percentile value is 0.5, PERCENTILE_CONT returns the same result set as the function [MEDIAN](#).

Behavior Type

Immutable

Syntax

```
PERCENTILE_CONT ( percentile ) WITHIN GROUP ( ORDER BY expression [ ASC | DESC ] ) OVER (
... [ window-partition-clause ] )
```

Parameters

<i>percentile</i>	Percentile value, a FLOAT constant that ranges from 0 to 1 (inclusive).
WITHIN GROUP (ORDER BY <i>expression</i>)	Specifies how to sort data within each group. ORDER BY takes only one column/expression that must be INTEGER, FLOAT, INTERVAL, or NUMERIC data type. NULL values are discarded. The WITHIN GROUP (ORDER BY) clause does not guarantee the order of the SQL result. To order the final result, use the SQL ORDER BY clause set.
ASC DESC	Specifies the ordering sequence as ascending (default) or descending. Specifying ASC or DESC in the WITHIN GROUP clause affects results as long as the <i>percentile</i> is not 0.5.
OVER()	See Analytic Functions

Examples

This query computes the median annual income per group for the first 300 customers in Wisconsin and the District of Columbia.

```
=> SELECT customer_state, customer_key, annual_income,  
        PERCENTILE_CONT(0.5) WITHIN GROUP(ORDER BY annual_income)  
        OVER (PARTITION BY customer_state) AS PERCENTILE_CONT  
FROM customer_dimension  
WHERE customer_state IN ('DC','WI')  
AND customer_key < 300  
ORDER BY customer_state, customer_key;  
customer_state | customer_key | annual_income | PERCENTILE_CONT  
-----+-----+-----+-----  
DC              |          52 |       168312 |          483266.5  
DC              |          118 |       798221 |          483266.5  
WI              |           62 |       283043 |          377691  
WI              |          139 |       472339 |          377691  
(4 rows)
```

- [SQL Analytics](#)

PERCENTILE_DISC [Analytic]

An inverse distribution function where, for each row, `PERCENTILE_DISC` returns the value that would fall into the specified percentile among a set of values in each partition within a window. `PERCENTILE_DISC()` assumes a discrete distribution data model. `NULL` values are ignored.

`PERCENTILE_DISC` examines the cumulative distribution values in each group until it finds one that is greater than or equal to the specified percentile. Vertica computes the percentile where, for each row, `PERCENTILE_DISC` outputs the first value of the `WITHIN GROUP (ORDER BY)` column whose `CUME_DIST` (cumulative distribution) value is \geq the argument `FLOAT` value—for example, `0.4`:

```
PERCENTILE_DIST(0.4) WITHIN GROUP (ORDER BY salary) OVER(PARTITION BY deptno)...
```

Given the following query:

```
SELECT CUME_DIST() OVER(ORDER BY salary) FROM table-name;
```

The smallest CUME_DIST value that is greater than 0.4 is also the PERCENTILE_DISC.

Behavior Type

Immutable

Syntax

```
PERCENTILE_DISC ( percentile ) WITHIN GROUP (
... ORDER BY expression [ ASC | DESC ] ) OVER (
... [ window-partition-clause ] )
```

Parameters

<i>percentile</i>	Percentile value, a FLOAT constant that ranges from 0 to 1 (inclusive).
WITHIN GROUP (ORDER BY <i>expression</i>)	Specifies how to sort data within each group. ORDER BY takes only one column/expression that must be INTEGER, FLOAT, INTERVAL, or NUMERIC data type. NULL values are discarded. The WITHIN GROUP (ORDER BY) clause does not guarantee the order of the SQL result. To order the final result, use the SQL ORDER BY clause set.
ASC DESC	Specifies the ordering sequence as ascending (default) or descending.
OVER()	See Analytic Functions

Example

This query computes the 20th percentile annual income by group for first 300 customers in Wisconsin and the District of Columbia.

```
=> SELECT customer_state, customer_key, annual_income,
        PERCENTILE_DISC(.2) WITHIN GROUP(ORDER BY annual_income)
        OVER (PARTITION BY customer_state) AS PERCENTILE_DISC
FROM customer_dimension
WHERE customer_state IN ('DC','WI')
AND customer_key < 300
ORDER BY customer_state, customer_key;
customer_state | customer_key | annual_income | PERCENTILE_DISC
-----+-----+-----+-----
DC              |          104 |      658383   |          417092
```

DC		168		417092		417092
DC		245		670205		417092
WI		106		227279		227279
WI		127		703889		227279
WI		209		458607		227279

RANK [Analytic]

Within each window partition, ranks all rows in the query results set according to the order specified by the window's `ORDER BY` clause.

RANK executes as follows:

1. Sorts partition rows as specified by the `ORDER BY` clause.
2. Compares the `ORDER BY` values of the preceding row and current row and ranks the current row as follows:
 - If `ORDER BY` values are the same, the current row gets the same ranking as the preceding row.

Note: Null values are considered equal. For detailed information on how null values are sorted, see [NULL Sort Order](#).
 - If the `ORDER BY` values are different, `DENSE_RANK` increments or decrements the current row's ranking by 1, plus the number of consecutive duplicate values in the rows that precede it.

The largest rank value is the equal to the total number of rows returned by the query.

Behavior Type

Immutable

Syntax

```
RANK() OVER(  
... [ window-partition-clause ]  
... window-order-clause )
```

Parameters

OVER()	See Analytic Functions
--------	--

Compared with DENSE_RANK

RANK can leave gaps in the ranking sequence, while DENSE_RANK does not. For more information, see [DENSE_RANK](#).

Examples

The following query ranks by state all company customers that have been customers since 2007. In rows where the `customer_since` dates are the same, RANK assigns the rows equal ranking. When the `customer_since` date changes, RANK skips one or more rankings—for example, within CA, from 12 to 14, and from 17 to 19.

```
=> SELECT customer_state, customer_name, customer_since,  
       RANK() OVER (PARTITION BY customer_state ORDER BY customer_since) AS rank  
   FROM customer_dimension WHERE customer_type='Company' AND customer_since > '01/01/2007'  
   ORDER BY customer_state;  
customer_state | customer_name | customer_since | rank

[SQL Analytics](#)

ROW_NUMBER [Analytic]

Assigns a sequence of unique numbers, starting from 1, to each row in a window partition. Use the optional window partition clause to group data into partitions before operating on it. For example:

```
SUM OVER (PARTITION BY col1, col2, ...)
```

Notes:

- ROW_NUMBER() is a Vertica extension, not part of the SQL-99 standard.
- ROW_NUMBER and RANK are generally interchangeable. ROW_NUMBER differs from RANK in that it assigns a unique ordinal number to each row in the ordered set, starting with 1.

Behavior Type

Immutable

Syntax

```
ROW_NUMBER ( ) OVER (  
... [ window-partition-clause ]  
... window-order-clause )
```

Parameters

OVER()	See Analytic Functions
--------	--

Examples

The following query partitions customers in the VMart table `customer_dimension` by occupation. It then ranks those customers according to the ordered set specified by the window partition clause.

```
=> SELECT occupation, customer_key, customer_since, annual_income,
       ROW_NUMBER() OVER (PARTITION BY occupation) AS customer_since_row_num
FROM public.customer_dimension
ORDER BY occupation, customer_since_row_num;
```

- [RANK \[Analytic\]](#)
- [SQL Analytics](#)

STDDEV [Analytic]

Computes the statistical sample standard deviation of the current row with respect to the group within a window. `STDDEV_SAMP` returns the same value as the square root of the variance defined for the `VAR_SAMP` function:

```
STDDEV( expression ) = SQRT(VAR_SAMP( expression ))
```

When `VAR_SAMP` returns NULL, this function returns NULL.

Note: The nonstandard function `STDDEV` is provided for compatibility with other databases. It is semantically identical to `STDDEV_SAMP`.

Behavior Type

Immutable

Syntax

```
STDDEV ( expression ) OVER (
... [ window-partition-clause ]
... [ window-order-clause ]
... [ window-frame-clause ] )
```

Parameters

<i>expression</i>	Any NUMERIC data type or any non-numeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument.
OVER()	See Analytic Functions

Example

The following example returns the standard deviations of salaries in the employee dimension table by job title Assistant Director:

```
=> SELECT employee_last_name, annual_salary,
        STDDEV(annual_salary) OVER (ORDER BY hire_date) as "stddev"
   FROM employee_dimension
  WHERE job_title = 'Assistant Director';
employee_last_name | annual_salary |      stddev
-----+-----+-----
Bauer              |      85003   |          NaN

STDDEV_POP [Analytic]

Computes the statistical population standard deviation and returns the square root of the population variance within a window. The `STDDEV_POP()` return value is the same as the square root of the `VAR_POP()` function:

```
STDDEV_POP( expression ) = SQRT(VAR_POP( expression ))
```

When `VAR_POP` returns null, `STDDEV_POP` returns null.

Behavior Type

Immutable

Syntax

```
STDDEV_POP ( expression ) OVER (
... [ window-partition-clause ]
... [ window-order-clause ]
... [ window-frame-clause ] )
```

Parameters

<i>expression</i>	Any NUMERIC data type or any non-numeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument.
OVER()	See Analytic Functions .

Examples

The following example returns the population standard deviations of salaries in the employee dimension table by job title Assistant Director:

```
=> SELECT employee_last_name, annual_salary,
        STDDEV_POP(annual_salary) OVER (ORDER BY hire_date) as "stddev_pop"
   FROM employee_dimension WHERE job_title = 'Assistant Director';
employee_last_name | annual_salary | stddev_pop
-----+-----+-----
Goldberg           |          61859 |           0
Miller             |          79582 |          8861.5

STDDEV_SAMP [Analytic]

Computes the statistical sample standard deviation of the current row with respect to the group within a window. `STDDEV_SAMP`'s return value is the same as the square root of the variance defined for the `VAR_SAMP` function:

```
STDDEV( expression ) = SQRT(VAR_SAMP( expression ))
```

When `VAR_SAMP` returns NULL, `STDDEV_SAMP` returns NULL.

Note: `STDDEV_SAMP()` is semantically identical to the nonstandard function, `STDDEV()`.

Behavior Type

Immutable

Syntax

```
STDDEV_SAMP ( expression ) OVER (
... [ window-partition-clause ]
... [ window-order-clause ]
... [ window-frame-clause ] )
```

Parameters

<i>expression</i>	Any NUMERIC data type or any non-numeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument..
OVER()	See Analytic Functions

Examples

The following example returns the sample standard deviations of salaries in the employee dimension table by job title Assistant Director:

```
=> SELECT employee_last_name, annual_salary,  
        STDDEV(annual_salary) OVER (ORDER BY hire_date) as "stddev_samp"  
FROM employee_dimension WHERE job_title = 'Assistant Director';  
employee_last_name | annual_salary | stddev_samp
```

employee_last_name	annual_salary	stddev_samp
Bauer	85003	NaN
Reyes	91051	4276.58181261624

- [STDDEV_SAMP \[Aggregate\]](#)
- [SQL Analytics](#)

SUM [Analytic]

Computes the sum of an expression over a group of rows within a window. It returns a DOUBLE PRECISION value for a floating-point expression. Otherwise, the return value is the same as the expression data type.

Behavior Type

Immutable

Syntax

```
SUM ( expression ) OVER (
... [ window-partition-clause ]
... [ window-order-clause ]
... [ window-frame-clause ] )
```

Parameters

<i>expression</i>	Any NUMERIC data type or any non-numeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument.
OVER()	See Analytic Functions

Overflow Handling

If you encounter data overflow when using SUM, use [SUM_FLOAT](#) which converts data to a floating point. By default, Vertica allows silent numeric overflow when you call this function on numeric data types. For more information on this behavior and how to change it, see [Numeric Data Type Overflow with SUM, SUM_FLOAT, and AVG](#).

Examples

The following query returns the cumulative sum all of the returns made to stores in January:

```
=> SELECT calendar_month_name AS month, transaction_type, sales_quantity,
SUM(sales_quantity)
OVER (PARTITION BY calendar_month_name ORDER BY date_dimension.date_key) AS SUM
FROM store.store_sales_fact JOIN date_dimension
USING(date_key) WHERE calendar_month_name IN ('January')
AND transaction_type= 'return';
 month | transaction_type | sales_quantity | SUM
-----+-----+-----+-----
January | return           |                | 7 | 651
January | return           |                | 3 | 651
```

January		return		7		651
January		return		7		651
January		return		7		651
January		return		3		651
January		return		7		651
January		return		5		651
January		return		1		651
January		return		6		651
January		return		6		651
January		return		3		651

VAR_POP [Analytic]

Returns the statistical population variance of a non-null set of numbers (nulls are ignored) in a group within a window. Results are calculated by the sum of squares of the difference of *expression* from the mean of *expression*, divided by the number of rows remaining:

```
(SUM( expression * expression ) - SUM( expression ) * SUM( expression ) / COUNT( expression )) /  
COUNT( expression )
```

Behavior Type

Immutable

Syntax

```
VAR_POP ( expression ) OVER (  
... [ window-partition-clause ]  
... [ window-order-clause ]  
... [ window-frame-clause ] )
```

Parameters

<i>expression</i>	Any NUMERIC data type or any non-numeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument
OVER()	See Analytic Functions

Examples

The following example calculates the cumulative population in the store orders fact table of sales in January 2007:

```
=> SELECT date_ordered,  
        VAR_POP(SUM(total_order_cost))  
        OVER (ORDER BY date_ordered) "var_pop"  
FROM store.store_orders_fact s  
WHERE date_ordered BETWEEN '2007-01-01' AND '2007-01-31'  
GROUP BY s.date_ordered;  
date_ordered |      var_pop  
-----+-----  
2007-01-01 |          0  
2007-01-02 |      89870400  
2007-01-03 |     3470302472  
2007-01-04 |    4466755450.6875  
2007-01-05 |    3816904780.80078  
2007-01-06 |     25438212385.25  
2007-01-07 |    22168747513.1016  
2007-01-08 |    23445191012.7344  
2007-01-09 |    39292879603.1113  
2007-01-10 |    48080574326.9609  
(10 rows)
```

VAR_SAMP [Analytic]

Returns the sample variance of a non-NULL set of numbers (NULL values in the set are ignored) for each row of the group within a window. Results are calculated as follows:

```
(SUM( expression * expression ) - SUM( expression ) * SUM( expression ) / COUNT( expression ) )  
/ (COUNT( expression ) - 1 )
```

This function and [VARIANCE](#) differ in one way: given an input set of one element, VARIANCE returns 0 and VAR_SAMP returns NULL.

Behavior Type

Immutable

Syntax

```
VAR_SAMP ( expression ) OVER (  
... [ window-partition-clause ]  
... [ window-order-clause ]  
... [ window-frame-clause ] )
```

Parameters

<i>expression</i>	Any NUMERIC data type or any non-numeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument
OVER()	See Analytic Functions

Null Handling

- VAR_SAMP returns the sample variance of a set of numbers after it discards the NULL values in the set.
- If the function is applied to an empty set, then it returns NULL.

Examples

The following example calculates the sample variance in the store orders fact table of sales in December 2007:

```
=> SELECT date_ordered,
         VAR_SAMP(SUM(total_order_cost))
         OVER (ORDER BY date_ordered) "var_samp"
FROM store.store_orders_fact s
WHERE date_ordered BETWEEN '2007-12-01' AND '2007-12-31'
GROUP BY s.date_ordered;
```

date_ordered	var_samp
2007-12-01	NaN
2007-12-02	90642601088
2007-12-03	48030548449.3359
2007-12-04	32740062504.2461
2007-12-05	32100319112.6992
2007-12-06	26274166814.668
2007-12-07	23017490251.9062
2007-12-08	21099374085.1406
2007-12-09	27462205977.9453
2007-12-10	26288687564.1758

(10 rows)

- [VAR_SAMP \[Aggregate\]](#)
- [SQL Analytics](#)

VARIANCE [Analytic]

Returns the sample variance of a non-NULL set of numbers (NULL values in the set are ignored) for each row of the group within a window. Results are calculated as follows:

```
( SUM( expression * expression ) - SUM( expression ) * SUM( expression ) / COUNT( expression ) ) /  
(COUNT( expression ) - 1 )
```

VARIANCE returns the variance of *expression*, which is calculated as follows:

- 0 if the number of rows in *expression* = 1
- [VAR_SAMP](#) if the number of rows in *expression* > 1

Note: The nonstandard function VARIANCE is provided for compatibility with other databases. It is semantically identical to [VAR_SAMP](#).

Behavior Type

Immutable

Syntax

```
VAR_SAMP ( expression ) OVER (  
... [ window-partition-clause ]  
... [ window-order-clause ]  
... [ window-frame-clause ] )
```

Parameters

<i>expression</i>	Any NUMERIC data type or any non-numeric data type that can be implicitly converted to a numeric data type. The function returns the same data type as the numeric data type of the argument.
OVER()	See Analytic Functions

Examples

The following example calculates the cumulative variance in the store orders fact table of sales in December 2007:

```
=> SELECT date_ordered,  
       VARIANCE(SUM(total_order_cost))  
       OVER (ORDER BY date_ordered) "variance"  
FROM store.store_orders_fact s
```

```
WHERE date_ordered BETWEEN '2007-12-01' AND '2007-12-31'  
GROUP BY s.date_ordered;  
date_ordered |      variance  
-----  
2007-12-01 |              NaN  
2007-12-02 |      2259129762  
2007-12-03 | 1809012182.33301  
2007-12-04 |   35138165568.25  
2007-12-05 | 26644110029.3003  
2007-12-06 |      25943125234  
2007-12-07 | 23178202223.9048  
2007-12-08 | 21940268901.1431  
2007-12-09 | 21487676799.6108  
2007-12-10 | 21521358853.4331  
(10 rows)
```

Current Load Source

The current load source function returns the source file name.

CURRENT_LOAD_SOURCE

Returns the file name used during the COPY statement.

Behavior Type

Stable

Syntax

```
CURRENT_LOAD_SOURCE()
```

Behavior

- If the function is called outside of the context of a COPY statement, it returns NULL.
- If the function is called by a UDL that does not set the source, it returns the string <unknown>.

Examples

This example creates a table and populates column c3 with the names of the two separate files being loaded.

```
=> CREATE TABLE t (c1 integer, c2 varchar(50), c3 varchar(200));
CREATE TABLE

=> COPY t (c1, c2, c3 AS CURRENT_LOAD_SOURCE()) FROM '/home/load_file_1' ON exampledb_node02,
'/home/load_file_2' ON exampledb_node03 DELIMITER ',';

Rows Loaded
-----
5
(1 row)

=> SELECT * FROM t;
c1 | c2 | c3
-----+-----+-----
2 | dogs | load_file_1
1 | cats | load_file_1
4 | superheroes | load_file_2
3 | birds | load_file_1
5 | whales | load_file_2
(5 rows)
```

Date/Time Functions

Date and time functions perform conversion, extraction, or manipulation operations on date and time data types and can return date and time information.

Usage

Functions that take `TIME` or `TIMESTAMP` inputs come in two variants:

- `TIME WITH TIME ZONE` or `TIMESTAMP WITH TIME ZONE`
- `TIME WITHOUT TIME ZONE` or `TIMESTAMP WITHOUT TIME ZONE`

For brevity, these variants are not shown separately.

The `+` and `*` operators come in commutative pairs; for example, both `DATE + INTEGER` and `INTEGER + DATE`. We show only one of each such pair.

Daylight Savings Time Considerations

When adding an `INTERVAL` value to (or subtracting an `INTERVAL` value from) a `TIMESTAMP WITH TIME ZONE` value, the days component advances (or decrements) the date of the `TIMESTAMP WITH TIME ZONE` by the indicated number of days. Across daylight saving time changes (with the session time zone set to a time zone that recognizes DST), this means `INTERVAL '1 day'` does not necessarily equal `INTERVAL '24 hours'`.

For example, with the session time zone set to `CST7CDT`:

```
TIMESTAMP WITH TIME ZONE '2014-04-02 12:00-07' + INTERVAL '1 day'
```

produces

```
TIMESTAMP WITH TIME ZONE '2014-04-03 12:00-06'
```

Adding `INTERVAL '24 hours'` to the same initial `TIMESTAMP WITH TIME ZONE` produces

```
TIMESTAMP WITH TIME ZONE '2014-04-03 13:00-06',
```

This result occurs because there is a change in daylight saving time at `2014-04-03 02:00` in time zone `CST7CDT`.

Date/Time Functions in Transactions

Certain date/time functions such as [CURRENT_TIMESTAMP](#) and [NOW](#) return the start time of the current transaction; for the duration of that transaction, they return the same value. Other date/time functions such as [TIMEOFDAY](#) always return the current time.

See Also

[Template Patterns for Date/Time Formatting](#)

ADD_MONTHS

Adds the specified number of months to a date and returns the sum as a DATE. The function returns the last day of the month if one of the following conditions is true:

- The *start-date* argument specifies the last day of the month. For example, `2015-01-28 +12` returns `2016-01-29` .
- The *start-date* argument's day component is greater than the last day of the month returned by `ADD_MONTHS`. For example, `2015-01-29 +1` returns `2015-02-28`.

Otherwise, `ADD_MONTHS` returns a date with the same day component as *start-date*. Thus, `2016-03-15 +2` returns `2016-05-15`.

Behavior Type

- Immutable if the *start-date* argument is a `TIMESTAMP` or `DATE`
- Stable if the *start-date* argument is a `TIMESTAMPTZ`

Syntax

```
ADD_MONTHS ( start-date, num-months );
```

Parameters

<i>start-date</i>	The date to process, an expression that evaluates to one of the following data types: <ul style="list-style-type: none">• DATE• TIMESTAMP• TIMESTAMPTZ
<i>num-months</i>	An integer expression that specifies the number of months to add to or subtract from <i>start-date</i> .

Examples

Add one month to the current date:

```
=> SELECT CURRENT_DATE Today;
      Today
-----
2016-05-05
(1 row)

VMart=> SELECT ADD_MONTHS(CURRENT_TIMESTAMP,1);
      ADD_MONTHS
-----
2016-06-05
(1 row)
```

Subtract four months from the current date:

```
=> SELECT ADD_MONTHS(CURRENT_TIMESTAMP, -4);
      ADD_MONTHS
-----
2016-01-05
(1 row)
```

Add one month to January 31 2016:

```
=> SELECT ADD_MONTHS('31-Jan-2016'::TIMESTAMP, 1) "Leap Month";
      Leap Month
-----
2016-02-29
(1 row)
```

The following example sets the timezone to EST; it then adds 24 months to a TIMESTAMPTZ that specifies a PST time zone, so ADD_MONTHS takes into account the time change:

```
=> SET TIME_ZONE 'America/New_York';
SET
VMart=> SELECT ADD_MONTHS('2008-02-29 23:30 PST'::TIMESTAMPTZ, 24);
  ADD_MONTHS
-----
 2010-03-01
(1 row)
```

AGE_IN_MONTHS

Returns the difference in months between two dates, expressed as an integer.

Behavior Type

- Immutable if both date arguments are of data type `TIMESTAMP`
- Stable if either date is a `TIMESTAMPTZ` or only one argument is supplied

Syntax

```
AGE_IN_MONTHS ( [ date1, ] date2 )
```

Parameters

<i>date1</i> <i>date2</i>	<p>Specify the boundaries of the period to measure. If you supply only one argument, Vertica sets <i>date1</i> to <code>CURRENT_DATE</code>. Both parameters must evaluate to one of the following data types:</p> <ul style="list-style-type: none">• <code>DATE</code>• <code>TIMESTAMP</code>• <code>TIMESTAMPTZ</code> <p>If <i>date1</i> < <i>date2</i>, <code>AGES_IN_MONTHS</code> returns a negative value.</p>
------------------------------	--

Examples

Get the age in months of someone born March 2 1972, as of June 21 1990:

```
=> SELECT AGE_IN_MONTHS('1990-06-21'::TIMESTAMP, '1972-03-02'::TIMESTAMP);
   AGE_IN_MONTHS
-----
                219
(1 row)
```

Get the age in months of someone who was born November 21 1939, as of today:

```
=> SELECT AGE_IN_MONTHS ('1939-11-21'::DATE);
   AGE_IN_MONTHS
-----
                930
(1 row)
```

AGE_IN_YEARS

Returns the difference in years between two dates, expressed as an integer.

Behavior Type

- Immutable if both date arguments are of data type `TIMESTAMP`
- Stable if either date is a `TIMESTAMPTZ` or only one argument is supplied

Syntax

```
AGE_IN_YEARS( [ date1, ] date2 )
```

Parameters

<i>date1</i> <i>date2</i>	<p>Specify the boundaries of the period to measure. If you supply only one argument, Vertica sets <i>date1</i> to <code>CURRENT_DATE</code>. Both parameters must evaluate to one of the following data types:</p> <ul style="list-style-type: none">• <code>DATE</code>
------------------------------	--

- `TIMESTAMP`
- `TIMESTAMPTZ`

If `date1 < date2`, `AGES_IN_YEARS` returns a negative value.

Examples

Get the age of someone born March 2 1972, as of June 21 1990:

```
=> SELECT AGES_IN_YEARS('1990-06-21'::TIMESTAMP, '1972-03-02'::TIMESTAMP);
 AGES_IN_YEARS
-----
              18
(1 row)
```

Get the age of someone who was born November 21 1939, as of today:

```
=> SELECT AGES_IN_YEARS('1939-11-21'::DATE);
 AGES_IN_YEARS
-----
              77
(1 row)
```

CLOCK_TIMESTAMP

Returns a value of type `TIMESTAMP WITH TIMEZONE` that represents the current system-clock time.

`CLOCK_TIMESTAMP` uses the date and time supplied by the operating system on the server to which you are connected, which should be the same across all servers. The value changes each time you call it.

Behavior Type

Volatile

Syntax

```
CLOCK_TIMESTAMP()
```

Examples

The following command returns the current time on your system:

```
SELECT CLOCK_TIMESTAMP() "Current Time";
      Current Time
-----
2010-09-23 11:41:23.33772-04
(1 row)
```

Each time you call the function, you get a different result. The difference in this example is in microseconds:

```
SELECT CLOCK_TIMESTAMP() "Time 1", CLOCK_TIMESTAMP() "Time 2";
      Time 1          |          Time 2
-----+-----
2010-09-23 11:41:55.369201-04 | 2010-09-23 11:41:55.369202-04
(1 row)
```

See Also

- [STATEMENT_TIMESTAMP](#)
- [TRANSACTION_TIMESTAMP](#)

CURRENT_DATE

Returns the date (date-type value) on which the current transaction started.

Behavior Type

Stable

Syntax

```
CURRENT_DATE()
```

Note: You can call this function without parentheses.

Examples

```
SELECT CURRENT_DATE;  
?column?  
-----  
2010-09-23  
(1 row)
```

CURRENT_TIME

Returns a value of type `TIME WITH TIMEZONE` that represents the start of the current transaction.

The return value does not change during the transaction. Thus, multiple calls to `CURRENT_TIME` within the same transaction return the same timestamp.

Behavior Type

Stable

Syntax

```
CURRENT_TIME [ ( precision ) ]
```

Note: If you specify a column label without precision, you must also omit parentheses.

Parameters

<i>precision</i>	An integer value between 0-6, specifies to round the seconds fraction field result to the specified number of digits.
------------------	---

Examples

```
=> SELECT CURRENT_TIME(1) AS Time;  
Time  
-----  
06:51:45.2-07
```

```
(1 row)
=> SELECT CURRENT_TIME(5) AS Time;
      Time
-----
06:51:45.18435-07
(1 row)
```

CURRENT_TIMESTAMP

Returns a value of type `TIME WITH TIMEZONE` that represents the start of the current transaction.

The return value does not change during the transaction. Thus, multiple calls to `CURRENT_TIMESTAMP` within the same transaction return the same timestamp.

Behavior Type

Stable

Syntax

```
CURRENT_TIMESTAMP ( precision )
```

Parameters

<i>precision</i>	An integer value between 0-6, specifies to round the seconds fraction field result to the specified number of digits.
------------------	---

Examples

```
=> SELECT CURRENT_TIMESTAMP(1) AS time;
      time
-----
2017-03-27 06:50:49.7-07
(1 row)
=> SELECT CURRENT_TIMESTAMP(5) AS time;
      time
-----
2017-03-27 06:50:49.69967-07
(1 row)
```

DATE_PART

Extracts a sub-field such as year or hour from a date/time expression, equivalent to the the SQL-standard function [EXTRACT](#).

Behavior Type

- Immutable if the specified date is a `TIMESTAMP`, `DATE`, or `INTERVAL`
- Stable if the specified date is a `TIMESTAMPTZ`

Syntax

```
DATE_PART ( 'field', date )
```

Parameters

<i>field</i>	A constant value that specifies the sub-field to extract from <i>date</i> (see Field Values below).
<i>date</i>	The date to process, an expression that evaluates to one of the following data types: <ul style="list-style-type: none">• <code>DATE</code> (cast to <code>TIMESTAMP</code>)• <code>TIMESTAMP</code>• <code>TIMESTAMPTZ</code>• <code>INTERVAL</code>

Field Values

CENTURY	The century number. The first century starts at 0001-01-01 00:00:00 AD. This definition applies to all Gregorian calendar countries. There is no century number
---------	--

	0, you go from -1 to 1.
DAY	The day (of the month) field (1–31).
DECADE	The year field divided by 10.
DOQ	The day within the current quarter. DOQ recognizes leap year days.
DOW	Zero-based day of the week, where Sunday=0. Note: EXTRACT's day of week numbering differs from the function TO_CHAR .
DOY	The day of the year (1–365/366)
EPOCH	Specifies to return one of the following: <ul style="list-style-type: none"> • For DATE and TIMESTAMP values: the number of seconds before or since 1970-01-01 00:00:00-00 (if before, a negative number). • For INTERVAL values, the total number of seconds in the interval.
HOUR	The hour field (0–23).
ISODOW	The ISO day of the week , an integer between 1 and 7 where Monday is 1.
ISOWEEK	The ISO week of the year, an integer between 1 and 53.
ISOYEAR	The ISO year .
MICROSECONDS	The seconds field, including fractional parts, multiplied by 1,000,000. This includes full seconds.
MILLENNIUM	The millennium number, where the first millennium is 1 and each millenium starts on 01-01-y001. For example, millennium 2 starts on 01-01-1001.
MILLISECONDS	The seconds field, including fractional parts, multiplied by 1000. This includes full seconds.
MINUTE	The minutes field (0 - 59).

MONTH	For <code>TIMESTAMP</code> values, the number of the month within the year (1 - 12) ; for <code>interval</code> values the number of months, modulo 12 (0 - 11).
QUARTER	The calendar quarter of the specified date as an integer, where the January-March quarter is 1, valid only for <code>TIMESTAMP</code> values.
SECOND	The seconds field, including fractional parts, 0–59, or 0-60 if the operating system implements leap seconds.
TIME_ZONE	The time zone offset from UTC, in seconds. Positive values correspond to time zones east of UTC, negative values to zones west of UTC.
TIMEZONE_HOUR	The hour component of the time zone offset.
TIMEZONE_MINUTE	The minute component of the time zone offset.
WEEK	The number of the week of the calendar year that the day is in.
YEAR	The year field. There is no 0 AD, so subtract BC years from AD years accordingly.

Examples

Extract the day value:

```
SELECT DATE_PART('DAY', TIMESTAMP '2009-02-24 20:38:40') "Day";
   Day
-----
   24
(1 row)
```

Extract the month value:

```
SELECT DATE_PART('MONTH', '2009-02-24 20:38:40'::TIMESTAMP) "Month";
   Month
-----
     2
(1 row)
```

Extract the year value:

```
SELECT DATE_PART('YEAR', '2009-02-24 20:38:40'::TIMESTAMP) "Year";
   Year
-----
  2009
(1 row)
```

Extract the hours:

```
SELECT DATE_PART('HOUR', '2009-02-24 20:38:40'::TIMESTAMP) "Hour";
Hour
-----
    20
(1 row)
```

Extract the minutes:

```
SELECT DATE_PART('MINUTES', '2009-02-24 20:38:40'::TIMESTAMP) "Minutes";
Minutes
-----
     38
(1 row)
```

Extract the day of quarter (DOQ):

```
SELECT DATE_PART('DOQ', '2009-02-24 20:38:40'::TIMESTAMP) "DOQ";
DOQ
-----
   55
(1 row)
```

DATE

Converts the input value to a [DATE](#) data type.

Behavior Type

- Immutable if the input value is a `TIMESTAMP`, `DATE`, `VARCHAR`, or integer
- Stable if the input value is a `TIMESTAMPTZ`

Syntax

```
DATE ( value )
```

Parameters

<i>value</i>	The value to convert, one of the following: <ul style="list-style-type: none">• <code>TIMESTAMP</code>, <code>TIMESTAMPTZ</code>, <code>VARCHAR</code>, or another <code>DATE</code>.
--------------	---

- Integer: Vertica treats the integer as the number of days since 01/01/0001 and returns the date.

Examples

```
=> SELECT DATE (1);
      DATE
-----
0001-01-01
(1 row)

=> SELECT DATE (734260);
      DATE
-----
2011-05-03
(1 row)

=> SELECT DATE('TODAY');
      DATE
-----
2016-12-07
(1 row)
```

See Also

- [TO_DATE](#)
- [TO_TIMESTAMP](#)
- [TO_TIMESTAMP_TZ](#)

DATE_TRUNC

Truncates date and time values to the specified precision.

The return value is of type TIME or TIMETZ. All fields that are less than the specified precision are set to 0, or to 1 for day and month.

Behavior Type

Stable

Syntax

`DATE_TRUNC(precision, trunc-target)`

Parameters

<i>precision</i>	A string constant that specifies precision for the truncated value. See Precision Field Values below.
<i>trunc-target</i>	Value expression of type TIME or TIMETZ.

Precision Field Values

MILLENNIUM	The millennium number.
CENTURY	The century number. The first century starts at 0001-01-01 00:00:00 AD. This definition applies to all Gregorian calendar countries.
DECADE	The year field divided by 10.
YEAR	The year field. Keep in mind there is no 0 AD, so subtract BC years from AD years with care.
MONTH	For <code>timestamp</code> values, the number of the month within the year (1–12) ; for <code>interval</code> values the number of months, modulo 12 (0–11).
WEEK	The number of the week of the year that the day is in. According to the ISO-8601 standard, the week starts on Monday, and the first week of a year contains January 4. Thus, an early January date can sometimes be in the week 52 or 53 of the previous calendar year. For example: <pre>=> SELECT YEAR_ISO('01-01-2016'::DATE), WEEK_ISO('01-01-2016'), DAYOFWEEK_ISO('01-01-2016'); YEAR_ISO WEEK_ISO DAYOFWEEK_ISO -----+-----+----- 2015 53 5 (1 row)</pre>

DAY	The day (of the month) field (1–31).
HOUR	The hour field (0–23).
MINUTE	The minutes field (0–59).
SECOND	The seconds field, including fractional parts (0–59) (60 if leap seconds are implemented by the operating system).
MILLISECOND S	The seconds field, including fractional parts, multiplied by 1000. Note that this includes full seconds.
MICROSECOND S	The seconds field, including fractional parts, multiplied by 1,000,000. This includes full seconds.

Examples

The following example sets the field value as hour and returns the hour, truncating the minutes and seconds:

```
=> SELECT DATE_TRUNC('HOUR', TIMESTAMP '2012-02-24 13:38:40') AS HOUR;
      HOUR
-----
2012-02-24 13:00:00
(1 row)
```

The following example returns the year from the input `timestampz '2012-02-24 13:38:40'`. The function also defaults the month and day to January 1, truncates the hour:minute:second of the timestamp, and appends the time zone (`-05`):

```
=> SELECT DATE_TRUNC('YEAR', TIMESTAMPTZ '2012-02-24 13:38:40') AS YEAR;
      YEAR
-----
2012-01-01 00:00:00-05
(1 row)
```

The following example returns the year and month and defaults day of month to 1, truncating the rest of the string:

```
=> SELECT DATE_TRUNC('MONTH', TIMESTAMP '2012-02-24 13:38:40') AS MONTH;
      MONTH
-----
2012-02-01 00:00:00
(1 row)
```

DATEDIFF

Returns the time span between two dates, in the intervals specified. DATEDIFF excludes the start date in its calculation.

Behavior Type

- Immutable if start and end dates are TIMESTAMPT , DATE, TIME, or INTERVAL
- Stable if start and end dates are TIMESTAMPTZ

Syntax

```
DATEDIFF ( datepart, start, end );
```

Parameters

<i>datepart</i>	<p>Specifies the type of date or time intervals that DATEDIFF returns. If <i>datepart</i> is an expression, it must be enclosed in parentheses:</p> <pre>DATEDIFF(<i>expression</i>), <i>start</i>, <i>end</i>;</pre> <p><i>datepart</i> must evaluate to one of the following string literals, either quoted or unquoted:</p> <ul style="list-style-type: none">• year yy yyyy• quarter qq q• month mm m• day dayofyear dd d dy y• week wk ww• hour hh• minute mi n• second ss s
-----------------	--

	<ul style="list-style-type: none"> • millisecond ms • microsecond mcs us
<i>start, end</i>	<p>Specify the start and end dates, where <i>start</i> and <i>end</i> evaluate to one of the following data types:</p> <ul style="list-style-type: none"> • TIMESTAMP/TIMESTAMPZ • DATE • TIMESTAMPTZ • TIME/TIMETZ • INTERVAL <p>If $end < start$, DATEDIFF returns a negative value.</p> <p>Note: TIME and INTERVAL data types are invalid for start and end dates if <i>datepart</i> is set to year, quarter, or month.</p>

Compatible Start and End Date Data Types

The following table shows which data types can be matched as start and end dates:

	DATE	TIMESTAMP	TIMESTAMPZ	TIME	INTERVAL
DATE	•	•	•		
TIMESTAMP	•	•	•		
TIMESTAMPZ	•	•	•		
TIME				•	
INTERVAL					•

For example, if you set the start date to an INTERVAL data type, the end date must also be an INTERVAL, otherwise Vertica returns an error:

```
SELECT DATEDIFF(day, INTERVAL '26 days', INTERVAL '1 month ');
datediff
```

```
-----  
      4  
(1 row)
```

Date Part Intervals

DATEDIFF uses the *datepart* argument to calculate the number of intervals between two dates, rather than the actual amount of time between them. DATEDIFF uses the following cutoff points to calculate those intervals:

- year: January 1
- quarter: January 1, April 1, July 1, October 1
- month: the first day of the month
- week: Sunday at midnight (24:00)

For example, if *datepart* is set to year, DATEDIFF uses January 01 to calculate the number of years between two dates. The following DATEDIFF statement sets *datepart* to year, and specifies a time span 01/01/2005 - 06/15/2008:

```
SELECT DATEDIFF(year, '01-01-2005'::date, '12-31-2008'::date);  
datediff  
-----  
      3  
(1 row)
```

DATEDIFF always excludes the start date when it calculates intervals—in this case, 01/01//2005. DATEDIFF considers only calendar year starts in its calculation, so in this case it only counts years 2006, 2007, and 2008. The function returns 3, although the actual time span is nearly four years.

If you change the start and end dates to 12/31/2004 and 01/01/2009, respectively, DATEDIFF also counts years 2005 and 2009. This time, it returns 5, although the actual time span is just over four years:

```
=> SELECT DATEDIFF(year, '12-31-2004'::date, '01-01-2009'::date);  
datediff  
-----  
      5  
(1 row)
```

Similarly, DATEDIFF uses month start dates when it calculates the number of months between two dates. Thus, given the following statement, DATEDIFF counts months February through September and returns 8:

```
=> SELECT DATEDIFF(month, '01-31-2005'::date, '09-30-2005'::date);
datediff
-----
        8
(1 row)
```

See Also

[TIMESTAMPDIFF](#)

DAY

Returns as an integer the day of the month from the input value.

Behavior Type

- Immutable if the input value is a `TIMESTAMP`, `DATE`, `VARCHAR`, or `INTEGER`
- Stable if the specified date is a `TIMESTAMPTZ`

Syntax

```
DAY ( value )
```

Parameters

<i>value</i>	The value to convert, one of the following: <code>TIMESTAMP</code> , <code>TIMESTAMPTZ</code> , <code>INTERVAL</code> , <code>VARCHAR</code> , or <code>INTEGER</code> .
--------------	--

Examples

```
=> SELECT DAY (6);
DAY
-----
    6
(1 row)

=> SELECT DAY(TIMESTAMP 'sep 22, 2011 12:34');
```

```
DAY
-----
 22
(1 row)

=> SELECT DAY('sep 22, 2011 12:34');
DAY
-----
 22
(1 row)

=> SELECT DAY(INTERVAL '35 12:34');
DAY
-----
 35
(1 row)
```

DAYOFMONTH

Returns the day of the month as an integer.

Behavior Type

- Immutable if the target date is a `TIMESTAMP`, `DATE`, or `VARCHAR`
- Stable if the target date is a `TIMESTAMPTZ`

Syntax

```
DAYOFMONTH ( date )
```

Parameters

<i>date</i>	The date to process, one of the following data types: <ul style="list-style-type: none">• <code>VARCHAR</code>• <code>DATE</code>• <code>TIMESTAMP</code>• <code>TIMESTAMPTZ</code>
-------------	--

Example

```
=> SELECT DAYOFMONTH (TIMESTAMP 'sep 22, 2011 12:34');
DAYOFMONTH
-----
                22
(1 row)
```

DAYOFWEEK

Returns the day of the week as an integer, where Sunday is day 1.

Behavior Type

- Immutable if the target date is a `TIMESTAMP`, `DATE`, or `VARCHAR`
- Stable if the target date is `aTIMESTAMPTZ`

Syntax

```
DAYOFWEEK ( date )
```

Parameters

<i>date</i>	The date to process, one of the following data types: <ul style="list-style-type: none">• <code>VARCHAR</code>• <code>DATE</code>• <code>TIMESTAMP</code>• <code>TIMESTAMPTZ</code>
-------------	--

Example

```
=> SELECT DAYOFWEEK (TIMESTAMP 'sep 17, 2011 12:34');
DAYOFWEEK
-----
              7
(1 row)
```

DAYOFWEEK_ISO

Returns the ISO 8061 day of the week as an integer, where Monday is day 1.

Behavior Type

- Immutable if the target date is a `TIMESTAMP`, `DATE`, or `VARCHAR`
- Stable if the target date is `aTIMESTAMPTZ`

Syntax

```
DAYOFWEEK_ISO ( date )
```

Parameters

<i>date</i>	The date to process, one of the following data types: <ul style="list-style-type: none">• VARCHAR• DATE• TIMESTAMP• TIMESTAMPTZ
-------------	--

Examples

```
=> SELECT DAYOFWEEK_ISO(TIMESTAMP 'Sep 22, 2011 12:34');
DAYOFWEEK_ISO
-----
                4
(1 row)
```

The following example shows how to combine the DAYOFWEEK_ISO, WEEK_ISO, and YEAR_ISO functions to find the ISO day of the week, week, and year:

```
=> SELECT DAYOFWEEK_ISO('Jan 1, 2000'), WEEK_ISO('Jan 1, 2000'), YEAR_ISO('Jan1,2000');
DAYOFWEEK_ISO | WEEK_ISO | YEAR_ISO
-----+-----+-----
                6 |         52 |      1999
(1 row)
```

See Also

- [WEEK_ISO](#)
- [DAYOFWEEK_ISO](#)
- http://en.wikipedia.org/wiki/ISO_8601

DAYOFYEAR

Returns the day of the year as an integer, where January 1 is day 1.

Behavior Type

- Immutable if the specified date is a `TIMESTAMP`, `DATE`, or `VARCHAR`
- Stable if the specified date is a `TIMESTAMPPTZ`

Syntax

```
DAYOFYEAR ( date )
```

Parameters

<i>date</i>	The date to process, one of the following data types: <ul style="list-style-type: none">• VARCHAR• DATE• TIMESTAMP• TIMESTAMPTZ
-------------	--

Example

```
=> SELECT DAYOFYEAR (TIMESTAMP 'SEPT 22,2011 12:34');
DAYOFYEAR
-----
          265
(1 row)
```

DAYS

Returns the integer value of the specified date, where 1 AD is 1. If the date precedes 1 AD, DAYS returns a negative integer.

Behavior Type

- Immutable if the specified date is a [TIMESTAMP](#), [DATE](#), or [VARCHAR](#)
- Stable if the specified date is a [TIMESTAMPTZ](#)

Syntax

```
DAYS ( date )
```

Parameters

<i>date</i>	The date to process, one of the following data types: <ul style="list-style-type: none">• VARCHAR• DATE• TIMESTAMP• TIMESTAMPTZ
-------------	--

Example

```
=> SELECT DAYS (DATE '2011-01-22');
   DAYS
-----
 734159
(1 row)

=> SELECT DAYS (DATE 'March 15, 0044 BC');
   DAYS
-----
-15997
(1 row)
```

EXTRACT

Retrieves sub-fields such as year or hour from date/time values and returns values of type [NUMERIC](#). EXTRACT is intended for computational processing, rather than for formatting date/time values for display.

Behavior Type

- Immutable if the specified date is a [TIMESTAMP](#), [DATE](#), or [INTERVAL](#)
- Stable if the specified date is a [TIMESTAMPTZ](#)

Syntax

EXTRACT (*field* FROM *date*)

Parameters

<i>field</i>	A constant value that specifies the sub-field to extract from <i>date</i> (see Field Values below).
<i>date</i>	The date to process, an expression that evaluates to one of the following data types: <ul style="list-style-type: none">• DATE (cast to TIMESTAMP)• TIMESTAMP• TIMESTAMPTZ• INTERVAL

Field Values

CENTURY	The century number. The first century starts at 0001-01-01 00:00:00 AD. This definition applies to all Gregorian calendar countries. There is no century number 0, you go from -1 to 1.
DAY	The day (of the month) field (1-31).
DECADE	The year field divided by 10.
DOQ	The day within the current quarter. DOQ recognizes leap year days.
DOW	Zero-based day of the week, where Sunday=0. Note: EXTRACT's day of week numbering differs from the function TO_CHAR .

DOY	The day of the year (1–365/366)
EPOCH	Specifies to return one of the following: <ul style="list-style-type: none"> • For DATE and TIMESTAMP values: the number of seconds before or since 1970-01-01 00:00:00-00 (if before, a negative number). • For INTERVAL values, the total number of seconds in the interval.
HOUR	The hour field (0–23).
ISODOW	The ISO day of the week , an integer between 1 and 7 where Monday is 1.
ISOWEEK	The ISO week of the year, an integer between 1 and 53.
ISOYEAR	The ISO year .
MICROSECONDS	The seconds field, including fractional parts, multiplied by 1,000,000. This includes full seconds.
MILLENNIUM	The millennium number, where the first millennium is 1 and each millenium starts on 01-01-y001. For example, millennium 2 starts on 01-01-1001.
MILLISECONDS	The seconds field, including fractional parts, multiplied by 1000. This includes full seconds.
MINUTE	The minutes field (0 - 59).
MONTH	For TIMESTAMP values, the number of the month within the year (1 - 12) ; for interval values the number of months, modulo 12 (0 - 11).
QUARTER	The calendar quarter of the specified date as an integer, where the January-March quarter is 1, valid only for TIMESTAMP values.
SECOND	The seconds field, including fractional parts, 0–59, or 0-60 if the operating system implements leap seconds.
TIME_ZONE	The time zone offset from UTC, in seconds. Positive values correspond to time zones east of UTC, negative values to zones west of UTC.
TIMEZONE_HOUR	The hour component of the time zone offset.
TIMEZONE_	The minute component of the time zone offset.

MINUTE	
WEEK	The number of the week of the calendar year that the day is in.
YEAR	The year field. There is no 0 AD, so subtract BC years from AD years accordingly.

Examples

Extract the day of the week and day in quarter from the current TIMESTAMP:

```
=> SELECT CURRENT_TIMESTAMP AS NOW;
      NOW
-----
2016-05-03 11:36:08.829004-04
(1 row)
=> SELECT EXTRACT (DAY FROM CURRENT_TIMESTAMP);
      date_part
-----
              3
(1 row)
=> SELECT EXTRACT (DOQ FROM CURRENT_TIMESTAMP);
      date_part
-----
              33
(1 row)
```

Extract the timezone hour from the current time:

```
=> SELECT CURRENT_TIMESTAMP;
      ?column?
-----
2016-05-03 11:36:08.829004-04
(1 row)
=> SELECT EXTRACT(TIMEZONE_HOUR FROM CURRENT_TIMESTAMP);
      date_part
-----
              -4
(1 row)
```

Extract the number of seconds since 01-01-1970 00:00:

```
=> SELECT EXTRACT(EPOCH FROM '2001-02-16 20:38:40-08'::TIMESTAMP_TZ);
      date_part
-----
982384720.000000
(1 row)
```

Extract the number of seconds between 01-01-1970 00:00 and 5 days 3 hours before:

```
=> SELECT EXTRACT(EPOCH FROM -'5 days 3 hours'::INTERVAL);
       date_part
-----
-442800.000000
(1 row)
```

Convert the results from the last example to a `TIMESTAMP`:

```
=> SELECT 'EPOCH'::TIMESTAMPTZ -442800 * '1 second'::INTERVAL;
       ?column?
-----
1969-12-26 16:00:00-05
(1 row)
```

GETDATE

Returns the current statement's start date and time as a `TIMESTAMP` value. This function is identical to [SYSDATE](#).

`GETDATE` uses the date and time supplied by the operating system on the server to which you are connected, which is the same across all servers. Internally, `GETDATE` converts [STATEMENT_TIMESTAMP](#) from `TIMESTAMPTZ` to `TIMESTAMP`.

Behavior Type

Stable

Syntax

```
GETDATE()
```

Example

```
=> SELECT GETDATE();
       GETDATE
-----
2011-03-07 13:21:29.497742
(1 row)
```

See Also

[Date/Time Expressions](#)

GETUTCDATE

Returns the current statement's start date and time as a `TIMESTAMP` value.

`GETUTCDATE` uses the date and time supplied by the operating system on the server to which you are connected, which is the same across all servers. Internally, `GETUTCDATE` converts [STATEMENT_TIMESTAMP](#) at TIME ZONE 'UTC'.

Behavior Type

Stable

Syntax

```
GETUTCDATE()
```

Example

```
=> SELECT GETUTCDATE();
      GETUTCDATE
-----
2011-03-07 20:20:26.193052
(1 row)
```

See Also

- [Date/Time Expressions](#)

HOUR

Returns the hour portion of the specified date as an integer, where 0 is 00:00 to 00:59.

Behavior Type

- Immutable if the specified date is a `TIMESTAMP`
- Stable if the specified date is a `TIMESTAMPTZ`

Syntax

`HOUR(date)`

Parameters

<i>date</i>	The date to process, one of the following data types: <ul style="list-style-type: none">• <code>VARCHAR</code>• <code>DATE</code>• <code>TIMESTAMP</code>• <code>TIMESTAMPTZ</code>• <code>INTERVAL</code>
-------------	--

Examples

```
=> SELECT HOUR (TIMESTAMP 'sep 22, 2011 12:34');
HOUR
-----
12
(1 row)
=> SELECT HOUR (INTERVAL '35 12:34');
HOUR
-----
12
(1 row)
=> SELECT HOUR ('12:34');
HOUR
-----
12
(1 row)
```

ISFINITE

Tests for the special `TIMESTAMP` constant `INFINITY` and returns a value of type `BOOLEAN`.

Behavior Type

Immutable

Syntax

```
ISFINITE ( timestamp )
```

Parameters

<i>timestamp</i>	Expression of type <code>TIMESTAMP</code>
------------------	---

Examples

```
SELECT ISFINITE(TIMESTAMP '2009-02-16 21:28:30');
ISFINITE
-----
t
(1 row)

SELECT ISFINITE(TIMESTAMP 'INFINITY');
ISFINITE
-----
f
(1 row)
```

JULIAN_DAY

Returns the integer value of the specified day according to the Julian calendar, where day 1 is the first day of the Julian period, January 1, 4713 BC (on the Gregorian calendar, November 24, 4714 BC).

Behavior Type

- Immutable if the specified date is a `TIMESTAMP`, `DATE`, or `VARCHAR`
- Stable if the specified date is a `TIMESTAMPTZ`

Syntax

```
JULIAN_DAY ( date )
```

Parameters

<i>date</i>	The date to process, one of the following data types: <ul style="list-style-type: none">• <code>VARCHAR</code>• <code>DATE</code>• <code>TIMESTAMP</code>• <code>TIMESTAMPTZ</code>
-------------	--

Example

```
=> SELECT JULIAN_DAY (DATE 'MARCH 15, 0044 BC');
JULIAN_DAY
-----
      1705428
(1 row)

=> SELECT JULIAN_DAY (DATE '2001-01-01');
JULIAN_DAY
-----
      2451911
(1 row)
```

LAST_DAY

Returns the last day of the month in the specified date.

Behavior Type

- Immutable if the specified is a `TIMESTAMP` or `DATE`
- Stable if the specified date is a `TIMESTAMPTZ`

Syntax

```
LAST_DAY ( date )
```

Parameters

<i>date</i>	The date to process, one of the following data types: <ul style="list-style-type: none">• <code>DATE</code>• <code>TIMESTAMP</code>• <code>TIMESTAMPTZ</code>
-------------	---

Examples

The following example returns the last day of February as 29 because 2016 is a leap year:

```
=> SELECT LAST_DAY('2016-02-28 23:30 PST') "Last Day";
   Last Day
-----
2016-02-29
(1 row)
```

The following example returns the last day of February in a non-leap year:

```
> SELECT LAST_DAY('2017/02/03') "Last";
   Last
-----
2017-02-28
(1 row)
```

The following example returns the last day of March, after converting the string value to the specified `DATE` type:

```
=> SELECT LAST_DAY('2003/03/15') "Last";
       Last
-----
2012-03-31
(1 row)
```

LOCALTIME

Returns a value of type `TIME` that represents the start of the current transaction.

The return value does not change during the transaction. Thus, multiple calls to `LOCALTIME` within the same transaction return the same timestamp.

Behavior Type

Stable

Syntax

```
LOCALTIME [ ( precision ) ]
```

Parameters

<i>precision</i>	Rounds the result to the specified number of fractional digits in the seconds field.
------------------	--

Example

```
=> CREATE TABLE t1 (a int, b int);
CREATE TABLE

=> INSERT INTO t1 VALUES (1,2);
OUTPUT
-----
      1
(1 row)

=> SELECT LOCALTIME time;
       time
-----
15:03:14.595296
```

```
(1 row)

=> INSERT INTO t1 VALUES (3,4);
OUTPUT
-----
      1
(1 row)

=> SELECT LOCALTIME;
      time
-----
15:03:14.595296
(1 row)

=> COMMIT;
COMMIT
=> SELECT LOCALTIME;
      time
-----
15:03:49.738032
(1 row)
```

LOCALTIMESTAMP

Returns a value of type `TIMESTAMP` that represents the start of the current transaction.

The return value does not change during the transaction. Thus, multiple calls to `LOCALTIMESTAMP` within the same transaction return the same timestamp.

Behavior Type

Stable

Syntax

```
LOCALTIMESTAMP [ ( precision ) ]
```

Parameters

<i>precision</i>	Rounds the result to the specified number of fractional digits in the seconds field.
------------------	--

Example

```
=> CREATE TABLE t1 (a int, b int);
CREATE TABLE

=> INSERT INTO t1 VALUES (1,2);
OUTPUT
-----
      1
(1 row)

=> SELECT CURRENT_TIMESTAMP(2) timestamp;
      timestamp
-----
2016-12-07 15:19:12.34-05
(1 row)

=> INSERT INTO t1 VALUES (3,4);
OUTPUT
-----
      1
(1 row)

=> SELECT CURRENT_TIMESTAMP(2) timestamp;
      timestamp
-----
2016-12-07 15:19:12.34-05
(1 row)

=> COMMIT;
COMMIT
=> SELECT CURRENT_TIMESTAMP(2) timestamp;
      timestamp
-----
2016-12-07 15:19:13.89-05
(1 row)
```

MICROSECOND

Returns the microsecond portion of the specified date as an integer.

Behavior Type

- Immutable if the specified date is a `TIMESTAMP`, `INTERVAL`, or `VARCHAR`
- Stable if the specified date is a `TIMESTAMP TZ`

Syntax

`MICROSECOND (date)`

Parameters

<i>date</i>	The date to process, one of the following data types: <ul style="list-style-type: none">• VARCHAR• TIMESTAMP• TIMESTAMPTZ• INTERVAL
-------------	--

Example

```
=> SELECT MICROSECOND (TIMESTAMP 'Sep 22, 2011 12:34:01.123456');
MICROSECOND
-----
          123456
(1 row)
```

MIDNIGHT_SECONDS

Within the specified date, returns the number of seconds between midnight and the date's time portion.

Behavior Type

- Immutable if the specified date is a `TIMESTAMP`, `DATE`, or `VARCHAR`
- Stable if the specified date is a `TIMESTAMPTZ`

Syntax

`MIDNIGHT_SECONDS (date)`

Parameters

<i>date</i>	The date to process, one of the following data types: <ul style="list-style-type: none">• VARCHAR• DATE• TIMESTAMP• TIMESTAMPTZ
-------------	--

Examples

Get the number of seconds since midnight:

```
=> SELECT MIDNIGHT_SECONDS(CURRENT_TIMESTAMP);
MIDNIGHT_SECONDS
-----
                36480
(1 row)
```

Get the number of seconds between midnight and noon on March 3 2016:

```
=> SELECT MIDNIGHT_SECONDS('3-3-2016 12:00'::TIMESTAMP);
MIDNIGHT_SECONDS
-----
                43200
(1 row)
```

MINUTE

Returns the minute portion of the specified date as an integer.

Behavior Type

- Immutable if the specified date is a [TIMESTAMP](#), [DATE](#), [VARCHAR](#) or [INTERVAL](#)
- Stable if the specified date is a [TIMESTAMPTZ](#)

Syntax

MINUTE (*date*)

Parameters

<i>date</i>	The date to process, one of the following data types: <ul style="list-style-type: none">• VARCHAR• DATE• TIMESTAMP• TIMESTAMPTZ• INTERVAL
-------------	---

Example

```
=> SELECT MINUTE('12:34:03.456789');
MINUTE
-----
      34
(1 row)
=>SELECT MINUTE (TIMESTAMP 'sep 22, 2011 12:34');
MINUTE
-----
      34
(1 row)
=> SELECT MINUTE(INTERVAL '35 12:34:03.456789');
MINUTE
-----
      34
(1 row)
```

MONTH

Returns the month portion of the specified date as an integer.

Behavior Type

- Immutable if the specified date is a `TIMESTAMP`, `DATE`, `VARCHAR` or `INTERVAL`
- Stable if the specified date is a `TIMESTAMPTZ`

Syntax

```
QUARTER ( date )
```

Parameters

<i>date</i>	The date to process, one of the following data types: <ul style="list-style-type: none">• <code>VARCHAR</code>• <code>DATE</code>• <code>TIMESTAMP</code>• <code>TIMESTAMPTZ</code>• <code>INTERVAL</code>
-------------	--

Examples

```
=> SELECT MONTH('6-9');
MONTH
-----
     9
(1 row)
=> SELECT MONTH (TIMESTAMP 'sep 22, 2011 12:34');
MONTH
-----
     9
(1 row)
=> SELECT MONTH(INTERVAL '2-35' year to month);
MONTH
-----
    11
(1 row)
```

MONTHS_BETWEEN

Returns the number of months between two dates. MONTHS_BETWEEN can return an integer or a FLOAT8:

- Integer: The day portions of *date1* and *date2* are the same, and neither date is the last day of the month. MONTHS_BETWEEN also returns an integer if both dates in *date1* and *date2* are the last days of their respective months. For example, MONTHS_BETWEEN calculates the difference between April 30 and March 31 as 1 month.
- FLOAT8: The day portions of *date1* and *date2* are different and one or both dates are not the last day of their respective months. For example, the difference between April 2 and March 1 is 1.03225806451613. To calculate month fractions, MONTHS_BETWEEN assumes all months contain 31 days.

MONTHS_BETWEEN disregards timestamp time portions.

Behavior Type

- Immutable if both date arguments are of data type TIMESTAMP or DATE
- Stable if either date is a TIMESTAMPTZ

Syntax

```
MONTHS_BETWEEN ( date1 , date2 );
```

Parameters

<i>date1</i> <i>date2</i>	<p>Specify the dates to evaluate where <i>date1</i> and <i>date2</i> evaluate to one of the following data types:</p> <ul style="list-style-type: none">• DATE• TIMESTAMP• TIMESTAMPTZ <p>If <i>date1</i> < <i>date2</i>, MONTHS_BETWEEN returns a negative value.</p>
------------------------------	---

Examples

Return the number of months between April 7 2016 and January 7 2015:

```
=> SELECT MONTHS_BETWEEN ('04-07-16'::TIMESTAMP, '01-07-15'::TIMESTAMP);
MONTHS_BETWEEN
-----
                15
(1 row)
```

Return the number of months between March 31 2016 and February 28 2016 (MONTHS_BETWEEN assumes both months contain 31 days):

```
=> SELECT MONTHS_BETWEEN ('03-31-16'::TIMESTAMP, '02-28-16'::TIMESTAMP);
MONTHS_BETWEEN
-----
1.09677419354839
(1 row)
```

Return the number of months between March 31 2016 and February 29 2016:

```
=> SELECT MONTHS_BETWEEN ('03-31-16'::TIMESTAMP, '02-29-16'::TIMESTAMP);
MONTHS_BETWEEN
-----
                1
(1 row)
```

NEW_TIME

Converts a timestamp value from one time zone to another and returns a `TIMESTAMP`.

Behavior Type

Immutable

Syntax

```
NEW_TIME( 'timestamp' , 'timezone1' , 'timezone2')
```

Parameters

<i>timestamp</i>	<p>The timestamp to convert, conforms to one of the following formats:</p> <ul style="list-style-type: none">• TIMESTAMP/TIMESTAMPTZ• DATE• Character string that can be converted to a <code>TIMESTAMP</code>— for example, <code>May 24, 2012 10:00</code>.
<i>timezone1</i> <i>timezone2</i>	<p>Specify the source and target timezones, one of the strings defined in <code>/opt/vertica/share/timezonesets</code>. For example:</p> <ul style="list-style-type: none">• GMT: Greenwich Mean Time• AST / ADT: Atlantic Standard/Daylight Time• EST / EDT: Eastern Standard/Daylight Time• CST / CDT: Central Standard/Daylight Time• MST / MDT: Mountain Standard/Daylight Time• PST / PDT: Pacific Standard/Daylight Time

Examples

Convert the specified time from Eastern Standard Time (EST) to Pacific Standard Time (PST):

```
=> SELECT NEW_TIME('05-24-12 13:48:00', 'EST', 'PST');
       NEW_TIME
-----
2012-05-24 10:48:00
(1 row)
```

Convert 1:00 AM January 2012 from EST to PST:

```
=> SELECT NEW_TIME('01-01-12 01:00:00', 'EST', 'PST');
       NEW_TIME
-----
```

```
2011-12-31 22:00:00
(1 row)
```

Convert the current time EST to PST:

```
=> SELECT NOW();
      NOW
-----
2016-12-09 10:30:36.727307-05
(1 row)

=> SELECT NEW_TIME('NOW', 'EDT', 'CDT');
      NEW_TIME
-----
2016-12-09 09:30:36.727307
(1 row)
```

The following example returns the year 45 before the Common Era in Greenwich Mean Time and converts it to Newfoundland Standard Time:

```
=> SELECT NEW_TIME('April 1, 45 BC', 'GMT', 'NST')::DATE;
      NEW_TIME
-----
0045-03-31 BC
(1 row)
```

NEXT_DAY

Returns the date of the first instance of a particular day of the week that follows the specified date.

Behavior Type

- Immutable if the specified date is a `TIMESTAMP`, `DATE`, or `VARCHAR`
- Stable if the specified date is a `TIMESTAMPTZ`

Syntax

```
NEXT_DAY( 'date', 'day-string')
```

Parameters

<i>date</i>	The date to process, one of the following data types: <ul style="list-style-type: none">• VARCHAR• DATE• TIMESTAMP• TIMESTAMPTZ
<i>day-string</i>	The day of the week to process, a CHAR or VARCHAR string or character constant. Supply the full English name such as Tuesday, or any conventional abbreviation, such as Tue or Tues. <i>day-string</i> is not case sensitive and trailing spaces are ignored.

Examples

Get the date of the first Monday that follows April 29 2016:

```
=> SELECT NEXT_DAY('4-29-2016'::TIMESTAMP, 'Monday') "NEXT DAY" ;
      NEXT DAY
-----
2016-05-02
(1 row)
```

Get the first Tuesday that follows today:

```
SELECT NEXT_DAY(CURRENT_TIMESTAMP, 'tues') "NEXT DAY" ;
      NEXT DAY
-----
2016-05-03
(1 row)
```

NOW [Date/Time]

Returns a value of type `TIMESTAMP WITH TIME ZONE` representing the start of the current transaction. `NOW` is equivalent to [CURRENT_TIMESTAMP](#) except that it does not accept a precision parameter.

The return value does not change during the transaction. Thus, multiple calls to `CURRENT_TIMESTAMP` within the same transaction return the same timestamp.

Behavior Type

Stable

Syntax

`NOW()`

Example

```
=> CREATE TABLE t1 (a int, b int);
CREATE TABLE
=> INSERT INTO t1 VALUES (1,2);
OUTPUT
-----
      1
(1 row)

=> SELECT NOW();
      NOW
-----
2016-12-09 13:00:08.74685-05
(1 row)

=> INSERT INTO t1 VALUES (3,4);
OUTPUT
-----
      1
(1 row)

=> SELECT NOW();
      NOW
-----
2016-12-09 13:00:08.74685-05
(1 row)

=> COMMIT;
COMMIT
dbadmin=> SELECT NOW();
      NOW
-----
2016-12-09 13:01:31.420624-05
(1 row)
```

OVERLAPS

Evaluates two time periods and returns true when they overlap, false otherwise.

Behavior Type

- Stable when `TIMESTAMP` and `TIMESTAMPTZ` are both used, or when `TIMESTAMPTZ` is used with `INTERVAL`
- Immutable otherwise

Syntax

```
( start, end ) OVERLAPS ( start, end )  
( start, interval ) OVERLAPS ( start, interval )
```

Parameters

<i>start</i>	DATE, TIME, or TIMESTAMP/TIMESTAMPTZ value that specifies the beginning of a time period.
<i>end</i>	DATE, TIME, or TIMESTAMP/TIMESTAMPTZ value that specifies the end of a time period.
<i>interval</i>	Value that specifies the length of the time period.

Examples

Evaluate whether date ranges Feb 16 - Dec 21, 2016 and Oct 10 2008 - Oct 3 2016 overlap:

```
=> SELECT (DATE '2016-02-16', DATE '2016-12-21') OVERLAPS (DATE '2008-10-30', DATE '2016-10-30');  
overlaps  
-----  
t  
(1 row)
```

Evaluate whether date ranges Feb 16 - Dec 21, 2016 and Jan 01 - Oct 30 2008 - Oct 3, 2016 overlap:

```
=> SELECT (DATE '2016-02-16', DATE '2016-12-21') OVERLAPS (DATE '2008-01-30', DATE '2008-10-30');
overlaps
-----
f
(1 row)
```

Evaluate whether date range Feb 02 2016 + 1 week overlaps with date range Oct 16 2016 - 8 months:

```
=> SELECT (DATE '2016-02-16', INTERVAL '1 week') OVERLAPS (DATE '2016-10-16', INTERVAL '-8 months');
overlaps
-----
t
(1 row)
```

QUARTER

Returns calendar quarter of the specified date as an integer, where the January-March quarter is 1.

Syntax

```
QUARTER ( date )
```

Behavior Type

- Immutable if the specified date is a `TIMESTAMP`, `DATE`, or `VARCHAR`.
- Stable if the specified date is a `TIMESTAMPTZ`

Parameters

<i>date</i>	The date to process, one of the following data types: <ul style="list-style-type: none">• <code>VARCHAR</code>• <code>DATE</code>• <code>TIMESTAMP</code>• <code>TIMESTAMPTZ</code>
-------------	--

Examples

```
=> SELECT QUARTER (TIMESTAMP 'sep 22, 2011 12:34');
   QUARTER
-----
          3
(1 row)
```

ROUND

Rounds the specified date or time. If you omit the precision argument, ROUND rounds to day (DD) precision.

Behavior Type

- Immutable if the target date is a `TIMESTAMP` or `DATE`
- Stable if the target date is a `TIMESTAMPTZ`

Syntax

```
ROUND( rounding-target [, 'precision' ] )
```

Parameters

<i>rounding-target</i>	An expression that evaluates to one of the following data types: <ul style="list-style-type: none">• <code>DATE</code>• <code>TIMESTAMP/TIMESTAMPTZ</code>• <code>TIMESTAMPTZ</code>
<i>precision</i>	A string constant that specifies precision for the rounded value, one of the following: <ul style="list-style-type: none">• Century: <code>CC</code> <code>SCC</code>

- **Year:** SYYY | YYYY | YEAR | YYY | YY | Y
- **ISO Year:** IYYY | IYY | IY | I
- **Quarter:** Q
- **Month:** MONTH | MON | MM | RM
- **Same weekday as first day of year:** WW
- **Same weekday as first day of ISO year:** IW
- **Same weekday as first day of month:** W
- **Day (default):** DDD | DD | J
- **First weekday:** DAY | DY | D
- **Hour:** HH | HH12 | HH24
- **Minute:** MI
- **Second:** SS

Note: Hour, minute, and second rounding is not supported by DATE expressions.

Examples

Round to the nearest hour:

```
=> SELECT ROUND(CURRENT_TIMESTAMP, 'HH');
      ROUND
-----
2016-04-28 15:00:00
(1 row)
```

Round to the nearest month:

```
=> SELECT ROUND('9-22-2011 12:34:00'::TIMESTAMP, 'MM');
      ROUND
-----
2011-10-01 00:00:00
(1 row)
```

See Also

[TIMESTAMP_ROUND](#)

SECOND

Returns the seconds portion of the specified date as an integer.

Syntax

```
SECOND ( date )
```

Behavior Type

Immutable, except for TIMESTAMPTZ arguments where it is stable.

Parameters

<i>date</i>	The date to process, one of the following data types: <ul style="list-style-type: none">• VARCHAR• TIMESTAMP• TIMESTAMPTZ• INTERVAL
-------------	--

Examples

```
=> SELECT SECOND ('23:34:03.456789');
SECOND
-----
      3
(1 row)
=> SELECT SECOND (TIMESTAMP 'sep 22, 2011 12:34');
SECOND
-----
```

```
0
(1 row)
=> SELECT SECOND (INTERVAL '35 12:34:03.456789');
SECOND
-----
3
(1 row)
```

STATEMENT_TIMESTAMP

Similar to [TRANSACTION_TIMESTAMP](#), returns a value of type `TIMESTAMP WITH TIME ZONE` that represents the start of the current statement.

The return value does not change during statement execution. Thus, different stages of statement execution always have the same timestamp.

Behavior Type

Stable

Syntax

```
STATEMENT_TIMESTAMP()
```

Example

```
=> SELECT foo, bar FROM (SELECT STATEMENT_TIMESTAMP() AS foo)foo, (SELECT STATEMENT_TIMESTAMP() as
bar)bar;
      foo                |      bar
-----+-----
2016-12-07 14:55:51.543988-05 | 2016-12-07 14:55:51.543988-05
(1 row)
```

See Also

- [CLOCK_TIMESTAMP](#)
- [TRANSACTION_TIMESTAMP](#)

SYSDATE

Returns the current statement's start date and time as a `TIMESTAMP` value. This function is identical to [GETDATE](#).

`SYSDATE` uses the date and time supplied by the operating system on the server to which you are connected, which is the same across all servers. Internally, `GETDATE` converts [STATEMENT_TIMESTAMP](#) from `TIMESTAMPTZ` to `TIMESTAMP`.

Behavior Type

Stable

Syntax

`SYSDATE()`

Note: You can call this function with no parentheses.

Example

```
=> SELECT SYSDATE;  
      sysdate  
-----  
2016-12-12 06:11:10.699642  
(1 row)
```

See Also

[Date/Time Expressions](#)

TIME_SLICE

Aggregates data by different fixed-time intervals and returns a rounded-up input `TIMESTAMP` value to a value that corresponds with the start or end of the time slice interval.

Given an input `TIMESTAMP` value such as `2000-10-28 00:00:01`, the start time of a 3-second time slice interval is `2000-10-28 00:00:00`, and the end time of the same time slice is `2000-10-28 00:00:03`.

Behavior Type

Immutable

Syntax

```
TIME_SLICE( expression, slice-length [, 'time--unit' [, 'start-or-end' ] ] )
```

Parameters

<i>expression</i>	<p>One of the following:</p> <ul style="list-style-type: none">• Column of type <code>TIMESTAMP</code>• String constant that can be parsed into a <code>TIMESTAMP</code> value. For example: <pre>'2004-10-19 10:23:54'</pre> <p>Vertica evaluates <i>expression</i> on each row.</p>
<i>slice-length</i>	A positive integer that specifies the slice length.
<i>time--unit</i>	<p>Time unit of the slice, one of the following:</p> <ul style="list-style-type: none">• <code>HOUR</code>• <code>MINUTE</code>• <code>SECOND</code> (default)• <code>MILLISECOND</code>• <code>MICROSECOND</code>
<i>'start-or-end'</i>	Specifies whether the returned value corresponds to the start or end time with one of the following strings:

- START (default)
- END

Note: This parameter can be included only if you also supply a non-null *time--unit* argument.

Null Argument Handling

TIME_SLICE handles null arguments as follows:

- TIME_SLICE returns an error when any one of *slice-length*, *time--unit*, or *start-or-end* parameters is null.
- If *expression* is null and *slice-length*, *time--unit*, or *start-or-end* contain legal values, TIME_SLICE returns a NULL value instead of an error.

Usage

The following command returns the (default) start time of a 3-second time slice:

```
=> SELECT TIME_SLICE('2009-09-19 00:00:01', 3);
      TIME_SLICE
-----
2009-09-19 00:00:00
(1 row)
```

The following command returns the end time of a 3-second time slice:

```
=> SELECT TIME_SLICE('2009-09-19 00:00:01', 3, 'SECOND', 'END');
      TIME_SLICE
-----
2009-09-19 00:00:03
(1 row)
```

This command returns results in milliseconds, using a 3-second time slice:

```
=> SELECT TIME_SLICE('2009-09-19 00:00:01', 3, 'ms');
      TIME_SLICE
-----
2009-09-19 00:00:00.999
(1 row)
```

This command returns results in microseconds, using a 9-second time slice:

```
=> SELECT TIME_SLICE('2009-09-19 00:00:01', 3, 'us');
       TIME_SLICE
-----
2009-09-19 00:00:00.999999
(1 row)
```

The next example uses a 3-second interval with an input value of '00:00:01'. To focus specifically on seconds, the example omits date, though all values are implied as being part of the timestamp with a given input of '00:00:01':

- '00:00:00' is the start of the 3-second time slice
- '00:00:03' is the end of the 3-second time slice.
- '00:00:03' is also the start of the *second* 3-second time slice. In time slice boundaries, the end value of a time slice does not belong to that time slice; it starts the next one.

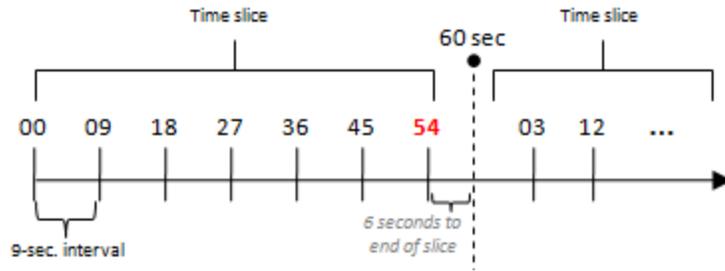

When the time slice interval is not a factor of 60 seconds, such as a given slice length of 9 in the following example, the slice does not always start or end on 00 seconds:

```
=> SELECT TIME_SLICE('2009-02-14 20:13:01', 9);
       TIME_SLICE
-----
2009-02-14 20:12:54
(1 row)
```

This is expected behavior, as the following properties are true for all time slices:

- Equal in length
- Consecutive (no gaps between them)
- Non-overlapping

To force the above example ('2009-02-14 20:13:01') to start at '2009-02-14 20:13:00', adjust the output timestamp values so that the remainder of 54 counts up to 60:

```
=> SELECT TIME_SLICE('2009-02-14 20:13:01', 9)+'6 seconds'::INTERVAL AS time;
       time
-----
2009-02-14 20:13:00
(1 row)
```

Alternatively, you could use a different slice length, which is divisible by 60, such as 5:

```
=> SELECT TIME_SLICE('2009-02-14 20:13:01', 5);
       TIME_SLICE
-----
2009-02-14 20:13:00
(1 row)
```

A TIMESTAMPTZ value is implicitly cast to TIMESTAMP. For example, the following two statements have the same effect.

```
=> SELECT TIME_SLICE('2009-09-23 11:12:01'::timestamptz, 3);
       TIME_SLICE
-----
2009-09-23 11:12:00
(1 row)

=> SELECT TIME_SLICE('2009-09-23 11:12:01'::timestamptz::timestamp, 3);
       TIME_SLICE
-----
2009-09-23 11:12:00
(1 row)
```

Examples

You can use the SQL analytic functions `FIRST_VALUE` and `LAST_VALUE` to find the first/last price within each time slice group (set of rows belonging to the same time slice). This structure could be useful if you want to sample input data by choosing one row from each time slice group.

```
=> SELECT date_key, transaction_time, sales_dollar_amount, TIME_SLICE(DATE '2000-01-01' + date_key +
transaction_time, 3),
FIRST_VALUE(sales_dollar_amount)
OVER (PARTITION BY TIME_SLICE(DATE '2000-01-01' + date_key + transaction_time, 3)
ORDER BY DATE '2000-01-01' + date_key + transaction_time) AS first_value
FROM store.store_sales_fact
LIMIT 20;
```

date_key	transaction_time	sales_dollar_amount	time_slice	first_value
1	00:41:16	164	2000-01-02 00:41:15	164
1	00:41:33	310	2000-01-02 00:41:33	310
1	15:32:51	271	2000-01-02 15:32:51	271
1	15:33:15	419	2000-01-02 15:33:15	419
1	15:33:44	193	2000-01-02 15:33:42	193
1	16:36:29	466	2000-01-02 16:36:27	466
1	16:36:44	250	2000-01-02 16:36:42	250
2	03:11:28	39	2000-01-03 03:11:27	39
3	03:55:15	375	2000-01-04 03:55:15	375
3	11:58:05	369	2000-01-04 11:58:03	369
3	11:58:24	174	2000-01-04 11:58:24	174
3	11:58:52	449	2000-01-04 11:58:51	449
3	19:01:21	201	2000-01-04 19:01:21	201
3	22:15:05	156	2000-01-04 22:15:03	156
4	13:36:57	-125	2000-01-05 13:36:57	-125
4	13:37:24	-251	2000-01-05 13:37:24	-251
4	13:37:54	353	2000-01-05 13:37:54	353
4	13:38:04	426	2000-01-05 13:38:03	426
4	13:38:31	209	2000-01-05 13:38:30	209
5	10:21:24	488	2000-01-06 10:21:24	488

(20 rows)

TIME_SLICE rounds the transaction time to the 3-second slice length.

The following example uses the [analytic \(window\) OVER clause](#) to return the last trading price (the last row ordered by TickTime) in each 3-second time slice partition:

```
=> SELECT DISTINCT TIME_SLICE(TickTime, 3), LAST_VALUE(price)OVER (PARTITION BY TIME_SLICE(TickTime,
3)
ORDER BY TickTime ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING);
```

Note: If you omit the windowing clause from an analytic clause, LAST_VALUE defaults to RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW. Results can seem non-intuitive, because instead of returning the value from the bottom of the current partition, the function returns the bottom of the *window*, which continues to change along with the current input row that is being processed. For more information, see [Time Series Analytics](#) and [SQL Analytics](#) in Analyzing Data.

In the next example, FIRST_VALUE is evaluated once for each input record and the data is sorted by ascending values. Use SELECT DISTINCT to remove the duplicates and return only one output record per TIME_SLICE:

```
=> SELECT DISTINCT TIME_SLICE(TickTime, 3), FIRST_VALUE(price)OVER (PARTITION BY TIME_SLICE(TickTime, 3)
ORDER BY TickTime ASC)
FROM tick_store;
  TIME_SLICE      | ?column?
-----+-----
2009-09-21 00:00:06 |    20.00
2009-09-21 00:00:09 |    30.00
2009-09-21 00:00:00 |    10.00
(3 rows)
```

The information output by the above query can also return MIN, MAX, and AVG of the trading prices within each time slice.

```
=> SELECT DISTINCT TIME_SLICE(TickTime, 3),FIRST_VALUE(Price) OVER (PARTITION BY TIME_SLICE(TickTime, 3)
ORDER BY TickTime ASC),
  MIN(price) OVER (PARTITION BY TIME_SLICE(TickTime, 3)),
  MAX(price) OVER (PARTITION BY TIME_SLICE(TickTime, 3)),
  AVG(price) OVER (PARTITION BY TIME_SLICE(TickTime, 3))
FROM tick_store;
```

TIMEOFDAY

Returns the wall-clock time as a text string. Function results advance during transactions.

Behavior Type

Volatile

Syntax

TIMEOFDAY()

Example

```
=> SELECT TIMEOFDAY();
      TIMEOFDAY
-----
Mon Dec 12 08:18:01.022710 2016 EST
(1 row)
```

TIMESTAMPADD

Adds the specified number of intervals to a `TIMESTAMP` or `TIMESTAMPTZ` value and returns a result of the same data type.

Behavior Type

- Immutable if the input date is a `TIMESTAMP`
- Stable if the input date is a `TIMESTAMPTZ`

Syntax

`TIMESTAMPADD (datepart, count, start-date);`

Parameters

<i>datepart</i>	<p>Specifies the type of time intervals that <code>TIMESTAMPADD</code> adds to the specified start date. If <i>datepart</i> is an expression, it must be enclosed in parentheses:</p> <pre>TIMESTAMPADD(<i>expression</i>, <i>interval</i>, <i>start</i>;</pre> <p><i>datepart</i> must evaluate to one of the following string literals, either quoted or unquoted:</p>
-----------------	--

	<ul style="list-style-type: none"> • year yy yyyy • quarter qq q • month mm m • day dayofyear dd d dy y • week wk ww • hour hh • minute mi n • second ss s • millisecond ms • microsecond mcs us
<i>count</i>	Integer or integer expression that specifies the number of <i>datepart</i> intervals to add to <i>start-date</i> .
<i>start-date</i>	TIMESTAMP or TIMESTAMPTZ value.

Examples

Add two months to the current date:

```
=> SELECT CURRENT_TIMESTAMP AS Today;
      Today
-----
2016-05-02 06:56:57.923045-04
(1 row)

=> SELECT TIMESTAMPADD (MONTH, 2, (CURRENT_TIMESTAMP)) AS TodayPlusTwoMonths;;
      TodayPlusTwoMonths
-----
2016-07-02 06:56:57.923045-04
(1 row)
```

Add 14 days to the beginning of the current month:

```
=> SELECT TIMESTAMPADD (DD, 14, (SELECT TRUNC((CURRENT_TIMESTAMP), 'MM')));
      timestampadd
-----
2016-05-15 00:00:00
(1 row)
```

TIMESTAMPDIFF

Returns the time span between two `TIMESTAMP` or `TIMESTAMPTZ` values, in the intervals specified. `TIMESTAMPDIFF` excludes the start date in its calculation.

Behavior Type

- Immutable if start and end dates are `TIMESTAMP`
- Stable if start and end dates are `TIMESTAMPTZ`

Syntax

```
TIMESTAMPDIFF ( datepart, start, end );
```

Parameters

<i>datepart</i>	<p>Specifies the type of date or time intervals that <code>TIMESTAMPDIFF</code> returns. If <i>datepart</i> is an expression, it must be enclosed in parentheses:</p> <pre>TIMESTAMPDIFF(<i>expression</i>), <i>start</i>, <i>end</i> ;</pre> <p><i>datepart</i> must evaluate to one of the following string literals, either quoted or unquoted:</p> <ul style="list-style-type: none">• year yy yyyy• quarter qq q• month mm m• day dayofyear dd d dy y• week wk ww• hour hh• minute mi n• second ss s
-----------------	--

	<ul style="list-style-type: none">• millisecond ms• microsecond mcs us
<i>start, end</i>	<p>Specify the start and end dates, where <i>start</i> and <i>end</i> evaluate to one of the following data types:</p> <ul style="list-style-type: none">• TIMESTAMP/TIMESTAMP TZ• TIMESTAMP TZ <p>If <i>end</i> < <i>start</i>, <code>TIMESTAMPDIFF</code> returns a negative value.</p>

Date Part Intervals

`TIMESTAMPDIFF` uses the *datepart* argument to calculate the number of intervals between two dates, rather than the actual amount of time between them. For detailed information, see [DATEDIFF](#).

Examples

```
=> SELECT TIMESTAMPDIFF (YEAR, '1-1-2006 12:34:00', '1-1-2008 12:34:00');
timestampdiff
-----
                2
(1 row)
```

See Also

[DATEDIFF](#)

TIMESTAMP_ROUND

Rounds the specified `TIMESTAMP`. If you omit the precision argument, `TIMESTAMP_ROUND` rounds to day (DD) precision.

Behavior Type

- Immutable if the target date is a `TIMESTAMP`
- Stable if the target date is a `TIMESTAMPTZ`

Syntax

```
TIMESTAMP_ROUND ( rounding-target [, 'precision' ] )
```

Parameters

<i>rounding-target</i>	An expression that evaluates to one of the following data types: <ul style="list-style-type: none">• TIMESTAMP/TIMESTAMPTZ• TIMESTAMPTZ
<i>precision</i>	A string constant that specifies precision for the rounded value, one of the following: <ul style="list-style-type: none">• Century: CC SCC• Year: SYYY YYYY YEAR YYY YY Y• ISO Year: IYYY IYY IY I• Quarter: Q• Month: MONTH MON MM RM• Same weekday as first day of year: WW• Same weekday as first day of ISO year: IW• Same weekday as first day of month: W• Day (default): DDD DD J• First weekday: DAY DY D

- **Hour:** HH | HH12 | HH24
- **Minute:** MI
- **Second:** SS

Note: Hour, minute, and second rounding is not supported by DATE expressions.

Examples

Round to the nearest hour:

```
=> SELECT TIMESTAMP_ROUND(CURRENT_TIMESTAMP, 'HH');  
        ROUND  
-----  
2016-04-28 15:00:00  
(1 row)
```

Round to the nearest month:

```
=> SELECT TIMESTAMP_ROUND('9-22-2011 12:34:00'::TIMESTAMP, 'MM');  
        ROUND  
-----  
2011-10-01 00:00:00  
(1 row)
```

See Also

[ROUND](#)

TIMESTAMP_TRUNC

Truncates the specified `TIMESTAMP`. If you omit the precision argument, `TIMESTAMP_TRUNC` truncates to day (DD) precision.

Behavior Type

- Immutable if the target date is a `TIMESTAMP`
- Stable if the target date is a `TIMESTAMPPTZ`

Syntax

```
TIMESTAMP_TRUNC( trunc-target [, 'precision' ] )
```

Parameters

<i>trunc-target</i>	An expression that evaluates to one of the following data types: <ul style="list-style-type: none">• TIMESTAMP/TIMESTAMP TZ• TIMESTAMP TZ
<i>precision</i>	A string constant that specifies precision for the truncated value, one of the following: <ul style="list-style-type: none">• Century: CC SCC• Year: SYYY YYYY YEAR YYY YY Y• ISO Year: IYYY IYY IY I• Quarter: Q• Month: MONTH MON MM RM• Same weekday as first day of year: WW• Same weekday as first day of ISO year: IW• Same weekday as first day of month: W• Day: DDD DD J• First weekday: DAY DY D• Hour: HH HH12 HH24• Minute: MI• Second: SS <p>Note: Hour, minute, and second truncating is not supported by</p>

DATE expressions.

Examples

Truncate to the current hour:

```
=> SELECT TIMESTAMP_TRUNC(CURRENT_TIMESTAMP, 'HH');
TIMESTAMP_TRUNC
-----
2016-04-29 08:00:00
(1 row)
```

Truncate to the month:

```
=> SELECT TIMESTAMP_TRUNC('9-22-2011 12:34:00'::TIMESTAMP, 'MM');
TIMESTAMP_TRUNC
-----
2011-09-01 00:00:00
(1 row)
```

See Also

[TRUNC](#)

TRANSACTION_TIMESTAMP

Returns a value of type `TIME WITH TIMEZONE` that represents the start of the current transaction.

The return value does not change during the transaction. Thus, multiple calls to `TRANSACTION_TIMESTAMP` within the same transaction return the same timestamp.

`TRANSACTION_TIMESTAMP` is equivalent to [CURRENT_TIMESTAMP](#), except it does not accept a precision parameter.

Behavior Type

Stable

Syntax

TRANSACTION_TIMESTAMP()

Example

```
=> SELECT foo, bar FROM (SELECT TRANSACTION_TIMESTAMP() AS foo)foo, (SELECT TRANSACTION_TIMESTAMP()
as bar)bar;
      foo                |                bar
-----+-----
2016-12-12 08:18:00.988528-05 | 2016-12-12 08:18:00.988528-05
(1 row)
```

See Also

- [CLOCK_TIMESTAMP](#)
- [STATEMENT_TIMESTAMP](#)

TRUNC

Truncates the specified date or time. If you omit the precision argument, TRUNC truncates to day (DD) precision.

Behavior Type

- Immutable if the target date is a `TIMESTAMP` or `DATE`
- Stable if the target date is a `TIMESTAMPTZ`

Syntax

TRUNC(*trunc-target* [, '*precision*'])

Parameters

<i>trunc-target</i>	<p>An expression that evaluates to one of the following data types:</p> <ul style="list-style-type: none">• DATE• TIMESTAMP/TIMESTAMPTZ• TIMESTAMPTZ
<i>precision</i>	<p>A string constant that specifies precision for the truncated value, one of the following:</p> <ul style="list-style-type: none">• Century: CC SCC• Year: SYYY YYYY YEAR YYY YY Y• ISO Year: IYYY IYY IY I• Quarter: Q• Month: MONTH MON MM RM• Same weekday as first day of year: WW• Same weekday as first day of ISO year: IW• Same weekday as first day of month: W• Day (default): DDD DD J• First weekday: DAY DY D• Hour: HH HH12 HH24• Minute: MI• Second: SS <p>Note: Hour, minute, and second truncating is not supported by DATE expressions.</p>

Examples

Truncate to the current hour:

```
=> => SELECT TRUNC(CURRENT_TIMESTAMP, 'HH');
      TRUNC
-----
2016-04-29 10:00:00
(1 row)
```

Truncate to the month:

```
=> SELECT TRUNC('9-22-2011 12:34:00'::TIMESTAMP, 'MM');
      TIMESTAMP_TRUNC
-----
2011-09-01 00:00:00
(1 row)
```

See Also

[TIMESTAMP_TRUNC](#)

WEEK

Returns the week of the year for the specified date as an integer, where the first week begins on the first Sunday on or preceding January 1.

Syntax

```
WEEK ( date )
```

Behavior Type

- Immutable if the specified date is a `TIMESTAMP`, `DATE`, or `VARCHAR`
- Stable if the specified date is a `TIMESTAMPPTZ`

Parameters

<i>date</i>	The date to process, one of the following data types: <ul style="list-style-type: none">• VARCHAR• DATE• TIMESTAMP• TIMESTAMPTZ
-------------	--

Examples

January 2 is on Saturday, so WEEK returns 1:

```
=> SELECT WEEK ('1-2-2016'::DATE);
WEEK
-----
    1
(1 row)
```

January 3 is the second Sunday in 2016, so WEEK returns 2:

```
=> SELECT WEEK ('1-3-2016'::DATE);
WEEK
-----
    2
(1 row)
```

WEEK_ISO

Returns the week of the year for the specified date as an integer, where the first week starts on Monday and contains January 4. This function conforms with the ISO 8061 standard.

Syntax

```
WEEK_ISO ( date )
```

Behavior Type

- Immutable if the specified date is a `TIMESTAMP`, `DATE`, or `VARCHAR`
- Stable if the specified date is a `TIMESTAMPTZ`

Parameters

<i>date</i>	The date to process, one of the following data types: <ul style="list-style-type: none">• <code>VARCHAR</code>• <code>DATE</code>• <code>TIMESTAMP</code>• <code>TIMESTAMPTZ</code>
-------------	--

Examples

The first week of 2016 begins on Monday January 4:

```
=> SELECT WEEK_ISO ('1-4-2016'::DATE);  
WEEK_ISO  
-----  
          1  
(1 row)
```

January 3 2016 returns week 53 of the previous year (2015):

```
=> SELECT WEEK_ISO ('1-3-2016'::DATE);  
WEEK_ISO  
-----  
          53  
(1 row)
```

In 2015, January 4 is on Sunday, so the first week of 2015 begins on the preceding Monday (December 29 2014):

```
=> SELECT WEEK_ISO ('12-29-2014'::DATE);  
WEEK_ISO  
-----  
          1
```

(1 row)

YEAR

Returns an integer that represents the year portion of the specified date.

Syntax

```
YEAR( date )
```

Behavior Type

- Immutable if the specified date is a `TIMESTAMP`, `DATE`, `VARCHAR`, or `INTERVAL`
- Stable if the specified date is a `TIMESTAMPTZ`

Parameters

<i>date</i>	The date to process, one of the following data types: <ul style="list-style-type: none">• <code>VARCHAR</code>• <code>DATE</code>• <code>TIMESTAMP</code>• <code>TIMESTAMPTZ</code>• <code>INTERVAL</code>
-------------	--

Examples

```
=> SELECT YEAR(CURRENT_DATE::DATE);  
YEAR  
-----  
2016  
(1 row)
```

See Also

[YEAR_ISO](#)

YEAR_ISO

Returns an integer that represents the year portion of the specified date. The return value is based on the ISO 8061 standard.

The first week of the ISO year is the week that contains January 4.

Syntax

```
YEAR_ISO ( date )
```

Behavior Type

- Immutable if the specified date is a `TIMESTAMP`, `DATE`, or `VARCHAR`
- Stable if the specified date is a `TIMESTAMPTZ`

Parameters

<i>date</i>	The date to process, one of the following data types: <ul style="list-style-type: none">• <code>VARCHAR</code>• <code>DATE</code>• <code>TIMESTAMP</code>• <code>TIMESTAMPTZ</code>
-------------	--

Examples

```
> SELECT YEAR_ISO(CURRENT_DATE::DATE);  
YEAR_ISO  
-----  
      2016  
(1 row)
```

See Also

[YEAR](#)

Error-handling Functions

Error-handling functions take a string and return the string when the query is executed.

THROW_ERROR

Returns a user-defined error message.

In a multi-node cluster, race conditions might cause the order of error messages to differ.

Syntax

```
THROW_ERROR ( message )
```

Parameters

<i>message</i>	The VARCHAR string to to return.
----------------	----------------------------------

Examples

Return an error message when a CASE statement is met:

```
=> CREATE TABLE pitcher_err (some_text varchar);
CREATE TABLE
=> COPY pitcher_err FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> big foo value
>> bigger foo other value
>> bar another foo value
>> \.
=> SELECT (CASE WHEN true THEN THROW_ERROR('Failure!!!') ELSE some_text END) FROM pitcher_err;
ERROR 7137:  USER GENERATED ERROR: Failure!!!
```

Return an error message when a CASE statement using [REGEXP_LIKE](#) is met:

```
=> SELECT (CASE WHEN REGEXP_LIKE(some_text, 'other') THEN THROW_ERROR('Failure at "' || some_text ||
''') END) FROM pitcher_err;
ERROR 4566:  USER GENERATED ERROR: Failure at "bar another foo value"
```

Formatting Functions

Formatting functions provide a powerful tool set for converting various data types (DATE/TIME, INTEGER, FLOATING POINT) to formatted strings and for converting from formatted strings to specific data types.

TO_BITSTRING

Returns a VARCHAR that represents the given VARBINARY value in bitstring format. This function is the inverse of [BITSTRING_TO_BINARY](#).

Behavior Type

Immutable

Syntax

```
TO_BITSTRING ( expression )
```

Parameters

<i>expression</i>	The VARCHAR string to process.
-------------------	--------------------------------

Examples

```
=> SELECT TO_BITSTRING('ab'::BINARY(2));
   to_bitstring
-----
0110000101100010
(1 row)
```

```
=> SELECT TO_BITSTRING(HEX_TO_BINARY('0x10'));
   to_bitstring
-----
00010000
(1 row)

=> SELECT TO_BITSTRING(HEX_TO_BINARY('0xF0'));
   to_bitstring
-----
11110000
(1 row)
```

See Also

[BITCOUNT](#)

TO_CHAR

Converts various date/time and numeric values into text strings.

Behavior Type

Stable

Syntax

`TO_CHAR (expression [, pattern])`

Parameters

<i>expression</i>	Specifies the value to convert, one of the following data types: <ul style="list-style-type: none">DOUBLE PRECISIONINTEGERINTERVALTIME/TIMETZTIMESTAMP/TIMESTAMPTZ
-------------------	--

<i>pattern</i>	A CHAR or VARCHAR that specifies an output pattern string. See: <ul style="list-style-type: none">• Template Patterns for Date/Time Formatting• Template Patterns for Numeric Formatting
----------------	---

Notes

- TO_CHAR(any) casts any type, except BINARY/VARBINARY, to VARCHAR.

The following example returns an error if you try to cast TO_CHAR to a binary data type:

```
=> SELECT TO_CHAR('abc'::VARBINARY);  
ERROR: cannot cast type varbinary to varchar
```

- TO_CHAR accepts TIME and TIMETZ data types as inputs if you explicitly cast TIME to TIMESTAMP and TIMETZ to TIMESTAMPTZ.

```
=> SELECT TO_CHAR(TIME '14:34:06.4', 'HH12:MI am');  
=> SELECT TO_CHAR(TIMETZ '14:34:06.4+6', 'HH12:MI am');
```

You can extract the timezone hour from TIMETZ:

```
=> SELECT EXTRACT(timezone_hour FROM TIMETZ '10:30+13:30');  
date_part  
-----  
13  
(1 row)
```

- Ordinary text is allowed in to_char templates and is output literally. You can put a substring in double quotes to force it to be interpreted as literal text even if it contains pattern key words. For example, in '"Hello Year "YYYY"', the YYYY is replaced by the year data, but the single Y in Year is not.
- TO_CHAR's day-of-the-week numbering (see the 'D' [template pattern](#)) is different from that of the EXTRACT function.
- Given an INTERVAL type, TO_CHAR formats HH and HH12 as hours in a single day, while HH24 can output hours exceeding a single day, for example, >24.
- To use a double quote character in the output, precede it with a double backslash. This is necessary because the backslash already has a special meaning in a string constant. For example: '\\\"YYYY Month\\\"'

- TO_CHAR does not support the use of V combined with a decimal point. For example: 99.9V99 is not allowed.
- When rounding, the last digit of the rounded representation is selected to be even if the number is exactly half way between the two.

Examples

Expression	Result
SELECT TO_CHAR(CURRENT_TIMESTAMP, 'Day, DD HH12:MI:SS');	'Tuesday , 06 05:39:18'
SELECT TO_CHAR(CURRENT_TIMESTAMP, 'FMDay, FMDD HH12:MI:SS');	'Tuesday, 6 05:39:18'

SELECT TO_CHAR(12.4, '99V999');	' 12400'
SELECT TO_CHAR(12.45, '99V9');	' 125'
SELECT TO_CHAR(-1234.567);	-1234.567
SELECT TO_CHAR('1999-12-25'::DATE);	1999-12-25
SELECT TO_CHAR('1999-12-25 11:31'::TIMESTAMP);	1999-12-25 11:31:00
SELECT TO_CHAR('1999-12-25 11:31 EST'::TIMESTAMPZ);	1999-12-25 11:31:00-05
SELECT TO_CHAR('3 days 1000.333 secs'::INTERVAL);	3 days 00:16:40.333

TO_DATE

Converts a string value to a DATE type.

Behavior Type

Stable

Syntax

TO_DATE (*expression* , *pattern*)

Parameters

<i>expression</i>	Specifies the string value to convert, either CHAR or VARCHAR.
<i>pattern</i>	A CHAR or VARCHAR that specifies an output pattern string. See: <ul style="list-style-type: none">Template Patterns for Date/Time FormattingTemplate Patterns for Numeric Formatting

Input Value Considerations

TO_DATE requires a CHAR or VARCHAR expression. For other input types, use [TO_CHAR](#) to perform an explicit cast to a CHAR or VARCHAR before using this function.

Notes

- To use a double quote character in the output, precede it with a double backslash. This is necessary because the backslash already has a special meaning in a string constant. For example: `'\\"YYYY Month\\"'`
- TO_TIMESTAMP, TO_TIMESTAMP_TZ, and TO_DATE skip multiple blank spaces in the input string if the FX option is not used. FX must be specified as the first item in the template. For example:
 - TO_TIMESTAMP('2000 JUN', 'YYYY MON') is correct.
 - TO_TIMESTAMP('2000 JUN', 'FXYYYY MON') returns an error, because TO_TIMESTAMP expects one space only.
- The YYYY conversion from string to TIMESTAMP or DATE has a restriction if you use a year with more than four digits. You must use a non-digit character or template after YYYY, otherwise the year is always interpreted as four digits. For example, given the following arguments, TO_DATE interprets the five-digit year 20000 as a four-digit year:

```
=> SELECT TO_DATE('200001131', 'YYYYMMDD');  
TO_DATE  
-----
```

```
2000-01-13  
(1 row)
```

Instead, use a non-digit separator after the year. For example:

```
=> SELECT TO_DATE('20000-1131', 'YYYY-MMDD');  
      TO_DATE  
-----  
20000-12-01  
(1 row)
```

- In conversions from string to `TIMESTAMP` or `DATE`, the `CC` field is ignored if there is a `YYY`, `YYYY` or `Y,YYY` field. If `CC` is used with `YY` or `Y`, then the year is computed as $(CC-1)*100+YY$.

Examples

```
=> SELECT TO_DATE('13 Feb 2000', 'DD Mon YYYY');  
      to_date  
-----  
2000-02-13  
(1 row)
```

See Also

[Date/Time Functions](#)

TO_HEX

Returns a `VARCHAR` or `VARBINARY` representing the hexadecimal equivalent of a number. This function is the inverse of [HEX_TO_BINARY](#).

Behavior Type

Immutable

Syntax

```
TO_HEX ( number )
```

Parameters

<i>number</i>	An INTEGER or VARBINARY value to convert to hexadecimal. If you supply a VARBINARY argument, the function's return value is not preceded by 0x.
---------------	--

Examples

```
=> SELECT TO_HEX(123456789);
   TO_HEX
-----
   75bcd15
(1 row)
```

For **VARBINARY** inputs, the returned value is not preceded by 0x. For example:

```
=> SELECT TO_HEX('ab'::binary(2));
   TO_HEX
-----
     6162
(1 row)
```

TO_TIMESTAMP

Converts a string value or a UNIX/POSIX epoch value to a **TIMESTAMP** type.

Behavior Type

Stable

Syntax

```
TO_TIMESTAMP ( expression, pattern )TO_TIMESTAMP ( unix-epoch )
```

Parameters

<i>expression</i>	Specifies the string value to convert, either CHAR or VARCHAR .
<i>pattern</i>	A CHAR or VARCHAR that specifies an output pattern string. See:

	<ul style="list-style-type: none"> • Template Patterns for Date/Time Formatting • Template Patterns for Numeric Formatting
<i>unix-epoch</i>	A DOUBLE PRECISION value that specifies some number of seconds elapsed since midnight UTC of January 1, 1970, not counting leap seconds. INTEGER values are implicitly cast to DOUBLE PRECISION.

Notes

- Millisecond (MS) and microsecond (US) values in a conversion from string to TIMESTAMP are used as part of the seconds after the decimal point. For example TO_TIMESTAMP('12:3', 'SS:MS') is not 3 milliseconds, but 300, because the conversion counts it as 12 + 0.3 seconds. This means for the format SS:MS, the input values 12:3, 12:30, and 12:300 specify the same number of milliseconds. To get three milliseconds, use 12:003, which the conversion counts as 12 + 0.003 = 12.003 seconds.

Here is a more complex example: TO_TIMESTAMP('15:12:02.020.001230', 'HH:MI:SS.MS.US') is 15 hours, 12 minutes, and 2 seconds + 20 milliseconds + 1230 microseconds = 2.021230 seconds.

- To use a double quote character in the output, precede it with a double backslash. This is necessary because the backslash already has a special meaning in a string constant. For example: '\\\"YYYY Month\\\"'
- TO_TIMESTAMP, TO_TIMESTAMP_TZ, and TO_DATE skip multiple blank spaces in the input string if the FX option is not used. FX must be specified as the first item in the template. For example:
 - TO_TIMESTAMP('2000 JUN', 'YYYY MON') is correct.
 - TO_TIMESTAMP('2000 JUN', 'FXYYYY MON') returns an error, because TO_TIMESTAMP expects one space only.
- The YYYY conversion from string to TIMESTAMP or DATE has a restriction if you use a year with more than four digits. You must use a non-digit character or template after YYYY, otherwise the year is always interpreted as four digits. For example, given the following arguments, TO_DATE interprets the five-digit year 20000 as a four-digit year:

```
=> SELECT TO_DATE('200001131', 'YYYYMMDD');
       TO_DATE
-----
2000-01-13
(1 row)
```

Instead, use a non-digit separator after the year. For example:

```
=> SELECT TO_DATE('20000-1131', 'YYYY-MMDD');
       TO_DATE
-----
20000-12-01
(1 row)
```

- In conversions from string to `TIMESTAMP` or `DATE`, the `CC` field is ignored if there is a `YYY`, `YYYY` or `Y,YYY` field. If `CC` is used with `YY` or `Y`, then the year is computed as $(CC-1)*100+YY$.

Examples

```
=> SELECT TO_TIMESTAMP('13 Feb 2009', 'DD Mon YYYY');
       TO_TIMESTAMP
-----
1200-02-13 00:00:00
(1 row)

=> SELECT TO_TIMESTAMP(200120400);
       TO_TIMESTAMP
-----
1976-05-05 01:00:00
(1 row)
```

See Also

[Date/Time Functions](#)

TO_TIMESTAMP_TZ

Converts a string value or a UNIX/POSIX epoch value to a `TIMESTAMP WITH TIME ZONE` type.

Behavior Type

Immutable if single argument form, Stable otherwise.

Syntax

`TO_TIMESTAMP_TZ (expression, pattern)TO_TIMESTAMP (unix-epoch)`

Parameters

<i>expression</i>	Specifies the string value to convert, either CHAR or VARCHAR.
<i>pattern</i>	A CHAR or VARCHAR that specifies an output pattern string. See: <ul style="list-style-type: none"> Template Patterns for Date/Time Formatting Template Patterns for Numeric Formatting
<i>unix-epoch</i>	A DOUBLE PRECISION value that specifies some number of seconds elapsed since midnight UTC of January 1, 1970, not counting leap seconds. INTEGER values are implicitly cast to DOUBLE PRECISION.

Notes

- Millisecond (MS) and microsecond (US) values in a conversion from string to TIMESTAMP are used as part of the seconds after the decimal point. For example `TO_TIMESTAMP ('12:3', 'SS:MS')` is not 3 milliseconds, but 300, because the conversion counts it as 12 + 0.3 seconds. This means for the format SS:MS, the input values 12:3, 12:30, and 12:300 specify the same number of milliseconds. To get three milliseconds, use 12:003, which the conversion counts as $12 + 0.003 = 12.003$ seconds.

Here is a more complex example: `TO_TIMESTAMP ('15:12:02.020.001230', 'HH:MI:SS.MS.US')` is 15 hours, 12 minutes, and 2 seconds + 20 milliseconds + 1230 microseconds = 2.021230 seconds.

- To use a double quote character in the output, precede it with a double backslash. This is necessary because the backslash already has a special meaning in a string constant. For example: `'\\"YYYY Month\\"'`
- `TO_TIMESTAMP`, `TO_TIMESTAMP_TZ`, and `TO_DATE` skip multiple blank spaces in the input string if the FX option is not used. FX must be specified as the first item in the template. For example:

- `TO_TIMESTAMP('2000 JUN', 'YYYY MON')` is correct.
- `TO_TIMESTAMP('2000 JUN', 'FXYYYY MON')` returns an error, because `TO_TIMESTAMP` expects one space only.
- The `YYYY` conversion from string to `TIMESTAMP` or `DATE` has a restriction if you use a year with more than four digits. You must use a non-digit character or template after `YYYY`, otherwise the year is always interpreted as four digits. For example, given the following arguments, `TO_DATE` interprets the five-digit year 20000 as a four-digit year:

```
=> SELECT TO_DATE('200001131', 'YYYYMMDD');
      TO_DATE
-----
2000-01-13
(1 row)
```

Instead, use a non-digit separator after the year. For example:

```
=> SELECT TO_DATE('20000-1131', 'YYYY-MMDD');
      TO_DATE
-----
20000-12-01
(1 row)
```

- In conversions from string to `TIMESTAMP` or `DATE`, the `CC` field is ignored if there is a `YYY`, `YYYY` or `Y,YYY` field. If `CC` is used with `YY` or `Y`, then the year is computed as $(CC-1)*100+YY$.

Examples

```
=> SELECT TO_TIMESTAMP_TZ('13 Feb 2009', 'DD Mon YYYY');
      TO_TIMESTAMP_TZ
-----
1200-02-13 00:00:00-05
(1 row)

=> SELECT TO_TIMESTAMP_TZ(200120400);
      TO_TIMESTAMP_TZ
-----
1976-05-05 01:00:00-04
(1 row)
```

See Also

[Date/Time Functions](#)

TO_NUMBER

Converts a string value to DOUBLE PRECISION.

Behavior Type

Stable

Syntax

```
TO_NUMBER ( expression, [ pattern ] )
```

Parameters

<i>expression</i>	Specifies the string value to convert, either CHAR or VARCHAR.
<i>pattern</i>	A string value, either CHAR or VARCHAR, that specifies an output pattern string using one of the supported Template Patterns for Numeric Formatting . If you omit this parameter, TO_NUMBER returns a floating point.

Notes

To use a double quote character in the output, precede it with a double backslash. This is necessary because the backslash already has a special meaning in a string constant. For example: '\\\"YYYY Month\\\"'

Note: To convert a date string to a numeric value, use the appropriate [date/time function](#), such as [EXTRACT](#).

Examples

```
=> SELECT TO_NUMBER('MCL', 'rn');  
TO_NUMBER  
-----
```

```
1950  
(1 row)
```

It the pattern parameter is omitted, the function returns a floating point. For example:

```
=> SELECT TO_NUMBER('-123.456e-01');  
TO_NUMBER  
-----  
-12.3456
```

Template Patterns for Date/Time Formatting

In an output template string (for TO_CHAR), there are certain patterns that are recognized and replaced with appropriately-formatted data from the value to be formatted. Any text that is not a template pattern is copied verbatim. Similarly, in an input template string (for anything other than TO_CHAR), template patterns identify the parts of the input data string to be looked at and the values to be found there.

Note: Vertica uses the ISO 8601:2004 style for date/time fields in Vertica *.log files. For example,
2008-09-16 14:40:59.123 TM Moveout:0x2aaaac002180 [Txn] <INFO>

Certain modifiers can be applied to any template pattern to alter its behavior as described in [Template Pattern Modifiers for Date/Time Formatting](#).

Pattern	Description
HH	Hour of day (00-23)
HH12	Hour of day (01-12)
HH24	Hour of day (00-23)
MI	Minute (00-59)
SS	Second (00-59)
MS	Millisecond (000-999)
US	Microsecond (000000-999999)
SSSS	Seconds past midnight (0-86399)
AM or A.M. or PM or P.M.	Meridian indicator (uppercase)
am or a.m. or pm or p.m.	Meridian indicator (lowercase)
Y,YYY	Year (4 and more digits) with comma
YYYY	Year (4 and more digits)
YYY	Last 3 digits of year

Pattern	Description
YY	Last 2 digits of year
Y	Last digit of year
IYYY	ISO year (4 and more digits)
IYY	Last 3 digits of ISO year
IY	Last 2 digits of ISO year
I	Last digits of ISO year
BC or B.C. or AD or A.D.	Era indicator (uppercase)
bc or b.c. or ad or a.d.	Era indicator (lowercase)
MONTH	Full uppercase month name (blank-padded to 9 chars)
Month	Full mixed-case month name (blank-padded to 9 chars)
month	Full lowercase month name (blank-padded to 9 chars)
MON	Abbreviated uppercase month name (3 chars)
Mon	Abbreviated mixed-case month name (3 chars)
mon	Abbreviated lowercase month name (3 chars)
MM	Month number (01-12)
DAY	Full uppercase day name (blank-padded to 9 chars)
Day	Full mixed-case day name (blank-padded to 9 chars)
day	full lowercase day name (blank-padded to 9 chars)
DY	Abbreviated uppercase day name (3 chars)
Dy	Abbreviated mixed-case day name (3 chars)
dy	Abbreviated lowercase day name (3 chars)
DDD	Day of year (001-366)
DD	Day of month (01-31) for TIMESTAMP

Pattern	Description
	Note: For INTERVAL, DD is day of year (001-366) because day of month is undefined.
D	Day of week (1-7; Sunday is 1)
W	Week of month (1-5) (The first week starts on the first day of the month.)
WW	Week number of year (1-53) (The first week starts on the first day of the year.)
IW	ISO week number of year (The first Thursday of the new year is in week 1.)
CC	Century (2 digits)
J	Julian Day (days since January 1, 4712 BC)
Q	Quarter
RM	Month in Roman numerals (I-XII; I=January) (uppercase)
rm	Month in Roman numerals (i-xii; i=January) (lowercase)
TZ	Time-zone name (uppercase)
tz	Time-zone name (lowercase)

Examples

Use `TO_TIMESTAMP` to convert an expression using the pattern 'YYY MON':

```
=> SELECT TO_TIMESTAMP('2017 JUN', 'YYYY MON');
       TO_TIMESTAMP
-----
2017-06-01 00:00:00
(1 row)
```

Use `TO_DATE` to convert an expression using the pattern 'YYY-MMDD':

```
=> SELECT TO_DATE('2017-1231', 'YYYY-MMDD');
       TO_DATE
-----
2017-12-31
```

(1 row)

Template Pattern Modifiers for Date/Time Formatting

Certain modifiers can be applied to any template pattern to alter its behavior. For example, FMMonth is the Month pattern with the FM modifier.

Modifier	Description
AM	Time is before 12:00
AT	Ignored
JULIAN, JD, J	Next field is Julian Day
FM prefix	Fill mode (suppress padding blanks and zeros) For example: FMMonth Note: The FM modifier suppresses leading zeros and trailing blanks that would otherwise be added to make the output of a pattern fixed width.
FX prefix	Fixed format global option For example: FX Month DD Day
ON	Ignored
PM	Time is on or after 12:00
T	Next field is time
TH suffix	Uppercase ordinal number suffix For example: DDTH
th suffix	Lowercase ordinal number suffix For example: DDth
TM prefix	Translation mode (print localized day and month names based on lc_ messages). For example: TMMonth

Template Patterns for Numeric Formatting

Pattern	Description
9	Value with the specified number of digits
0	Value with leading zeros
. (period)	Decimal point
, (comma)	Group (thousand) separator
PR	Negative value in angle brackets
S	Sign anchored to number (uses locale)
L	Currency symbol (uses locale)
D	Decimal point (uses locale)
G	Group separator (uses locale)
MI	Minus sign in specified position (if number < 0)
PL	Plus sign in specified position (if number > 0)
SG	Plus/minus sign in specified position
RN	Roman numeral (input between 1 and 3999)
TH or th	Ordinal number suffix
V	Shift specified number of digits (see notes)
EEEE	Scientific notation (not implemented yet)

Usage

- A sign formatted using SG, PL, or MI is not anchored to the number; for example:
 - `TO_CHAR(-12, 'S9999')` produces ' -12'
 - `TO_CHAR(-12, 'MI9999')` produces '- 12'
- 9 results in a value with the same number of digits as there are 9s. If a digit is not available it outputs a space.
- TH does not convert values less than zero and does not convert fractional numbers.
- V effectively multiplies the input values by 10^n , where n is the number of digits following V. `TO_CHAR` does not support the use of V combined with a decimal point. For example: 99.9V99 is not allowed.

Geospatial Functions

The following topics describe the Vertica geospatial functions.

Function-Naming Conventions

The geospatial functions use the following naming conventions:

- The `ST_<function_name>` functions are compliant with the latest Open Geospatial Consortium standard OGC SFA-SQL version 1.2.1 (reference. number is OGC 06-104r4, date: 2010-08-04). Currently, some `ST_<function_name>` functions may not support all data types. Each function page contains details about the supported data types.

Note: Some functions, such as `ST_GeomFromText`, are based on previous versions of the standard.

- The `STV_<function_name>` functions are unique to Vertica and not compliant with OGC standards. Each function page explains its functionality in detail.

Verifying Spatial Objects Validity

Many spatial functions do not verify the validity of the parameters. If you pass an invalid spatial object to an ST_ or STV_ function, the function may return an error or produce incorrect results.

To avoid this issue, Micro Focus recommends that you first run ST_IsValid on all spatial objects to verify their validity. If your object is not valid, run STV_IsValidReason to get information about the location of the invalidity.

Note: If you pass a valid polygon to STV_IsValidReason, it returns NULL.

ST_AsText

Creates the Well-Known Text (WKT) representation of a spatial object. Use this function when you need to specify a spatial object in ASCII form.

The [Open Geospatial Consortium \(OGC\)](#) defines the format of a WKT string in the [Simple Feature Access Part 1 - Common Architecture](#) specification.

Behavior Type

Immutable

Syntax

```
ST_AsText( g )
```

Arguments

<i>g</i>	Spatial object for which you want the WKT string, type GEOMETRY or GEOGRAPHY
----------	--

Returns

LONG VARCHAR

Supported Data Types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	Yes	Yes
Linestring	Yes	Yes	Yes
Multilinestring	Yes	Yes	Yes
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	Yes
GeometryCollection	Yes	No	No

Example

The following example shows how to use ST_AsText.

Retrieve WKB and WKT representations:

```
=> CREATE TABLE locations (id INTEGER, name VARCHAR(100), geom1 GEOMETRY(800),
    geom2 GEOGRAPHY);
CREATE TABLE
=> COPY locations
    (id, geom1x FILLER LONG VARCHAR(800), geom1 AS ST_GeomFromText(geom1x), geom2x FILLER LONG
    VARCHAR (800),
    geom2 AS ST_GeographyFromText(geom2x))
    FROM stdin;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1|POINT(2 3)|
>> 2|LINESTRING(2 4,1 5)|
>> 3||POLYGON((-70.96 43.27,-70.67 42.95,-66.90 44.74,-67.81 46.08,-67.81 47.20,-69.22 47.43,-71.09
45.25,-70.96 43.27))
>> \.
=> SELECT id, ST_AsText(geom1),ST_AsText(geom2) FROM locations ORDER BY id ASC;
id |          ST_AsText          |          ST_AsText
-----+-----+-----
1 | POINT (2 3)                |
2 | LINESTRING (2 4, 1 5)      |
3 | POLYGON ((-70.96 43.27, -70.67 42.95, -66.9 44.74, -67.81 46.08, -67.81
47.2, -69.22 47.43, -71.09 45.25, -70.96 43.27))
```

(3 rows)

Calculate the length of a WKT using the Vertica SQL function [LENGTH](#):

```
=> SELECT LENGTH(ST_AsText(St_GeomFromText('POLYGON ((-1 2, 0 3, 1 2,
                                           0 1, -1 2))')));

LENGTH
-----
      37
(1 row)
```

See Also

- [ST_AsBinary](#)

ST_Area

Calculates the area of a spatial object.

The units are:

- GEOMETRY objects: spatial reference system identifier (SRID) units
- GEOGRAPHY objects: square meters

Behavior Type

Immutable

Syntax

```
ST_Area( g )
```

Arguments

<i>g</i>	Spatial object for which you want to calculate the area, type GEOMETRY or GEOGRAPHY
----------	---

Returns

FLOAT

Supported Data Types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)
Point	Yes	Yes
Multipoint	Yes	Yes
Linestring	Yes	Yes
Multilinestring	Yes	Yes
Polygon	Yes	Yes
Multipolygon	Yes	Yes
GeometryCollection	Yes	No

Examples

The following examples show how to use ST_Area.

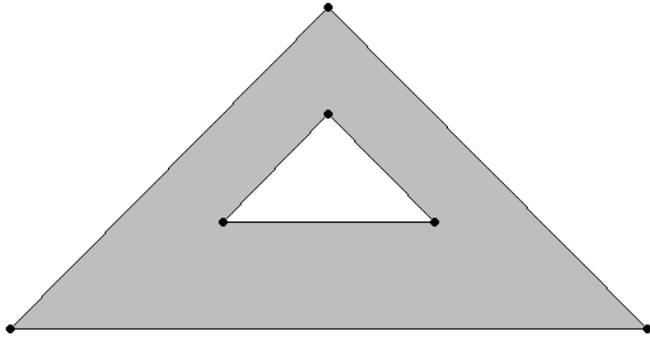

Calculate the area of a polygon:

```
=> SELECT ST_Area(ST_GeomFromText('POLYGON((0 0,1 0,1 1,0 1,0 0))'));
   ST_Area
-----
         1
(1 row)
```

Calculate the area of a multipolygon:

```
=> SELECT ST_Area(ST_GeomFromText('MultiPolygon(((0 0,1 0,1 1,0 1,0 0)),
((2 2,2 3,4 6,3 3,2 2)))'));
   ST_Area
-----
         3
(1 row)
```

Suppose the polygon has a hole, as in the following figure.

Calculate the area, excluding the area of the hole:

```
=> SELECT ST_Area(ST_GeomFromText('POLYGON((2 2,5 5,8 2,2 2),
(4 3,5 4,6 3,4 3))'));
ST_Area
-----
      8
(1 row)
```

Calculate the area of a geometry collection:

```
=> SELECT ST_Area(ST_GeomFromText('GEOMETRYCOLLECTION(POLYGON((20.5 20.45,
20.51 20.52,20.69 20.32,20.5 20.45)),POLYGON((10 20,30 40,25 50,10 20))'));
ST_Area
-----
150.0073
(1 row)
```

Calculate the area of a geography object:

```
=> SELECT ST_Area(ST_GeographyFromText('POLYGON((20.5 20.45,20.51 20.52,
20.69 20.32,20.5 20.45))'));
ST_Area
-----
84627437.116037
(1 row)
```

ST_AsBinary

Creates the Well-Known Binary (WKB) representation of a spatial object. Use this function when you need to convert an object to binary form for porting spatial data to or from other applications.

The [Open Geospatial Consortium \(OGC\)](#) defines the format of a WKB representation in the [Simple Feature Access Part 1 - Common Architecture](#) specification.

Behavior Type

Immutable

Syntax

```
ST_AsBinary( g )
```

Arguments

<i>g</i>	Spatial object for which you want the WKB, type GEOMETRY or GEOGRAPHY
----------	---

Returns

LONG VARBINARY

Supported Data Types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	Yes	Yes
Linestring	Yes	Yes	Yes
Multilinestring	Yes	Yes	Yes
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	Yes
GeometryCollection	Yes	No	No

Example

The following example shows how to use `ST_AsBinary`.

Retrieve WKB and WKT representations:

```
=> CREATE TABLE locations (id INTEGER, name VARCHAR(100), geom1 GEOMETRY(800), geom2 GEOGRAPHY);
CREATE TABLE
=> COPY locations
  (id, geom1x FILLER LONG VARCHAR(800), geom1 AS ST_GeomFromText(geom1x), geom2x FILLER LONG
  VARCHAR (800),
  geom2 AS ST_GeographyFromText(geom2x))
  FROM stdin;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1|POINT(2 3)|
>> 2|LINESTRING(2 4,1 5)|
>> 3||POLYGON((-70.96 43.27,-70.67 42.95,-66.90 44.74,-67.81 46.08,-67.81 47.20,-69.22 47.43,-71.09
45.25,-70.96 43.27))
>> \.
=> SELECT id, ST_AsText(geom1),ST_AsText(geom2) FROM locations ORDER BY id ASC;
 id |          ST_AsText          |          ST_AsText
-----+-----+-----
  1 | POINT (2 3)                 |
  2 | LINESTRING (2 4, 1 5)       |
  3 |                             | POLYGON ((-70.96 43.27, -70.67 42.95, -66.9 44.74, -67.81 46.08, -67.81
47.2, -69.22 47.43, -71.09 45.25, -70.96 43.27))
=> SELECT id, ST_AsBinary(geom1),ST_AsBinary(geom2) FROM locations ORDER BY id ASC;
.
.
.
(3 rows)
```

Calculate the length of a WKB using the Vertica SQL function [LENGTH](#):

```
=> SELECT LENGTH(ST_AsBinary(ST_GeomFromText('POLYGON ((-1 2, 0 3, 1 2,
                                0 1, -1 2)))));
 LENGTH
-----
      93
(1 row)
```

See Also

[ST_AsText](#)

ST_Boundary

Calculates the boundary of the specified GEOMETRY object. An object's boundary is the set of points that define the limit of the object.

For a linestring, the boundary is the start and end points. For a polygon, the boundary is a linestring that begins and ends at the same point.

Behavior Type

Immutable

Syntax

```
ST_Boundary( g )
```

Arguments

<i>g</i>	Spatial object for which you want the boundary, type GEOMETRY
----------	---

Returns

GEOMETRY

Supported Data Types

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes

Polygon	Yes
Multipolygon	Yes
GeometryCollection	No

Examples

The following examples show how to use `ST_Boundary`.

Returns a linestring that represents the boundary:

```
=> SELECT ST_AsText(ST_Boundary(ST_GeomFromText('POLYGON((-1 -1,2 2,
  0 1,-1 -1)'))));
   ST_AsText
-----
LINESTRING(-1 -1, 2 2, 0 1, -1 -1)
(1 row)
```

Returns a multilinestring that contains the boundaries of both polygons:

```
=> SELECT ST_AsText(ST_Boundary(ST_GeomFromText('POLYGON((2 2,5 5,8 2,2 2),
  (4 3,5 4,6 3,4 3)'))));
   ST_AsText
-----
MULTILINESTRING ((2 2, 5 5, 8 2, 2 2), (4 3, 5 4, 6 3, 4 3))
(1 row)
```

The boundary of a linestring is its start and end points:

```
=> SELECT ST_AsText(ST_Boundary(ST_GeomFromText(
  'LINESTRING(1 1,2 2,3 3,4 4)'));
   ST_AsText
-----
MULTIPOINT (1 1, 4 4)
(1 row)
```

A closed linestring has no boundary because it has no start and end points:

```
=> SELECT ST_AsText(ST_Boundary(ST_GeomFromText(
  'LINESTRING(1 1,2 2,3 3,4 4,1 1)'));
   ST_AsText
-----
MULTIPOINT EMPTY
(1 row)
```

ST_Buffer

Creates a GEOMETRY object greater than or equal to a specified distance from the boundary of a spatial object. The distance is measured in Cartesian coordinate units. ST_Buffer does not accept a distance size greater than +1e15 or less than -1e15.

Behavior Type

Immutable

Syntax

```
ST_Buffer( g, d )
```

Arguments

<i>g</i>	Spatial object for which you want to calculate the buffer, type GEOMETRY
<i>d</i>	Distance from the object in Cartesian coordinate units, type FLOAT

Returns

GEOMETRY

Supported Data Types

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes

Polygon	Yes
Multipolygon	Yes
GeometryCollection	Yes

Usage Tips

- If you specify a positive distance, `ST_Buffer` returns a polygon that represents the points within or equal to the distance outside the object. If you specify a negative distance, `ST_Buffer` returns a polygon that represents the points within or equal to the distance inside the object.
- For points, multipoints, linestrings, and multilinestrings, if you specify a negative distance, `ST_Buffer` returns an empty polygon.
- The Vertica Place version of `ST_Buffer` returns the buffer as a polygon, so the buffer object has corners at its vertices. It does not contain rounded corners.

Example

The following example shows how to use `ST_Buffer`.

Returns a `GEOMETRY` object:

```
=> SELECT ST_AsText(ST_Buffer(ST_GeomFromText('POLYGON((0 1,1 4,4 3,0 1))'),1));
           ST_AsText
-----
POLYGON ((-0.188847498856 -0.159920845081, -1.12155598386 0.649012935089, 0.290814745534
4.76344136152,
0.814758063466 5.02541302048, 4.95372324225 3.68665254814, 5.04124517538 2.45512549204, -
0.188847498856 -0.159920845081))
(1 row)
```

ST_Centroid

Calculates the geometric center—the centroid—of a spatial object. If points or linestrings or both are present in a geometry with polygons, only the polygons contribute to the calculation of the centroid. Similarly, if points are present with linestrings, the points do not contribute to the calculation of the centroid.

To calculate the centroid of a `GEOGRAPHY` object, see the examples for [STV_Geometry](#) and [STV_Geography](#).

Behavior Type

Immutable

Syntax

```
ST_Centroid( g )
```

Arguments

<i>g</i>	Spatial object for which you want to calculate the centroid, type GEOMETRY
----------	--

Returns

GEOMETRY (POINT only)

Supported Data Types

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	Yes

Examples

The following examples show how to use ST_Centroid.

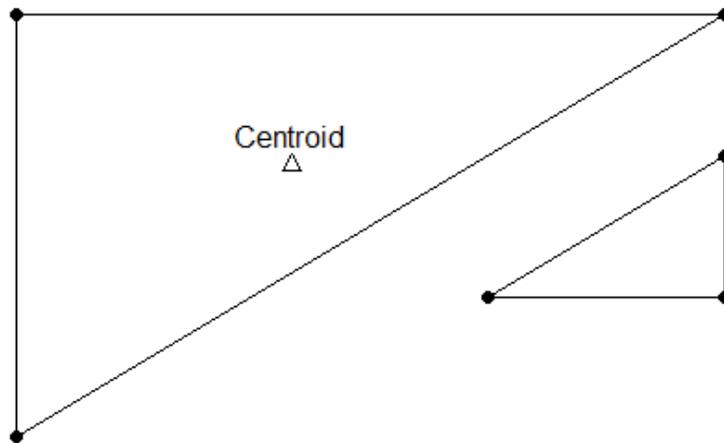

Calculate the centroid for a polygon:

```
=> SELECT ST_AsText(ST_Centroid(ST_GeomFromText('POLYGON((-1 -1,2 2,-1 2,
  -1 -1)'))));
  ST_AsText
-----
POINT (-0 1)
(1 row)
```

Calculate the centroid for a multipolygon:

```
=> SELECT ST_AsText(ST_Centroid(ST_GeomFromText('MULTIPOLYGON(((1 0,2 1,2 0,
  1 0)),((-1 -1,2 2,-1 2,-1 -1)'))));
  ST_AsText
-----
POINT (0.166666666667 0.933333333333)
(1 row)
```

This figure shows the centroid for the multipolygon.

ST_Contains

Determines if a spatial object is entirely inside another spatial object without existing only on its boundary. Both arguments must be the same spatial data type. Either specify two GEOMETRY objects or two GEOGRAPHY objects.

If an object such as a point or linestring only exists along a spatial object's boundary, then `ST_Contains` returns false. The interior of a linestring is all the points on the linestring except the start and end points.

`ST_Contains(g1, g2)` is functionally equivalent to `ST_Within(g2, g1)`.

GEOGRAPHY Polygons with a vertex or border on the International Date Line (IDL) or the North or South pole are not supported.

Behavior Type

Immutable

Syntax

```
ST_Contains( g1, g2
            [USING PARAMETERS spheroid={true | false}] )
```

Arguments

<i>g1</i>	Spatial object, type GEOMETRY or GEOGRAPHY
<i>g2</i>	Spatial object, type GEOMETRY or GEOGRAPHY

Parameters

<code>spheroid = {true false}</code>	(Optional) BOOLEAN that specifies whether to use a perfect sphere or WGS84. Default: False
--	--

Returns

BOOLEAN

Supported Data Types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	No	No
Linestring	Yes	Yes	No
Multilinestring	Yes	No	No
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	No
GeometryCollection	Yes	No	No

Compatible GEOGRAPHY pairs:

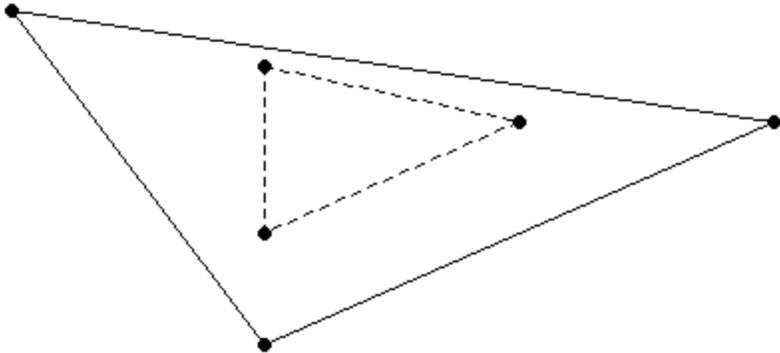

Data Type	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point-Point	Yes	No
Linestring-Point	Yes	No
Polygon-Point	Yes	Yes
Multipolygon-Point	Yes	No

Examples

The following examples show how to use ST_Contains.

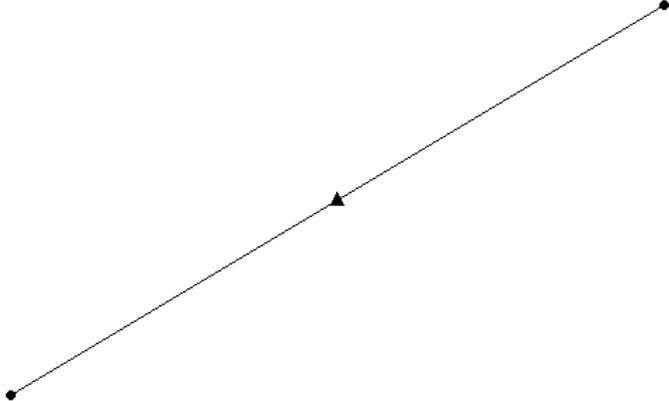

The first polygon does not completely contain the second polygon:

```
=> SELECT ST_Contains(ST_GeomFromText('POLYGON((0 2,1 1,0 -1,0 2))'),
  ST_GeomFromText('POLYGON((-1 3,2 1,0 -3,-1 3))'));
  ST_Contains
  -----
  f
  (1 row)
```

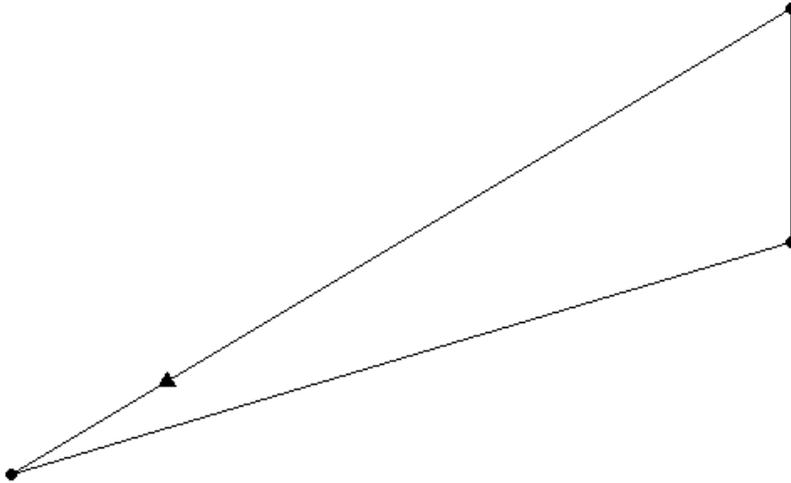

If a point is on a linestring, but not on an end point:

```
=> SELECT ST_Contains(ST_GeomFromText('LINESTRING(20 20,30 30)'),
  ST_GeomFromText('POINT(25 25)'));
  ST_Contains
  -----
  t
(1 row)
```

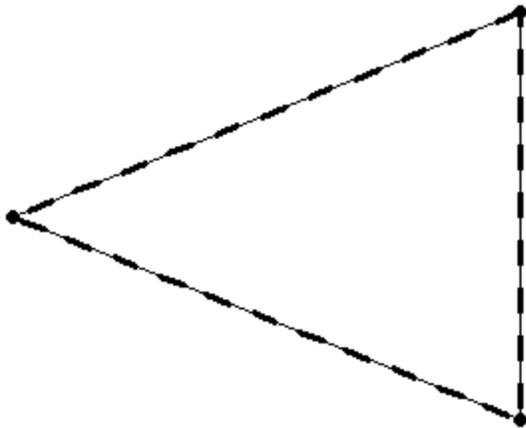

If a point is on the boundary of a polygon:

```
=> SELECT ST_Contains(ST_GeographyFromText('POLYGON((20 20,30 30,30 25,20 20))'),
  ST_GeographyFromText('POINT(20 20)'));
  ST_Contains
  -----
  f
(1 row)
```

Two spatially equivalent polygons:

```
=> SELECT ST_Contains (ST_GeomFromText('POLYGON((-1 2, 0 3, 0 1, -1 2))'),  
    ST_GeomFromText('POLYGON((0 3, -1 2, 0 1, 0 3))'));  
ST_Contains  
-----  
t  
(1 row)
```

See Also

- [ST_Within](#)

ST_ConvexHull

Calculates the smallest convex GEOMETRY object that contains a GEOMETRY object.

Behavior Type

Immutable

Syntax

```
ST_ConvexHull( g )
```

Arguments

<i>g</i>	Spatial object for which you want the convex hull, type GEOMETRY
----------	--

Returns

GEOMETRY

Supported Data Types

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	Yes

Examples

The following examples show how to use ST_ConvexHull.

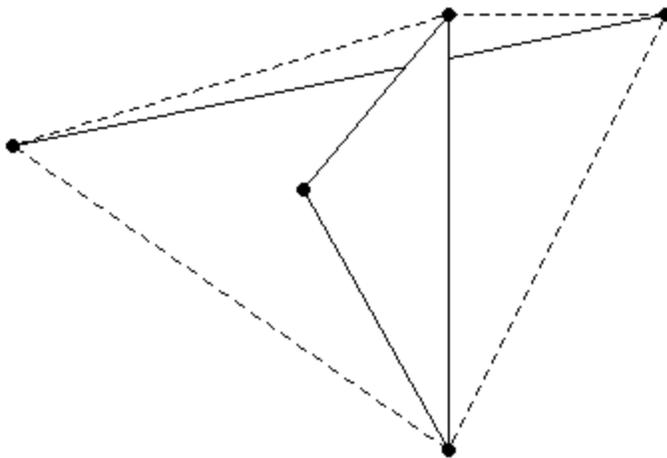

For a pair of points in a geometry collection:

```
=> SELECT ST_AsText(ST_ConvexHull(ST_GeomFromText('GEOMETRYCOLLECTION(  
  POINT(1 1),POINT(0 0)'))));  
      ST_AsText  
-----  
LINESTRING (1 1, 0 0)  
(1 row)
```

For a geometry collection:

```
=> SELECT ST_AsText(ST_ConvexHull(ST_GeomFromText('GEOMETRYCOLLECTION(  
  LINESTRING(2.5 3,-2 1.5), POLYGON((0 1,1 3,1 -2,0 1)))')));  
      ST_AsText  
-----  
POLYGON ((1 -2, -2 1.5, 1 3, 2.5 3, 1 -2))  
(1 row)
```

The solid lines represent the original geometry collection and the dashed lines represent the convex hull.

ST_Crosses

Determines if one GEOMETRY object spatially crosses another GEOMETRY object. If two objects touch only at a border, ST_Crosses returns FALSE.

Two objects spatially cross when both of the following are true:

- The two objects have some, but not all, interior points in common.
- The dimension of the result of their intersection is less than the maximum dimension of the two objects.

Behavior Type

Immutable

Syntax

```
ST_Crosses( g1, g2 )
```

Arguments

<i>g1</i>	Spatial object, type GEOMETRY
<i>g2</i>	Spatial object, type GEOMETRY

Returns

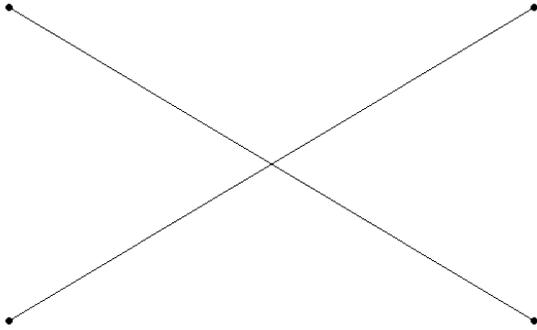

BOOLEAN

Supported Data Types

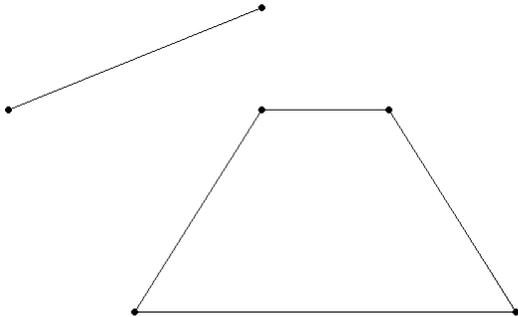

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	Yes

Examples

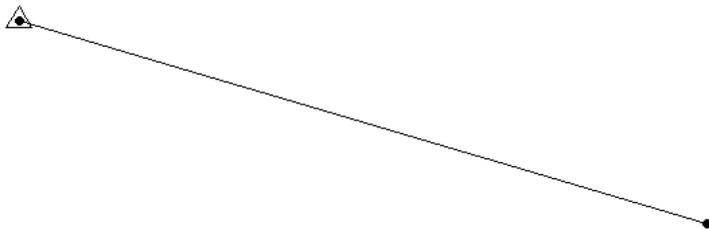

The following examples show how to use `ST_Crosses`.

```
=> SELECT ST_Crosses(ST_GeomFromText('LINESTRING(-1 3,1 4)'),  
  ST_GeomFromText('LINESTRING(-1 4,1 3)'));  
  ST_Crosses  
-----  
t  
(1 row)
```

```
=> SELECT ST_Crosses(ST_GeomFromText('LINESTRING(-1 1,1 2)'),  
  ST_GeomFromText('POLYGON((1 1,0 -1,3 -1,2 1,1 1))'));  
  ST_Crosses  
-----  
f  
(1 row)
```

```
=> SELECT ST_Crosses(ST_GeomFromText('POINT(-1 4)'),
  ST_GeomFromText('LINESTRING(-1 4,1 3)'));
ST_ Crosses
-----
f
(1 row)
```

ST_Difference

Calculates the part of a spatial object that does not intersect with another spatial object.

Behavior Type

Immutable

Syntax

```
ST_Difference( g1, g2 )
```

Arguments

<i>g1</i>	Spatial object, type GEOMETRY
<i>g2</i>	Spatial object, type GEOMETRY

Returns

GEOMETRY

Supported Data Types

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes

Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	Yes

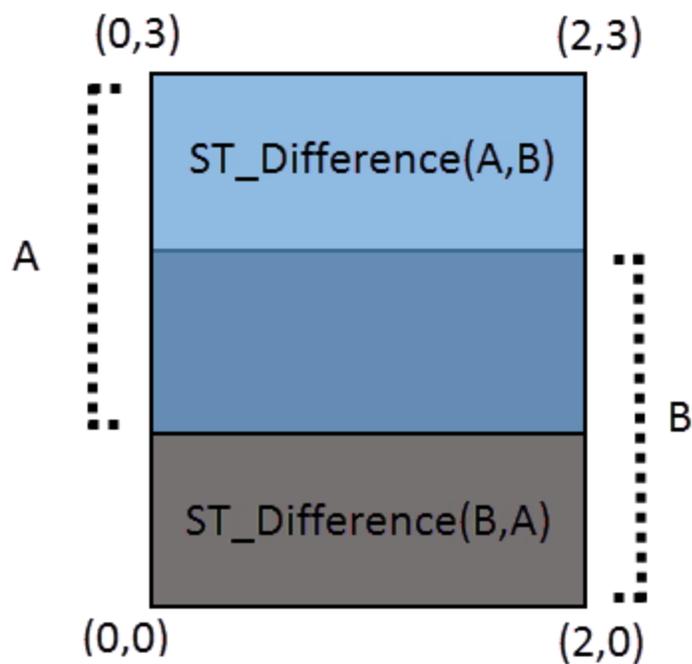

Examples

The following examples show how to use ST_Difference.

Two overlapping linestrings:

```
=> SELECT ST_AsText(ST_Difference(ST_GeomFromText('LINESTRING(0 0,0 2)'),
  ST_GeomFromText('LINESTRING(0 1,0 2)')));
  ST_AsText
-----
LINESTRING (0 0, 0 1)
(1 row)
=> SELECT ST_AsText(ST_Difference(ST_GeomFromText('LINESTRING(0 0,0 3)'),
  ST_GeomFromText('LINESTRING(0 1,0 2)')));
  ST_AsText
-----
MULTILINESTRING ((0 0, 0 1), (0 2, 0 3))
(1 row)
```

Two overlapping polygons:

```
=> SELECT ST_AsText(ST_Difference(ST_GeomFromText('POLYGON((0 1,0 3,2 3,2 1,0 1))'),
  ST_GeomFromText('POLYGON((0 0,0 2,2 2,2 0,0 0))'));
      ST_AsText
-----
POLYGON ((0 2, 0 3, 2 3, 2 2, 0 2))
(1 row)
```

Two non-intersecting polygons:

```
=> SELECT ST_AsText(ST_Difference(ST_GeomFromText('POLYGON((1 1,1 3,3 3,3 1,
  1 1))'),ST_GeomFromText('POLYGON((1 5,1 7,-1 7,-1 5,1 5))'));
      ST_AsText
-----
POLYGON ((1 1, 1 3, 3 3, 3 1, 1 1))
(1 row)
```

ST_Disjoint

Determines if two GEOMETRY objects do not intersect or touch.

If ST_Disjoint returns TRUE for a pair of GEOMETRY objects, ST_Intersects returns FALSE for the same two objects.

GEOGRAPHY Polygons with a vertex or border on the International Date Line (IDL) or the North or South pole are not supported.

Behavior Type

Immutable

Syntax

```
ST_Disjoint( g1, g2
             [USING PARAMETERS spheroid={true | false}] )
```

Arguments

<i>g1</i>	Spatial object, type GEOMETRY
<i>g2</i>	Spatial object, type GEOMETRY

Parameters

spheroid = {true false}	(Optional) BOOLEAN that specifies whether to use a perfect sphere or WGS84. Default: False
---------------------------	--

Returns

BOOLEAN

Supported Data Types

Data Type	GEOMETRY	GEOGRAPHY (WGS84)
Point	Yes	Yes
Multipoint	Yes	No
Linestring	Yes	No
Multilinestring	Yes	No
Polygon	Yes	Yes
Multipolygon	Yes	No
GeometryCollection	Yes	No

Compatible GEOGRAPHY pairs:

Data Type	GEOGRAPHY (WGS84)
Point-Point	No
Linestring-Point	No
Polygon-Point	Yes
Multipolygon-Point	No

Examples

The following examples show how to use `ST_Disjoint`.

Two non-intersecting or touching polygons:

```
=> SELECT ST_Disjoint (ST_GeomFromText('POLYGON((-1 2,0 3,0 1,-1 2))'),
  ST_GeomFromText('POLYGON((1 0, 1 1, 2 2, 1 0))'));
  ST_Disjoint
-----
t
(1 row)
```

Two intersecting linestrings:

```
=> SELECT ST_Disjoint(ST_GeomFromText('LINESTRING(-1 2,0 3)'),
  ST_GeomFromText('LINESTRING(0 2,-1 3)'));
  ST_Disjoint
-----
f
(1 row)
```

Two polygons touching at a single point:

```
=> SELECT ST_Disjoint (ST_GeomFromText('POLYGON((-1 2, 0 3, 0 1, -1 2))'),
  ST_GeomFromText('POLYGON((0 2, 1 1, 1 2, 0 2))'));
  ST_Disjoint
-----
f
(1 row)
```

See Also

- [ST_Intersects](#)

ST_Distance

Calculates the shortest distance between two spatial objects. For `GEOMETRY` objects, the distance is measured in Cartesian coordinate units. For `GEOGRAPHY` objects, the distance is measured in meters.

Parameters `g1` and `g2` must be both `GEOMETRY` objects or both `GEOGRAPHY` objects.

Behavior Type

Immutable

Syntax

```
ST_Distance( g1, g2  
            [USING PARAMETERS spheroid={ true | false } ] )
```

Arguments

<i>g1</i>	Spatial object, type GEOMETRY or GEOGRAPHY
<i>g2</i>	Spatial object, type GEOMETRY or GEOGRAPHY

Parameters

spheroid = { true false }	(Optional) BOOLEAN that specifies whether to use a perfect sphere or WGS84. Default: False
-----------------------------	--

Returns

FLOAT

Supported Data Types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	Yes	Yes
Linestring	Yes	Yes	Yes

Multilinestring	Yes	Yes	Yes
Polygon	Yes	Yes	No
Multipolygon	Yes	Yes	No
GeometryCollection	Yes	No	No

Compatible GEOGRAPHY pairs:

Data Type	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point-Point	Yes	Yes
Linestring-Point	Yes	Yes
Multilinestring- Point	Yes	Yes
Polygon-Point	Yes	No
Multipoint-Point	Yes	Yes
Multipoint- Multilinestring	Yes	No
Multipolygon- Point	Yes	No

Recommendations

Micro Focus recommends pruning invalid data before using ST_Distance. Invalid geography values could return non-guaranteed results.

Examples

The following examples show how to use ST_Distance.

Distance between two polygons:

```
=> SELECT ST_Distance(ST_GeomFromText('POLYGON((-1 -1,2 2,0 1,-1 -1)'),
                        ST_GeomFromText('POLYGON((5 2,7 4,5 5,5 2))'));
   ST_Distance
-----
                3
(1 row)
```

Distance between a point and a linestring in meters:

```
=> SELECT ST_Distance(ST_GeographyFromText('POINT(31.75 31.25)'),
                    ST_GeographyFromText('LINESTRING(32 32,32 35,40.5 35,32 35,32 32)'));
   ST_Distance
-----
86690.3950562969
(1 row)
```

ST_Envelope

Calculates the minimum bounding rectangle that contains the specified GEOMETRY object.

Behavior Type

Immutable

Syntax

```
ST_Envelope( g )
```

Arguments

<i>g</i>	Spatial object for which you want to find the minimum bounding rectangle, type GEOMETRY
----------	---

Returns

GEOMETRY

Supported Data Types

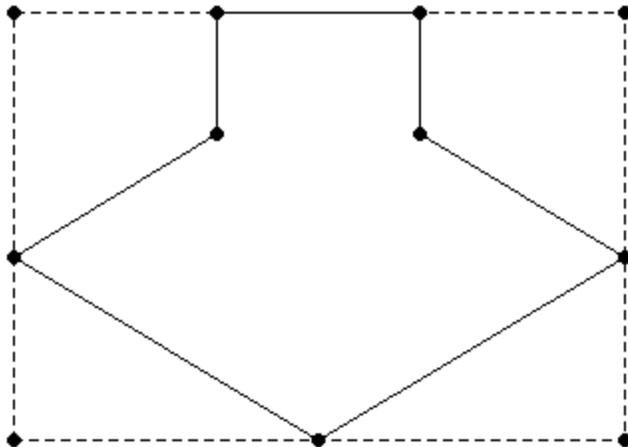

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	Yes

Example

The following example shows how to use `ST_Envelope`.

Returns the minimum bounding rectangle:

```
=> SELECT ST_AsText(ST_Envelope(ST_GeomFromText('POLYGON((0 0,1 1,1 2,2 2,
  2 1,3 0,1.5 -1.5,0 0)'))));
      ST_AsText
-----
POLYGON ((0 -1.5, 3 -1.5, 3 2, 0 2, 0 -1.5))
(1 row)
```

ST_Equals

Determines if two spatial objects are spatially equivalent. The coordinates of the two objects and their WKT/WKB representations must match exactly for ST_Equals to return TRUE.

The order of the points do not matter in determining spatial equivalence:

- `LINESTRING(1 2, 4 3)` equals `LINESTRING(4 3, 1 2)`.
- `POLYGON ((0 0, 1 1, 1 2, 2 2, 2 1, 3 0, 1.5 -1.5, 0 0))` equals `POLYGON((1 1 , 1 2, 2 2, 2 1, 3 0, 1.5 -1.5, 0 0, 1 1))`.
- `MULTILINESTRING((1 2, 4 3),(0 0, -1 -4))` equals `MULTILINESTRING((0 0, -1 -4),(1 2, 4 3))`.

Coordinates are stored as FLOAT types. Thus, rounding errors are expected when importing Well-Known Text (WKT) values because the limitations of floating-point number representation.

g1 and *g2* must both be GEOMETRY objects or both be GEOGRAPHY objects. Also, *g1* and *g2* cannot both be of type GeometryCollection.

Behavior Type

Immutable

Syntax

```
ST_Equals( g1, g2 )
```

Arguments

<i>g1</i>	Spatial object to compare to <i>g2</i> , type GEOMETRY or GEOGRAPHY
<i>g2</i>	Spatial object to compare to <i>g1</i> , type GEOMETRY or GEOGRAPHY

Returns

BOOLEAN

Supported Data Types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	Yes	Yes
Linestring	Yes	Yes	Yes
Multilinestring	Yes	Yes	Yes
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	Yes
GeometryCollection	No	No	No

Examples

The following examples show how to use ST_Equals.

Two linestrings:

```
=> SELECT ST_Equals (ST_GeomFromText('LINESTRING(-1 2, 0 3)'),
  ST_GeomFromText('LINESTRING(0 3, -1 2)'));
  ST_Equals
  -----
  t
(1 row)
```

Two polygons:

```
=> SELECT ST_Equals (ST_GeographyFromText('POLYGON((43.22 42.21,40.3 39.88,
  42.1 50.03,43.22 42.21))'),ST_GeographyFromText('POLYGON((43.22 42.21,
  40.3 39.88,42.1 50.31,43.22 42.21))'));
  ST_Equals
  -----
  f
(1 row)
```

ST_GeographyFromText

Converts a Well-Known Text (WKT) string into its corresponding GEOGRAPHY object. Use this function to convert a WKT string into the format expected by the Vertica Place functions.

A GEOGRAPHY object is a spatial object with coordinates (longitude, latitude) defined on the surface of the earth. Coordinates are expressed in degrees (longitude, latitude) from reference planes dividing the earth.

The maximum size of a GEOGRAPHY object is 10 MB. If you pass a WKT to ST_GeographyFromText, the result is a spatial object whose size is greater than 10 MB, ST_GeographyFromText returns an error.

The [Open Geospatial Consortium \(OGC\)](#) defines the format of a WKT string in Section 7 in the [Simple Feature Access Part 1 - Common Architecture](#) specification.

Behavior Type

Immutable

Syntax

```
ST_GeographyFromText( wkt [ USING PARAMETERS ignore_errors={'y' | 'n'} ] )
```

Arguments

<i>wkt</i>	Well-Known Text (WKT) string of a GEOGRAPHY object, type LONG VARCHAR
<i>ignore_errors</i>	(Optional) ST_GeographyFromText returns the following, based on the parameters supplied: <ul style="list-style-type: none">• NULL—If <i>wkt</i> is invalid and <i>ignore_errors</i>='y'.• Error—If <i>wkt</i> is invalid and <i>ignore_errors</i>='n' or is unspecified.

Returns

GEOGRAPHY

Supported Data Types

Data Type	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes
Multipoint	Yes	Yes
Linestring	Yes	Yes
Multilinestring	Yes	Yes
Polygon	Yes	Yes
Multipolygon	Yes	Yes
GeometryCollection	No	No

Example

The following example shows how to use `ST_GeographyFromText`.

Convert WKT into a GEOGRAPHY object:

```
=> CREATE TABLE wkt_ex (g GEOGRAPHY);
CREATE TABLE
=> INSERT INTO wkt_ex VALUES(ST_GeographyFromText('POLYGON((1 2,3 4,2 3,1 2))'));
OUTPUT
-----
      1
(1 row)
```

ST_GeographyFromWKB

Converts a Well-Known Binary (WKB) value into its corresponding GEOGRAPHY object. Use this function to convert a WKB into the format expected by Vertica Place functions.

A GEOGRAPHY object is a spatial object defined on the surface of the earth. Coordinates are expressed in degrees (longitude, latitude) from reference planes dividing the earth. All calculations are in meters.

The maximum size of a GEOGRAPHY object is 10 MB. If you pass a WKB to ST_GeographyFromWKB that results in a spatial object whose size is greater than 10 MB, ST_GeographyFromWKB returns an error.

The [Open Geospatial Consortium \(OGC\)](#) defines the format of a WKB representation in Section 8 in the [Simple Feature Access Part 1 - Common Architecture](#) specification.

Behavior Type

Immutable

Syntax

```
ST_GeographyFromWKB( wkb [ USING PARAMETERS ignore_errors={'y' | 'n'} ] )
```

Arguments

<i>wkb</i>	Well-Known Binary (WKB) value of a GEOGRAPHY object, type LONG VARBINARY
<i>ignore_errors</i>	(Optional) ST_GeographyFromWKB returns the following, based on the parameters supplied: <ul style="list-style-type: none">• NULL—If <i>wkb</i> is invalid and <i>ignore_errors</i>='y'.• Error—If <i>wkb</i> is invalid and <i>ignore_errors</i>='n' or is unspecified.

Returns

GEOGRAPHY

Supported Data Types

Data Type	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes
Multipoint	Yes	Yes

Linestring	Yes	Yes
Multilinestring	Yes	Yes
Polygon	Yes	Yes
Multipolygon	Yes	Yes
GeometryCollection	No	No

Example

The following example shows how to use `ST_GeographyFromWKB`.

Convert WKB into a GEOGRAPHY object:

```
=> CREATE TABLE wkb_ex (g GEOGRAPHY);
CREATE TABLE
=> INSERT INTO wkb_ex VALUES(ST_GeographyFromWKB(X'0103000000010000000 ... ));
OUTPUT
-----
      1
(1 row)
```

ST_GeoHash

Returns a GeoHash in the shape of the specified geometry.

Behavior Type

Immutable

Syntax

```
ST_GeoHash( SpatialObject [ USING PARAMETERS numchars=n] )
```

Arguments

<i>Spatial object</i>	A GEOMETRY or GEOGRAPHY spatial object. Inputs must be in polar coordinates (-180 <= x <= 180 and -90 <= y <= 90) for all points inside the given geometry.
-----------------------	---

<i>n</i>	Specifies the length, in characters, of the returned GeoHash.
----------	---

Returns

GEOHASH

Supported Data Types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	Yes	Yes
Linestring	Yes	Yes	Yes
Multilinestring	Yes	Yes	Yes
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	Yes
GeometryCollection	Yes	No	No

Examples

The following examples show how to use ST_PointFromGeoHash.

Generate a full precision GeoHash for the specified geometry:

```
=> SELECT ST_GeoHash(ST_GeographyFromText('POINT(3.14 -1.34)'));
ST_GeoHash
-----
kpf0rkn3zmcswks75010
(1 row)
```

Generate a GeoHash based on the first five characters of the specified geometry:

```
=> select ST_GeoHash(ST_GeographyFromText('POINT(3.14 -1.34)')USING PARAMETERS numchars=5);
ST_GeoHash
-----
kpf0r
```

(1 row)

ST_GeometryN

Returns the n^{th} geometry within a geometry object.

If n is out of range of the index, then NULL is returned.

Behavior Type

Immutable

Syntax

`ST_GeometryN(g , n)`

Arguments

g	Spatial object of type GEOMETRY.
n	The geometry's index number, 1-based.

Returns

GEOMETRY

Supported Data Types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	Yes	Yes

Linestring	Yes	Yes	Yes
Multilinestring	Yes	Yes	Yes
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	Yes
GeometryCollection	No	No	No

Examples

The following examples show how to use ST_GeometryN.

Return the second geometry in a multipolygon:

```
=> CREATE TABLE multipolygon_geom (gid int, geom GEOMETRY(1000));
CREATE TABLE
=> COPY multipolygon_geom(gid, gx FILLER LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin
delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>9|MULTIPOLYGON(((2 6, 2 9, 6 9, 7 7, 4 6, 2 6)),((0 0, 0 5, 1 0, 0 0)),((0 2, 2 5, 4 5, 0 2)))
>>\.
=> SELECT gid, ST_AsText(ST_GeometryN(geom, 2)) FROM multipolygon_geom;
gid |          ST_AsText
-----+-----
  9 | POLYGON ((0 0, 0 5, 1 0, 0 0))
(1 row)
```

Return all the geometries within a multipolygon:

```
=> CREATE TABLE multipolygon_geom (gid int, geom GEOMETRY(1000));
CREATE TABLE
=> COPY multipolygon_geom(gid, gx FILLER LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin
delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>9|MULTIPOLYGON(((2 6, 2 9, 6 9, 7 7, 4 6, 2 6)),((0 0, 0 5, 1 0, 0 0)),((0 2, 2 5, 4 5, 0 2)))
>>\.
=> CREATE TABLE series_numbers (numbs int);
CREATE TABLE
=> COPY series_numbers FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1
>> 2
>> 3
>> 4
>> 5
>> \.
=> SELECT numbs, ST_AsText(ST_GeometryN(geom, numbs))
FROM multipolygon_geom, series_numbers
```

```
WHERE ST_AsText(ST_GeometryN(geom, numbs)) IS NOT NULL
ORDER BY numbs ASC;
numbs |          ST_AsText
-----+-----
1 | POLYGON ((2 6, 2 9, 6 9, 7 7, 4 6, 2 6))
2 | POLYGON ((0 0, 0 5, 1 0, 0 0))
3 | POLYGON ((0 2, 2 5, 4 5, 0 2))
(3 rows)
```

See Also

[ST_NumGeometries](#)

ST_GeometryType

Determines the class of a spatial object.

Behavior Type

Immutable

Syntax

```
ST_GeometryType( g )
```

Arguments

<i>g</i>	Spatial object for which you want the class, type GEOMETRY or GEOGRAPHY
----------	---

Returns

VARCHAR

Supported Data Types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)
-----------	----------	----------------------------

Point	Yes	Yes
Multipoint	Yes	Yes
Linestring	Yes	Yes
Multilinestring	Yes	Yes
Polygon	Yes	Yes
Multipolygon	Yes	Yes
GeometryCollection	Yes	No

Example

The following example shows how to use `ST_GeometryType`.

Returns spatial class:

```
=> SELECT ST_GeometryType(ST_GeomFromText('GEOMETRYCOLLECTION(LINESTRING(1 1,
  2 2), POLYGON((1 3,4 5,2 2,1 3))')));
   ST_GeometryType
-----
ST_GeometryCollection
(1 row)
```

ST_GeomFromGeoHash

Returns a polygon in the shape of the specified GeoHash.

Behavior Type

Immutable

Syntax

```
ST_GeomFromGeoHash(GeoHash)
```

Arguments

<i>GeoHash</i>	A valid GeoHash string of arbitrary length.
----------------	---

Returns

GEOGRAPHY

Examples

The following examples show how to use `ST_GeomFromGeoHash`.

Converts a GeoHash string to a Geography object and back to a GeoHash

```
=> SELECT ST_GeoHash(ST_GeomFromGeoHash('vert1c9'));
ST_GeoHash
-----
vert1c9
(1 row)
```

Returns a polygon of the specified GeoHash and uses `ST_AsText` to convert the polygon, rectangle map tile, into Well-Known Text:

```
=> SELECT ST_AsText(ST_GeomFromGeoHash('drt3jj9n4dpcbcdef'));
ST_AsText
-----
POLYGON ((-71.1459699298 42.3945346513, -71.1459699297 42.3945346513, -71.1459699297 42.3945346513, -
71.1459699298 42.3945346513, -71.1459699298 42.3945346513))
(1 row)
```

Returns multiple polygons and their areas for the specified GeoHashes. The polygon for the high level GeoHash (1234) has a significant area, while the low level GeoHash (1234567890bcdefhjkmn) has an area of zero.

```
=> SELECT ST_Area(short) short_area, ST_AsText(short) short_WKT, ST_Area(long) long_area, ST_AsText
(long) long_WKT from (SELECT ST_GeomFromGeoHash('1234') short, ST_GeomFromGeoHash
('1234567890bcdefhjkmn') long) as foo;
-[ RECORD 1 ]-----
short_area | 24609762.8991076
short_WKT  | POLYGON ((-122.34375 -88.2421875, -121.9921875 -88.2421875, -121.9921875 -88.06640625, -
122.34375 -88.06640625, -122.34375 -88.2421875))
long_area  | 0
long_WKT   | POLYGON ((-122.196077187 -88.2297377551, -122.196077187 -88.2297377551, -122.196077187 -
```

```
88.2297377551, -122.196077187 -88.2297377551, -122.196077187 -88.2297377551))
```

ST_GeomFromText

Converts a Well-Known Text (WKT) string into its corresponding GEOMETRY object. Use this function to convert a WKT string into the format expected by the Vertica Place functions.

A GEOMETRY object is a spatial object defined by the coordinates of a plane. Coordinates are expressed as points on a Cartesian plane (x,y). SRID values of 0 to $2^{32}-1$ are valid. SRID values outside of this range will generate an error.

The maximum size of a GEOMETRY object is 10 MB. If you pass a WKT to ST_GeomFromText and the result is a spatial object whose size is greater than 10 MB, ST_GeomFromText returns an error.

The [Open Geospatial Consortium \(OGC\)](#) defines the format of a WKT representation. See section 7 in the [Simple Feature Access Part 1 - Common Architecture](#) specification.

Behavior Type

Immutable

Syntax

```
ST_GeomFromText( wkt [, srid] [ USING PARAMETERS ignore_errors={'y' | 'n'} ] )
```

Arguments

<i>wkt</i>	Well-Known Text (WKT) string of a GEOMETRY object, type LONG VARCHAR.
<i>srid</i>	(Optional when not performing operations) Spatial reference system identifier (SRID) of the GEOMETRY object, type INTEGER. The SRID is stored in the GEOMETRY object, but does not influence the results of spatial computations.
<i>ignore_errors</i>	(Optional) ST_GeomFromText returns the following, based on parameters supplied:

	<ul style="list-style-type: none">• NULL—If <i>wkt</i> is invalid and <i>ignore_errors</i>='y'.• Error—If <i>wkt</i> is invalid and <i>ignore_errors</i>='n' or is unspecified.
--	--

Returns

GEOMETRY

Supported Data Types

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	No

Example

The following example shows how to use `ST_GeomFromText`.

Convert WKT into a GEOMETRY object:

```
=> SELECT ST_Area(ST_GeomFromText('POLYGON((1 1,2 3,3 5,0 5,1 -2,0 0,1 1))'));
   ST_Area
-----
          6
(1 row)
```

ST_GeomFromWKB

Converts the Well-Known Binary (WKB) value to its corresponding GEOMETRY object. Use this function to convert a WKB into the format expected by many of the Vertica Place functions.

A GEOMETRY object is a spatial object with coordinates (x,y) defined in the Cartesian plane.

The maximum size of a GEOMETRY object is 10 MB. If you pass a WKB to ST_GeomFromWKB and the result is a spatial object whose size is greater than 10 MB, ST_GeomFromWKB returns an error.

The [Open Geospatial Consortium \(OGC\)](#) defines the format of a WKB representation in section 8 in the [Simple Feature Access Part 1 - Common Architecture](#) specification.

Behavior Type

Immutable

Syntax

```
ST_GeomFromWKB( wkb [, srid] [ USING PARAMETERS ignore_errors={'y'|'n'} ] )
```

Arguments

<i>wkb</i>	Well-Known Binary (WKB) value of a GEOMETRY object, type LONG VARBINARY
<i>srid</i>	(Optional) Spatial reference system identifier (SRID) of the GEOMETRY object, type INTEGER. The SRID is stored in the GEOMETRY object, but does not influence the results of spatial computations.
<i>ignore_errors</i>	(Optional) ST_GeomFromWKB returns the following, based on the parameters supplied: <ul style="list-style-type: none">• NULL—If <i>wkb</i> is invalid and <i>ignore_errors</i>='y'.• Error—If <i>wkb</i> is invalid and <i>ignore_errors</i>='n' or is unspecified.

ST_Intersection

Calculates the set of points shared by two GEOMETRY objects.

Behavior Type

Immutable

Syntax

```
ST_Intersection( g1, g2 )
```

Arguments

<i>g1</i>	Spatial object, type GEOMETRY
<i>g2</i>	Spatial object, type GEOMETRY

Returns

GEOMETRY

Supported Data Types

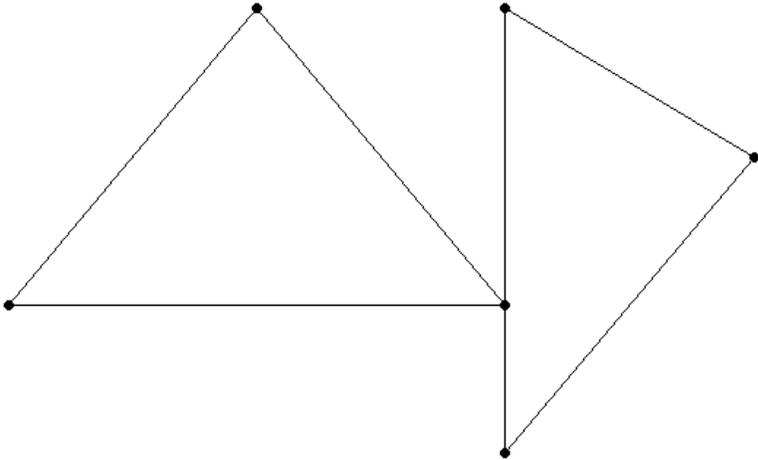

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes

Multipolygon	Yes
GeometryCollection	Yes

Examples

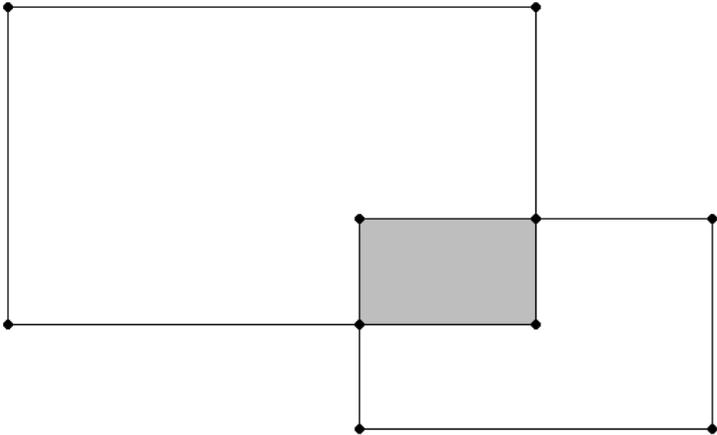

The following examples show how to use ST_Intersection.

Two polygons intersect at a single point:

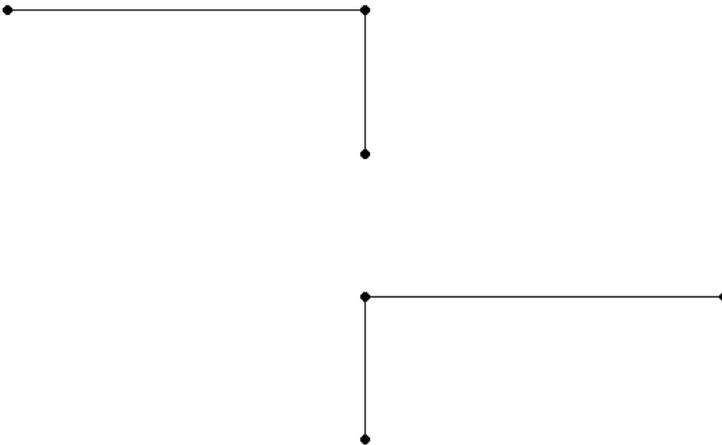

```
=> SELECT ST_AsText(ST_Intersection(ST_GeomFromText('POLYGON((0 2,1 1,0 -1,
  0 2))'),ST_GeomFromText('POLYGON((-1 2,0 0,-2 0,-1 2))'));
  ST_AsText
-----
POINT(0 0)
(1 row)
```

Two polygons:

```
=> SELECT ST_AsText(ST_Intersection(ST_GeomFromText('POLYGON((1 2,1 5,4 5,
  4 2,1 2))'), ST_GeomFromText('POLYGON((3 1,3 3,5 3,5 1,3 1)'))));
  ST_AsText
-----
POLYGON ((4 3, 4 2, 3 2, 3 3, 4 3))
(1 row)
```

Two non-intersecting linestrings:

```
=> SELECT ST_AsText(ST_Intersection(ST_GeomFromText('LINESTRING(1 1,1 3,3 3)'),
  ST_GeomFromText('LINESTRING(1 5,1 7,-1 7)')));
  ST_AsText
-----
GEOMETRYCOLLECTION EMPTY
(1 row)
```

ST_Intersects

Determines if two GEOMETRY or GEOGRAPHY objects intersect or touch at a single point. If ST_Disjoint returns TRUE, ST_Intersects returns FALSE for the same GEOMETRY or GEOGRAPHY objects.

GEOGRAPHY Polygons with a vertex or border on the International Date Line (IDL) or the North or South pole are not supported.

Behavior Type

Immutable

Syntax

```
ST_Intersects(g1, g2  
             [USING PARAMETERS bbox={true | false}, spheroid={true | false}])
```

Arguments

<i>g1</i>	Spatial object, type GEOMETRY
<i>g2</i>	Spatial object, type GEOMETRY

Parameters

<code>bbox = {true false}</code>	Boolean. Intersects the bounding box of <i>g1</i> and <i>g2</i> . Default: False
<code>spheroid = {true false}</code>	(Optional) BOOLEAN that specifies whether to use a perfect sphere or WGS84. Default: False

Returns

BOOLEAN

Supported Data Types

Data Type	GEOMETRY	GEOGRAPHY (WGS84)
Point	Yes	Yes
Multipoint	Yes	No
Linestring	Yes	No
Multilinestring	Yes	No

Polygon	Yes	Yes
Multipolygon	Yes	No
GeometryCollection	Yes	No

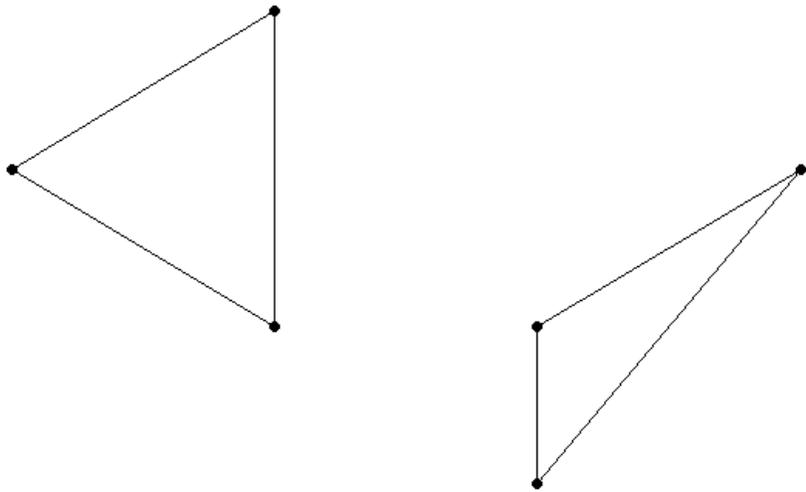

Compatible GEOGRAPHY pairs:

Data Type	GEOGRAPHY (WGS84)
Point-Point	No
Linestring-Point	No
Polygon-Point	Yes
Multipolygon-Point	No

Examples

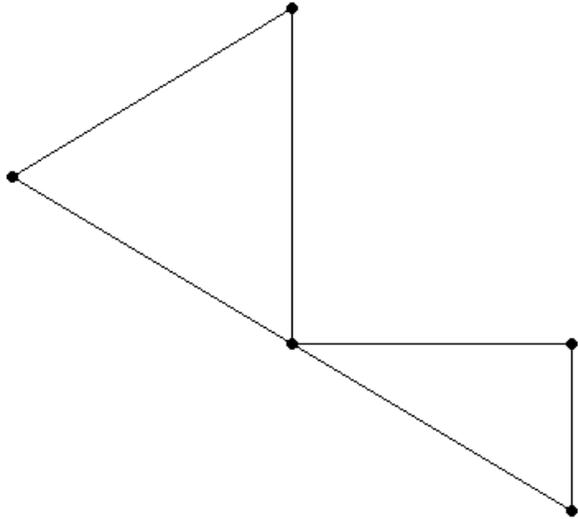

The following examples show how to use ST_Intersects.

Two polygons do not intersect or touch:

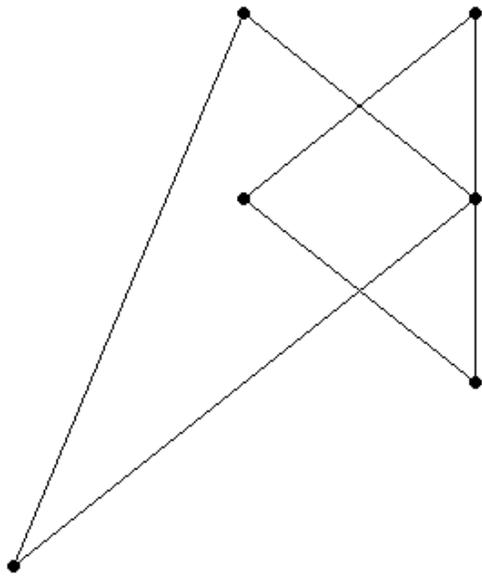

```
=> SELECT ST_Intersects (ST_GeomFromText('POLYGON((-1 2,0 3,0 1,-1 2)'),
    ST_GeomFromText('POLYGON((1 0,1 1,2 2,1 0)'));
    ST_Intersects
    -----
    f
    (1 row)
```

Two polygons touch at a single point:

```
=> SELECT ST_Intersects (ST_GeomFromText('POLYGON((-1 2,0 3,0 1,-1 2))'),  
    ST_GeomFromText('POLYGON((1 0,1 1,0 1,1 0))'));  
ST_Intersects  
-----  
t  
(1 row)
```

Two polygons intersect:

```
=> SELECT ST_Intersects (ST_GeomFromText('POLYGON((-1 2, 0 3, 0 1, -1 2))'),  
    ST_GeomFromText('POLYGON((0 2, -1 3, -2 0, 0 2))'));  
ST_Intersects  
-----  
t  
(1 row)
```

See Also

[ST_Disjoint](#)

ST_IsEmpty

Determines if a spatial object represents the empty set. An empty object has no dimension.

Behavior Type

Immutable

Syntax

```
ST_IsEmpty( g )
```

Arguments

<i>g</i>	Spatial object, type GEOMETRY or GEOGRAPHY
----------	--

Returns

BOOLEAN

Supported Data Types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	Yes	Yes
Linestring	Yes	Yes	Yes

Multilinestring	Yes	Yes	Yes
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	Yes
GeometryCollection	Yes	No	No

Example

The following example shows how to use ST_IsEmpty.

An empty polygon:

```
=> SELECT ST_IsEmpty(ST_GeomFromText('GeometryCollection EMPTY'));
   ST_IsEmpty
-----
t
(1 row)
```

ST_IsSimple

Determines if a spatial object does not intersect itself or touch its own boundary at any point.

Behavior Type

Immutable

Syntax

```
ST_IsSimple( g )
```

Arguments

<i>g</i>	Spatial object, type GEOMETRY or GEOGRAPHY
----------	--

Returns

BOOLEAN

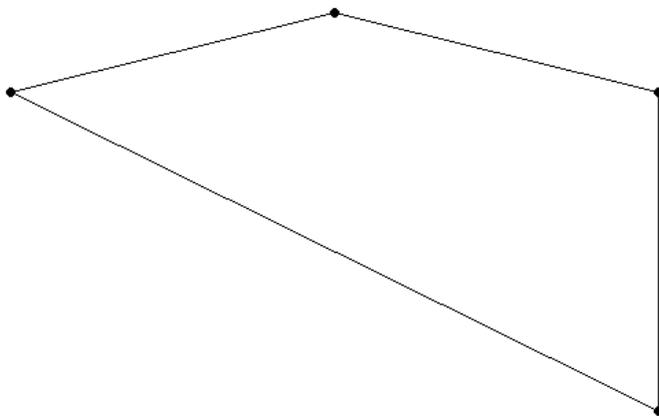

Supported Data Types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)
Point	Yes	Yes
Multipoint	Yes	No
Linestring	Yes	Yes
Multilinestring	Yes	No
Polygon	Yes	Yes
Multipolygon	Yes	No
GeometryCollection	No	No

Examples

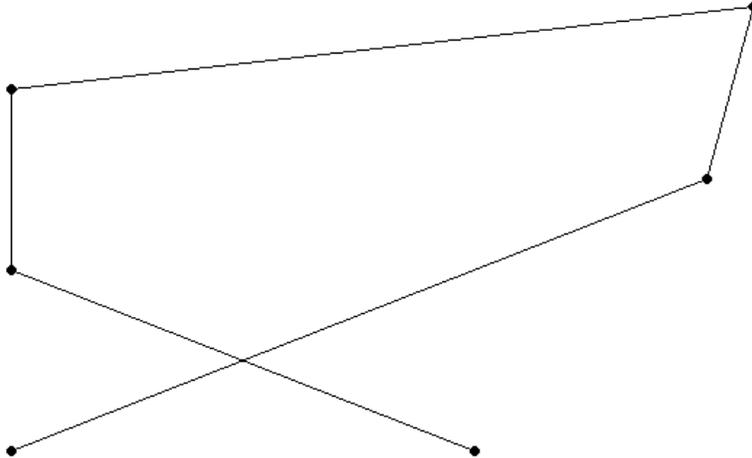

The following examples show how to use `ST_IsSimple`.

Polygon does not intersect itself:

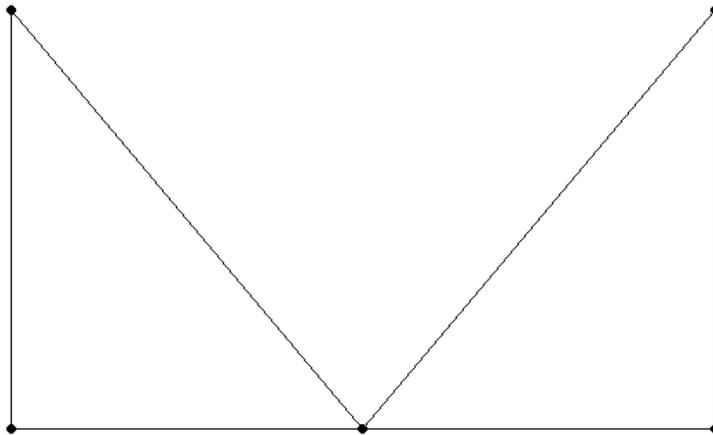

```
=> SELECT ST_IsSimple(ST_GeomFromText('POLYGON((-1 2,0 3,1 2,1 -2,-1 2))'));
ST_IsSimple
-----
t
(1 row)
```

Linestring intersects itself.:

```
=> SELECT ST_IsSimple(ST_GeographyFromText('LINESTRING(10 10,25 25,26 34.5,
      10 30,10 20,20 10)'));
St_IsSimple
-----
f
(1 row)
```

Linestring touches its interior at one or more locations:

```
=> SELECT ST_IsSimple(ST_GeomFromText('LINESTRING(0 0,0 1,1 0,2 1,2 0,0 0)'));
ST_IsSimple
-----
f
(1 row)
```

ST_IsValid

Determines if a spatial object is well formed or valid. If the object is valid, `ST_IsValid` returns TRUE; otherwise, it returns FALSE. Use `STV_IsValidReason` to identify the location of the invalidity.

Spatial validity applies only to polygons and multipolygons. A polygon or multipolygon is valid if all of the following are true:

- The polygon is closed; its start point is the same as its end point.
- Its boundary is a set of linestrings.
- The boundary does not touch or cross itself.
- Any polygons in the interior do not touch the boundary of the exterior polygon except at a vertex.

The [Open Geospatial Consortium \(OGC\)](#) defines the validity of a polygon in section 6.1.11.1 of the [Simple Feature Access Part 1 - Common Architecture](#) specification.

If you are not sure if a polygon is valid, run `ST_IsValid` first. If you pass an invalid spatial object to a Vertica Place function, the function fails or returns incorrect results.

Behavior Type

Immutable

Syntax

```
ST_IsValid( g )
```

Arguments

<i>g</i>	Geospatial object to test for validity, value of type GEOMETRY or GEOGRAPHY (WGS84).
----------	--

Returns

BOOLEAN

Supported Data Types

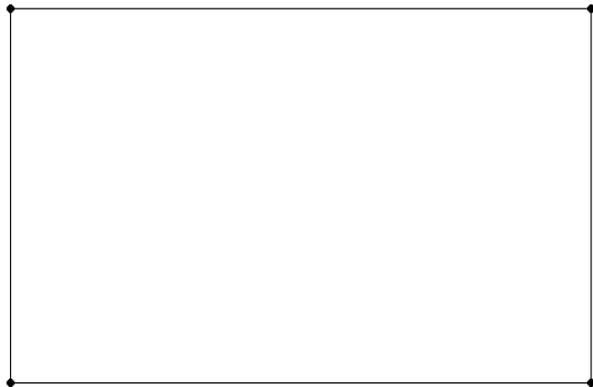

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
-----------	----------	----------------------------	-------------------

Point	Yes	No	No
Multipoint	Yes	No	No
Linestring	Yes	No	No
Multilinestring	Yes	No	No
Polygon	Yes	No	Yes
Multipolygon	Yes	No	No
GeometryCollection	Yes	No	No

Examples

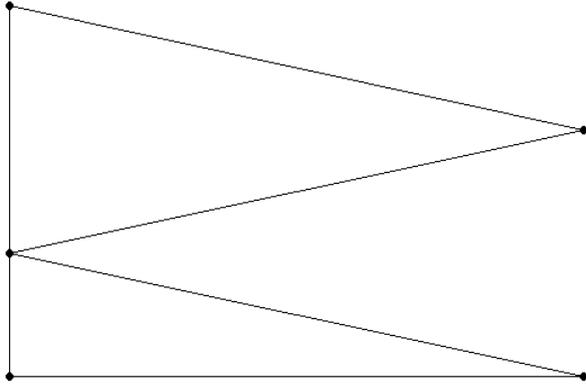

The following examples show how to use ST_IsValid.

Valid polygon:

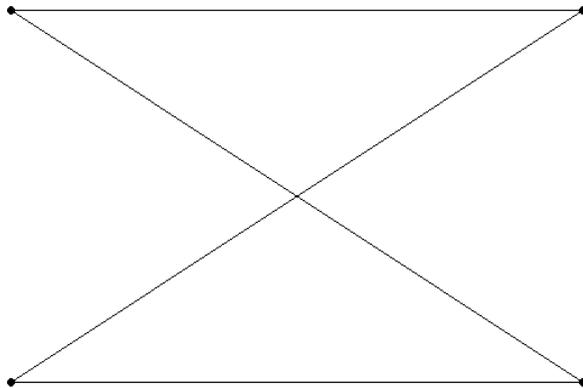

```
=> SELECT ST_IsValid(ST_GeomFromText('POLYGON((1 1,1 3,3 3,3 1,1 1))'));
   ST_IsValid
-----
t
(1 row)
```

Invalid polygon:

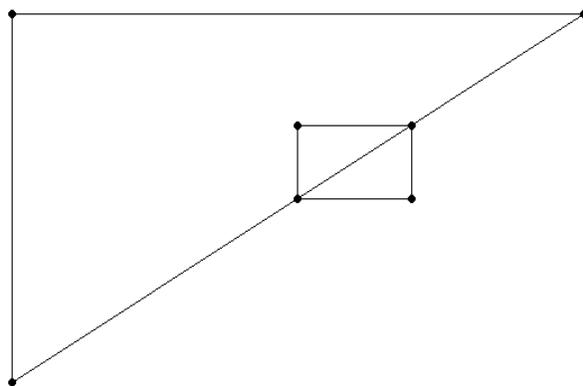

```
=> SELECT ST_IsValid(ST_GeomFromText('POLYGON((1 3,3 2,1 1,3 0,1 0,1 3))'));
   ST_IsValid
-----
          f
(1 row)
```

Invalid polygon:

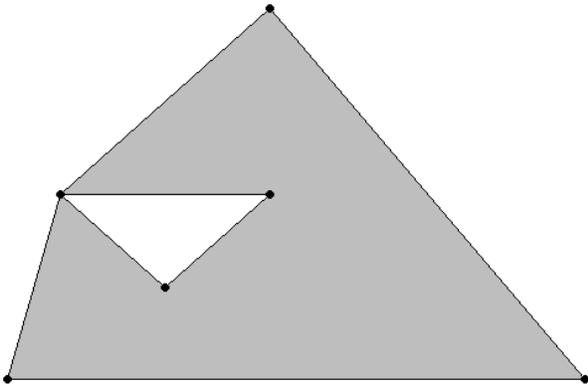

```
=> SELECT ST_IsValid(ST_GeomFromText('POLYGON((0 0,2 2,0 2,2 0,0 0))'));
   ST_IsValid
-----
          f
(1 row)
```

Invalid multipolygon:.

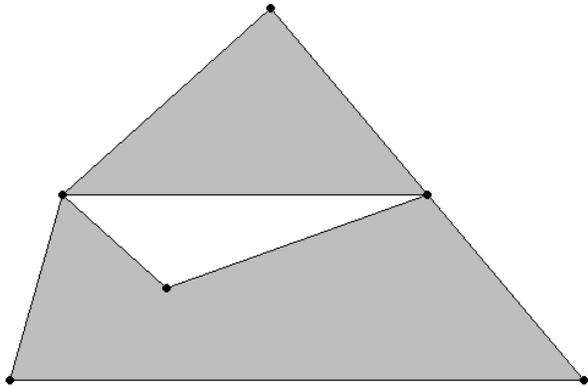

```
=> SELECT ST_IsValid(ST_GeomFromText('MULTIPOLYGON(((0 0, 0 1, 1 1, 0 0)),  
  ((0.5 0.5, 0.7 0.5, 0.7 0.7, 0.5 0.7, 0.5 0.5)))'));  
  ST_IsValid  
-----  
  f  
(1 row)
```

Valid polygon with hole:

```
=> SELECT ST_IsValid(ST_GeomFromText('POLYGON((1 1,3 3,6 -1,0.5 -1,1 1),  
  (1 1,3 1,2 0,1 1))'));  
  ST_IsValid  
-----  
  t  
(1 row)
```

Invalid polygon with hole:

```
=> SELECT ST_IsValid(ST_GeomFromText('POLYGON((1 1,3 3,6 -1,0.5 -1,1 1),  
  (1 1,4.5 1,2 0,1 1))'));  
  ST_IsValid  
-----  
  f  
(1 row)
```

ST_Length

Calculates the length of a spatial object. For GEOMETRY objects, the length is measured in Cartesian coordinate units. For GEOGRAPHY objects, the length is measured in meters.

Calculates the length as follows:

- The length of a point or multipoint object is 0.
- The length of a linestring is the sum of the lengths of each line segment. The length of a line segment is the distance from the start point to the end point.
- The length of a polygon is the sum of the lengths of the exterior boundary and any interior boundaries.
- The length of a multilinestring, multipolygon, or geometrycollection is the sum of the lengths of all the objects it contains.

Note: ST_Length does not calculate the length of WKTs or WKBs. To calculate the lengths of those objects, use the Vertica [LENGTH](#) SQL function with ST_AsBinary or ST_AsText.

Behavior Type

Immutable

Syntax

```
ST_Length( g )
```

Arguments

<i>g</i>	Spatial object for which you want to calculate the length, type GEOMETRY or GEOGRAPHY
----------	---

Returns

FLOAT

Supported Data Types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)
Point	Yes	Yes
Multipoint	Yes	Yes
Linestring	Yes	Yes
Multilinestring	Yes	Yes
Polygon	Yes	Yes
Multipolygon	Yes	Yes
GeometryCollection	Yes	No

Examples

The following examples show how to use ST_Length.

Returns length in Cartesian coordinate units:

```
=> SELECT ST_Length(ST_GeomFromText('LINESTRING(-1 -1,2 2,4 5,6 7)'));
      ST_Length
-----
10.6766190873295
(1 row)
```

Returns length in meters:

```
=> SELECT ST_Length(ST_GeographyFromText('LINESTRING(-56.12 38.26,-57.51 39.78,
      -56.37 45.24)'));
      ST_Length
-----
821580.025733461
(1 row)
```

ST_NumGeometries

Returns the number of geometries contained within a spatial object. Single GEOMETRY or GEOGRAPHY objects return 1 and empty objects return NULL.

Behavior Type

Immutable

Syntax

```
ST_NumGeometries( g )
```

Arguments

<i>g</i>	Spatial object of type GEOMETRY or GEOGRAPHY
----------	--

Returns

INTEGER

Supported Data Types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	Yes	Yes
Linestring	Yes	Yes	Yes
Multilinestring	Yes	Yes	Yes
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	Yes
GeometryCollection	No	No	No

Examples

The following example shows how to use ST_NumGeometries.

Return the number of geometries:

```
=> SELECT ST_NumGeometries(ST_GeomFromText('MULTILINESTRING ((1 5, 2 4, 5 3, 6 6), (3 5, 3 7))'));
   ST_NumGeometries
-----
                2
(1 row)
```

See Also

[ST_GeometryN](#)

ST_NumPoints

Calculates the number of vertices of a spatial object, empty objects return NULL.

The first and last vertex of polygons and multipolygons are counted separately.

Behavior Type

Immutable

Syntax

```
ST_NumPoints( g )
```

Arguments

<i>g</i>	Spatial object for which you want to count the vertices, type GEOMETRY or GEOGRAPHY
----------	---

Returns

INTEGER

Supported Data Types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	Yes	Yes
Linestring	Yes	Yes	Yes
Multilinestring	Yes	Yes	Yes
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	Yes
GeometryCollection	No	No	No

Examples

The following examples show how to use ST_NumPoints.

Returns the number of vertices in a linestring:

```
=> SELECT ST_NumPoints(ST_GeomFromText('LINESTRING(1.33 1.56,2.31 3.4,2.78 5.82,
      3.76 3.9,4.11 3.27,5.85 4.34,6.9 4.231,7.61 5.77)'));
ST_NumPoints
-----
                8
(1 row)
```

Use ST_Boundary and ST_NumPoints to return the number of vertices of a polygon:

```
=> SELECT ST_NumPoints(ST_Boundary(ST_GeomFromText('POLYGON((1 2,1 4,
      2 5,3 6,4 6,5 5,4 4,3 3,1 2))')));
ST_NumPoints
-----
                9
(1 row)
```

ST_Overlaps

Determines if a GEOMETRY object shares space with another GEOMETRY object, but is not completely contained within that object. They must overlap at their interiors. If two objects touch at a single point or intersect only along a boundary, they do not overlap. Both parameters must have the same dimension; otherwise, ST_Overlaps returns FALSE.

Behavior Type

Immutable

Syntax

```
ST_Overlaps ( g1, g2 )
```

Arguments

<i>g1</i>	Spatial object, type GEOMETRY
<i>g2</i>	Spatial object, type GEOMETRY

Returns

BOOLEAN

Supported Data Types

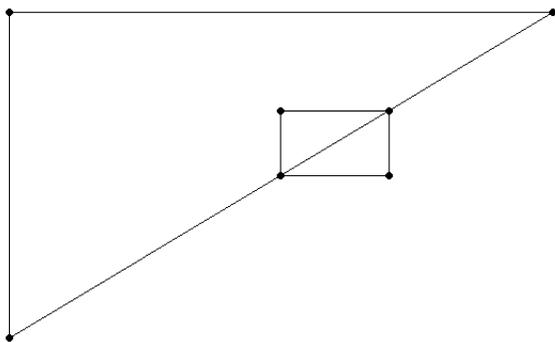

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes

Polygon	Yes
Multipolygon	Yes
GeometryCollection	Yes

Examples

The following examples show how to use `ST_Overlaps`.

`Polygon_1` overlaps but does not completely contain `Polygon_2`:

```
=> SELECT ST_Overlaps(ST_GeomFromText('POLYGON((0 0, 0 1, 1 1, 0 0))'),
  ST_GeomFromText('POLYGON((0.5 0.5, 0.7 0.5, 0.7 0.7, 0.5 0.7, 0.5 0.5))'));
 ST_Overlaps
-----
t
(1 row)
```

Two objects with different dimensions:

```
=> SELECT ST_Overlaps(ST_GeomFromText('LINESTRING(2 2,4 4)'),
  ST_GeomFromText('POINT(3 3)'));
 ST_Overlaps
-----
f
(1 row)
```

ST_PointFromGeoHash

Returns the center point of the specified GeoHash.

Behavior Type

Immutable

Syntax

`ST_PointFromGeoHash(GeoHash)`

Arguments

<i>GeoHash</i>	A valid GeoHash string of arbitrary length.
----------------	---

Returns

GEOGRAPHY POINT

Examples

The following examples show how to use `ST_PointFromGeoHash`.

Returns the geography point of a high-level GeoHash and uses [ST_AsText](#) to convert that point into Well-Known Text:

```
=> SELECT ST_AsText(ST_PointFromGeoHash('dr'));
ST_AsText
-----
POINT (-73.125 42.1875)
(1 row)
```

Returns the geography point of a detailed GeoHash and uses `ST_AsText` to convert that point into Well-Known Text:

```
=> SELECT ST_AsText(ST_PointFromGeoHash('1234567890bcdefhjkmn'));
ST_AsText
-----
POINT (-122.196077187 -88.2297377551)
(1 row)
```

ST_PointN

Finds the n^{th} point of a spatial object. If you pass a negative number, zero, or a number larger than the total number of points on the linestring, `ST_PointN` returns NULL.

The vertex order is based on the Well-Known Text (WKT) representation of the spatial object.

Behavior Type

Immutable

Syntax

```
ST_PointN( g, n )
```

Arguments

<i>g</i>	Spatial object to search, type GEOMETRY or GEOGRAPHY
<i>n</i>	Point in the spatial object to be returned. The index is one-based, type INTEGER

Returns

GEOMETRY or GEOGRAPHY

Supported Data Types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	Yes	Yes
Linestring	Yes	Yes	Yes
Multilinestring	Yes	Yes	Yes
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	Yes
GeometryCollection	No	No	No

Examples

The following examples show how to use `ST_PointN`.

Returns the fifth point:

```
=> SELECT ST_AsText(ST_PointN(ST_GeomFromText('
      POLYGON(( 2 6, 2 9, 6 9, 7 7, 4 6, 2 6))'), 5));
   ST_AsText
-----
POINT (4 6)
(1 row)
```

Returns the second point:

```
=> SELECT ST_AsText(ST_PointN(ST_GeographyFromText('
      LINestring(23.41 24.93,34.2 32.98,40.7 41.19)'), 2));
   ST_AsText
-----
POINT (34.2 32.98)
(1 row)
```

ST_Relate

Determines if a given `GEOMETRY` object is spatially related to another `GEOMETRY` object, based on the specified DE-9IM pattern matrix string.

The DE-9IM standard identifies how two objects are spatially related to each other.

Behavior Type

Immutable

Syntax

```
ST_Relate( g1, g2, matrix )
```

Arguments

<i>g1</i>	Spatial object, type <code>GEOMETRY</code>
<i>g2</i>	Spatial object, type <code>GEOMETRY</code>

<i>matrix</i>	<p>DE-9IM pattern matrix string, type CHAR(9). This string represents a 3 x 3 matrix of restrictions on the dimensions of the respective intersections of the interior, boundary, and exterior of the two geometries. Must contain exactly 9 of the following characters:</p> <ul style="list-style-type: none">• T• F• 0• 1• 2• *
---------------	---

Returns

BOOLEAN

Supported Data Types

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	Yes

Examples

The following examples show how to use ST_Relate.

The DE-9IM pattern for "equals" is 'T*F**FFF2':

```
=> SELECT ST_Relate(ST_GeomFromText('LINESTRING(0 1,2 2)'),
  ST_GeomFromText('LINESTRING(2 2,0 1)'), 'T*F**FFF2');
  ST_Relate
-----
t
(1 row)
```

The DE-9IM pattern for "overlaps" is 'T*T***T**':

```
=> SELECT ST_Relate(ST_GeomFromText('POLYGON((-1 -1,0 1,2 2,-1 -1))'),
  ST_GeomFromText('POLYGON((0 1,1 -1,1 1,0 1))'), 'T*T***T**');
  ST_Relate
-----
t
(1 row)
```

ST_SRID

Identifies the spatial reference system identifier (SRID) stored with a spatial object.

The SRID of a GEOMETRY object can only be determined when passing an SRID to either ST_GeomFromText or ST_GeomFromWKB. ST_SRID returns this stored value. SRID values of 0 to $2^{32}-1$ are valid.

Behavior Type

Immutable

Syntax

```
ST_SRID( g )
```

Arguments

<i>g</i>	Spatial object for which you want the SRID, type GEOMETRY or GEOGRAPHY
----------	--

Returns

INTEGER

Supported Data Types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	Yes	Yes
Linestring	Yes	Yes	Yes
Multilinestring	Yes	Yes	Yes
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	Yes
GeometryCollection	Yes	No	No

Examples

The following examples show how to use ST_SRID.

The default SRID of a GEOMETRY object is 0:

```
=> SELECT ST_SRID(ST_GeomFromText(
      'POLYGON((-1 -1,2 2,0 1,-1 -1))');
ST_SRID
-----
0
(1 row)
```

The default SRID of a GEOGRAPHY object is 4326:

```
=> SELECT ST_SRID(ST_GeographyFromText(
      'POLYGON((22 35,24 35,26 32,22 35))');
ST_SRID
-----
4326
(1 row)
```

ST_SymDifference

Calculates all the points in two GEOMETRY objects except for the points they have in common, but including the boundaries of both objects.

This result is called the symmetric difference and is represented mathematically as: $\text{Closure}(g1 - g2) \cup \text{Closure}(g2 - g1)$

Behavior Type

Immutable

Syntax

```
ST_SymDifference( g1, g2 )
```

Arguments

<i>g1</i>	Spatial object, type GEOMETRY
<i>g2</i>	Spatial object, type GEOMETRY

Returns

GEOMETRY

Supported Data Types

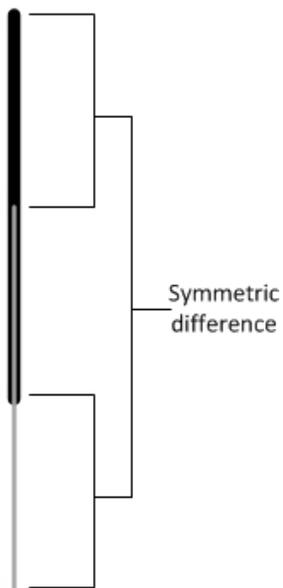

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes

Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	Yes

Examples

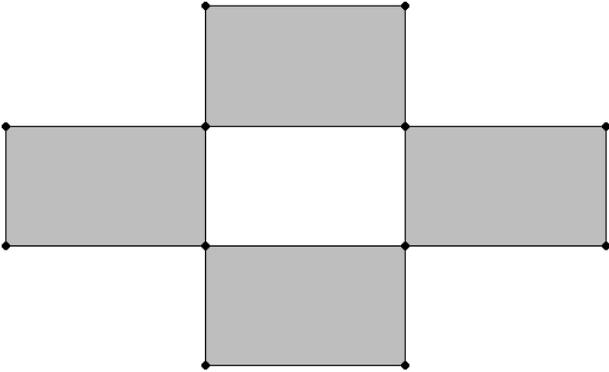

The following examples show how to use ST_SymDifference.

Returns the two linestrings:

```
=> SELECT ST_AsText(ST_SymDifference(ST_GeomFromText('LINESTRING(30 40,
30 55)'),ST_GeomFromText('LINESTRING(30 32.5,30 47.5)'));
ST_AsText
-----
MULTILINESTRING ((30 47.5, 30 55),(30 32.5,30 40))
(1 row)
```

Returns four squares:

```
=> SELECT ST_AsText(ST_SymDifference(ST_GeomFromText('POLYGON((2 1,2 4,3 4,
  3 1,2 1))'),ST_GeomFromText('POLYGON((1 2,1 3,4 3,4 2,1 2))'));
      ST_AsText
-----
MULTIPOLYGON (((2 1, 2 2, 3 2, 3 1, 2 1)), ((1 2, 1 3, 2 3, 2 2, 1 2)),
((2 3, 2 4, 3 4, 3 3, 2 3)), ((3 2, 3 3, 4 3, 4 2, 3 2)))
(1 row)
```

ST_Touches

Determines if two GEOMETRY objects touch at a single point or along a boundary, but do not have interiors that intersect.

GEOGRAPHY Polygons with a vertex or border on the International Date Line (IDL) or the North or South pole are not supported.

Behavior Type

Immutable

Syntax

```
ST_Touches( g1, g2
            [USING PARAMETERS spheroid={true | false}] )
```

Arguments

<i>g1</i>	Spatial object, value of type GEOMETRY
<i>g2</i>	Spatial object, value of type GEOMETRY

Parameters

spheroid = {true false}	(Optional) BOOLEAN that specifies whether to use a perfect sphere or WGS84. Default: False
---------------------------	--

Returns

BOOLEAN

Supported Data Types

Data Type	GEOMETRY	GEOGRAPHY (WGS84)
Point	Yes	Yes
Multipoint	Yes	No
Linestring	Yes	No
Multilinestring	Yes	No
Polygon	Yes	Yes
Multipolygon	Yes	No
GeometryCollection	Yes	No

Compatible GEOGRAPHY pairs:

Data Type	GEOGRAPHY (WGS84)
Point-Point	No
Linestring-Point	No
Polygon-Point	Yes
Multipolygon-Point	No

Examples

The following examples show how to use `ST_Touches`.

Two polygons touch at a single point:

```
=> SELECT ST_Touches(ST_GeomFromText('POLYGON((-1 2,0 3,0 1,-1 2))'),
  ST_GeomFromText('POLYGON((1 3,0 3,1 2,1 3))'));
  ST_Touches
-----
t
(1 row)
```

Two polygons touch only along part of the boundary:

```
=> SELECT ST_Touches(ST_GeomFromText('POLYGON((-1 2,0 3,0 1,-1 2))'),
  ST_GeomFromText('POLYGON((1 2,0 3,0 1,1 2))'));
  ST_Touches
-----
t
(1 row)
```

Two polygons do not touch at any point:

```
=> SELECT ST_Touches(ST_GeomFromText('POLYGON((-1 2,0 3,0 1,-1 2))'),
  ST_GeomFromText('POLYGON((0 2,-1 3,-2 0,0 2))'));
  ST_Touches
-----
f
(1 row)
```

ST_Transform

Returns a new `GEOMETRY` with its coordinates converted to the spatial reference system identifier (SRID) used by the `srid` argument.

This function supports the following transformations:

- EPSG 4326 (WGS84) to EPSG 3857 (Web Mercator)
- EPSG 3857 (Web Mercator) to EPSG 4326 (WGS84)

For EPSG 4326 (WGS84), unless the coordinates fall within the following ranges, conversion results in failure:

- Longitude limits: -572 to +572
- Latitude limits: -89.9999999 to +89.9999999

Behavior Type

Immutable

Syntax

```
ST_Transform( g1, srid )
```

Arguments

<i>g1</i>	Spatial object of type GEOMETRY.
<i>srid</i>	Spatial reference system identifier (SRID) to which you want to convert your spatial object, of type INTEGER.

Returns

GEOMETRY

Supported Data Types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	No	No
Multipoint	Yes	No	No
Linestring	Yes	No	No
Multilinestring	Yes	No	No
Polygon	Yes	No	No

Multipolygon	Yes	No	No
GeometryCollection	Yes	No	No

Examples

The following example shows how you can transform data from Web Mercator (3857) to WGS84 (4326):

```
=> SELECT ST_AsText(ST_Transform(STV_GeometryPoint(7910240.56433, 5215074.23966, 3857), 4326));
           ST_AsText
-----
POINT (71.0589 42.3601)
(1 row)
```

The following example shows how you can transform linestring data in a table from WGS84 (4326) to Web Mercator (3857):

```
=> CREATE TABLE transform_line_example (g GEOMETRY);
CREATE TABLE
=> COPY transform_line_example (gx FILLER LONG VARCHAR, g AS ST_GeomFromText(gx, 4326)) FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> LINESTRING(0 0, 1 1, 2 2, 3 4)
>> \.
=> SELECT ST_AsText(ST_Transform(g, 3857)) FROM transform_line_example;
           ST_AsText
-----
LINESTRING (0 -7.08115455161e-10, 111319.490793 111325.142866, 222638.981587 222684.208506,
333958.47238 445640.109656)
(1 row)
```

The following example shows how you can transform point data in a table from WGS84 (4326) to Web Mercator (3857):

```
=> CREATE TABLE transform_example (x FLOAT, y FLOAT, srid INT);
CREATE TABLE
=> COPY transform_example FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 42.3601|71.0589|4326
>> 122.4194|37.7749|4326
>> 94.5786|39.0997|4326
>> \.
=> SELECT ST_AsText(ST_Transform(STV_GeometryPoint(x, y, srid), 3857)) FROM transform_example;
           ST_AsText
-----
POINT (4715504.76195 11422441.5961)
POINT (13627665.2712 4547675.35434)
POINT (10528441.5919 4735962.8206)
(3 rows)
```

ST_Union

Calculates the union of all points in two spatial objects.

This result is represented mathematically by: $g1 \cup g2$

Behavior Type

Immutable

Syntax

```
ST_Union( g1, g2 )
```

Arguments

<i>g1</i>	Spatial object, type GEOMETRY
<i>g2</i>	Spatial object, type GEOMETRY

Returns

GEOMETRY

Supported Data Types

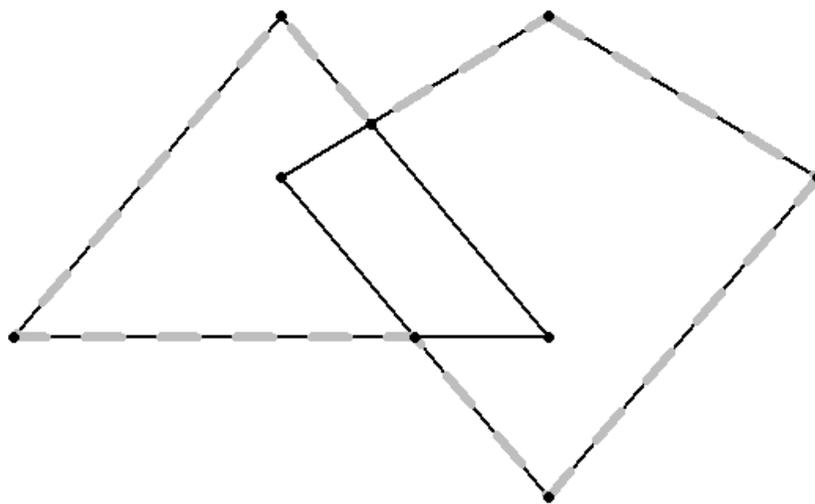

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes

Multipolygon	Yes
GeometryCollection	Yes

Example

The following example shows how to use `ST_Union`.

Returns a polygon that represents all the points contained in these two polygons:

```
=> SELECT ST_AsText(ST_Union(ST_GeomFromText('POLYGON((0 2,1 1,0 -1,-1 1,0 2))'),
  ST_GeomFromText('POLYGON((-1 2, 0 0, -2 0, -1 2)'))));
      ST_AsText
-----
POLYGON ((0 2, 1 1, 0 -1, -0.5 0, -2 0, -1 2, -0.6666666666667 1.333333333333, 0 2))
(1 row)
```

ST_Within

If spatial object `g1` is completely inside of spatial object `g2`, then `ST_Within` returns true. Both parameters must be the same spatial data type. Either specify two `GEOMETRY` objects or two `GEOGRAPHY` objects.

If an object such as a point or linestring only exists along a polygon's boundary, then `ST_Within` returns false. The interior of a linestring is all the points along the linestring except the start and end points.

`ST_Within(g1, g2)` is functionally equivalent to `ST_Contains(g2, g1)`.

GEOGRAPHY Polygons with a vertex or border on the International Date Line (IDL) or the North or South pole are not supported.

Behavior Type

Immutable

Syntax

```
ST_Within( g1, g2  
          [USING PARAMETERS spheroid={true | false}] )
```

Arguments

<i>g1</i>	Spatial object, type GEOMETRY or GEOGRAPHY
<i>g2</i>	Spatial object, type GEOMETRY or GEOGRAPHY

Parameters

spheroid = {true false}	(Optional) BOOLEAN that specifies whether to use a perfect sphere or WGS84. Default: False
---------------------------	--

Returns

BOOLEAN

Supported Data Types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes

Multipoint	Yes	No	No
Linestring	Yes	Yes	No
Multilinestring	Yes	No	No
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	No
GeometryCollection	Yes	No	No

Compatible GEOGRAPHY pairs:

Data Type	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point-Point	Yes	No
Point-Linestring	Yes	No
Point-Polygon	Yes	Yes
Point-Multipolygon	Yes	No

Examples

The following examples show how to use ST_Within.

The first polygon is completely contained within the second polygon:

```
=> SELECT ST_Within(ST_GeomFromText('POLYGON((0 2,1 1,0 -1,0 2))'),
  ST_GeomFromText('POLYGON((-1 3,2 1,0 -3,-1 3))'));
  ST_Within
-----
t
(1 row)
```

The point is on a vertex of the polygon, but not in its interior:

```
=> SELECT ST_Within (ST_GeographyFromText('POINT(30 25)'),
  ST_GeographyFromText('POLYGON((25 25,25 35,32.2 35,30 25,25 25))'));
  ST_Within
-----
f
(1 row)
```

Two polygons are spatially equivalent:

```
=> SELECT ST_Within (ST_GeomFromText('POLYGON((-1 2, 0 3, 0 1, -1 2))'),  
    ST_GeomFromText('POLYGON((0 3, -1 2, 0 1, 0 3))'));  
    ST_Within  
-----  
    t  
(1 row)
```

See Also

- [ST_Contains](#)
- [ST_Overlaps](#)

ST_X

Determines the *x*- coordinate for a GEOMETRY point or the longitude value for a GEOGRAPHY point.

Behavior Type

Immutable

Syntax

```
ST_X( g )
```

Arguments

<i>g</i>	Point of type GEOMETRY or GEOGRAPHY
----------	-------------------------------------

Returns

FLOAT

Supported Data Types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	No	No	No
Linestring	No	No	No
Multilinestring	No	No	No
Polygon	No	No	No
Multipolygon	No	No	No
GeometryCollection	No	No	No

Examples

The following examples show how to use ST_X.

Returns the x-coordinate:

```
=> SELECT ST_X(ST_GeomFromText('POINT(3.4 1.25)'));
   ST_X
-----
    3.4
(1 row)
```

Returns the longitude value:

```
=> SELECT ST_X(ST_GeographyFromText('POINT(25.34 45.67)'));
   ST_X
-----
    25.34
(1 row)
```

ST_XMax

Returns the maximum x-coordinate of the minimum bounding rectangle of the GEOMETRY or GEOGRAPHY object.

For GEOGRAPHY types, Vertica Place computes maximum coordinates by calculating the maximum longitude of the great circle arc from (MAX(longitude), ST_YMin(GEOGRAPHY)) to (MAX(longitude), ST_YMax(GEOGRAPHY)). In this case, MAX(longitude) is the maximum longitude value of the geography object.

If either latitude or longitude is out of range, ST_XMax returns the maximum plain value of the geography object.

Behavior Type

Immutable

Syntax

```
ST_XMax( g )
```

Arguments

<i>g</i>	Spatial object for which you want to find the maximum x-coordinate, type GEOMETRY or GEOGRAPHY.
----------	---

Returns

FLOAT

Supported Data Types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)
Point	Yes	Yes
Multipoint	Yes	Yes
Linestring	Yes	Yes
Multilinestring	Yes	Yes
Polygon	Yes	Yes

Multipolygon	Yes	Yes
GeometryCollection	Yes	No

Examples

The following examples show how to use ST_XMax.

Returns the maximum x-coordinate within a rectangle:

```
=> SELECT ST_XMax(ST_GeomFromText('POLYGON((0 1,0 2,1 2,1 1,0 1))'));
   ST_XMax
-----
         1
(1 row)
```

Returns the maximum longitude value within a rectangle:

```
=> SELECT ST_XMax(ST_GeographyFromText(
  'POLYGON((-71.50 42.35, -71.00 42.35, -71.00 42.38, -71.50 42.38, -71.50 42.35))');
   ST_XMax
-----
        -71
(1 row)
```

ST_XMin

Returns the minimum x-coordinate of the minimum bounding rectangle of the GEOMETRY or GEOGRAPHY object.

For GEOGRAPHY types, Vertica Place computes minimum coordinates by calculating the minimum longitude of the great circle arc from (MIN(longitude), ST_YMin(GEOGRAPHY)) to (MIN(longitude), ST_YMax(GEOGRAPHY)). In this case, MIN(longitude) represents the minimum longitude value of the geography object

If either latitude or longitude is out of range, ST_XMin returns the minimum plain value of the geography object.

Behavior Type

Immutable

Syntax

`ST_XMin(g)`

Arguments

<i>g</i>	Spatial object for which you want to find the minimum <i>x</i> -coordinate, type GEOMETRY or GEOGRAPHY.
----------	---

Returns

FLOAT

Supported Data Types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)
Point	Yes	Yes
Multipoint	Yes	Yes
Linestring	Yes	Yes
Multilinestring	Yes	Yes
Polygon	Yes	Yes
Multipolygon	Yes	Yes
GeometryCollection	Yes	No

Examples

The following examples show how to use ST_XMin.

Returns the minimum *x*-coordinate within a rectangle:

```
=> SELECT ST_XMin(ST_GeomFromText('POLYGON((0 1,0 2,1 2,1 1,0 1))'));
   ST_XMin
-----
        0
(1 row)
```

Returns the minimum longitude value within a rectangle:

```
=> SELECT ST_XMin(ST_GeographyFromText(
   'POLYGON((-71.50 42.35, -71.00 42.35, -71.00 42.38, -71.50 42.38, -71.50 42.35))');
   ST_XMin
-----
     -71.5
(1 row)
```

ST_YMax

Returns the maximum *y*-coordinate of the minimum bounding rectangle of the GEOMETRY or GEOGRAPHY object.

For GEOGRAPHY types, Vertica Place computes maximum coordinates by calculating the maximum latitude of the great circle arc from (ST_XMin(GEOGRAPHY), MAX(latitude)) to (ST_XMax(GEOGRAPHY), MAX(latitude)). In this case, MAX(latitude) is the maximum latitude value of the geography object.

If either latitude or longitude is out of range, ST_YMax returns the maximum plain value of the geography object.

Behavior Type

Immutable

Syntax

```
ST_YMax( g )
```

Arguments

<i>g</i>	Spatial object for which you want to find the maximum <i>y</i> -coordinate, type GEOMETRY or GEOGRAPHY.
----------	---

Returns

FLOAT

Supported Data Types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)
Point	Yes	Yes
Multipoint	Yes	Yes
Linestring	Yes	Yes
Multilinestring	Yes	Yes
Polygon	Yes	Yes
Multipolygon	Yes	Yes
GeometryCollection	Yes	No

Examples

The following examples show how to use ST_YMax.

Returns the maximum *y*-coordinate within a rectangle:

```
=> SELECT ST_YMax(ST_GeomFromText('POLYGON((0 1,0 4,1 4,1 1,0 1))'));
   ST_YMax
-----
         4
(1 row)
```

Returns the maximum latitude value within a rectangle:

```
=> SELECT ST_YMax(ST_GeographyFromText(
  'POLYGON((-71.50 42.35, -71.00 42.35, -71.00 42.38, -71.50 42.38, -71.50 42.35))');
   ST_YMax
-----
42.3802715689979
(1 row)
```

ST_YMin

Returns the minimum *y*-coordinate of the minimum bounding rectangle of the GEOMETRY or GEOGRAPHY object.

For GEOGRAPHY types, Vertica Place computes minimum coordinates by calculating the minimum latitude of the great circle arc from (ST_XMin(GEOGRAPHY), MIN(latitude)) to (ST_XMax(GEOGRAPHY), MIN(latitude)). In this case, MIN(latitude) represents the minimum latitude value of the geography object.

If either latitude or longitude is out of range, ST_YMin returns the minimum plain value of the geography object.

Behavior Type

Immutable

Syntax

```
ST_YMin( g )
```

Arguments

<i>g</i>	Spatial object for which you want to find the minimum <i>y</i> -coordinate, type GEOMETRY or GEOGRAPHY.
----------	---

Returns

FLOAT

Supported Data Types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)
Point	Yes	Yes

Multipoint	Yes	Yes
Linestring	Yes	Yes
Multilinestring	Yes	Yes
Polygon	Yes	Yes
Multipolygon	Yes	Yes
GeometryCollection	Yes	No

Examples

The following examples show how to use ST_YMin.

Returns the minimum y-coordinate within a rectangle:

```
=> SELECT ST_YMin(ST_GeomFromText('POLYGON((0 1,0 4,1 4,1 1,0 1))'));
   ST_YMin
-----
         1
(1 row)
```

Returns the minimum latitude value within a rectangle:

```
=> SELECT ST_YMin(ST_GeographyFromText(
  'POLYGON((-71.50 42.35, -71.00 42.35, -71.00 42.38, -71.50 42.38, -71.50 42.35))');
   ST_YMin
-----
    42.35
(1 row)
```

ST_Y

Determines the y-coordinate for a GEOMETRY point or the latitude value for a GEOGRAPHY point.

Behavior Type

Immutable

Syntax

`ST_Y(g)`

Arguments

<i>g</i>	Point of type GEOMETRY or GEOGRAPHY
----------	-------------------------------------

Returns

FLOAT

Supported Data Types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	No	No	No
Linestring	No	No	No
Multilinestring	No	No	No
Polygon	No	No	No
Multipolygon	No	No	No
GeometryCollection	No	No	No

Examples

The following examples show how to use `ST_Y`.

Returns the *y*-coordinate:

```
=> SELECT ST_Y(ST_GeomFromText('POINT(3 5.25)'));
   ST_Y
-----
   5.25
(1 row)
```

Returns the latitude value:

```
=> SELECT ST_Y(ST_GeographyFromText('POINT(35.44 51.04)'));
   ST_Y
-----
   51.04
(1 row)
```

STV_AsGeoJSON

Returns the geometry or geography argument as a Geometry Javascript Object Notation (GeoJSON) object.

Behavior Type

Immutable

Syntax

```
STV_AsGeoJSON(g, [USING PARAMETERS maxdecimals=dec_value])
```

Arguments

<i>g</i>	Spatial object of type GEOMETRY or GEOGRAPHY
maxdecimals = <i>dec_value</i>	(Optional) Integer value. Determines the maximum number of digits to output after the decimal of floating point coordinates. Valid values: Between 0 and 15. Default value: 6

Returns

LONG VARCHAR

Supported Data Types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes	Yes
Multipoint	Yes	Yes	Yes
Linestring	Yes	Yes	Yes
Multilinestring	Yes	Yes	Yes
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	Yes
GeometryCollection	No	No	No

Examples

The following examples show how you can use STV_AsGeoJSON.

Convert a geometry polygon to GeoJSON:

```
=> SELECT STV_AsGeoJSON(ST_GeomFromText('POLYGON((3 2, 4 3, 5 1, 3 2), (3.5 2, 4 2.5, 4.5 1.5, 3.5 2))'));
          STV_AsGeoJSON
-----
{"type": "Polygon", "coordinates": [[[3,2],[4,3],[5,1],[3,2]],[[3.5,2],[4,2.5],[4.5,1.5],[3.5,2]]]}
(1 row)
```

Convert a geography point to GeoJSON:

```
=> SELECT STV_AsGeoJSON(ST_GeographyFromText('POINT(42.36011 71.05899)') USING PARAMETERS
maxdecimals=4);
          STV_AsGeoJSON
-----
{"type": "Point", "coordinates": [42.3601,71.059]}
(1 row)
```

STV_Create_Index

Creates a spatial index on a set of polygons to speed up spatial intersection with a set of points.

A spatial index is created from an input polygon set, which can be the result of a query. Spatial indexes are created in a global name space. Vertica uses a distributed plan whenever the input table or projection is segmented across nodes of the cluster.

The OVER() clause must be empty.

Important: You cannot access spatial indexes on newly added nodes without rebalancing your cluster. For more information, see [REBALANCE_CLUSTER](#).

Behavior Type

Immutable

Note: Indexes are not connected to any specific table. Subsequent DML commands on the underlying table or tables of the input data source do not modify the index.

Syntax

```
STV_Create_Index( gid, g
                 USING PARAMETERS index='index_name'
                               [, overwrite={ true | false } ]
                               [, max_mem_mb=mem_value]
                               [, skip_nonindexable_polygons={true | false } ] )
OVER()
[ AS (polygons, srid, min_x, min_y, max_x, max_y, info) ]
```

Arguments

<i>gid</i>	Name of an integer column that uniquely identifies the polygon. The gid cannot be NULL.
<i>g</i>	Name of a geometry or geography (WGS84) column or expression that contains polygons and multipolygons. Only polygon and multipolygon can be indexed. Other shape types are excluded from the index.

Parameters

<code>index = 'index_name'</code>	Name of the index, type VARCHAR. Index names cannot exceed 110 characters. The slash, backslash, and tab characters are not
-----------------------------------	---

	allowed in index names.
<code>overwrite = [true false]</code>	<p>(Optional) BOOLEAN value that specifies whether to overwrite the index, if an index exists. This parameter cannot be NULL.</p> <p>Default: False</p>
<code>max_mem_mb = maxmem_value</code>	<p>(Optional) A positive integer that assigns a limit to the amount of memory in megabytes that <code>STV_Create_Index</code> can allocate during index construction. On a multi-node database this is the memory limit per node. The default value is 256. Do not assign a value higher than the amount of memory in the GENERAL resource pool. For more information about this pool, see Using Queries to Monitor Resource Pool Size and Usage.</p> <p>Setting a value for <code>max_mem_mb</code> that is at or near the maximum memory available on the node can negatively affect your system's performance. For example, it could cause other queries to time out waiting for memory resources during index construction.</p>
<code>skip_nonindexable_polygons = [true false]</code>	<p>(Optional) BOOLEAN</p> <p>In rare cases, intricate polygons (for instance, with too high resolution or anomalous spikes) cannot be indexed. These polygons are considered non-indexable. When set to False, non-indexable polygons cause the index creation to fail. When set to True, index creation can succeed by excluding non-indexable polygons from the index.</p> <p>To review the polygons that were not able to be indexed, use <code>STV_Describe_Index</code> with the parameter <code>list_polygon</code>.</p> <p>Default: False</p>

Returns

<i>polygons</i>	Number of polygons indexed.
<i>SRID</i>	Spatial reference system identifier.
<i>min_x, min_y, max_x, max_y</i>	Coordinates of the minimum bounding rectangle (MBR) of the indexed geometries. (<i>min_x, min_y</i>) are the south-west coordinates, and (<i>max_x, max_y</i>) are the north-east coordinates.
<i>info</i>	Lists the number of excluded spatial objects as well as their type that were excluded from the index.

Supported Data Types

Data Type	GEOMETRY	GEOGRAPHY (WGS84)
Point	No	No
Multipoint	No	No
Linestring	No	No
Multilinestring	No	No
Polygon	Yes	Yes
Multipolygon	Yes	No
GeometryCollection	No	No

Privileges

Any user with access to the STV_*_Index functions can describe, rename, or drop indexes created by any other user.

Recommendations

- Segment large polygon tables across multiple nodes. Table segmentation causes index creation to run in parallel, leveraging the Massively Parallel Processing (MPP) architecture in Vertica. This significantly reduces execution time on large tables.

Vertica recommends that you segment the table from which you are building the index when the total number of polygons is large.

- `STV_Create_Index` can consume large amounts of processing time and memory.

Vertica recommends that when indexing new data for the first time, you monitor memory usage to be sure it stays within safe limits. Memory usage depends on number of polygons, number of vertices, and the amount of overlap among polygons.

- `STV_Create_Index` tries to allocate memory before it starts creating the index. If it cannot allocate enough memory, the function fails. If not enough memory is available, try the following:
 - Create the index at a time of less load on the system.
 - Avoid concurrent index creation.
 - Try segmenting the input table across the nodes of the cluster.
- Ensure that all of the polygons you plan to index are valid polygons. `STV_Create_Index` and `STV_Refresh_Index` do not check polygon validity when building an index.

For more information, see [Ensuring Polygon Validity Before Creating or Refreshing an Index](#).

Limitations

- Any indexes created prior to 8.1.x need to be re-created.
- Index creation fails if there are WGS84 polygons with vertices on the International Date Line (IDL) or the North and South Poles.
- The backslash or tab characters are not allowed in index names.
- Indexes cannot have names greater than 110 characters.

- The following geometries are excluded from the index:
 - Non-polygons
 - Geometries with NULL identifiers
 - NULL (multi) polygon
 - EMPTY (multi) polygon
 - Invalid (multi) polygon
- The following geographies are excluded from the index:
 - Polygons with holes
 - Polygons crossing the International Date Line
 - Polygons covering the north or south pole
 - Antipodal polygons

Usage Tips

- To cancel an STV_Create_Index run, use **Ctrl + C**.
- If there are no valid polygons in the geom column, STV_Create_Index reports an error in vertica.log and stops index creation.
- If index creation uses a large amount of memory, consider segmenting your data to utilize parallel index creation.

Examples

The following examples show how to use STV_Create_Index.

Create an index with a single literal argument:

```
=> SELECT STV_Create_Index(1, ST_GeomFromText('POLYGON((0 0,0 15.2,3.9 15.2,3.9 0,0 0))')
      USING PARAMETERS index='my_polygon') OVER();
polygons | SRID | min_x | min_y | max_x | max_y | info
-----+-----+-----+-----+-----+-----+-----
        1 |    0 |    0 |    0 |    3.9 |   15.2 |
(1 row)
```

Create an index from a table:

```
=> CREATE TABLE polys (gid INT, geom GEOMETRY(1000));
CREATE TABLE
=> COPY polys(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1|POLYGON((-31 74,8 70,8 50,-36 53,-31 74))
>> 2|POLYGON((-38 50,4 13,11 45,0 65,-38 50))
>> 3|POLYGON((10 20,15 60,20 45,46 15,10 20))
>> 4|POLYGON((5 20,9 30,20 45,36 35,5 20))
>> 5|POLYGON((12 23,9 30,20 45,36 35,37 67,45 80,50 20,12 23))
>> \.
=> SELECT STV_Create_Index(gid, geom USING PARAMETERS index='my_polygons_1', overwrite=true,
    max_mem_mb=256) OVER() FROM polys;
polygons | SRID | min_x | min_y | max_x | max_y | info
-----+-----+-----+-----+-----+-----+-----
      5 |    0 |   -38 |    13 |    50 |    80 |
(1 row)
```

Create an index in parallel from a partitioned table:

```
=> CREATE TABLE polys (p INT, gid INT, geom GEOMETRY(1000)) SEGMENTED BY HASH(p) ALL NODES;
CREATE TABLE
=> COPY polys (p, gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1|10|POLYGON((-31 74,8 70,8 50,-36 53,-31 74))
>> 1|11|POLYGON((-38 50,4 13,11 45,0 65,-38 50))
>> 3|12|POLYGON((-12 42,-12 42,27 48,14 26,-12 42))
>> \.
=> SELECT STV_Create_Index(gid, geom USING PARAMETERS index='my_polygons', overwrite=true,
    max_mem_mb=256) OVER() FROM polys;
polygons | SRID | min_x | min_y | max_x | max_y | info
-----+-----+-----+-----+-----+-----+-----
      3 |    0 |   -38 |    13 |    27 |    74 |
(1 row)
```

STV_Describe_Index

Retrieves information about an index that contains a set of polygons. If you do not pass any parameters, `STV_Describe_Index` returns all of the defined indexes.

The `OVER()` clause must be empty.

Behavior Type

Immutable

Syntax

```
STV_Describe_Index ( [ USING PARAMETERS [index='index_name']  
                    [, list_polygons={true | false } ] ] ) OVER ( )
```

Arguments

<code>index = 'index_name'</code>	Name of the index, type VARCHAR. Index names cannot exceed 110 characters. The slash, backslash, and tab characters are not allowed in index names.
<code>list_polygon</code>	(Optional) BOOLEAN that specifies whether to list the polygons in the index. The index argument must be used with this argument.

Returns

<code>polygons</code>	Number of polygons indexed.
<code>SRID</code>	Spatial reference system identifier.
<code>min_x, min_y, max_x, max_y</code>	Coordinates of the minimum bounding rectangle (MBR) of the indexed geometries. (<code>min_x, min_y</code>) are the south-west coordinates, and (<code>max_x, max_y</code>) are the north-east coordinates.
<code>name</code>	The name of the spatial index(es).

<i>gid</i>	Name of an integer column that uniquely identifies the polygon. The gid cannot be NULL.
<i>state</i>	The spatial object's state in the index. Possible values are: <ul style="list-style-type: none"> INDEXED - The spatial object was successfully indexed. SELF_INTERSECT - (WGS84 Only) The spatial object was not indexed because one of its edges intersects with another of its edges. EDGE_CROSS_IDL - (WGS84 Only) The spatial object was not indexed because one of its edges crosses the International Date Line. EDGE_HALF_CIRCLE - (WGS84 Only) The spatial object was not indexed because it contains two adjacent vertices that are antipodal. NON_INDEXABLE - The spatial object was not able to be indexed.
<i>geography</i>	The Well-Known Binary (WKB) representation of the spatial object.
<i>geometry</i>	The Well-Known Binary (WKB) representation of the spatial object.

Privileges

Any user with access to the STV_*_Index functions can describe, rename, or drop indexes created by any other user.

Limitations

Some functionality will require the index to be rebuilt if the index was created with 7.0.x or earlier.

Examples

The following examples show how to use STV_Describe_Index.

Retrieve information about the index:

```
=> SELECT STV_Describe_Index (USING PARAMETERS index='my_polygons') OVER ();
   type | polygons | SRID | min_x | min_y | max_x | max_y
-----+-----+-----+-----+-----+-----+-----
GEOMETRY |      4 |    0 |   -1 |   -1 |    12 |    12
(1 row)
```

Return the names of all the defined indexes:

```
=> SELECT STV_Describe_Index() OVER ();
      name
-----
MA_counties_index
my_polygons
NY_counties_index
US_States_Index
(4 rows)
```

Return the polygons included in an index:

```
=> SELECT STV_Describe_Index(USING PARAMETERS index='my_polygons', list_polygons=TRUE) OVER ();
gid | state | geometry
-----+-----+-----
 12 | INDEXED | \260\000\000\000\000\000\000\ ...
 14 | INDEXED | \200\000\000\000\000\000\000\ ...
 10 | NON_INDEXABLE | \274\000\000\000\000\000\000\ ...
 11 | INDEXED | \260\000\000\000\000\000\000\ ...
(4 rows)
```

- [STV_Intersect Scalar Function](#)
- [STV_Intersect Transform Function](#)
- [STV_Drop_Index](#)
- [STV_Rename_Index](#)

STV_Drop_Index

Deletes a spatial index. If `STV_Drop_Index` cannot find the specified spatial index, it returns an error.

The `OVER` clause must be empty.

Behavior Type

Immutable

Syntax

```
STV_Drop_Index( USING PARAMETERS index = 'index_name' ) OVER ( )
```

Arguments

<code>index = 'index_name'</code>	Name of the index, type VARCHAR. Index names cannot exceed 110 characters. The slash, backslash, and tab characters are not allowed in index names.
-----------------------------------	---

Example

The following example shows how to use STV_Drop_Index.

Drop an index:

```
=> SELECT STV_Drop_Index(USING PARAMETERS index ='my_polygons') OVER ();
 drop_index
-----
Index dropped
(1 row)
```

See Also

- [STV_Describe_Index](#)
- [STV_Rename_Index](#)
- [STV_Intersect Scalar Function](#)
- [STV_Intersect Transform Function](#)

STV_DWithin

Determines if the shortest distance from the boundary of one spatial object to the boundary of another object is within a specified distance.

Parameters *g1* and *g2* must be both GEOMETRY objects or both GEOGRAPHY objects.

Behavior Type

Immutable

Syntax

```
STV_DWithin( g1, g2, d )
```

Arguments

<i>g1</i>	Spatial object of type GEOMETRY or GEOGRAPHY
<i>g2</i>	Spatial object of type GEOMETRY or GEOGRAPHY
<i>d</i>	Value of type FLOAT indicating a distance. For GEOMETRY objects, the distance is measured in Cartesian coordinate units. For GEOGRAPHY objects, the distance is measured in meters.

Returns

BOOLEAN

Supported Data Types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)
Point	Yes	Yes
Multipoint	Yes	Yes

Linestring	Yes	Yes
Multilinestring	Yes	Yes
Polygon	Yes	Yes
Multipolygon	Yes	Yes
GeometryCollection	Yes	No

Compatible GEOGRAPHY pairs:

Data Type	GEOGRAPHY (Perfect Sphere)
Point-Point	Yes
Point-Linestring	Yes
Point-Polygon	Yes
Point-Multilinestring	Yes
Point-Multipolygon	Yes

Examples

The following examples show how to use STV_DWithin.

Two geometries are one Cartesian coordinate unit from each other at their closest points:

```
=> SELECT STV_DWithin(ST_GeomFromText('POLYGON((-1 -1,2 2,0 1,-1 -1)'),
  ST_GeomFromText('POLYGON((4 3,2 3,4 5,4 3)'),1);
  STV_DWithin
-----
t
(1 row)
```

If you reduce the distance to 0.99 units:

```
=> SELECT STV_DWithin(ST_GeomFromText('POLYGON((-1 -1,2 2,0 1,-1 -1)'),
  ST_GeomFromText('POLYGON((4 3,2 3,4 5,4 3)'),0.99);
  STV_DWithin
-----
f
(1 row)
```

The first polygon touches the second polygon:

```
=> SELECT STV_DWithin(ST_GeomFromText('POLYGON((-1 -1,2 2,0 1,-1 -1)'),
    ST_GeomFromText('POLYGON((1 1,2 3,4 5,1 1)'),0.00001);
    STV_DWithin
-----
t
(1 row)
```

The first polygon is not within 1000 meters from the second polygon:

```
=> SELECT STV_DWithin(ST_GeomFromText('POLYGON((45.2 40,50.65 51.29,
    55.67 47.6,50 47.6,45.2 40)'),ST_GeomFromText('POLYGON((25 25,25 30,
    30 30,30 25,25 25)'), 1000);
    STV_DWithin
-----
t
(1 row)
```

STV_Export2Shapefile

Exports GEOGRAPHY or GEOMETRY data from a database table or a subquery to a shapefile. Writes the output to the directory specified using [STV_SetExportShapefileDirectory](#).

Behavior Type

Immutable

Syntax

```
STV_Export2Shapefile( columns
                    USING PARAMETERS shapefile = 'name_of_shapefile'
                               [, overwrite = { TRUE | FALSE } ]
                               [, shape = ' { Point | Polygon | Linestring | Multipoint |
Multipolygon | Multilinestring } ' ] )
                    OVER()
```

Parameters

```
shapefile = 'name_of_shapefile'
```

Prefix of the component names of the shapefile, type VARCHAR. Must

	<p>end with the file extension <code>.shp</code>. Limited to 128 octets in length. For example, <code>city-data.shp</code>.</p> <p>If you want to save the shapefile to a sub-directory you can do so by concatenating the sub-directory to <code>name_of_shapefile</code>. For example, <code>visualizations/city-data.shp</code>.</p>
<pre>overwrite = { TRUE FALSE }</pre>	<p>(Optional) BOOLEAN value that specifies whether to overwrite the index, if an index exists. This parameter cannot be NULL.</p> <p>Default: False</p> <p>Overwriting may corrupt the existing files.</p>
<pre>shape = ' { Point Polygon Linestring Multipoint Multipolygon Multilinestring } '</pre>	<p>Must be one of the following spatial classes: Point, Polygon, Linestring, Multipoint, Multipolygon,</p>

	Multilinestring. Polygons and multipolygons always have a clockwise orientation. Default: Polygon
--	---

Arguments

<i>columns</i>	The columns to export to the shapefile. A value of asterisk (*) is the equivalent to listing all columns of the FROM clause.
----------------	---

Returns

Three files in the shapefile export directory with the extensions .shp, .shx, and .dbf.

Limitations

- If a multipolygon, multilinestring, or multipoint contains only one element, then it is written as a polygon, line, or point, respectively.
- Column names longer than 10 characters are truncated.
- Empty POINTS cannot be exported.
- All rows with NULL geometry or geography data are skipped.
- Unsupported or invalid dates are replaced with NULLs.
- Numeric values may lose precision when they are exported. This loss occurs because the target field in the .dbf file is a 64-bit FLOAT column, which can only represent about 15 significant digits.

Examples

The following example shows how you can use `STV_Export2Shapefile` to export all columns from the table `geo_data` to a shapefile named `city-data.shp`:

```
=> SELECT STV_Export2Shapefile(*
        USING PARAMETERS shapefile = 'visualizations/city-data.shp',
                          overwrite = true, shape = 'Point')
        OVER()
        FROM geo_data
        WHERE REVENUE > 25000;
Rows Exported | File Path
-----+-----
6442892 | v_geo-db_node0001: /home/geo/temp/visualizations/city-data.shp
(1 row)
```

STV_Extent

Returns a bounding box containing all of the input data.

Use `STV_Extent` inside of a nested query for best results. The `OVER` clause must be empty.

Important: `STV_Extent` does not return a valid polygon when the input is a single point.

Behavior Type

Immutable

Syntax

```
STV_Extent( g )
```

Arguments

<i>g</i>	Spatial object, type GEOMETRY.
----------	--------------------------------

Returns

GEOMETRY

Supported Data Types

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	Yes

Examples

The following examples show how you can use STV_Extent.

Return the bounding box of a linestring, and verify that it is a valid polygon:

```
=> SELECT ST_AsText(geom) AS bounding_box, ST_IsValid(geom)
      FROM (SELECT STV_Extent(ST_GeomFromText('LineString(0 0, 1 1)')) OVER() AS geom) AS g;
      bounding_box          | ST_IsValid
-----+-----
POLYGON ((0 0, 1 0, 1 1, 0 1, 0 0)) | t
(1 row)
```

Return the bounding box of spatial objects in a table:

```
=> CREATE TABLE misc_geo_shapes (id IDENTITY, geom GEOMETRY);
CREATE TABLE
=> COPY misc_geo_shapes (gx FILLER LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> POINT(-71.03 42.37)
>> LINESTRING(-71.058849 42.367501, -71.062240 42.371276, -71.067938 42.371246)
>> POLYGON((-71.066030 42.380617, -71.055827 42.376734, -71.060811 42.376011, -71.066030 42.380617))
>> \.
=> SELECT ST_AsText(geom_col) AS bounding_box
      FROM (SELECT STV_Extent(geom) OVER() AS geom_col FROM misc_geo_shapes) AS g;
      bounding_box
-----
-----
```

```
POLYGON ((-71.067938 42.367501, -71.03 42.367501, -71.03 42.380617, -71.067938 42.380617, -71.067938 42.367501))  
(1 row)
```

STV_ForceLHR

Alters the order of the vertices of a spatial object to follow the left-hand-rule.

Behavior Type

Immutable

Syntax

```
STV_ForceLHR( g, [USING PARAMETERS skip_nonreorientable_polygons={true | false} ])
```

Arguments

<i>g</i>	Spatial object, type GEOGRAPHY.
<code>skip_nonreorientable_polygons = { true false }</code>	<p>(Optional) Boolean</p> <p>When set to False, non-orientable polygons generate an error. For example, if you use <code>STV_ForceLHR</code> or <code>STV_Reverse</code> with <code>skip_nonorientable_polygons</code> set to False, a geography polygon containing a hole generates an error. When set to True, the result returned is the polygon, as passed to the API, without alteration.</p> <p>This argument can help you when you are creating an index from a table containing polygons that cannot be re-oriented.</p> <p>Vertica Place considers these polygons non-orientable:</p> <ul style="list-style-type: none">• Polygons with a hole

	<ul style="list-style-type: none"> • Multipolygons • Multipolygons with a hole <p>Default value: False</p>
--	---

Returns

GEOGRAPHY

Supported Data Types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	No	No	No
Multipoint	No	No	No
Linestring	No	No	No
Multilinestring	No	No	No
Polygon	No	Yes	Yes
Multipolygon	No	Yes	Yes
GeometryCollection	No	No	No

Examples

The following example shows how you can use STV_ForceLHR.

Re-orient a geography polygon to left-hand orientation:

```
=> SELECT ST_AsText(STV_ForceLHR(ST_GeographyFromText('Polygon((1 1, 3 1, 2 2, 1 1))')));
      ST_AsText
-----
POLYGON ((1 1, 3 1, 2 2, 1 1))
(1 row)
```

Reverse the orientation of a geography polygon by forcing left-hand orientation:

```
=> SELECT ST_AsText(STV_ForceLHR(ST_GeographyFromText('Polygon((1 1, 2 2, 3 1, 1 1))')));
       ST_AsText
-----
POLYGON ((1 1, 3 1, 2 2, 1 1))
(1 row)
```

See Also

[STV_Reverse](#)

STV_Geography

Casts a GEOMETRY object into a GEOGRAPHY object. The SRID value does not affect the results of Vertica Place queries.

When STV_Geography converts a GEOMETRY object to a GEOGRAPHY object, it sets its SRID to 4326.

Behavior Type

Immutable

Syntax

```
STV_Geography( geom )
```

Arguments

<i>geom</i>	Spatial object that you want to cast into a GEOGRAPHY object, type GEOMETRY
-------------	---

Returns

GEOGRAPHY

Supported Data Types

Data Type	GEOMETRY
Point	Yes
Multipoint	Yes
Linestring	Yes
Multilinestring	Yes
Polygon	Yes
Multipolygon	Yes
GeometryCollection	No

Example

The following example shows how to use STV_Geography.

To calculate the centroid of the GEOGRAPHY object, convert it to a GEOMETRY object, then convert it back to a GEOGRAPHY object:

```
=> CREATE TABLE geogs(g GEOGRAPHY);
CREATE TABLE
=> COPY geogs(gx filler LONG VARCHAR, geog AS ST_GeographyFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> MULTIPOINT(-108.619726 45.000284,-107.866813 45.00107,-106.363711 44.994223,-70.847746 41.205814)
>> \.
=> SELECT ST_AsText(STV_Geography(ST_Centroid(STV_Geometry(g)))) FROM geogs;
      ST_AsText
-----
POINT (-98.424499 44.05034775)
(1 row)
```

STV_GeographyPoint

Returns a GEOGRAPHY point based on the input values.

This is the optimal way to convert raw coordinates to GEOGRAPHY points.

Behavior Type

Immutable

Syntax

```
STV_GeographyPoint( x, y )
```

Arguments

x	x-coordinate or longitude, FLOAT.
y	y-coordinate or latitude, FLOAT.

Returns

GEOGRAPHY

Examples

The following examples show how to use STV_GeographyPoint.

Return a GEOGRAPHY point:

```
=> SELECT ST_AsText(STV_GeographyPoint(-114.101588, 47.909677));
           ST_AsText
-----
POINT (-114.101588 47.909677)
(1 row)
```

Return GEOGRAPHY points using two columns:

```
=> CREATE TABLE geog_data (id IDENTITY, x FLOAT, y FLOAT);
CREATE TABLE
=> COPY geog_data FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> -114.101588|47.909677
>> -111.532377|46.430753
>> \.
=> SELECT id, ST_AsText(STV_GeographyPoint(x, y)) FROM geog_data;
id |           ST_AsText
```

```
-----+-----  
 1 | POINT (-114.101588 47.909677)  
 2 | POINT (-111.532377 46.430753)  
(2 rows)
```

Create GEOGRAPHY points by manipulating data source columns during load:

```
=> CREATE TABLE geog_data_load (id IDENTITY, geog GEOGRAPHY);  
CREATE TABLE  
=> COPY geog_data_load (lon FILLER FLOAT,  
                        lat FILLER FLOAT,  
                        geog AS STV_GeographyPoint(lon, lat))  
FROM 'test_coords.csv' DELIMITER ',';  
Rows Loaded  
-----  
      2  
(1 row)  
=> SELECT id, ST_AsText(geog) FROM geog_data_load;  
id |          ST_AsText  
-----+-----  
 1 | POINT (-75.101654451 43.363830536)  
 2 | POINT (-75.106444487 43.367093798)  
(2 rows)
```

See Also

[STV_GeometryPoint](#)

STV_Geometry

Casts a GEOGRAPHY object into a GEOMETRY object.

The SRID value does not affect the results of Vertica Place queries.

Behavior Type

Immutable

Syntax

```
STV_Geometry( geog )
```

Arguments

<i>geog</i>	Spatial object that you want to cast into a GEOMETRY object, type GEOGRAPHY
-------------	---

Returns

GEOMETRY

Supported Data Types

Data Type	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	Yes
Multipoint	Yes	Yes
Linestring	Yes	Yes
Multilinestring	Yes	Yes
Polygon	Yes	Yes
Multipolygon	Yes	Yes
GeometryCollection	No	No

Example

The following example shows how to use STV_Geometry.

Convert the GEOGRAPHY values to GEOMETRY values, then convert the result back to a GEOGRAPHY type:

```
=> CREATE TABLE geogs(g GEOGRAPHY);
CREATE TABLE
=> COPY geogs(gx filler LONG VARCHAR, geog AS ST_GeographyFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> MULTIPOINT(-108.619726 45.000284,-107.866813 45.00107,-106.363711 44.994223,-70.847746 41.205814)
>> \.
=> SELECT ST_AsText(STV_Geography(ST_Centroid(STV_Geometry(g)))) FROM geogs;
      ST_AsText
```

```
-----  
POINT (-98.424499 44.05034775)
```

STV_GeometryPoint

Returns a GEOMETRY point, based on the input values.

This approach is the most-optimal way to convert raw coordinates to GEOMETRY points.

Behavior Type

Immutable

Syntax

```
STV_GeometryPoint( x, y [, srid] )
```

Arguments

<i>x</i>	x-coordinate or longitude, FLOAT.
<i>y</i>	y-coordinate or latitude, FLOAT.
<i>srid</i>	(Optional) Spatial Reference Identifier (SRID) assigned to the point, INT.

Returns

GEOMETRY

Examples

The following examples show how to use STV_GeometryPoint.

Return a GEOMETRY point with an SRID:

```
=> SELECT ST_AsText(STV_GeometryPoint(71.148562, 42.989374, 4326));  
      ST_AsText
```

```
POINT (-71.148562 42.989374)
(1 row)
```

Return GEOMETRY points using two columns:

```
=> CREATE TABLE geom_data (id IDENTITY, x FLOAT, y FLOAT, SRID int);
CREATE TABLE
=> COPY geom_data FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 42.36383053600048|-71.10165445099966|4326
>> 42.3670937980005|-71.10644448699964|4326
>> \.
=> SELECT id, ST_AsText(STV_GeometryPoint(x, y, SRID)) FROM geom_data;
 id |          ST_AsText
-----+-----
  1 | POINT (-71.101654451 42.363830536)
  2 | POINT (-71.106444487 42.367093798)
(2 rows)
```

Create GEOMETRY points by manipulating data source columns during load:

```
=> CREATE TABLE geom_data_load (id IDENTITY, geom GEOMETRY);
CREATE TABLE
=> COPY geom_data_load (lon FILLER FLOAT,
                       lat FILLER FLOAT,
                       geom AS STV_GeometryPoint(lon, lat))
FROM 'test_coords.csv' DELIMITER ',';
Rows Loaded
-----
      2
(1 row)
=> SELECT id, ST_AsText(geom) FROM geom_data_load;
 id |          ST_AsText
-----+-----
  1 | POINT (-75.101654451 43.363830536)
  2 | POINT (-75.106444487 43.367093798)
(2 rows)
```

See Also

[STV_GeographyPoint](#)

STV_GetExportShapefileDirectory

Returns the path of the export directory.

Behavior Type

Immutable

Syntax

```
STV_GetExportShapefileDirectory( )
```

Returns

The path of the shapefile export directory.

Examples

The following example shows how you can use `STV_GetExportShapefileDirectory` to query the path of the shapefile export directory:

```
=> SELECT STV_GetExportShapefileDirectory();
       STV_GetExportShapefileDirectory
-----
Shapefile export directory: [/home/user/temp]
(1 row)
```

STV_Intersect Scalar Function

Spatially intersects a point or points with a set of polygons. The `STV_Intersect` scalar function returns the identifier associated with an intersecting polygon.

Behavior Type

Immutable

Syntax

```
STV_Intersect( { g | x , y }
              USING PARAMETERS index= 'index_name')
```

Arguments

<i>g</i>	A geometry or geography (WGS84) column that contains points. The <i>g</i> column can contain only point geometries or geographies. If the column contains a different geometry or geography type, STV_Intersect terminates with an error.
<i>x</i>	x-coordinate or longitude, FLOAT.
<i>y</i>	y-coordinate or latitude, FLOAT.

Parameters

<code>index = 'index_name'</code>	Name of the spatial index, of type VARCHAR.
-----------------------------------	---

Returns

The identifier of a matching polygon. If the point does not intersect any of the index's polygons, then the STV_Intersect scalar function returns NULL.

Examples

The following examples show how you can use STV_Intersect scalar.

Using two floats, return the gid of a matching polygon or NULL:

```
=> CREATE TABLE polys (gid INT, geom GEOMETRY(1000));
CREATE TABLE
=> COPY polys(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1|POLYGON((31 74,8 70,8 50,36 53,31 74))
>> \.
=> SELECT STV_Create_Index(gid, geom USING PARAMETERS index='my_polygons_1', overwrite=true,
                           max_mem_mb=256) OVER() FROM polys;
   type | polygons | SRID | min_x | min_y | max_x | max_y | info
-----+-----+-----+-----+-----+-----+-----+-----
GEOMETRY |      1 |    0 |    8 |   50 |   36 |   74 |
(1 row)

=> SELECT STV_Intersect(12.5683, 55.6761 USING PARAMETERS index = 'my_polygons_1');
STV_Intersect
-----
```

```
1
(1 row)
```

Using a GEOMETRY column, return the gid of a matching polygon or NULL:

```
=> CREATE TABLE polygons (gid INT, geom GEOMETRY(700));
CREATE TABLE
=> COPY polygons (gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1|POLYGON((-31 74,8 70,8 50,-36 53,-31 74))
>> 2|POLYGON((-38 50,4 13,11 45,0 65,-38 50))
>> 3|POLYGON((-18 42,-10 65,27 48,14 26,-18 42))
>> \.
=> SELECT STV_Create_Index(gid, geom USING PARAMETERS index='my_polygons', overwrite=true,
      max_mem_mb=256) OVER() FROM polygons;
  type | polygons | SRID | min_x | min_y | max_x | max_y | info
-----+-----+-----+-----+-----+-----+-----+-----
GEOMETRY |      3 |    0 |   -38 |    13 |    27 |    74 |
(1 row)

=> CREATE TABLE points (gid INT, geom GEOMETRY(700));
CREATE TABLE
=> COPY points (gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 100|POINT(-1 52)
>> 101|POINT(-20 0)
>> 102|POINT(-8 25)
>> 103|POINT(0 0)
>> 104|POINT(1 5)
>> 105|POINT(20 45)
>> 106|POINT(-20 5)
>> 107|POINT(-20 1)
>> \.
=> SELECT gid AS pt_gid, STV_Intersect(geom USING PARAMETERS index='my_polygons') AS pol_gid
      FROM points ORDER BY pt_gid;
 pt_gid | pol_gid
-----+-----
    100 |      1
    101 |
    102 |      2
    103 |
    104 |
    105 |      3
    106 |
    107 |
(8 rows)
```

STV_Intersect Transform Function

Spatially intersects points and polygons. The STV_Intersect transform function returns a tuple with matching point/polygon pairs. For every point, Vertica returns either one or many matching polygons.

You can improve performance when you parallelize the computation of the STV_Intersect transform function over multiple nodes. To parallelize the computation, use an OVER (PARTITION BEST) clause.

Behavior Type

Immutable

Syntax

```
STV_Intersect ( { gid | i }, { g | x , y }  
              USING PARAMETERS index='index_name')  
              OVER() AS (pt_gid, pol_gid)
```

Arguments

<i>gid i</i>	An integer column or integer that uniquely identifies the spatial object(s) of <i>g</i> or <i>x</i> and <i>y</i> .
<i>g</i>	A geometry or geography (WGS84) column that contains points. The <i>g</i> column can contain only point geometries or geographies. If the column contains a different geometry or geography type, STV_Intersect terminates with an error.
<i>x</i>	x-coordinate or longitude, FLOAT.
<i>y</i>	y-coordinate or latitude, FLOAT.

Parameters

<code>index = 'index_name'</code>	Name of the spatial index, of type VARCHAR.
-----------------------------------	---

Returns

<code>pt_gid</code>	Unique identifier of the point geometry or geography, of type INTEGER.
<code>pol_gid</code>	Unique identifier of the polygon geometry or geography, of type INTEGER.

Examples

The following examples show how you can use STV_Intersect transform.

Using two floats, return the matching point-polygon pairs.

```
=> CREATE TABLE pols (gid INT, geom GEOMETRY(1000));
CREATE TABLE
=> COPY pols(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1|POLYGON((31 74,8 70,8 50,36 53,31 74))
>> \.
=> SELECT STV_Create_Index(gid, geom USING PARAMETERS index='my_polygons_1', overwrite=true,
                           max_mem_mb=256) OVER() FROM pols;
   type | polygons | SRID | min_x | min_y | max_x | max_y | info
-----+-----+-----+-----+-----+-----+-----+-----
GEOMETRY |      1 |    0 |    8 |    50 |   36 |   74 |
(1 row)

=> SELECT STV_Intersect(56, 12.5683, 55.6761 USING PARAMETERS index = 'my_polygons_1') OVER();
 pt_gid | pol_gid
-----+-----
    56 |      1
(1 row)
```

Using a GEOMETRY column, return the matching point-polygon pairs.

```
=> CREATE TABLE polygons (gid int, geom GEOMETRY(700));
CREATE TABLE
=> COPY polygons (gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin;
Enter data to be copied followed by a new line.
End with a backslash and a period on a line by itself.
>> 10|POLYGON((5 5, 5 10, 10 10, 10 5, 5 5))
>> 11|POLYGON((0 0, 0 2, 2 2, 2 0, 0 0))
>> 12|POLYGON((1 1, 1 3, 3 3, 3 1, 1 1))
```

```

>> 14|POLYGON((-1 -1, -1 12, 12 12, 12 -1, -1 -1))
>> \.
=> SELECT STV_Create_Index(gid, geom USING PARAMETERS index='my_polygons', overwrite=true, max_mem_
mb=256)
      OVER() FROM polygons;
      type | polygons | SRID | min_x | min_y | max_x | max_y | info
-----+-----+-----+-----+-----+-----+-----+-----
GEOMETRY |         4 |     0 |    -1 |    -1 |     12 |     12 |
(1 row)

=> CREATE TABLE points (gid INT, geom GEOMETRY(700));
CREATE TABLE
=> COPY points (gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1|POINT(9 9)
>> 2|POINT(0 1)
>> 3|POINT(2.5 2.5)
>> 4|POINT(0 0)
>> 5|POINT(1 5)
>> 6|POINT(1.5 1.5)
>> \.
=> SELECT STV_Intersect(gid, geom USING PARAMETERS index='my_polygons') OVER (PARTITION BEST)
      AS (point_id, polygon_gid)
      FROM points;
point_id | polygon_gid
-----+-----
         5 |          14
         1 |          14
         1 |          10
         4 |          14
         4 |          11
         6 |          12
         6 |          14
         6 |          11
         2 |          14
         2 |          11
         3 |          12
         3 |          14
(12 rows)

```

You can improve query performance by using the `STV_Intersect` transform function in a `WHERE` clause. Performance improves because this syntax eliminates all points that do not intersect polygons in the index.

Return the count of points that intersect with the polygon, where `gid = 14`:

```

=> SELECT COUNT(pt_id) FROM
      (SELECT STV_Intersect(gid, geom USING PARAMETERS index='my_polygons')
      OVER (PARTITION BEST) AS (pt_id, pol_id) FROM points)
      AS T WHERE pol_id = 14;
COUNT
-----
         6
(1 row)

```

STV_IsValidReason

Determines if a spatial object is well formed or valid. If the object is not valid, `STV_IsValidReason` returns a string that explains where the invalidity occurs.

A polygon or multipolygon is valid if all of the following are true:

- The polygon is closed; its start point is the same as its end point.
- Its boundary is a set of linestrings.
- The boundary does not touch or cross itself.
- Any polygons in the interior that do not have more than one point touching the boundary of the exterior polygon.

If you pass an invalid object to a Vertica Place function, the function fails or returns incorrect results. To determine if a polygon is valid, first run `ST_IsValid`. `ST_IsValid` returns `TRUE` if the polygon is valid, `FALSE` otherwise.

Important: `STV_IsValidReason` supports only polygon and multipolygon `GEOMETRY` data types.

Behavior Type

Immutable

Syntax

```
STV_IsValidReason( g )
```

Arguments

<i>g</i>	Geospatial object to test for validity, value of type GEOMETRY or GEOGRAPHY (WGS84).
----------	--

Returns

LONG VARCHAR

Supported Data Types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	Yes	No	No
Multipoint	Yes	No	No
Linestring	Yes	No	No
Multilinestring	Yes	No	No
Polygon	Yes	No	Yes
Multipolygon	Yes	No	No
GeometryCollection	Yes	No	No

Example

The following example shows how to use STV_IsValidReason.

Returns a string describing where the polygon is invalid:

```
=> SELECT STV_IsValidReason(ST_GeomFromText('POLYGON((1 3,3 2,1 1,
      3 0,1 0,1 3))'));
      STV_IsValidReason
-----
Ring Self-intersection at or near POINT (1 1)
(1 row)
```

See Also

[ST_IsValid](#)

STV_LineStringPoint

Retrieves the vertices of a linestring or multilinestring. The values returned are points of either GEOMETRY or GEOGRAPHY type depending on the input object's type. GEOMETRY points inherit the SRID of the input object.

STV_LineStringPoint is an analytic function. For more information, see [Analytic Functions](#).

Behavior Type

Immutable

Syntax

```
STV_LineStringPoint( g )  
    OVER( [PARTITION NODES] ) AS
```

Arguments

<i>g</i>	Linestring or multilinestring, value of type GEOMETRY or GEOGRAPHY
----------	--

Returns

GEOMETRY or GEOGRAPHY

Supported Data Types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)

Point	No	No	No
Multipoint	No	No	No
Linestring	Yes	Yes	Yes
Multilinestring	Yes	Yes	Yes
Polygon	No	No	No
Multipolygon	No	No	No
GeometryCollection	No	No	No

Examples

The following examples show how to use STV_LineStringPoint.

Returns the vertices of the geometry linestring and their SRID:

```
=> SELECT ST_AsText(Point), ST_SRID(Point)
      FROM (SELECT STV_LineStringPoint(
              ST_GeomFromText('MULTILINESTRING((1 2, 2 3, 3 1, 4 2),
                              (10 20, 20 30, 30 10, 40 20))', 4269)) OVER () AS Point) AS foo;
 ST_AsText | ST_SRID
-----+-----
POINT (1 2) | 4269
POINT (2 3) | 4269
POINT (3 1) | 4269
POINT (4 2) | 4269
POINT (10 20) | 4269
POINT (20 30) | 4269
POINT (30 10) | 4269
POINT (40 20) | 4269
(8 rows)
```

Returns the vertices of the geography linestring:

```
=> SELECT ST_AsText(g)
      FROM (SELECT STV_LineStringPoint(
              ST_GeographyFromText('MULTILINESTRING ((42.1 71.0, 41.4 70.0, 41.3 72.9),
                                   (42.99 71.46, 44.47 73.21)', 4269)) OVER () AS g) AS line_geog_points;
 ST_AsText
-----
POINT (42.1 71.0)
POINT (41.4 70.0)
POINT (41.3 72.9)
POINT (42.99 71.46)
POINT (44.47 73.21)
(5 rows)
```

See Also

[STV_PolygonPoint](#)

STV_MemSize

Returns the length of the spatial object in bytes as an INTEGER.

Use this function to determine the optimal column width for your spatial data.

Behavior Type

Immutable

Syntax

```
STV_MemSize( g )
```

Arguments

<i>g</i>	Spatial object, value of type GEOMETRY or GEOGRAPHY
----------	---

Returns

INTEGER

Examples

The following example shows how you can optimize your table by sizing the GEOMETRY or GEOGRAPHY column to the maximum value returned by STV_MemSize:

```
=> CREATE TABLE mem_size_table (id int, geom geometry(800));  
CREATE TABLE  
=> COPY mem_size_table (id, gx filler LONG VARCHAR, geom as ST_GeomFromText(gx)) FROM STDIN DELIMITER  
'|';  
Enter data to be copied followed by a newline.
```

```
End with a backslash and a period on a line by itself.
>>1|POINT(3 5)
>>2|MULTILINESTRING((1 5, 2 4, 5 3, 6 6),(3 5, 3 7))
>>3|MULTIPOLYGON(((2 6, 2 9, 6 9, 7 7, 4 6, 2 6)),((0 0, 0 5, 1 0, 0 0)),((0 2, 2 5, 4 5, 0 2)))
>>\.
=> SELECT max(STV_MemSize(geom)) FROM mem_size_table;
  max
-----
  336
(1 row)

=> CREATE TABLE production_table(id int, geom geometry(336));
CREATE TABLE
=> INSERT INTO production_table SELECT * FROM mem_size_table;
OUTPUT
-----
      3
(1 row)
=> DROP mem_size_table;
DROP TABLE
```

STV_NN

Calculates the distance of spatial objects from a reference object and returns (object, distance) pairs in ascending order by distance from the reference object.

Parameters *g1* and *g2* must be both GEOMETRY objects or both GEOGRAPHY objects.

STV_NN is an analytic function. For more information, see [Analytic Functions](#).

Behavior Type

Immutable

Syntax

```
STV_NN( g, ref_obj, k ) OVER()
```

Arguments

<i>g</i>	Spatial object, value of type GEOMETRY or GEOGRAPHY
<i>ref_obj</i>	Reference object, type GEOMETRY or GEOGRAPHY
<i>k</i>	Number of rows to return, type INTEGER

Returns

(Object, distance) pairs, in ascending order by distance. If a parameter is EMPTY or NULL, then 0 rows are returned.

Supported Data Types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)
Point	Yes	Yes
Multipoint	Yes	Yes
Linestring	Yes	Yes
Multilinestring	Yes	Yes
Polygon	Yes	Yes
Multipolygon	Yes	Yes
GeometryCollection	Yes	No

Example

The following example shows how to use STV_NN.

Create a table and insert nine GEOGRAPHY points:

```
=> CREATE TABLE points (g geography);
CREATE TABLE
=> COPY points (gx filler LONG VARCHAR, g AS ST_GeographyFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> POINT (21.5 18.4)
>> POINT (21.5 19.2)
>> POINT (21.5 20.7)
>> POINT (22.5 16.4)
>> POINT (22.5 17.15)
>> POINT (22.5 18.33)
>> POINT (23.5 13.68)
>> POINT (23.5 15.9)
>> POINT (23.5 18.4)
>> \.
```

Calculate the distances (in meters) of objects in table `points` from the GEOGRAPHY point (23.5, 20).

Returns the five objects that are closest to that point:

```
=> SELECT ST_AsText(nn), dist FROM (SELECT STV_NN(g,  
  ST_GeographyFromText('POINT(23.5 20)'),5) OVER() AS (nn,dist) FROM points) AS example;  
-----+-----  
ST_AsText | dist  
-----+-----  
POINT (23.5 18.4) | 177912.12757541  
POINT (22.5 18.33) | 213339.210738322  
POINT (21.5 20.7) | 222561.43679943  
POINT (21.5 19.2) | 227604.371833335  
POINT (21.5 18.4) | 275239.416790128  
(5 rows)
```

STV_PolygonPoint

Retrieves the vertices of a polygon as individual points. The values returned are points of either GEOMETRY or GEOGRAPHY type depending on the input object's type. GEOMETRY points inherit the SRID of the input object.

STV_PolygonPoint is an analytic function. For more information, see [Analytic Functions](#).

Behavior Type

Immutable

Syntax

```
STV_PolygonPoint( g )  
  OVER( [PARTITION NODES] ) AS
```

Arguments

<i>g</i>	Polygon, value of type GEOMETRY or GEOGRAPHY
----------	--

Returns

GEOMETRY or GEOGRAPHY

Supported Data Types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	No	No	No
Multipoint	No	No	No
Linestring	No	No	No
Multilinestring	No	No	No
Polygon	Yes	Yes	Yes
Multipolygon	Yes	Yes	Yes
GeometryCollection	No	No	No

Examples

The following examples show how to use STV_PolygonPoint.

Returns the vertices of the geometry polygon:

```
=> SELECT ST_AsText(g) FROM (SELECT STV_PolygonPoint(ST_GeomFromText('POLYGON((1 2, 2 3, 3 1, 1 2))'))
    OVER (PARTITION NODES) AS g) AS poly_points;
    ST_AsText
-----
POINT (1 2)
POINT (2 3)
POINT (3 1)
POINT (1 2)
(4 rows)
```

Returns the vertices of the geography polygon:

```
=> SELECT ST_AsText(g) FROM (SELECT STV_PolygonPoint(ST_GeographyFromText('
    POLYGON((25.5 28.76, 28.83 29.13, 27.2 30.99, 25.5 28.76))'))
    OVER (PARTITION NODES) AS g) AS poly_points;
    ST_AsText
-----
POINT (25.5 28.76)
POINT (28.83 29.13)
POINT (27.2 30.99)
POINT (25.5 28.76)
```

(4 rows)

See Also

[STV_LineStringPoint](#)

STV_Reverse

Reverses the order of the vertices of a spatial object.

Behavior Type

Immutable

Syntax

```
STV_Reverse( g, [USING PARAMETERS skip_nonreorientable_polygons={true | false} ])
```

Arguments

<i>g</i>	Spatial object, type GEOGRAPHY.
skip_nonreorientable_polygons = { true false }	<p>(Optional) Boolean</p> <p>When set to False, non-orientable polygons generate an error. For example, if you use STV_ForceLHR or STV_Reverse with skip_nonreorientable_polygons set to False, a geography polygon containing a hole generates an error. When set to True, the result returned is the polygon, as passed to the API, without alteration.</p> <p>This argument can help you when you are creating an index from a table containing polygons that cannot be re-oriented.</p> <p>Vertica Place considers these polygons non-</p>

	<p>orientable:</p> <ul style="list-style-type: none"> • Polygons with a hole • Multipolygons • Multipolygons with a hole <p>Default value: False</p>
--	--

Returns

GEOGRAPHY

Supported Data Types

Data Type	GEOMETRY	GEOGRAPHY (Perfect Sphere)	GEOGRAPHY (WGS84)
Point	No	No	No
Multipoint	No	No	No
Linestring	No	No	No
Multilinestring	No	No	No
Polygon	No	Yes	Yes
Multipolygon	No	Yes	Yes
GeometryCollection	No	No	No

Examples

The following examples show how you can use STV_Reverse.

Reverse vertices of a geography polygon:

```
=> SELECT ST_AsText(STV_Reverse(ST_GeographyFromText('Polygon((1 1, 3 1, 2 2, 1 1))')));
      ST_AsText
-----
```

```
POLYGON ((1 1, 2 2, 3 1, 1 1))  
(1 row)
```

Force the polygon to reverse orientation:

```
=> SELECT ST_AsText(STV_Reverse(ST_GeographyFromText('Polygon((1 1, 2 2, 3 1, 1 1)'))));  
ST_AsText  
-----  
POLYGON ((1 1, 3 1, 2 2, 1 1))  
(1 row)
```

See Also

[STV_ForceLHR](#)

STV_Rename_Index

Renames a spatial index. If the index format is out of date, you cannot rename the index.

A spatial index is created from an input polygon set, which can be the result of a query. Spatial indexes are created in a global name space. Vertica uses a distributed plan whenever the input table or projection is segmented across nodes of the cluster.

The OVER() clause must be empty.

Behavior Type

Immutable

Syntax

```
STV_Rename_Index( USING PARAMETERS  
                  source = 'old_index_name',  
                  dest = 'new_index_name',  
                  overwrite = [ 'true' | 'false' ]  
                )  
OVER ( )
```

Arguments

<code>source = 'old_index_name'</code>	Current name of the spatial index, type VARCHAR.
--	--

<code>dest = 'new_index_name'</code>	New name of the spatial index, type VARCHAR.
<code>overwrite = ['true' 'false']</code>	(Optional) BOOLEAN value that specifies whether to overwrite the index, if an index exists. This parameter cannot be NULL. Default: False

Privileges

Any user with access to the STV_*_Index functions can describe, rename, or drop indexes created by any other user.

Limitations

- Index names cannot exceed 110 characters.
- The backslash or tab characters are not allowed in index names.

Example

The following example shows how to use STV_Rename_Index.

Rename an index:

```
=> SELECT STV_Rename_Index (  
    USING PARAMETERS  
    source = 'my_polygons',  
    dest = 'US_states',  
    overwrite = 'false'  
    )  
    OVER ();  
rename_index  
-----  
Index renamed  
(1 Row)
```

STV_Refresh_Index

Appends newly added or updated polygons and removes deleted polygons from an existing spatial index.

The OVER() clause must be empty.

Behavior Type

Mutable

Syntax

```
STV_Refresh_Index( gid, g
                  USING PARAMETERS index='index_name'
                               [, skip_nonindexable_polygons={ true | false } ] )
OVER()
  [ AS (type, polygons, srid, min_x, min_y, max_x, max_y, info,
        indexed, appended, updated, deleted) ]
```

Arguments

<i>gid</i>	Name of an integer column that uniquely identifies the polygon. The gid cannot be NULL.
<i>g</i>	Name of a geometry or geography (WGS84) column or expression that contains polygons and multipolygons. Only polygon and multipolygon can be indexed. Other shape types are excluded from the index.

Parameters

<code>index = 'index_name'</code>	Name of the index, type VARCHAR. Index names cannot exceed 110 characters. The slash, backslash, and tab characters are not allowed in index names.
<code>skip_nonindexable_polygons = { true false }</code>	(Optional) BOOLEAN In rare cases, intricate polygons (for instance, with too high resolution or anomalous spikes) cannot be indexed. These polygons are considered non-indexable. When set to False, non-indexable polygons cause the index creation to fail. When set to True, index creation can succeed by excluding non-indexable polygons from the index.

	<p>To review the polygons that were not able to be indexed, use <code>STV_Describe_Index</code> with the parameter <code>list_polygon</code>.</p> <p>Default: <code>False</code></p>
--	--

Returns

<i>type</i>	Spatial object type of the index.
<i>polygons</i>	Number of polygons indexed.
<i>SRID</i>	Spatial reference system identifier.
<i>min_x, min_y, max_x, max_y</i>	Coordinates of the minimum bounding rectangle (MBR) of the indexed geometries. (<i>min_x, min_y</i>) are the south-west coordinates, and (<i>max_x, max_y</i>) are the north-east coordinates.
<i>info</i>	Lists the number of excluded spatial objects as well as their type that were excluded from the index.
<i>indexed</i>	Number of polygons indexed during the operation.
<i>appended</i>	Number of appended polygons.
<i>updated</i>	Number of updated polygons.
<i>deleted</i>	Number of deleted polygons.

Supported Data Types

Data Type	GEOMETRY	GEOGRAPHY (WGS84)
Point	No	No
Multipoint	No	No
Linestring	No	No
Multilinestring	No	No

Polygon	Yes	Yes
Multipolygon	Yes	No
GeometryCollection	No	No

Privileges

Any user with access to the STV_*_Index functions can describe, rename, or drop indexes created by any other user.

Limitations

- In rare cases, intricate polygons (such as those with too-high a resolution or anomalous spikes) cannot be indexed. See the parameter `skip_nonindexable_polygons`.
- If you replace a valid polygon in the source table with an invalid polygon, STV_Refresh_Index ignores the invalid polygon. As a result, the polygon originally indexed persists in the index.
- The following geometries cannot be indexed:
 - Non-polygons
 - NULL gid
 - NULL (multi) polygon
 - EMPTY (multi) polygon
 - Invalid (multi) polygon
- The following geographies are excluded from the index:
 - Polygons with holes
 - Polygons crossing the International Date Line
 - Polygons covering the north or south pole
 - Antipodal polygons

Usage Tips

- To cancel an `STV_Refresh_Index` run, use **Ctrl + C**.
- If you use source data not previously associated with the index, then the index will be overwritten.
- If `STV_Refresh_Index` has insufficient memory to process the query, then rebuild the index using `STV_Create_Index`.
- If there are no valid polygons in the `geom` column, `STV_Refresh_Index` reports an error in `vertica.log` and stops the index refresh.
- Ensure that all of the polygons you plan to index are valid polygons. `STV_Create_Index` and `STV_Refresh_Index` do not check polygon validity when building an index.

For more information, see [Ensuring Polygon Validity Before Creating or Refreshing an Index](#).

Examples

The following examples show how to use `STV_Refresh_Index`.

Refresh an index with a single literal argument:

```
=> SELECT STV_Create_Index(1, ST_GeomFromText('POLYGON((0 0,0 15.2,3.9 15.2,3.9 0,0 0))')
      USING PARAMETERS index='my_polygon') OVER();
   type | polygons | SRID | min_x | min_y | max_x | max_y | info
-----+-----+-----+-----+-----+-----+-----+-----
GEOMETRY |          1 |      0 |      0 |      0 |    3.9 |   15.2 |
(1 row)

=> SELECT STV_Refresh_Index(2, ST_GeomFromText('POLYGON((0 0,0 13.2,3.9 18.2,3.9 0,0 0))')
      USING PARAMETERS index='my_polygon') OVER();
   type | polygons | SRID | min_x | min_y | max_x | max_y | info | indexed | appended | updated |
deleted
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----
GEOMETRY |          1 |      0 |      0 |      0 |    3.9 |   18.2 |      |          1 |          1 |          0 |
1
(1 row)
```

Refresh an index from a table:

```
=> CREATE TABLE polys (gid INT, geom GEOMETRY);
CREATE TABLE
=> COPY polys(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
```

```

End with a backslash and a period on a line by itself.
>> 1|POLYGON((-31 74,8 70,8 50,-36 53,-31 74))
>> 2|POLYGON((5 20,9 30,20 45,36 35,5 20))
>> 3|POLYGON((12 23,9 30,20 45,36 35,37 67,45 80,50 20,12 23))
>> \.
=> SELECT STV_Create_Index(gid, geom USING PARAMETERS index='my_polygons_1', overwrite=true)
      OVER() FROM pols;
      type | polygons | SRID | min_x | min_y | max_x | max_y | info
-----+-----+-----+-----+-----+-----+-----+-----
GEOMETRY |         3 |    0 |   -36 |    20 |    50 |    80 |
(1 row)

=> COPY pols(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 6|POLYGON((-32 74,8 70,8 50,-36 53,-32 74))
>> \.
=> SELECT STV_Refresh_Index(gid, geom USING PARAMETERS index='my_polygons_1') OVER() FROM pols;
      type | polygons | SRID | min_x | min_y | max_x | max_y | info | indexed | appended | updated |
deleted
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----
-----
GEOMETRY |         4 |    0 |   -36 |    20 |    50 |    80 |      |         1 |         1 |         0 |
0
(1 row)

```

- [Ensuring Polygon Validity Before Creating or Refreshing an Index](#)

STV_SetExportShapefileDirectory

Specifies the directory to export GEOMETRY or GEOGRAPHY data to a shapefile. The validity of the path is not checked, and the path cannot be empty.

Behavior Type

Immutable

Syntax

```
STV_SetExportShapefileDirectory( USING PARAMETERS path='shapefile_path' )
```

Arguments

<code>path = ' shapefile_path '</code>	The path where you want the shapefile exported. For example, '/home/user/temp'.
--	---

Returns

The path of the shapefile export directory.

Privileges

Only a superuser can use this function.

Examples

The following example shows how you can use `STV_SetExportShapefileDirectory` to set the shapefile export directory to `/home/user/temp`:

```
=> SELECT STV_SetExportShapefileDirectory(USING PARAMETERS path = '/home/user/temp');
          STV_SetExportShapefileDirectory
-----
SUCCESS. Set shapefile export directory: [/home/user/temp]
(1 row)
```

STV_ShpSource and STV_ShpParser

These two functions work with a `COPY` command to parse and load the geometries and attributes from a shapefile into a database table and convert them to the `GEOMETRY` data type format. You must use these two functions together. An SRID is required. An empty multipoint or an invalid multipolygon can not be loaded from a shapefile.

Behavior Type

Immutable

Syntax

```
COPY table_name( col2, col3, ..., colN )
  WITH SOURCE STV_ShpSource( file = 'filename'[[, SRID=spatial reference identifier]
                               [, flatten_2d={true | false }]] )
  PARSER STV_ShpParser()
```

Arguments

<i>table_name</i>	Name of the table in which to load the geometry data.
<i>col1</i> , <i>col2</i> , ...	Column names in the table that match the fields in the external file. Run the CREATE TABLE command that STV_ShpCreateTable creates. When you do so, these columns correspond to the second through the second-to-last columns.
file = ' <i>filename</i> '	Fully qualified path of the .dbf, .shp, or .shx file.
SRID= <i>spatial reference identifier</i>	Spatial reference identifier (SRID) associated with the shape file, type INTEGER.
flatten_2d	(Optional) BOOLEAN that excludes 3D or 4D coordinates during COPY commands. True - Excludes geometries with 3D or 4D coordinates before a COPY command. False - Causes the load to fail if a geometry with 3D or 4D coordinate is found. Default: False

Usage Tips

- The COPY command fails if:
 - The shapefile cannot be located or opened.
 - The number of columns or the data types of the columns that STV_ShParser creates do not match the columns in the destination table. Use STV_ShpCreateTable to generate the appropriate CREATE TABLE command.
 - One of the mandatory files is missing or cannot be opened. When opening a shapefile, you must have three files: .dbf, .shp, and .shx.
- If the .shp and .shx files are corrupt, STV_ShpSource returns an error. If the .shp and .shx files are valid, but the .dbf file is corrupt, STV_ShpSource ignores the .dbf file and does not create columns for that data.
- Any rejected records are saved in the /CopyErrorLogs directory under the catalog directory.
- If the .dbf component of a shapefile contains a numeric attribute, this field's values may lose precision when the Vertica Place shapefile loader loads it into a table. The target field is a 64-bit FLOAT column, which can only represent about 15 significant digits; in a .dbf file, Numeric fields can be up to 30 digits.

Example

The following example shows how to use STV_ShpSource and STV_ShParser.

```
=> COPY t1_2010_us_state10 WITH SOURCE
STV_ShpSource(file='/shapefiles/t1_2010_us_state10.shp', SRID=4269) PARSER STV_ShParser();

Rows loaded
-----
          52
```

See Also

- [STV_ShpCreateTable](#)

STV_ShpCreateTable

Returns a CREATE TABLE statement with the columns and types of the attributes found in the specified shapefile.

The column types are sized according to the shapefile metadata. The size of the column is based on the largest geometry found in the shapefile. The first column in the table is `gid`, which is an auto-increment IDENTITY primary key column. The cache value is set to 64 by default. The last column is a GEOMETRY data type for storing the actual geometry data.

Behavior Type

Immutable

Syntax

```
STV_ShpCreateTable(USING PARAMETERS file='filename') OVER()
```

Arguments

<code>file = 'filename'</code>	Fully qualified path of the .dbf, .shp, or .shx file. (The extension is optional.)
--------------------------------	--

Returns

CREATE TABLE statement that matches the specified shapefile

Usage Tips

- STV_ShpCreateTable returns a CREATE TABLE statement; but it does not create the table. Modify the CREATE TABLE statement as needed, and then create the table before loading the shapefile into the table.
- To create a table with characters other than alphanumeric and underscore (`_`) characters, you must specify the table name enclosed in double quotes, such as `"counties%NY"`.

- The name of the table is the same as the name of the shapefile, without the directory name or extension.
- The shapefile must be accessible from the initiator node.
- If the .shp and .shx files are corrupt, STV_ShpCreateTable returns an error. If the .shp and .shx files are valid, but the .dbf file is corrupt, STV_ShpCreateTable ignores the .dbf file and does not create columns for that data.
- All the mandatory files (.dbf, .shp, .shx) must be in the same directory. If not, STV_ShpCreateTable returns an error.
- If the .dbf component of a shapefile contains a Numeric attribute, this field's values may lose precision when the Vertica shapefile loader loads it into a table. The target field is a 64-bit FLOAT column, which can only represent about 15 significant digits. In a .dbf file, numeric fields can be up to 30 digits.

Vertica records all instances of shapefile values that are too long in the `vertica.log` file.

Example

The following example shows how to use STV_ShpCreateTable.

Returns a CREATE TABLE statement:

```
=> SELECT STV_ShpCreateTable
      (USING PARAMETERS file='/shapefiles/tl_2010_us_state10.shp')
      OVER() as create_table_states;
      create_table_states
-----
CREATE TABLE tl_2010_us_state10(
  gid IDENTITY(64) PRIMARY KEY,
  REGION10 VARCHAR(2),
  DIVISION10 VARCHAR(2),
  STATEFP10 VARCHAR(2),
  STATENS10 VARCHAR(8),
  GEOID10 VARCHAR(2),
  STUSPS10 VARCHAR(2),
  NAME10 VARCHAR(100),
  LSAD10 VARCHAR(2),
  MTFCC10 VARCHAR(5),
  FUNCSTAT10 VARCHAR(1),
  ALAND10 INT8,
  AWATER10 INT8,
  INTPTLAT10 VARCHAR(11),
  INTPTLON10 VARCHAR(12),
  geom GEOMETRY(940845)
);
(18 rows)
```

IP Conversion Functions

IP functions perform conversion, calculation, and manipulation operations on IP, network, and subnet addresses.

INET_ATON

Returns an integer that represents the value of the address in host byte order, given the dotted-quad representation of a network address as a string.

Behavior Type

Immutable

Syntax

```
INET_ATON ( expression )
```

Parameters

<i>expression</i>	(VARCHAR) is the string to convert.
-------------------	-------------------------------------

Notes

The following syntax converts an IPv4 address represented as the string A to an integer I. INET_ATON trims any spaces from the right of A, calls the Linux function [inet_pton](#), and converts the result from network byte order to host byte order using [ntohl](#).

```
=> INET_ATON(VARCHAR A) -> INT8 I
```

If A is NULL, too long, or [inet_pton](#) returns an error, the result is NULL.

Examples

The generated number is always in host byte order. In the following example, the number is calculated as $209 \times 256^3 + 207 \times 256^2 + 224 \times 256 + 40$.

```
=> SELECT INET_ATON('209.207.224.40');
inet_aton
-----
3520061480
(1 row)

=> SELECT INET_ATON('1.2.3.4');
inet_aton
-----
16909060
(1 row)

=> SELECT TO_HEX(INET_ATON('1.2.3.4'));
to_hex
-----
1020304
(1 row)
```

See Also

- [INET_NTOA](#)

INET_NTOA

Returns the dotted-quad representation of the address as a VARCHAR, given a network address as an integer in network byte order.

Behavior Type

Immutable

Syntax

```
INET_NTOA ( expression )
```

Parameters

<i>expression</i>	(INTEGER) is the network address to convert.
-------------------	--

Notes

The following syntax converts an IPv4 address represented as integer I to a string A.

INET_NTOA converts I from host byte order to network byte order using [htonl](#), and calls the Linux function [inet_ntop](#).

```
=> INET_NTOA(INT8 I) -> VARCHAR A
```

If I is NULL, greater than 2^{32} or negative, the result is NULL.

Examples

```
=> SELECT INET_NTOA(16909060);
inet_ntoa
-----
1.2.3.4
(1 row)

=> SELECT INET_NTOA(03021962);
inet_ntoa
-----
0.46.28.138
(1 row)
```

See Also

- [INET_ATON](#)

V6_ATON

Converts an IPv6 address represented as a character string to a binary string.

Behavior Type

Immutable

Syntax

V6_ATON (*expression*)

Parameters

<i>expression</i>	(VARCHAR) is the string to convert.
-------------------	-------------------------------------

Notes

The following syntax converts an IPv6 address represented as the character string A to a binary string B.

V6_ATON trims any spaces from the right of A and calls the Linux function [inet_pton](#).

```
=> V6_ATON(VARCHAR A) -> VARBINARY(16) B
```

If A has no colons it is prepended with '::ffff:'. If A is NULL, too long, or if `inet_pton` returns an error, the result is NULL.

Examples

```
=> SELECT V6_ATON('2001:DB8::8:800:200C:417A');
           v6_aton
-----
\001\015\270\000\000\000\000\000\010\010\000 \014Az
(1 row)

=> SELECT V6_ATON('1.2.3.4');
           v6_aton
-----
\000\000\000\000\000\000\000\000\000\000\377\377\001\002\003\004
(1 row)
SELECT TO_HEX(V6_ATON('2001:DB8::8:800:200C:417A'));
           to_hex
-----
20010db8000000000000008000200c417a
```

```
(1 row)
=> SELECT V6_ATON('::1.2.3.4');
      v6_aton
-----
\000\000\000\000\000\000\000\000\000\000\000\000\001\002\003\004
(1 row)
```

See Also

- [V6_NTOA](#)

V6_NTOA

Converts an IPv6 address represented as varbinary to a character string.

Behavior Type

Immutable

Syntax

V6_NTOA (*expression*)

Parameters

<i>expression</i>	(VARBINARY) is the binary string to convert.
-------------------	--

Notes

The following syntax converts an IPv6 address represented as VARBINARY B to a string A.

V6_NTOA right-pads B to 16 bytes with zeros, if necessary, and calls the Linux function [inet_ntop](#).

```
=> V6_NTOA(VARBINARY B) -> VARCHAR A
```

If B is NULL or longer than 16 bytes, the result is NULL.

Vertica automatically converts the form '::ffff:1.2.3.4' to '1.2.3.4'.

Examples

```
=> SELECT V6_NTOA(' \001\015\270\000\000\000\000\000\010\010\000 \014Az ');
      v6_ntoa
-----
2001:db8::8:800:200c:417a
(1 row)

=> SELECT V6_NTOA(V6_ATON('1.2.3.4'));
      v6_ntoa
-----
1.2.3.4
(1 row)

=> SELECT V6_NTOA(V6_ATON('::1.2.3.4'));
      v6_ntoa
-----
::1.2.3.4
(1 row)
```

See Also

- [V6_ATON](#)

V6_SUBNETA

Calculates a subnet address in CIDR (Classless Inter-Domain Routing) format from a binary or alphanumeric IPv6 address.

Behavior Type

Immutable

Syntax

V6_SUBNETA (*expression1*, *expression2*)

Parameters

<i>expression1</i>	(VARBINARY or VARCHAR) is the string to calculate.
<i>expression2</i>	(INTEGER) is the size of the subnet.

Notes

The following syntax calculates a subnet address in CIDR format from a binary or varchar IPv6 address.

V6_SUBNETA masks a binary IPv6 address B so that the N leftmost bits form a subnet address, while the remaining rightmost bits are cleared. It then converts to an alphanumeric IPv6 address, appending a slash and N.

```
=> V6_SUBNETA(BINARY B, INT8 N) -> VARCHAR C
```

The following syntax calculates a subnet address in CIDR format from an alphanumeric IPv6 address.

```
=> V6_SUBNETA(VARCHAR A, INT8 N) -> V6_SUBNETA(V6_ATON(A), N) -> VARCHAR C
```

Examples

```
=> SELECT V6_SUBNETA(V6_ATON('2001:db8::8:800:200c:417a'), 28);
 v6_subnetA
-----
2001:db8::/28
(1 row)
```

See Also

- [V6_SUBNETN](#)

V6_SUBNETN

Calculates a subnet address in CIDR (Classless Inter-Domain Routing) format from a varbinary or alphanumeric IPv6 address.

Behavior Type

Immutable

Syntax

`V6_SUBNETN (expression1, expression2)`

Parameters

<i>expression1</i>	(VARBINARY or VARCHAR) is the string to calculate. Notes: <ul style="list-style-type: none">• <code>V6_SUBNETN(<VARBINARY>, <INTEGER>)</code> returns VARBINARY. OR <ul style="list-style-type: none">• <code>V6_SUBNETN(<VARCHAR>, <INTEGER>)</code> returns VARBINARY, after using <code>V6_ATON</code> to convert the <VARCHAR> string to <VARBINARY>.
<i>expression2</i>	(INTEGER) is the size of the subnet.

Notes

The following syntax masks a BINARY IPv6 address **B** so that the **N** left-most bits of **S** form a subnet address, while the remaining right-most bits are cleared.

`V6_SUBNETN` right-pads **B** to 16 bytes with zeros, if necessary and masks **B**, preserving its **N**-bit subnet prefix.

```
=> V6_SUBNETN(VARBINARY B, INT8 N) -> VARBINARY(16) S
```

If **B** is NULL or longer than 16 bytes, or if **N** is not between 0 and 128 inclusive, the result is NULL.

$S = [B]/N$ in [Classless Inter-Domain Routing](#) notation (CIDR notation).

The following syntax masks an alphanumeric IPv6 address **A** so that the **N** leftmost bits form a subnet address, while the remaining rightmost bits are cleared.

```
=> V6_SUBNETN(VARCHAR A, INT8 N) -> V6_SUBNETN(V6_ATON(A), N) -> VARBINARY(16) S
```

Example

This example returns VARBINARY, after using V6_ATON to convert the VARCHAR string to VARBINARY:

```
=> SELECT V6_SUBNETN(V6_ATON('2001:db8::8:800:200c:417a'), 28);
      v6_subnetn
-----
\001\015\260\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000
```

See Also

- [V6_ATON](#)
- [V6_SUBNETA](#)

V6_TYPE

Characterizes a binary or alphanumeric IPv6 address B as an integer type.

Behavior Type

Immutable

Syntax

```
V6_TYPE ( expression )
```

Parameters

<i>expression</i>	(VARBINARY or VARCHAR) is the type to convert.
-------------------	--

Notes

V6_TYPE(VARBINARY B) returns INT8 T.

```
=> V6_TYPE(VARCHAR A) -> V6_TYPE(V6_ATON(A)) -> INT8 T
```

The IPv6 types are defined in the Network Working Group's [IP Version 6 Addressing Architecture memo](#).

```
GLOBAL = 0      Global unicast addresses
LINKLOCAL = 1   Link-Local unicast (and Private-Use) addresses
LOOPBACK = 2    Loopback
UNSPECIFIED = 3 Unspecified
MULTICAST = 4   Multicast
```

IPv4-mapped and IPv4-compatible IPv6 addresses are also interpreted, as specified in [IPv4 Global Unicast Address Assignments](#).

- For IPv4, Private-Use is grouped with Link-Local.
- If B is VARBINARY, it is right-padded to 16 bytes with zeros, if necessary.
- If B is NULL or longer than 16 bytes, the result is NULL.

Details

IPv4 (either kind):

0.0.0.0/8	UNSPECIFIED	10.0.0.0/8	LINKLOCAL
127.0.0.0/8	LOOPBACK		
169.254.0.0/16	LINKLOCAL		
172.16.0.0/12	LINKLOCAL		
192.168.0.0/16	LINKLOCAL		
224.0.0.0/4	MULTICAST		
others	GLOBAL		

IPv6:

::0/128	UNSPECIFIED	:::1/128	LOOPBACK
fe80::/10	LINKLOCAL		
ff00::/8	MULTICAST		
others	GLOBAL		

Examples

```
=> SELECT V6_TYPE(V6_ATON('192.168.2.10'));
v6_type
-----
      1
(1 row)

=> SELECT V6_TYPE(V6_ATON('2001:db8::8:800:200c:417a'));
v6_type
-----
      0
(1 row)
```

Machine Learning Functions

The machine learning functions contain algorithms for machine learning and data preparation. Additionally, these functions provide evaluation metrics for models. You can use these evaluation metrics to determine the accuracy of your models.

Vertica machine learning functions do not support temp tables.

Important: Before using a machine learning function, be aware that all the ongoing transactions might be committed.

Data Preparation Functions

You can use the following functions to pre-process your data:

- [APPLY_NORMALIZE](#) - Use this function to apply normalization parameters saved in a model to specific columns.

- [BALANCE](#) - Use this function to balance your data.
- [DETECT_OUTLIERS](#) - Use this function to remove the outliers from your data.
- [IMPUTE](#) - Imputes missing values in a data set.
- [NORMALIZE](#) - Use this function before running one of the machine learning algorithms on your data.
- [NORMALIZE_FIT](#) - Use this function to compute normalization parameters for specific columns in an input table. The normalization parameters are saved.
- [REVERSE_NORMALIZE](#) - Use this function to reverse the normalization transformation.

Evaluation Functions

You can use the following functions to evaluate your data:

- [APPLY_KMEANS](#) - Assigns each row of an input table to a cluster center from an already-existing k-means model.
- [CONFUSION_MATRIX](#) - Returns a confusion matrix based on both predicted and observed values.
- [GET_MODEL_ATTRIBUTE](#) - Extracts specific model attributes.
- [ERROR_RATE](#) - Returns a table that calculates the rate of incorrect classifications.
- [LIFT_TABLE](#) - Returns a table that compares the predictive quality of a binary classifier model.
- [MSE](#) - Returns a table that displays the mean squared error.
- [ROC](#) - Returns a table that displays the points on a receiver operating characteristic curve.
- [RSQUARED](#) - Returns a table with the R-squared value of the predictions in a linear regression model.
- [SUMMARIZE_MODEL](#) - Returns the summary information of a model.

Prediction Functions

You can use the following functions to apply a model to a table:

- [PREDICT_LINEAR_REG](#) - Applies a linear regression model on an input table.
- [PREDICT_LOGISTIC_REG](#) - Applies a logistic regression model on an input table.
- [PREDICT_NAIVE_BAYES](#) - Applies a Naïve Bayes model on an input table.
- [PREDICT_NAIVE_BAYES_CLASSES](#) - Applies a Naïve Bayes model on an input table and returns the probabilities of classes.
- [PREDICT_RF_CLASSIFIER_CLASSES](#) - Applies a random forest model on an input table and returns the probabilities of classes.
- [PREDICT_RF_CLASSIFIER](#) - Applies a random forest model on an input table.
- [PREDICT_SVM_CLASSIFIER](#) - Applies an SVM classification model on an input table.
- [PREDICT_SVM_REGRESSOR](#) - Applies an SVM regressor model on an input table.

Supervised Learning Functions

You can use the following supervised learning functions to run predictive analytics on a data set:

- [LINEAR_REG](#) - Use this function to model the linear relationship between independent variables and some dependent variable.
- [LOGISTIC_REG](#) - Use this function to model the relationship between independent variables and some dependent variable.
- [NAIVE_BAYES](#) - Use this function to classify your data when features can be assumed independent.
- [RF_CLASSIFIER](#) - Use this function to create an ensemble model of decision trees.
- [SVM_CLASSIFIER](#) - Use this function to assign data to one category or the other.
- [SVM_REGRESSOR](#) - Use this function to predict continuous ordered variables.

Unsupervised Learning Functions

You can use the following unsupervised learning functions to run analytics on a data set:

- [KMEANS](#) - Use this function to cluster data points into k different groups.

APPLY_KMEANS

Assigns each row of an input table or view to a cluster center from an already-existing k-means model.

Important: Before using a machine learning function, be aware that all the ongoing transactions might be committed.

Syntax

```
APPLY_KMEANS ( col1, col2, ..., coln  
              USING PARAMETERS model_name='name_of_model_created_previously'  
                               [,match_by_pos = 'method'] )
```

Arguments

<code>col1, col2, ..., coln</code>	The columns to use from the input table or view.
------------------------------------	--

Parameters

<code>model_name='name_of_kmeans_model_created_previously'</code>	The name of the k-means model.
<code>match_by_pos= 'method'</code>	<p>(Optional) Valid Values:</p> <ul style="list-style-type: none">• false (default): Input columns will be matched to features in the model based on their names.• true: Input columns will be matched to features in the model based on their position in the list of indicated input columns.

Privileges

To use `APPLY_KMEANS`, you must either be the `dbadmin`, owner of the model or have `USAGE` privileges. There are no privileges needed on the function itself.

See [GRANT \(Schema\)](#) and [GRANT \(Table\)](#).

Examples

The following example shows how you can use the `APPLY_KMEANS` function on an input table. Note that you can mix column names and constants:

```
=> SELECT id, APPLY_KMEANS(Sepal_Length, 2.2, 1.3,
                          Petal_Width USING PARAMETERS
                          model_name='myKmeansModel', match_by_pos='true') FROM iris2;
```

id	APPLY_KMEANS
5	1
10	1
14	1
15	1
21	1
22	1
24	1
25	1
32	1
33	1
34	1
35	1
38	1
39	1
42	1
.	.
.	.
.	.

(60 rows)

The following example shows how you can use the `APPLY_KMEANS` function on an input table, using the `match_by_pos` parameter. Note that providing constants instead of column names works with this parameter:

```
=> SELECT id, APPLY_KMEANS(0,0,0,0 USING PARAMETERS
                          model_name='myKmeansModel', match_by_pos='true')
FROM iris ORDER BY id;
```

id	APPLY_KMEANS
1	1
2	1

```

- [KMEANS](#)

APPLY_NORMALIZE

Applies the normalization parameters saved in a model to a set of specified columns in the input table or view. If any column specified in the function is not contained in the model, the data will pass through unchanged to APPLY_NORMALIZE.

Important: Before using a machine learning function, be aware that all the ongoing transactions might be committed.

Syntax

```
APPLY_NORMALIZE ( col1,col2 ..., coln
                  USING PARAMETERS model_name='model_name');
```

Arguments

col1, col2 ..., coln

The columns to use from the input table or view.

Parameters

<i>model_name</i>	The name of the model. Model names are case-insensitive. Value must be VARCHAR.
-------------------	---

Privileges

To use `APPLY_NORMALIZE`, you must either be a superuser or have `CREATE` privileges for the schema of the output view and `SELECT` privileges for the input table or view. There are no privileges needed on the function itself.

See [GRANT \(Schema\)](#) and [GRANT \(Table\)](#).

Examples

This example shows how you can use the `APPLY_NORMALIZE` function on the `hp` and `cyl` columns in the `mtcars` table, where `hp` is in the normalization model and `cyl` is not in the normalization model.

```
=> SELECT APPLY_NORMALIZE (hp, cyl USING PARAMETERS model_name = 'mtcars_normfit') FROM mtcars;
hp          | cyl

BALANCE

Returns a view with an equal distribution of the input data based on the dependent variable.

Important: Before using a machine learning function, be aware that all the ongoing transactions might be committed.

Behavior Type

Immutable

Syntax

```
BALANCE ( 'output_view', 'input_relation', 'response_column', 'balance_method'
          [USING PARAMETERS [sampling_ratio=value] ])
```

Arguments

<i>output_view</i>	The name of the View where Vertica saves the balanced data from the chosen <i>input_relation</i> .
--------------------	--

<i>input_relation</i>	The table or view that contains the data the function uses to create a more balanced data set.
<i>response_column</i>	The dependent variable: a VARCHAR or INT column in the <i>input_relation</i> .
<i>balance_method</i>	<p>The imbalanced processing method to use. Selects data from the minority and majority classes.</p> <p>Valid values</p> <ul style="list-style-type: none"> • hybrid_sampling: Performs oversampling and undersampling on different classes so each class is equally represented. • over_sampling: Oversamples on all classes, with the exception of the most majority class, towards the most majority class's cardinality. • under_sampling: Undersamples on all classes, with the exception of the most minority class, towards the most minority class's cardinality. An alias of weighted_sampling. • weighted_sampling: An alias of under_sampling.

Parameters

<i>sampling_ratio=value</i>	<p>The desired ratio between the majority class and the minority class. This value has no effect when used with balance method hybrid_sampling.</p> <p>Default: 1.0</p>
-----------------------------	---

Privileges

To use **BALANCE**, you must either be a superuser or have **CREATE** privileges for the schema of the output view and **SELECT** privileges for the input table or view. There are no privileges needed on the function itself.

See [GRANT \(Schema\)](#) and [GRANT \(Table\)](#).

Examples

The following example shows how you can use the BALANCE function:

```
=> CREATE TABLE backyard_bugs (id identity, bug_type int, finder varchar(20));
CREATE TABLE

=> COPY backyard_bugs FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1|Ants
>> 1|Beetles
>> 3|Ladybugs
>> 3|Ants
>> 3|Beetles
>> 3|Caterpillars
>> 2|Ladybugs
>> 3|Ants
>> 3|Beetles
>> 1|Ladybugs
>> 3|Ladybugs
>> \.

=> SELECT bug_type, COUNT(bug_type) FROM backyard_bugs GROUP BY bug_type;
 bug_type | COUNT
-----+-----
          2 |      1
          1 |      3
          3 |      7
(3 rows)

=> SELECT BALANCE('backyard_bugs_balanced', 'backyard_bugs', 'bug_type', 'under_sampling');
          BALANCE
-----
Finished in 1 iteration

(1 row)

=> SELECT bug_type, COUNT(bug_type) FROM backyard_bugs_balanced GROUP BY bug_type;
-----+-----
          2 |      1
          1 |      2
          3 |      1
(3 rows)
```

- [Balancing Imbalanced Data](#)

CONFUSION_MATRIX

Using an input table, returns a confusion matrix based on observed and predicted values.

You cannot pass any inputs to the `OVER()` clause.

Important: Before using a machine learning function, be aware that all the ongoing transactions might be committed.

Syntax

```
CONFUSION_MATRIX ( target, predictions  
                  [ USING PARAMETERS [num_classes=C] ] )  
                  OVER()
```

Arguments

<i>target</i>	The column in the input table containing the response variable. Must be an integer.
<i>predictions</i>	The column in the input table containing the prediction variables. Must be an integer.

Parameters

<i>num_classes=C</i>	(Optional) The number of classes you want to pass to the function. Must be a positive integer. The result of <code>CONFUSION_MATRIX</code> is a table with $C+1$ columns and C rows.
----------------------	---

Examples

This example shows how you can execute the `CONFUSION_MATRIX` function on an input table named `mtcars`. The response variables appear in the column `obs`, while the prediction variables appear in the column `pred`. Because this problem regards classification, both the response variable values and the prediction variable values are either 0 or 1, indicating binary classification.

In the table returned, all 12 cars with a value of 1 in the `am` column were correctly predicted by `PREDICT_LOGISTIC_REG` as having a value of 1. Out of the 20 cars that had a value of 0 in the `am` column, 19 were correctly predicted to have the value 0. One car was incorrectly classified as having the value 1.

```
=> SELECT CONFUSION_MATRIX(obs, pred USING PARAMETERS num_classes=2) OVER()
      FROM (SELECT am AS obs, PREDICT_LOGISTIC_REG(mpg, cyl, disp, hp, drat, wt, qsec, vs, gear, carb
            USING PARAMETERS model_name='mtcars_log')::INT AS pred
            FROM mtcars) AS prediction_output;
class | 0 | 1 |
-----+---+---+-----
      0 | 19 | 0 |
      1 | 1 | 12 | Of 32 rows, 32 were used and 0 were ignored
(2 rows)
```

DETECT_OUTLIERS

Returns the outliers in a data set based on the outlier threshold. The output is a view containing the outliers.

Important: Before using a machine learning function, be aware that all the ongoing transactions might be committed.

Behavior Type

Immutable

Syntax

```
DETECT_OUTLIERS ( 'output_table', 'input_relation', 'input_columns', 'outlier_method'
                  USING PARAMETERS outlier_threshold=value
                  [, exclude_columns='col1, col2, ... coln',]
                  [partition_columns='col1, col2, ... coln'])
```

Arguments

<code>output_table</code>	The name of the table where Vertica saves the outliers from the chosen <code>input_columns</code> .
<code>input_relation</code>	The table or view that contains outlier data.
<code>input_columns</code>	The columns of <code>input_relation</code> to be used for determining outliers. The

	<code>input_columns</code> argument supports the use of a wildcard (*) character in place of column names.
<code>outlier_method</code>	The outlier method to use: Valid Values: <ul style="list-style-type: none"> robust_zscore

Parameters

<code>outlier_threshold=value</code>	(Optional) The value beyond which a data point becomes an outlier. Default value: 3.0
<code>exclude_columns='col1, col2, ... col'</code>	(Optional) The columns from <code>input_relation</code> which you want to exclude from the <code>input_columns</code> argument.
<code>partition_columns='col1, col2, ... coln'</code>	(Optional) A comma-separated list of column names from the <code>input_relation</code> which defines the partitions. The function will detect outliers among each partition separately. The default value is empty.

Privileges

To use `DETECT_OUTLIERS`, you must either be a superuser or have `CREATE` privileges for the schema and `SELECT` privileges for the table.

See [GRANT \(Schema\)](#) and [GRANT \(Table\)](#).

Examples

The following example shows how you can use the `DETECT_OUTLIERS` function:

```
=> CREATE TABLE baseball_roster (id identity, last_name varchar(30), hr int, avg float);
CREATE TABLE

=> COPY baseball_roster FROM STDIN;
Enter data to be copied followed by a newline.
```

End with a backslash and a period on a line by itself.

```
>> Polo|7|.233
>> Gloss|45|.170
>> Gus|12|.345
>> Gee|1|.125
>> Laus|3|.095
>> Hilltop|16|.222
>> Wicker|78|.333
>> Scooter|0|.121
>> Hank|999999|.8888
>> Popup|35|.378
>> \.
```

```
=> SELECT * FROM baseball_roster;
```

id	last_name	hr	avg
3	Gus	12	0.345
4	Gee	1	0.125
6	Hilltop	16	0.222
10	Popup	35	0.378
1	Polo	7	0.233
7	Wicker	78	0.333
9	Hank	999999	0.8888
2	Gloss	45	0.17
5	Laus	3	0.095
8	Scooter	0	0.121

(10 rows)

```
=> SELECT DETECT_OUTLIERS('baseball_outliers', 'baseball_roster', '*', 'robust_zscore' USING
PARAMETERS
outlier_threshold=3.0, exclude_columns='id');
```

```
DETECT_OUTLIERS
-----
Detected 2 outliers

(1 row)
```

```
=> SELECT * FROM baseball_outliers;
```

id	last_name	hr	avg
7	Wicker	78	0.333
9	Hank	999999	0.8888

(2 rows)

ERROR_RATE

Using an input table, returns a table which calculates the rate of incorrect classifications.

You cannot pass any inputs to the OVER() clause.

Important: Before using a machine learning function, be aware that all the ongoing transactions might be committed.

Syntax

```
ERROR_RATE ( target, predictions  
            [ USING PARAMETERS [num_classes=C] ] )  
OVER()
```

Arguments

<i>target</i>	The column in the input table containing the response variable. Must be an integer.
<i>predictions</i>	The column in the input table containing the prediction variables. Must be an integer.

Parameters

num_classes= <i>C</i>	(Optional) The number of classes you want to pass to the function. Must be a positive integer. The result of ERROR_RATE is a table with 2 columns and <i>C</i> +1 rows. The +1 row is an additional row for the total error rate across classes.
-----------------------	---

Privileges

To use ERROR_RATE, you must either be the dbadmin, owner of the model or have USAGE privileges. There are no privileges needed on the function itself.

See [GRANT \(Schema\)](#) and [GRANT \(Table\)](#).

Examples

This example shows how you can execute the ERROR_RATE function on an input table named `mtcars`. The response variables appear in the column `obs`, while the prediction variables appear in the column `pred`. Because this example is a classification problem, all of the response variable values and the prediction variable values are either 0 or 1, indicating binary classification.

In the table returned by the function, the first column displays the class id column. The second column displays the corresponding error rate for the class id. The third column indicates how many rows were successfully used by the function and whether any rows were ignored.

```
=> SELECT ERROR_RATE(obs, pred::int USING PARAMETERS num_classes=2) OVER()
      FROM (SELECT am AS obs, PREDICT_LOGISTIC_REG (mpg, cyl, disp, hp, drat, wt, qsec, vs, gear, carb
            USING PARAMETERS model_name='logisticRegModel', type='response') AS pred
            FROM mtcars) AS prediction_output;
class | error_rate | comment
-----+-----+-----
0 | 0 | 
1 | 0.0769230797886848 | 
| 0.03125 | Of 32 rows, 32 were used and 0 were ignored
(3 rows)
```

GET_MODEL_ATTRIBUTE

Extracts either a specific attribute from a model or all attributes from a model. Use this function to view a list of attributes and row counts or view detailed information about a single attribute. The output of GET_MODEL_ATTRIBUTE is a table format where users can select particular columns or rows.

Important: Before using a machine learning function, be aware that all the ongoing transactions might be committed.

Syntax

```
GET_MODEL_ATTRIBUTE (USING PARAMETERS model_name='model name',
                    [attr_name='value'])
```

Parameters

<i>model_name</i>	The name of the model. Model names are case-insensitive.
<i>attr_name</i>	(Optional) The name of the model attribute. If the value is not specified, the function shows all available attributes. Attribute names are case-sensitive.

Privileges

To use `GET_MODEL_ATTRIBUTE`, you must either be the `dbadmin`, owner of the model or have `USAGE` privileges. There are no privileges needed on the function itself.

See [GRANT \(Schema\)](#) and [GRANT \(Table\)](#).

Examples

This example shows how you can view a summary of all available attributes for a model.

```
=> SELECT GET_MODEL_ATTRIBUTE (USING PARAMETERS model_name='myLinearRegModel');
attr_name      | attr_fields | #_of_rows
-----+-----+-----
data           | coeffNames, coeff, stdErr, zValue, pValue | 2
regularization | type, lambda | 1
iterations     | iterations | 1
skippedRows    | skippedRows | 1
processedRows  | processedRows | 1
callStr        | callStr | 1
(6 rows)
```

This example shows how you can extract the *data* attribute from the *myLinearRegModel* model.

```
=> SELECT GET_MODEL_ATTRIBUTE (USING PARAMETERS model_name='myLinearRegModel', attr_name='data');
coeffNames | coeff | stdErr | zValue | pValue
-----+-----+-----+-----+-----
Intercept | -1.87401598641074 | 0.160143331525544 | -11.7021169008952 | 7.3592939615234e-26
waiting | 0.0756279479518627 | 0.00221854185633525 | 34.0890336307608 | 8.13028381124448e-100
(2 rows)
```

IMPUTE

Imputes missing values in a data set with either the mean or the mode, based on observed values for a variable. This function supports both numeric and categorical data types.

Important: Before using a machine learning function, be aware that all the ongoing transactions might be committed.

Syntax

```
IMPUTE( 'output_view', 'input_relation', 'input_columns', 'method'
        [ USING PARAMETERS [exclude_columns='col1, col2, ... coln'],]
```

[partition_columns='col1, col2, ... coln'])

Arguments

<i>output_view</i>	<p>The name of the View where the missing-value imputed rows and rows without missing values are stored.</p> <p>The value must be VARCHAR.</p>
<i>input_relation</i>	<p>The table or view that contains the data for missing-value imputation. The value must be VARCHAR.</p>
<i>input_columns</i>	<p>A comma-separated list of the columns in <i>input_relation</i> containing the values used in missing value imputation. The value must be VARCHAR.</p>
<i>method</i>	<p>The missing-value imputation method to use.</p> <p>Valid Values:</p> <ul style="list-style-type: none"> • mean: for numeric missing-value imputation • mode: for categorical missing-value imputation <p>Numeric and categorical input values are supported.</p>

Parameters

<i>exclude_columns=col1, col2, ... coln</i>	<p>(Optional) The columns from <i>input_relation</i> that you want to exclude from the <i>input_columns</i> argument.</p> <p>Default Value: Empty</p>
<i>partition_columns=col1, col2, ... coln</i>	<p>(Optional) A comma-separated list of column names from <i>input_relation</i> for the partition clause.</p> <p>Default Value: Empty</p>

Privileges

To use IMPUTE, you must either be a superuser or have CREATE privileges for the schema of the output view and SELECT privileges for the input table or view. There are no privileges

needed on the function itself.

See [GRANT \(Schema\)](#) and [GRANT \(Table\)](#).

Examples

These examples show how you can use the IMPUTE function on the `small_input_impute` table.

Execute the IMPUTE function, specifying the mean method:

```
=> SELECT impute('output_view','small_input_impute', 'pid, x1,x2,x3,x4','mean' USING PARAMETERS
exclude_columns='pid');
impute
-----
Finished in 1 iteration
(1 row)
```

Execute the IMPUTE function, specifying the mode method:

```
=> SELECT impute('output_view3','small_input_impute', 'pid, x5,x6','mode' USING PARAMETERS exclude_
columns='pid');
impute
-----
Finished in 1 iteration
(1 row)
```

See Also

[Imputing Missing Values](#)

KMEANS

Executes the k-means algorithm on an input table or view. The result is a model with a list of cluster centers.

Important: Before using a machine learning function, be aware that all the ongoing transactions might be committed.

Syntax

```
KMEANS ( 'model_name', 'input_relation', 'input_columns', num_clusters
        [ USING PARAMETERS [exclude_columns=['col1, col2, ... coln'],]
```

```
[max_iterations=value,]
[epsilon=value,]
[init_method=method,]
[initial_centers_table=table_name,]
[output_view='output_view',]
[key_columns='key_columns' ])
```

Arguments

<i>model_name</i>	The name of the k-means model. Model names are case insensitive.
<i>input_relation</i>	The table or view that contains the input data for k-means.
<i>input_columns</i>	The columns of <i>input_relation</i> to be used for clustering. The <i>input_columns</i> argument supports the use of wildcard (*) characters in place of column names.
<i>num_clusters</i>	The number of clusters you want to create. This argument represents the <i>k</i> in k-means. Must be an INT and greater than zero.

Parameters

<i>exclude_columns='col1, col2, ... coln'</i>	(Optional) The columns from <i>input_relation</i> that you want to exclude from clustering.
<i>max_iterations=value</i>	(Optional) The maximum number of iterations the algorithm performs. If you set this value to a number lower than the number of iterations needed for convergence, the algorithm may not converge. Default Value: 10
<i>epsilon=value</i>	(Optional) Determines whether the algorithm has converged. If, after an iteration, no component of any cluster center changes more than the value of epsilon, the algorithm has converged. Default Value: 1e-4
<i>init_method=method</i>	(Optional) The method used to find the initial cluster centers. You cannot use this parameter if the <i>initial_centers</i> parameter has a value. Providing

	<p>a value for both <code>init_method</code> and <code>initial_centers_table</code> causes Vertica to return an error.</p> <p>Valid Values:</p> <ul style="list-style-type: none"> • random • kmeanspp — kmeans++ algorithm <p>Default Value: kmeanspp</p>
<code>initial_centers_table=table_name</code>	<p>(Optional) The table with the initial cluster centers to use. Supply this value if you know the initial centers you want to use and do not want Vertica to find the initial cluster centers for you.</p> <p>You cannot use this parameter if the <code>init_method</code> parameter has a value. Providing a value for both <code>init_method</code> and <code>initial_centers_table</code> causes Vertica to return an error.</p>
<code>output_view='output_view'</code>	<p>(Optional) The name of the View where you save the assignments of each point to its cluster.</p>
<code>key_columns='key_columns'</code>	<p>(Optional) A comma-separated list of column names from the <code>input_relation</code> which you use to identify each row of the output in the <code>output_view</code>.</p>

Privileges

To use KMEANS, you must either be a superuser or have CREATE privileges for the schema of the output view and SELECT privileges for the input table or view. There are no privileges needed on the function itself.

See [GRANT \(Schema\)](#) and [GRANT \(Table\)](#).

Examples

The following example shows how you can use the KMEANS function and view the results of the model in the `output_view`.

```
=> SELECT KMEANS('myKmeansModel', 'iris1', '*', 5
                USING PARAMETERS max_iterations=20, output_view='myKmeansView', key_columns='id',
```

```
                exclude_columns='Species, id');
KMEANS
-----
Finished in 12 iterations

(1 row)
```

LIFT_TABLE

Returns a table that compares the predictive quality of a logistic regression model. This function is also known as a *lift chart*.

You cannot pass any inputs to the `OVER()` clause.

Important: Before using a machine learning function, be aware that all the ongoing transactions might be committed.

Syntax

```
LIFT_TABLE ( target, probabilities
            [ USING PARAMETERS [num_bins=nBins] ])
OVER()
```

Arguments

<i>target</i>	The column in the input table containing the response variable. Must be an integer.
<i>probabilities</i>	The column in the input table where the observation is of class 1. Must be a float.

Parameters

<code>num_bins=<i>nBins</i></code>	<p>(Optional) Groups rows together, based upon the probability column, for faster processing. You use this parameter to determine the number of different decision boundaries to consider. The parameter partitions the number line from 0 to 1 in <i>nBin</i> points that are equally spaced. It evaluates the table at each of the <i>nBin</i> points. Must be an integer.</p> <p>Default Value: 100</p>
------------------------------------	---

Examples

This example demonstrates how you can execute the `LIFT_TABLE` function on an input table named `mtcars`.

```
=> SELECT LIFT_TABLE(obs, prob USING PARAMETERS num_bins=2) OVER()
       FROM (SELECT am AS obs, PREDICT_LOGISTIC_REG(mpg, cyl, disp, hp, drat, wt, qsec, vs, gear, carb
                                                    USING PARAMETERS model_name='logisticRegModel',
                                                    type='probability') AS prob
              FROM mtcars) AS prediction_output;
```

decision_boundary	positive_prediction_ratio	lift	comment
1	0	NaN	
0.5	0.40625	2.46153846153846	
0	1	1	Of 32 rows, 32 were used and 0 were ignored (3 rows)

The first column, `decision_boundary`, indicates the cut-off point for whether to classify a response as 0 or 1. For instance, for each row, if `prob` is greater than `decision_boundary`, the response is classified as 1. If `prob` is less than `decision_boundary`, the response is classified as 0.

The second column, `positive_prediction_ratio`, shows the percentage of samples in class 1 that the function classified correctly using the corresponding `decision_boundary` value.

For the third column, `lift`, the function divides the `positive_prediction_ratio` by the percentage of rows correctly classified as class 1.

LINEAR_REG

Executes linear regression on an input table or view. The result is a linear regression model.

Important: Before using a machine learning function, be aware that all the ongoing transactions might be committed.

Syntax

```
LINEAR_REG ( 'model_name', 'input_relation', 'response_column', 'predictor_columns'  
            [ USING PARAMETERS[exclude_columns='col1, col2, ... coln',]  
              [optimizer='value',]  
              [epsilon=value,]  
              [max_iterations=value,]  
              [regularization= 'value',]  
              [lambda= value] ])
```

Arguments

<i>model_name</i>	The name of the linear regression model. You can use the resulting model for prediction with the PREDICT_LINEAR_REG function. Model names are case insensitive.
<i>input_relation</i>	The table or view that contains the training data for building the model.
<i>response_column</i>	The name of the column in the <i>input_relation</i> that represents the dependent variable, or outcome. For the model to be valid, all values in this column must be of type numeric.
<i>predictor_columns</i>	A comma-separated list of the columns in the <i>input_relation</i> that represent the independent variables for the model. For the model to be valid, all values in this column must be of type numeric. Supports the use of wildcard (*) characters in place of column names. If you use a wildcard character (*) in place of a column name, all the columns in <i>input_relation</i> are selected. In this case, the <i>response_column</i> must be explicitly excluded using the list assigned to <i>exclude_columns</i> .

Parameters

<code>exclude_columns=col1, col2, ... coln</code>	<p>(Optional) The columns from <code>input_relation</code> that you want to exclude from the <code>predictor_columns</code> argument.</p>
<code>optimizer=value</code>	<p>(Optional) The optimizer method used to train the model.</p> <p>Valid Values:</p> <ul style="list-style-type: none">• BFGS• Newton (default value)
<code>epsilon=value</code>	<p>(Optional) Determines whether the algorithm has reached the specified accuracy result.</p> <p>Default Value: 1e-6</p>
<code>max_iterations=value</code>	<p>(Optional) Determines the maximum number of iterations the algorithm performs before achieving the specified accuracy result.</p> <p>Default Value: 100</p>
<code>regularization=value</code>	<p>(Optional) Determines the method of regularization.</p> <p>Default Value: None</p> <p>Valid Values:</p> <ul style="list-style-type: none">• L2• None
<code>lambda=value</code>	<p>(Optional) The regularization parameter value. The value must be zero or positive.</p> <p>Default Value: 0.0</p>

Privileges

To use `LINEAR_REG`, you must either be a superuser or have `CREATE` privileges for the schema of the output view and `SELECT` privileges for the input table or view. There are no privileges needed on the function itself.

See [GRANT \(Schema\)](#) and [GRANT \(Table\)](#).

Examples

This example shows how you can use the `LINEAR_REG` function.

```
=> SELECT LINEAR_REG('myLinearRegModel', 'faithful', 'eruptions', 'waiting'
                    USING PARAMETERS optimizer='BFGS');
          LINEAR_REG
-----
Finished in 10 iterations

(1 row)
```

LOGISTIC_REG

Executes logistic regression on an input table or view. The result is a logistic regression model.

Important: Before using a machine learning function, be aware that all the ongoing transactions might be committed.

Syntax

```
LOGISTIC_REG ( 'model_name', 'input_relation', 'response_column', 'predictor_columns'
               [ USING PARAMETERS[exclude_columns='col1, col2, ... coln',]
               [optimizer='value',]
               [epsilon=value, ]
               [max_iterations=value]
               [regularization= 'value',]
               [lambda= value] ])
```

Arguments

<code>model_name</code>	The name of the linear regression model. You can use the resulting model for prediction with the PREDICT_LOGISTIC_REG function.
-------------------------	---

	Model names are case insensitive.
<i>input_relation</i>	The table or view that contains the training data for building the model.
<i>response_column</i>	<p>The name of the column in the <code>input_relation</code> that represents the dependent variable, or outcome.</p> <p>For the model to be valid, all values in this column must be INTEGER types with a value of either 0 or 1. The function automatically skips all other values.</p>
<i>predictor_columns</i>	<p>A comma-separated list of the columns in the <code>input_relation</code> that represent the independent variables for the model.</p> <p>For the model to be valid, all values in this column must be of type numeric.</p> <p>Supports the use of wildcard (*) characters in place of column names. If you use a wildcard character (*) in place of a column name, all the columns in <code>input_relation</code> are selected. In this case, the <code>response_column</code> must be explicitly excluded using the list assigned to <code>exclude_columns</code>.</p>

Parameters

<code>exclude_columns=col1, col2, ... coln</code>	<p>(Optional) The columns from <code>input_relation</code> that you want to exclude from the <code>predictor_columns</code> argument.</p>
<code>optimizer=value</code>	<p>(Optional) The optimizer method to be used to train the model.</p> <p>Valid Values:</p> <ul style="list-style-type: none"> • BFGS • Newton (default value)
<code>epsilon=value</code>	<p>(Optional) Determines whether the algorithm has reached the specified accuracy result.</p> <p>Default Value: 0.000001</p>
<code>max_iterations=value</code>	<p>(Optional) Determines the maximum number of iterations the algorithm performs before achieving the</p>

	<p>specified accuracy result.</p> <p>Default Value: 100</p>
<code>regularization=value</code>	<p>(Optional) Determines the method of regularization.</p> <p>Default Value: None</p> <p>Valid Values:</p> <ul style="list-style-type: none"> • L2 • None
<code>lambda=value</code>	<p>(Optional) The regularization parameter value. The value must be zero or positive.</p> <p>Default Value: 0.0</p>

Privileges

To use LOGISTIC_REG, you must either be a superuser or have CREATE privileges for the schema of the output view and SELECT privileges for the input table or view. There are no privileges needed on the function itself.

See [GRANT \(Schema\)](#) and [GRANT \(Table\)](#).

Examples

This example shows how you can use the LOGISTIC_REG function.

```
=> SELECT LOGISTIC_REG('myLogisticRegModel', 'mtcars', 'am',
                        'mpg, cyl, disp, hp, drat, wt, qsec, vs, gear, carb'
                        USING PARAMETERS exclude_columns='hp', optimizer='BFGS');
LOGISTIC_REG
-----
Finished in 20 iterations

(1 row)
```

MSE

Returns a table that displays the mean squared error of the prediction and response columns in a linear regression model.

You cannot pass any inputs to the OVER() clause.

Important: Before using a machine learning function, be aware that all the ongoing transactions might be committed.

Syntax

```
MSE ( target, prediction)  
      OVER()
```

Parameters

<i>target</i>	The response variable for the model. Must be a float.
<i>prediction</i>	The output from the PREDICT_LINEAR_REG function. If that output is saved as a table, the column containing the prediction from the function is used. Must be a float.

Examples

This example shows how you can execute the MSE function on an input table named `faithful_testing`. The response variables appear in the column `obs`, while the prediction variables appear in the column `pred`.

```
=> SELECT MSE(obs, prediction) OVER()  
      FROM (SELECT eruptions AS obs,  
              PREDICT_LINEAR_REG (waiting USING PARAMETERS model_name='linearRegModel') AS  
prediction  
              FROM faithful_testing) AS prediction_output;  
      mse | Comments  
-----+-----  
0.244712410708555 | Of 272 rows, 272 were used and 0 were ignored  
(1 row)
```

NAIVE_BAYES

Executes the Naive Bayes algorithm on an input table or view. The result is a Naive Bayes model.

The following explains how columns are treated based on their data type:

- FLOAT - Values are assumed to follow some Gaussian distribution.
- INTEGER - Values are assumed to belong to one multinomial distribution.
- CHAR/VARCHAR - Values are assumed to follow some categorical distribution.
- BOOLEAN - Values are treated as categorical with two values.

Important: Before using a machine learning function, be aware that all the ongoing transactions might be committed.

Syntax

```
NAIVE_BAYES ( 'model_name', 'input_relation', 'response_column', 'predictor_col1, predictor_col2, ..., predictor_coln'
              [ USING PARAMETERS[exclude_columns='col1, col2, ..., coln',]
                [alpha=value] ] )
```

Arguments

<i>model_name</i>	The name of the model. Model names are case insensitive.
<i>input_relation</i>	The table or view that contains the training data for building the model.
<i>response_column</i>	The name of the column in the <i>input_relation</i> that represents the dependent variable, or outcome. This column must be discrete labels that represent different class labels.
<i>predictor_columns</i>	A comma-separated list of the columns in the <i>input_relation</i> that represent the independent variables for the model. Supported Data Types: INT, CHAR/VARCHAR, FLOAT, BOOLEAN Supports the use of wildcard (*) characters in place of column names. If you use a wildcard character (*) in place of a column name, the function selects all the columns in <i>input_relation</i> . In this case, the <i>response_column</i> must be explicitly excluded, using the list assigned to <i>exclude_columns</i> .

Parameters

<code>exclude_columns=col1, col2, ..., coln</code>	(Optional) The columns from <code>input_relation</code> that you want to exclude from the <code>predictor_columns</code> argument.
<code>alpha=value</code>	(Optional) The parameter used to control Laplace smoothing. Specifies use of Laplace smoothing if the event model is categorical, multinomial, or Bernoulli. Default Value: 1.0

Privileges

To use `NAIVE_BAYES`, you must either be a superuser or have `CREATE` privileges for the schema of the output view and `SELECT` privileges for the input table or view. There are no privileges needed on the function itself.

See [GRANT \(Schema\)](#) and [GRANT \(Table\)](#).

Examples

This example shows how you can use the `NAIVE_BAYES` function.

```
=> SELECT NAIVE_BAYES('naive_house84_model', 'house84_train', 'party', '*'
                     USING PARAMETERS exclude_columns='party, id');
                     NAIVE_BAYES
-----
Finished. Accepted Rows: 324 Rejected Rows: 0
(1 row)
```

- [PREDICT_NAIVE_BAYES_CLASSES](#)

NORMALIZE

Runs a normalization algorithm on an input table or view. The output is a view with the normalized data.

Note: This function differs from `NORMALIZE_FIT`, which creates and stores a model rather than creating a view definition. This could lead to different performance characteristics between the two algorithms.

Important: Before using a machine learning function, be aware that all the ongoing transactions might be committed.

Syntax

```
NORMALIZE ( 'output_view', 'input_relation', 'input_columns', 'normalization_method'  
           [ USING PARAMETERS [exclude_columns= 'col1, col2, ... coln ' ] ]
```

Arguments

<i>output_view</i>	The name of the View where you save the normalized data from the chosen <code>input_columns</code> .
<i>input_relation</i>	The table or view that contains the data to be normalized.
<i>input_columns</i>	A comma-separated list of the columns in the <code>input_relation</code> containing the values to be normalized. To include all of the columns from the <code>input_relation</code> , specify this argument as a wildcard (*).
<i>normalization_method</i>	The normalization method to use. Valid Values: <ul style="list-style-type: none">• minmax• zscore• robust_zscore

	If infinity values appear in the table, the method ignores those values.
--	--

Parameters

<code>exclude_columns=col1, col2, ... coln</code>	(Optional) The columns from <code>input_relation</code> that you want to exclude from the <code>input_columns</code> argument.
---	--

Privileges

To use `NORMALIZE`, you must either be a superuser or have `CREATE` privileges for the schema of the output view and `SELECT` privileges for the input table or view.

See [GRANT \(Schema\)](#) and [GRANT \(Table\)](#).

Examples

These examples show how you can use the `NORMALIZE` function on the `wt` and `hp` columns in the `mtcars` table.

Execute the `NORMALIZE` function, and specify the `minmax` method:

```
=> SELECT NORMALIZE('mtcars_norm', 'mtcars',
                   'wt, hp', 'minmax');
      NORMALIZE
-----
Finished in 1 iteration

(1 row)
```

Execute the `NORMALIZE` function, and specify the `zscore` method:

```
=> SELECT NORMALIZE('mtcars_normz', 'mtcars',
                   'wt, hp', 'zscore');
      NORMALIZE
-----
Finished in 1 iteration

(1 row)
```

Execute the `NORMALIZE` function, and specify the `robust_zscore` method:

```
=> SELECT NORMALIZE('mtcars_normz', 'mtcars',
                   'wt, hp', 'robust_zscore');
```

```
NORMALIZE
-----
Finished in 1 iteration

(1 row)
```

See Also

- [Normalizing Data](#)

NORMALIZE_FIT

Computes normalization parameters for each of the specified columns in an input table or view. The resulting model stores the normalization parameters. For example, for MinMax normalization, the minimum and maximum value of each column are stored in the model. The generated model will serve as input to the functions [APPLY_NORMALIZE](#) and [REVERSE_NORMALIZE](#).

For robust_zscore, `NORMALIZE_FIT` uses the [APPROXIMATE_MEDIAN \[Aggregate\]](#) function.

This function differs from `NORMALIZE`, which directly outputs a view with normalized results, rather than storing normalization parameters into a model for later operation.

Important: Before using a machine learning function, be aware that all the ongoing transactions might be committed.

Syntax

```
NORMALIZE_FIT ( 'model_name', 'input_relation', 'input_columns', 'normalization_method'
                [USING PARAMETERS [exclude_columns='col1, col2, ... coln',]
                [output_view='output_view' ] ] )
```

Arguments

<i>model_name</i>	The name of the model. Model names are case-insensitive.
<i>input_relation</i>	The table or view that contains the data to be normalized.
<i>input_columns</i>	A comma-separated list of the columns in <code>input_relation</code> that contains the values to be normalized.

	To include all of the columns from the <code>input_relation</code> , specify this argument as a wildcard (*).
<code>normalization_method</code>	<p>The normalization method to use.</p> <p>Valid Values:</p> <ul style="list-style-type: none"> • minmax • zscore • robust_zscore <p>If infinity values, negative infinity values, or NULL values appear in the table, the method ignores those values.</p>

Parameters

<code>exclude_columns='col1, col2, ... coln'</code>	(Optional) The columns from the <code>input_relation</code> that you want to exclude from the <code>input_columns</code> argument.
<code>output_view = output view</code>	(Optional) The name of the View that contains all columns from the <code>input_relation</code> , with the specified <code>input_columns</code> normalized.

Privileges

To use `NORMALIZE_FIT`, you must either be a superuser or have `CREATE` privileges for the schema of the output view and `SELECT` privileges for the input table or view.

See [GRANT \(Schema\)](#) and [GRANT \(Table\)](#).

Examples

These examples show how you can use the `NORMALIZE_FIT` function on the `wt` and `hp` columns in the `mtcars` table.

Note: If a column contains only one distinct value, when you use the `APPLY_NORMALIZE` function, it returns NaN for values in that column.

Execute the `NORMALIZE_FIT` function, and specify the `minmax` method:

```
=> SELECT NORMALIZE_FIT('mtcars_normfit', 'mtcars', 'wt,hp', 'minmax');  
NORMALIZE_FIT  
-----  
Success  
(1 row)
```

Execute the `NORMALIZE_FIT` function, and specify the `zscore` method:

```
=> SELECT NORMALIZE_FIT('mtcars_normfitz', 'mtcars', 'wt,hp', 'zscore');  
NORMALIZE_FIT  
-----  
Success  
(1 row)
```

Execute the `NORMALIZE_FIT` function, and specify the `robust_zscore` method:

```
=> SELECT NORMALIZE_FIT('mtcars_normfitrz', 'mtcars', 'wt,hp', 'robust_zscore');  
NORMALIZE_FIT  
-----  
Success  
(1 row)
```

- [Normalizing Data](#)
- [REVERSE_NORMALIZE](#)

PREDICT_LINEAR_REG

Applies a linear regression model on an input table or view.

Important: Before using a machine learning function, be aware that all the ongoing transactions might be committed.

Syntax

```
PREDICT_LINEAR_REG ( col1, col2, ... coln  
                    USING PARAMETERS model_name = 'name_of_model'  
                               [, match_by_pos = 'method'] )
```

Arguments

<code>col1, col2, ..., coln</code>	The columns to use from the input table or view.
------------------------------------	--

Parameters

<code>model_name = 'name_of_model'</code>	The name of the linear regression model.
<code>match_by_pos = 'method'</code>	(Optional) Valid Values: <ul style="list-style-type: none">• false (default): Input columns will be matched to features in the model based on their names.• true: Input columns will be matched to features in the model based on their position in the list of indicated input columns.

Return

Return data type:FLOAT	Returns the predicted value.
------------------------	------------------------------

Examples

The following example shows how you can use the PREDICT_LINEAR_REG function on an input table.

```
=> SELECT PREDICT_LINEAR_REG(waiting USING PARAMETERS model_name='linear_reg_faithful')FROM faithful  
ORDER BY id;
```

```
PREDICT_LINEAR_REG
```

```
-----

```

```
.  
. .  
(272 rows)
```

PREDICT_LOGISTIC_REG

Applies a logistic regression model on an input table or view.

Important: Before using a machine learning function, be aware that all the ongoing transactions might be committed.

Syntax

```
PREDICT_LOGISTIC_REG ( col1, col2, ... coln  
                       USING PARAMETERS model_name = 'name_of_model'
```

```
[, type = 'prediction_type',]
[cutoff = probability_cutoff,]
[match_by_pos = 'method'])
```

Arguments

<code>col1, col2, ..., coln</code>	The columns to use from the input table or view.
------------------------------------	--

Parameters

<code>model_name = 'name_of_model'</code>	The name of the logistic regression model.
<code>type = 'prediction_type'</code>	<p>(Optional) Determines the type of prediction for logistic regression.</p> <p>When response is selected the predicted values are 0 or 1. When probability is selected, the output will be the probability of the predicted category to be 1.</p> <p>Valid Values</p> <ul style="list-style-type: none"> • response (Default Value) • probability
<code>cutoff = probability_cutoff</code>	<p>(Optional). Used in conjunction with type. Valid responses are between 0 and 1, exclusive. When the value of type is "response", the returned value of prediction would be 1 if its corresponding probability is bigger than or equal to the value of cutoff; otherwise, it is 0.</p> <p>Default Value: 0.5</p>
<code>match_by_pos= 'method'</code>	<p>(Optional) Valid Values:</p> <ul style="list-style-type: none"> • false (default): Input columns will be matched to features in the model based on their names. • true: Input columns will be matched to features in the model based on their position in the list of indicated input columns.

Return

Return data type: FLOAT	Returns the predicted class or the probability of the predicted class, depending on the response input. The return can be cast to INT or other numeric types when the return is in the probability of the predicted class.
----------------------------	--

Examples

The following example shows how you can use the PREDICT_LOGISTIC_REG function on an input table.

```
=> SELECT car_model,
        PREDICT_LOGISTIC_REG(mpg, cyl, disp, drat, wt, qsec, vs, gear, carb
                               USING PARAMETERS model_name='myLogisticRegModel')
        FROM mtcars;
car_model | PREDICT_LOGISTIC_REG
-----|-----
Camaro Z28 | 0
Fiat 128 | 1

PREDICT_NAIVE_BAYES

Applies a Naive Bayes model on an input table or view.

Important: Before using a machine learning function, be aware that all the ongoing transactions might be committed.

Syntax

```
PREDICT_NAIVE_BAYES ( predictor_columns
                     USING PARAMETERS model_name = 'model_name'
                                     [, type = ' { RESPONSE | PROBABILITY } ',]
                                     [class = 'user_input_class', ]
                                     [match_by_pos = 'method' ] )
```

Arguments

<i>predictor_columns</i>	<p>A comma-separated list of the columns in <code>input_relation</code> that represent the independent features for the model.</p> <p>Supports the use of wildcard (*) characters in place of column names.</p>
--------------------------	---

Parameters

<code><i>model_name</i> = '<i>model_name</i>'</code>	<p>The name of the model. Model names are case insensitive.</p>
<code><i>type</i> = '{ RESPONSE PROBABILITY }'</code>	<p>(Optional) Specifies that the function can take the value RESPONSE or PROBABILITY. RESPONSE, using the class result of the prediction. This value uses the highest probability among all possible classes. PROBABILITY defers to the second argument 'class'.</p> <p>Default Value: response</p>
<code><i>class</i> = '<i>user_input_class</i>'</code>	<p>(Optional) Specifies a specific class to use when <code>type</code> is set to PROBABILITY. The predict function returns the probability of belonging to this given class as predicted by the classifier. If <code>class</code> is not specified, its default value is the predicted class -- the highest will be returned. Thus, the predict function returns the probability that the input instance belonging to its predicted class.</p>
<code><i>match_by_pos</i> = '<i>method</i>'</code>	<p>(Optional) Valid Values:</p>

	<ul style="list-style-type: none"> • false (default): Input columns will be matched to features in the model based on their names. • true: Input columns will be matched to features in the model based on their position in the list of indicated input columns.
--	---

Return

Return data type: VARCHAR	Returns the predicted class or the probability of the predicted class, depending on the response input. The return can be cast to INT or other numeric types when the return is in the probability of the predicted class.
------------------------------	--

Examples

This example shows how you can use the PREDICT_NAIVE_BAYES function.

```
=> SELECT party, PREDICT_NAIVE_BAYES (vote1, vote2, vote3
                                     USING PARAMETERS model_name = 'naive_house84_model',
                                     type = 'response')
       AS Predicted_Party
FROM house84_test;
```

party	Predicted_Party

PREDICT_NAIVE_BAYES_CLASSES

Applies a Naive Bayes model on an input table or view and returns the probabilities of classes.

Important: Before using a machine learning function, be aware that all the ongoing transactions might be committed.

Syntax

```
PREDICT_NAIVE_BAYES_CLASSES ( predictor_columns
                               USING PARAMETERS model_name = 'model_name'
                                               [,key_columns = 'key_columns',]
                                               [exclude_columns = 'col1, col2, ..., coln',]
                                               [classes = 'class1, class2, ..., classn', ]
                                               [match_by_pos = 'method' ] )
                               OVER()
                               AS (key_columns, Predicted, Probability, class1, class2, ..., classn)
```

Arguments

<i>predictor_columns</i>	A comma-separated list of the columns in <i>input_relation</i> that represent the independent variables for the model. Supports the use of wildcard (*) characters in place of column names. If you use a wildcard character (*) in place of a column name, all the columns in <i>input_relation</i> are selected.
--------------------------	---

Parameters

<i>model_name</i> = ' <i>model_name</i> '	The name of the model. Model names are case
---	---

	insensitive.
<code>key_columns = 'key_columns'</code>	(Optional) A comma-separated list of column names from the <code>input_relation</code> which you use to identify each row of the output.
<code>exclude_columns = 'col1, col2, ..., coln'</code>	(Optional) The columns from <code>predictor_columns</code> that you want to exclude. This parameter is useful when using the wildcard (*) in the <code>predictor_columns</code> .
<code>classes = 'class1, class2, ..., classn'</code>	(Optional) Class labels in the model. The probability of belonging to this given class as predicted by the classifier. The values are case sensitive.
<code>match_by_pos= 'method'</code>	<p>(Optional) Valid Values:</p> <ul style="list-style-type: none"> • false (default): Input columns will be matched to features in the model based on their names. • true: Input columns will be matched to features in the model based on their position in the list of indicated input columns.

Return

Return data type: One VARCHAR column and multiple FLOAT columns	The VARCHAR column is named <code>predicted</code> and contains the class label with the highest probability. The first FLOAT column is named <code>probability</code> and contains the probability for the class specified in the <code>predicted</code>
---	---

	column. The other FLOAT columns contain each class listed in the classes column.
--	--

Examples

This example shows how you can use the PREDICT_NAIVE_BAYES_CLASSES function.

```
=> SELECT PREDICT_NAIVE_BAYES_CLASSES (id, vote1, vote2
                                     USING PARAMETERS model_name = 'naive_house84_model',
                                                         key_columns = 'id',
                                                         exclude_columns = 'id',
                                                         classes = 'democrat, republican',
                                                         match_by_pos = 'false')
       OVER() FROM house84_test;
 id | Predicted | Probability | democrat | republican
-----+-----+-----+-----+-----

PREDICT_RF_CLASSIFIER_CLASSES

Applies a random forest model on an input table or view and returns the probabilities of classes. The predicted class is selected only based on the popular vote of the decision trees in the forest. Therefore, in special cases the calculated probability of the predicted class may not be the highest.

Important: Before using a machine learning function, be aware that all the ongoing transactions might be committed.

Syntax

```
PREDICT_RF_CLASSIFIER_CLASSES ( col1, col2, ... coln
                               USING PARAMETERS model_name = 'name_of_model'
                               [,key_columns = 'key_columns',]
                               [exclude_columns = 'col1, col2, ..., coln',]
                               [classes = 'class1, class2, ..., classn', ]
                               [match_by_pos = 'method' ] )
                               OVER([window-partition-clause])
```

Arguments

<i>col1, col2, ..., coln</i>	The columns to use from the input table or view.
------------------------------	--

Parameters

<code>model_name = 'name_of_model'</code>	The name of the random forest model. Model names are case-insensitive.
<code>key_columns = 'key_columns'</code>	(Optional) A comma-separated list of column names from <code>input_relation</code> which you use to identify each row of the output.
<code>exclude_columns = 'col1, col2, ..., coln'</code>	(Optional) The columns from <code>predictor_columns</code> that you want to exclude. This parameter is useful when using the wildcard (*) in the <code>predictor_columns</code> .
<code>classes = 'class1, class2, ..., classn'</code>	(Optional) Class labels in the model. The probability

	of belonging to this given class as predicted by the classifier. The values are case sensitive.
<code>match_by_pos= 'method'</code>	<p>(Optional) Valid Values:</p> <ul style="list-style-type: none"> • false (default): Input columns will be matched to features in the model based on their names. • true: Input columns will be matched to features in the model based on their position in the list of indicated input columns.

Return

Return data type: One VARCHAR column and multiple FLOAT columns	The predicted column, of type VARCHAR, contains the class label with the highest vote (popular vote). The first FLOAT column is named probability and contains the probability for the class reported in the predicted column. The other FLOAT columns contain the probability of each class specified in the <code>classes</code> input parameter.
Key columns	Columns with the same value and data type as the matching input columns that are specified in the <code>key_columns</code> input parameter.

Examples

This example shows how you can use the `PREDICT_RF_CLASSIFIER_CLASSES` function.

```
=> SELECT PREDICT_RF_CLASSIFIER_CLASSES(Sepal_Length, Sepal_Width, Petal_Length, Petal_Width
      USING PARAMETERS model_name='myRFModel') OVER () FROM iris;
```

predicted	probability

PREDICT_RF_CLASSIFIER

Applies a random forest model on an input table or view. The predicted class is selected only based on the popular vote of the decision trees in the forest. Therefore, in special cases the calculated probability of the predicted class may not be the highest.

Important: Before using a machine learning function, be aware that all the ongoing transactions might be committed.

Syntax

```
PREDICT_RF_CLASSIFIER ( col1, col2, ... coln
                      USING PARAMETERS model_name = 'name_of_model'
                                     [, type= ' { RESPONSE | PROBABILITY } ',]
                                     [class= 'user_input_class',]
                                     [match_by_pos = 'method'])
```

Arguments

<i>col1, col2, ..., coln</i>	The columns to use from the input table or view.
------------------------------	--

Parameters

<code>model_name = 'name_of_model'</code>	The name of the random forest model. Model names are case-insensitive.
<code>type = 'method'</code>	<p>(Optional) Determines the type of prediction for random forest.</p> <p>When response is selected the result of the prediction is the class with the highest probability among all possible classes. When probability is selected, the 'class' parameter is considered.</p> <p>Valid Values</p> <ul style="list-style-type: none"> • response (Default Value) • probability
<code>class = 'user_input_class'</code>	(Optional) Specifies a specific class to use when type is set to PROBABILITY. The predict function returns the probability of the specified class to be the response. If class is not specified, its default value is the predicted class -- the one with popular vote. Thus, the predict function returns the probability that the input instance belonging to its predicted class.

	Default Value: Auto
match_by_pos= 'method'	<p>(Optional) Valid Values:</p> <ul style="list-style-type: none"> • false (default): Input columns will be matched to features in the model based on their names. • true: Input columns will be matched to features in the model based on their position in the list of indicated input columns.

Return

Return data type: VARCHAR	The predict function returns the predicted class (based on popular votes) or probability of a class (depending on the value of the optional input parameters type and class) for each input instance.
------------------------------	---

Examples

This example shows how you can use the PREDICT_RF_CLASSIFIER function.

```
=> SELECT PREDICT_RF_CLASSIFIER (Sepal_Length, Sepal_Width, Petal_Length, Petal_Width
                                USING PARAMETERS model_name='myRFModel') FROM iris;

PREDICT_SVM_CLASSIFIER

Applies an SVM model on an input table or view.

Important: Before using a machine learning function, be aware that all the ongoing transactions might be committed.

Syntax

```
PREDICT_SVM_CLASSIFIER (input_columns
                        USING PARAMETERS model_name='model_name'
                        [, match_by_pos = 'method'])
```

Arguments

<i>input_columns</i>	A comma-separated list of the columns to be used for prediction.
----------------------	--

Parameters

<i>model_name</i> ='model_name'	The name of the model. Model names are case-insensitive.
<i>match_by_pos</i> = 'method'	(Optional) Valid Values: <ul style="list-style-type: none">false (default): Input columns will be matched to features in the model based on their names.true: Input columns will be matched to features in the model based on their position in the list of indicated input columns.

Return

Return data type: FLOAT	Returns the predicted value.
-------------------------	------------------------------

Examples

This example shows how you can use the PREDICT_SVM_CLASSIFIER function on the mtcars table:

```
=> SELECT PREDICT_SVM_CLASSIFIER (mpg,cyl,disp,wt,qsec,vs,gear,carb USING PARAMETERS model_
name='mySvmClassModel') FROM mtcars;
PREDICT_SVM_CLASSIFIER
```

PREDICT_SVM_REGRESSOR

Applies an SVM model on an input table or view.

Important: Before using a machine learning function, be aware that all the ongoing transactions might be committed.

Syntax

```
PREDICT_SVM_REGRESSOR(input_columns
    USING PARAMETERS model_name='model_name'
    [, match_by_pos = 'method'])
```

Arguments

<code>input_columns</code>	A comma-separated list of the columns to be used for prediction.
----------------------------	--

Parameters

<code>model_name='model_name'</code>	The name of the model. Model names are case-insensitive.
<code>match_by_pos= 'method'</code>	(Optional) Valid Values: <ul style="list-style-type: none">• false (default): Input columns will be matched to features in the model based on their names.• true: Input columns will be matched to features in the model based on their position in the list of indicated input columns.

Return

Return data type: FLOAT	Returns the predicted value.
-------------------------	------------------------------

Examples

This example shows how you can use the `PREDICT_SVM_REGRESSOR` function on the `faithful` table:

```
=> SELECT PREDICT_SVM_REGRESSOR(waiting USING PARAMETERS model_name='mySvmRegModel')
       FROM faithful ORDER BY id;
PREDICT_SVM_REGRESSOR
-----

REVERSE_NORMALIZE

Reverses the normalization transformation on normalized data, thereby de-normalizing the normalized data. If normalized data is used as the input, the original data is returned. If you specify a column that is not in the specified model, `REVERSE_NORMALIZE` returns that column unchanged.

Important: Before using a machine learning function, be aware that all the ongoing transactions might be committed.

Syntax

```
REVERSE_NORMALIZE ( col1, col2 ..., coln  
                    USING PARAMETERS model_name='model_name');
```

Arguments

<code>col1, col2 ..., coln</code>	The columns to use from the input table or view.
-----------------------------------	--

Parameters

<code>model_name</code>	The name of the model. Model names are case-insensitive. Value must be VARCHAR.
-------------------------	---

Privileges

To use REVERSE_NORMALIZE, you must either be the dbadmin, owner of the model or have USAGE privileges. There are no privileges needed on the function itself.

See [GRANT \(Schema\)](#) and [GRANT \(Table\)](#).

Examples

This example shows how you can use the REVERSE_NORMALIZE function on the hp and cyl columns in the mtcars table, where hp is in the normalization model and cyl is not in the normalization model.

```
=> SELECT REVERSE_NORMALIZE (hp, cyl USING PARAMETERS model_name = 'mtcars_normfit') FROM mtcars;  
hp   | cyl

- [Normalizing Data](#)

RF_CLASSIFIER

Trains a random forest model for classification on an input table or view.

Important: Before using a machine learning function, be aware that all the ongoing transactions might be committed.

Syntax

```
RF_CLASSIFIER ( 'model_name', 'input_relation', 'response_column',
                'predictor_col1, predictor_col2, ..., predictor_coln'

                [USING PARAMETERS [exclude_columns= 'col1, col2, ..., coln',]
                [ntree= value,]
                [mtry= value,]
                [sampling_size= value,]
                [max_depth= value,]
                [max_breadth= value,]
                [min_leaf_size= value,]
                [min_info_gain= value,]
                [nbins= value] ])
```

Arguments

<i>model_name</i>	The name of the model stored as a result of the training. Model names are case insensitive.
<i>input_relation</i>	The table or view that contains the training samples.
<i>response_column</i>	The name of the column in <i>input_relation</i> that represents the dependent variable. This column must be of data type CHAR or VARCHAR.
<i>predictor_columns</i>	A comma-separated list of the columns in the <i>input_relation</i> that represent the independent variables for the model. These columns must be of CHAR, VARCHAR, BOOLEAN, INT and FLOAT data types. CHAR, VARCHAR and BOOLEAN are treated as categorical data types. All other data types are treated as numeric data types.

Parameters

<i>exclude_columns='col1, col2, ..., coln'</i>	(Optional) The columns from <i>input_relation</i> that you want to exclude from the <i>predictor_columns</i> argument.
<i>ntree=value</i>	(Optional) A positive integer number that indicates the number of trees in the forest. Default Value: 20

	Valid Range: (0 to 1000]
<code>mtry=value</code>	<p>(Optional) A positive integer number that indicates the number of features to be considered at the split of a tree node.</p> <p>Default Value: When no value is specified for <code>mtry</code>, its default value is the square root of the total number of predictors.</p> <p>Valid Range: A positive integer number, smaller than or equal to the number of predictors.</p>
<code>sampling_size=value</code>	<p>(Optional) A number that indicates what portion of the input data set will randomly be picked for training each tree</p> <p>Default Value: 0.632</p> <p>Valid Range:(0.0,1.0]</p>
<code>max_depth=value</code>	<p>(Optional) A positive integer number that specifies the maximum depth for growing each tree.</p> <p>Default Value: 5</p> <p>Valid Range: [1 to 100]</p>
<code>max_breadth=value</code>	<p>(Optional) A positive integer number that specifies the maximum number of leaf nodes a tree in the forest can have.</p> <p>Default Value: 32</p> <p>Valid Range: [1 to 1e9]</p>
<code>min_leaf_size=value</code>	<p>(Optional) A positive integer number that specifies the minimum samples each branch must have after splitting a node. A split that causes fewer remaining samples will be discarded.</p> <p>Default Value: 1</p> <p>Valid Range: [1 to 1e6]</p>
<code>min_info_gain=value</code>	<p>(Optional) A non-negative number. Any split with information gain less than this threshold will be discarded.</p>

	Default Value: 0.0 Valid Range: [0.0 to 1.0]
<code>nbins=<i>value</i></code>	(Optional) A positive integer number that indicates the number of bins to use for continuous features. Default Value: 32 Valid Range: [2 to 1000]

Privileges

To use `RF_CLASSIFIER`, you must either be a superuser or have `CREATE` privileges for the schema of the output view and `SELECT` privileges for the input table or view. There are no privileges needed on the function itself.

See [GRANT \(Schema\)](#) and [GRANT \(Table\)](#).

Examples

This example shows how you can use the `RF_CLASSIFIER` function.

```
=> SELECT RF_CLASSIFIER ('myRFModel', 'iris', 'Species', 'Sepal_Length, Sepal_Width, Petal_Length,
Petal_Width'
USING PARAMETERS ntree=100, sampling_size=0.3);

RF_CLASSIFIER
-----
The random forest is trained
(1 row)
```

- [PREDICT_RF_CLASSIFIER](#)
- [PREDICT_RF_CLASSIFIER_CLASSES](#)
- [SUMMARIZE_MODEL](#)

ROC

Returns a table that displays the points on a receiver operating characteristic curve. The ROC function tells you the accuracy of a classification model as you raise the discrimination threshold for the model.

You cannot pass any inputs to the `OVER()` clause.

Important: Before using a machine learning function, be aware that all the ongoing transactions might be committed.

Syntax

```
ROC ( target, probabilities  
      [USING PARAMETERS [num_bins=nBins] ] )  
OVER()
```

Arguments

<i>target</i>	The column in the input table containing the response variable. Must be an integer. Greater values result in more precise approximations of the AUC.
<i>probabilities</i>	The column in the input table where the observation is of class 1. Must be a float.

Parameters

<i>num_bins</i> = <i>nBins</i>	(Optional) Groups rows together, based upon the probability column, for faster processing. You use this parameter to determine the number of different decision boundaries to consider. The parameter partitions the number line from 0 to 1 in <i>nBin</i> points that are equally spaced. It evaluates the table at each of the <i>nBin</i> points. Must be an integer. Default Value: 100
--------------------------------	--

Examples

This example show how you can execute the ROC function on an input table named `mtcars`. The response variables appear in the column `obs`, while the prediction variables appear in the column `pred`.

```
=> SELECT ROC(obs, prob USING PARAMETERS num_bins=2) OVER()
      FROM (SELECT am AS obs,
                PREDICT_LOGISTIC_REG (mpg, cyl, disp, hp, drat, wt,
                                     qsec, vs, gear, carb
                                     USING PARAMETERS model_name='logisticRegModel',
                                                         type='probability') AS prob
                FROM mtcars) AS prediction_output;
```

decision_boundary	false_positive_rate	true_positive_rate	comment
0	1	1	
0.5	0	1	
1	0	0	Of 32 rows, 32 were used and 0 were

ignored
(3 rows)

The first column, `decision_boundary`, indicates the cut-off point for whether to classify a response as 0 or 1. For instance, in each row, if `prob` is greater than `decision_boundary`, the response is classified as 1. If `prob` is less than `decision_boundary`, the response is classified as 0.

The second column, `false_positive_rate`, shows the percentage of false positives (when 0 is classified as 1) in the corresponding `decision_boundary`.

The third column, `true_positive_rate`, shows the percentage of rows that were classified as 1 and also belong to class 1.

RSQUARED

Returns a table with the R-squared value of the predictions in a linear regression model.

Important: Before using a machine learning function, be aware that all the ongoing transactions might be committed.

Syntax

```
RSQUARED ( target, prediction )
         OVER()
```

Important: You cannot pass any inputs to the OVER() clause.

Parameters

<i>target</i>	The response variable for the model. Must be a float.
<i>prediction</i>	The output from the PREDICT_LINEAR_REG function. If that output is saved as a table, the column containing the prediction from the function is used. Must be a float.

Examples

This example shows how you can execute the RSQUARED function on an input table named `faithful_testing`. The response variables appear in the column, `obs`, while the prediction variables appear in the column, `pred`.

```
=> SELECT RSQUARED(obs, prediction) OVER()  
      FROM (SELECT eruptions AS obs,  
              PREDICT_LINEAR_REG (waiting  
                                USING PARAMETERS model_name='linear_reg_faithful') AS  
prediction  
      FROM faithful_testing) AS prediction_output;  
      rsq      |      comment  
-----+-----  
0.819686091991332 | Of 162 rows, 162 were used and 0 were ignored  
(1 row)
```

SUMMARIZE_MODEL

Returns the summary information of a model.

Note: If you are using Vertica 8.1.0, you must include the owner parameter. For Vertica 8.1.1 and later, the owner parameter has been deprecated.

Important: Before using a machine learning function, be aware that all the ongoing transactions might be committed.

Syntax

```
SUMMARIZE_MODEL ( 'model_name' [, 'owner' ] )
```

Parameters

<i>model_name</i>	The name of the model you want to summarize. Model names are case insensitive.
<i>owner</i>	(Optional) The name of the user who created the model.

Privileges

Any user can see summary information about any model in the database.

Examples

This example shows how you can view the summary of a linear regression model.

```
=> SELECT SUMMARIZE_MODEL('linear_reg_faithful');
-[ RECORD 1 ]-----+-----
SUMMARIZE_MODEL | coeff names : {Intercept, waiting}
coefficients: {-2.067947819, 0.07875927383}
std_err:      {0.21063, 0.0029203}
t_value:      {-9.8178, 26.969}
p_value:      {4.2157e-18, 2.1094e-61}
Number of iterations: 6, Number of skipped samples: 0, Number of processed samples: 162
Call: linearReg(model_name=linear_reg_faithful, input_table=faithful_training, response_
column=eruptions, predictor_columns=waiting,
exclude_columns=, optimizer=bfgs, epsilon=0.0001, max_iterations=50)
```

SVM_CLASSIFIER

Trains the SVM model on an input table or view. You can view the model using [SUMMARIZE_MODEL](#).

Important: Before using a machine learning function, be aware that all the ongoing transactions might be committed.

Syntax

```
SVM_CLASSIFIER ( 'model_name', 'input_relation', 'response_column', 'predictor_columns'
                [USING PARAMETERS [exclude_columns='col1, col2, ... coln',]
```

```
[C='value',]  
[epsilon='value',]  
[max_iterations='value' ] )
```

Arguments

<i>model_name</i>	The name of the model. Model names are case-insensitive.
<i>input_relation</i>	The table or view that contains the training data.
<i>response_column</i>	<p>The name of the column in <i>input_relation</i> that represents the dependent variable, or outcome. The value must be 0 or 1.</p> <p>Valid Types:</p> <ul style="list-style-type: none"> • FLOAT • INT • NUMERIC
<i>predictor_columns</i>	<p>A comma-separated list of the columns in <i>input_relation</i> that represent the independent variables for the model.</p> <p>Valid Types:</p> <ul style="list-style-type: none"> • INT • FLOAT • NUMERIC <p>If the column name contains special characters, it must use double quotes.</p>

Parameters

<code>exclude_columns='col1, col2, ... coln'</code>	<p>(Optional) The columns from <i>input_relation</i> that you want to exclude from the <i>input_columns</i> argument.</p> <p>Default Value: Empty</p>
<code>C='value'</code>	(Optional) Sets the weight for misclassification cost.

	The algorithm minimizes the regularization cost and the misclassification cost. Default Value: 1.0
epsilon= <i>value</i>	(Optional) Used to control accuracy. Default Value: 1e-3
max_iterations= <i>value</i>	(Optional) Determines the maximum number of iterations that the algorithm performs before achieving the specified accuracy result. Default Value: 100

Privileges

To use SVM_CLASSIFIER, you must either be a superuser or have CREATE privileges for the schema of the output view and SELECT privileges for the input table or view. There are no privileges needed on the function itself.

See [GRANT \(Schema\)](#) and [GRANT \(Table\)](#).

Examples

This example shows how you can use the SVM_CLASSIFIER function on the mtcars table:

```
=> SELECT SVM_CLASSIFIER('mySvmClassModel', 'mtcars', 'am',  
  'mpg,cyl,disp,hp,drat,wt,qsec,vs,gear,carb'  
  USING PARAMETERS exclude_columns = 'hp,drat');  
  
SVM_CLASSIFIER  
-----  
Finished in 15 iterations.  
Accepted Rows: 32 Rejected Rows: 0  
(1 row)
```

See Also

SVM_REGRESSOR

Trains the SVM model on an input table or view. You can view the model using [SUMMARIZE_MODEL](#).

Important: Before using a machine learning function, be aware that all the ongoing transactions might be committed.

Syntax

```
SVM_REGRESSOR ( 'model_name', 'input_relation', 'response_column', 'predictor_columns'  
                [USING PARAMETERS [exclude_columns='col1, col2, ... coln',]  
                [error_tolerance = value,]  
                [C=value,]  
                [epsilon= value,]  
                [max_iterations= value] ] )
```

Arguments

<i>model_name</i>	The name of the model. Model names are case-insensitive.
<i>input_relation</i>	The table or view that contains the training data.
<i>response_column</i>	The name of the column in <i>input_relation</i> that represents the dependent variable, or outcome. Valid Types: <ul style="list-style-type: none">• FLOAT• INT• NUMERIC
<i>predictor_columns</i>	A comma-separated list of the columns in <i>input_relation</i> that represent the independent variables for the model. Valid Types:

	<ul style="list-style-type: none"> • FLOAT • INT • NUMERIC <p>If the column name contains special characters, it must use double quotes.</p>
--	---

Parameters

<code>exclude_columns='col1, col2, ... coln'</code>	<p>(Optional) The columns from <code>input_relation</code> that you want to exclude from the <code>input_columns</code> argument.</p> <p>Default Value: Empty</p>
<code>error_tolerance=value</code>	<p>(Optional) Defines the acceptable error margin. Any data points outside this region add a penalty to the cost function.</p> <p>Default Value: 1.0</p>
<code>C=value</code>	<p>(Optional) Sets the weight for misclassification cost. The algorithm minimizes the regularization cost and the misclassification cost.</p> <p>Default Value: 1.0</p>
<code>epsilon=value</code>	<p>(Optional) Used to control accuracy.</p> <p>Default Value: 1e-3</p>
<code>max_iterations=value</code>	<p>(Optional) Determines the maximum number of iterations that the algorithm performs before achieving the specified accuracy result.</p> <p>Default Value: 100</p>

Privileges

To use `SVM_REGRESSOR`, you must either be a superuser or have `CREATE` privileges for the schema of the output view and `SELECT` privileges for the input table or view. There are no

privileges needed on the function itself.

See [GRANT \(Schema\)](#) and [GRANT \(Table\)](#).

Examples

This example shows how you can use the `SVM_REGRESSOR` function on the `faithful` table:

```
=> SELECT SVM_REGRESSOR('mySvmRegModel', 'faithful', 'eruptions', 'waiting'  
                        USING PARAMETERS error_tolerance=0.1, max_iterations=100);  
  
SVM_REGRESSOR  
-----  
Finished in 5 iterations.  
Accepted Rows: 272 Rejected Rows: 0  
(1 row)
```

Mathematical Functions

Some of these functions are provided in multiple forms with different argument types. Except where noted, any given form of a function returns the same data type as its argument. The functions working with `DOUBLE PRECISION` data could vary in accuracy and behavior in boundary cases depending on the host system.

ABS

Returns the absolute value of the argument. The return value has the same data type as the argument..

Behavior Type

Immutable

Syntax

`ABS (expression)`

Parameters

<i>expression</i>	Is a value of type <code>INTEGER</code> or <code>DOUBLE PRECISION</code>
-------------------	--

Examples

```
SELECT ABS(-28.7);
 abs
-----
 28.7
(1 row)
```

ACOS

Returns a DOUBLE PRECISION value representing the trigonometric inverse cosine of the argument.

Behavior Type

Immutable

Syntax

`ACOS (expression)`

Parameters

<i>expression</i>	Is a value of type DOUBLE PRECISION
-------------------	-------------------------------------

Example

```
SELECT ACOS (1);
acos
-----
0
(1 row)
```

ASIN

Returns a DOUBLE PRECISION value representing the trigonometric inverse sine of the argument.

Behavior Type

Immutable

Syntax

`ASIN (expression)`

Parameters

<i>expression</i>	Is a value of type DOUBLE PRECISION
-------------------	-------------------------------------

Example

```
SELECT ASIN(1);
      asin
-----
1.5707963267949
(1 row)
```

ATAN

Returns a DOUBLE PRECISION value representing the trigonometric inverse tangent of the argument.

Behavior Type

Immutable

Syntax

`ATAN (expression)`

Parameters

<i>expression</i>	Is a value of type DOUBLE PRECISION
-------------------	-------------------------------------

Example

```
SELECT ATAN(1);
       atan
-----
0.785398163397448
(1 row)
```

ATAN2

Returns a DOUBLE PRECISION value representing the trigonometric inverse tangent of the arithmetic dividend of the arguments.

Behavior Type

Immutable

Syntax

```
ATAN2 ( quotient, divisor )
```

Parameters

<i>quotient</i>	Is an expression of type DOUBLE PRECISION representing the quotient
<i>divisor</i>	Is an expression of type DOUBLE PRECISION representing the divisor

Example

```
SELECT ATAN2(2,1);
       ATAN2
-----
1.10714871779409
(1 row)
```

CBRT

Returns the cube root of the argument. The return value has the type DOUBLE PRECISION.

Behavior Type

Immutable

Syntax

```
CBRT ( expression )
```

Parameters

<i>expression</i>	Value of type DOUBLE PRECISION
-------------------	--------------------------------

Examples

```
SELECT CBRT(27.0);  
  cbrt  
-----  
     3  
(1 row)
```

CEILING (CEIL)

Rounds the returned value up to the next whole number. Any expression that contains even a slight decimal is rounded up.

Behavior Type

Immutable

Syntax

```
CEILING ( expression ) CEIL ( expression )
```

Parameters

<i>expression</i>	Is a value of type INTEGER or DOUBLE PRECISION
-------------------	--

Notes

CEILING is the opposite of [FLOOR](#), which rounds the returned value down:

```
=> SELECT CEIL(48.01) AS ceiling, FLOOR(48.01) AS floor;
   ceiling | floor
-----+-----
         49 |    48
(1 row)
```

Examples

```
=> SELECT CEIL(-42.8);
   CEIL
-----
    -42
(1 row)

SELECT CEIL(48.01);
   CEIL
-----
     49
(1 row)
```

COS

Returns a DOUBLE PRECISION value that represents the trigonometric cosine of the passed parameter.

Behavior Type

Immutable

Syntax

`COS (expression)`

Parameters

<i>expression</i>	An expression of type DOUBLE PRECISION
-------------------	--

Example

```
SELECT COS(-1);
      COS
-----
0.54030230586814
(1 row)
```

COSH

Returns a DOUBLE PRECISION value that represents the hyperbolic cosine of the passed parameter.

Behavior Type

Immutable

Syntax

`COSH (expression)`

Parameters

<i>expression</i>	An expression of type DOUBLE PRECISION
-------------------	--

Example

```
=> SELECT COSH(-1);
      COSH
-----
1.54308063481524
```

COT

Returns a DOUBLE PRECISION value representing the trigonometric cotangent of the argument.

Behavior Type

Immutable

Syntax

COT (*expression*)

Parameters

<i>expression</i>	Is a value of type DOUBLE PRECISION
-------------------	-------------------------------------

Example

```
SELECT COT(1);
      cot
-----
0.642092615934331
(1 row)
```

DEGREES

Converts an expression from [RADIAN](#)S to fractional degrees, or from degrees, minutes, and seconds to fractional degrees. The return value has the type DOUBLE PRECISION.

Behavior Type

Immutable

Syntax 1

DEGREES (*radians*)

Syntax 2

DEGREES (*degrees, minutes, seconds*)

Parameters

<i>radians</i>	A unit of angular measure, 2π radians is equal to a full rotation.
<i>degrees</i>	A unit of angular measure, equal to 1/360 of a full rotation.
<i>minutes</i>	A unit of angular measurement, representing 1/60 of a degree.
<i>seconds</i>	A unit of angular measurement, representing 1/60 of a minute.

Examples

```
SELECT DEGREES(0.5);
      DEGREES
-----
28.6478897565412
(1 row)

SELECT DEGREES(1,2,3);
      DEGREES
-----
1.034166666666667
(1 row)
```

DISTANCE

Returns the distance (in kilometers) between two points. You specify the latitude and longitude of both the starting point and the ending point. You can also specify the radius of curvature for

greater accuracy when using an ellipsoidal model.

Behavior Type

Immutable

Syntax

```
DISTANCE ( Lat0, Lon0, Lat1, Lon1, radius_of_curvature )
```

Parameters

<i>Lat0</i>	Specifies the latitude of the starting point.
<i>Lon0</i>	Specifies the longitude of the starting point.
<i>Lat1</i>	Specifies the latitude of the ending point
<i>Lon1</i>	Specifies the longitude of the ending point.
<i>radius_of_curvature</i>	Specifies the radius of the curvature of the earth at the midpoint between the starting and ending points. This parameter allows for greater accuracy when using an ellipsoidal earth model. If you do not specify this parameter, it defaults to the WGS-84 average r1 radius, about 6371.009 km.

Example

This example finds the distance in kilometers for 1 degree of longitude at latitude 45 degrees, assuming earth is spherical.

```
SELECT DISTANCE(45,0, 45,1);
      DISTANCE
-----
78.6262959272162
(1 row)
```

DISTANCEV

Returns the distance (in kilometers) between two points using the Vincenty formula. Because the Vincenty formula includes the parameters of the WGS-84 ellipsoid model, you need not specify a radius of curvature. You specify the latitude and longitude of both the starting point and the ending point. This function is more accurate, but will be slower, than the `DISTANCE` function.

Behavior Type

Immutable

Syntax

```
DISTANCEV (lat0, lon0, lat1, lon1);
```

Parameters

<i>lat0</i>	Specifies the latitude of the starting point.
<i>lon0</i>	Specifies the longitude of the starting point.
<i>lat1</i>	Specifies the latitude of the ending point.
<i>lon1</i>	Specifies the longitude of the ending point.

Example

This example finds the distance in kilometers for 1 degree of longitude at latitude 45 degrees, assuming earth is ellipsoidal.

```
SELECT DISTANCEV(45,0, 45,1);
       distanceV
-----
78.8463347095916
(1 row)
```

EXP

Returns the exponential function, e to the power of a number. The return value has the same data type as the argument.

Behavior Type

Immutable

Syntax

EXP (*exponent*)

Parameters

<i>exponent</i>	Is an expression of type INTEGER or DOUBLE PRECISION
-----------------	--

Example

```
SELECT EXP(1.0);
      exp
-----
2.71828182845905
(1 row)
```

FLOOR

Rounds the returned value down to the next whole number. For example, each of these functions evaluates to 5:

```
floor(5.01)
floor(5.5)
floor(5.99)
```

Behavior Type

Immutable

Syntax

FLOOR (*expression*)

Parameters

<i>expression</i>	Is an expression of type INTEGER or DOUBLE PRECISION.
-------------------	---

Notes

FLOOR is the opposite of [CEILING](#), which rounds the returned value up:

```
=> SELECT FLOOR(48.01) AS floor, CEIL(48.01) AS ceiling;
 floor | ceiling
-----+-----
    48 |      49
(1 row)
```

Examples

```
=> SELECT FLOOR((TIMESTAMP '2005-01-17 10:00' - TIMESTAMP '2005-01-01') / INTERVAL '7');
 FLOOR
-----
      2
(1 row)

=> SELECT FLOOR(-42.8);
 FLOOR
-----
    -43
(1 row)

=> SELECT FLOOR(42.8);
 FLOOR
-----
     42
(1 row)
```

Although the following example looks like an INTEGER, the number on the left is 2^{49} as an INTEGER, but the number on the right is a FLOAT:

```
=> SELECT 1<<49, FLOOR(1 << 49);
   ?column?      |      floor
-----+-----
 562949953421312 | 562949953421312
(1 row)
```

Compare the above example to:

```
=> SELECT 1<<50, FLOOR(1 << 50);
   ?column?      |      floor
-----+-----
1125899906842624 | 1.12589990684262e+15
(1 row)
```

HASH

Calculates a hash value over the function arguments, producing a value in the range $0 \leq x < 2^{63}$.

The HASH function is typically used to segment a projection over a set of cluster nodes. The function selects a specific node for each row based on the values of the row columns. The HASH function distributes data evenly across the cluster, which facilitates optimal query execution.

Behavior Type

Immutable

Syntax

```
HASH ( expression-arg[,... ] )
```

Parameters

<i>expression-arg</i>	An expression of any data type, up to 32 arguments. Any functions that are included in <i>expression</i> must be deterministic. For the purpose of hash segmentation, each expression typically resolves to a column reference .
-----------------------	--

Examples

```
=> SELECT HASH(product_price, product_cost) FROM product_dimension
      WHERE product_price = '11';
      hash
-----
4157497907121511878
1799398249227328285
3250220637492749639
(3 rows)
```

See Also

[Hash Segmentation Clause](#)

LN

Returns the natural logarithm of the argument. The return data type is the same as the argument.

Behavior Type

Immutable

Syntax

LN (*expression*)

Parameters

<i>expression</i>	Is an expression of type INTEGER or DOUBLE PRECISION
-------------------	--

Example

```
SELECT LN(2);
ln
```

```
-----  
0.693147180559945  
(1 row)
```

LOG

Returns the logarithm to the specified base of the argument. The data type of the return value is the same data type as the passed parameter.

Behavior Type

Immutable

Syntax

```
LOG ( [ base, ] expression )
```

Parameters

<i>base</i>	Specifies the base (default is base 10)
<i>expression</i>	An expression of type INTEGER or DOUBLE PRECISION

Examples

```
=> SELECT LOG(2.0, 64);  
LOG  
-----  
6  
(1 row)  
  
SELECT LOG(100);  
LOG  
-----  
2  
(1 row)
```

LOG10

Returns the base 10 logarithm of the argument, also known as the *common logarithm*. The data type of the return value is the same as the data type of the passed parameter.

Behavior Type

Immutable

Syntax

```
LOG10 ( expression )
```

Parameters

<i>expression</i>	An expression of type INTEGER or DOUBLE PRECISION
-------------------	---

Examples

```
=> SELECT LOG10(30);
      LOG10
-----
 1.47712125471966
(1 row)
```

MOD

Returns the remainder of a division operation. MOD is also called `modulo`.

Behavior Type

Immutable

Syntax

`MOD(expression1, expression2)`

Parameters

<i>expression1</i>	Specifies the dividend (INTEGER, NUMERIC, or FLOAT)
<i>expression2</i>	Specifies the divisor (type same as dividend)

Notes

When computing `mod(N,M)`, the following rules apply:

- If either N or M is the null value, then the result is the null value.
- If M is zero, then an exception condition is raised: data exception — division by zero.
- Otherwise, the result is the unique exact numeric value R with scale 0 (zero) such that all of the following are true:
 - R has the same sign as N.
 - The absolute value of R is less than the absolute value of M.
 - $N = M * K + R$ for some exact numeric value K with scale 0 (zero).

Examples

```
SELECT MOD(9,4);
mod
-----
1
(1 row)

SELECT MOD(10,3);
mod
-----
1
(1 row)

SELECT MOD(-10,3);
mod
```

```
-----  
-1  
(1 row)  
SELECT MOD(-10,-3);  
mod  
-----  
-1  
(1 row)  
SELECT MOD(10,-3);  
mod  
-----  
1  
(1 row)
```

MOD(<float>, 0) gives an error:

```
=> SELECT MOD(6.2,0);  
ERROR: numeric division by zero
```

PI

Returns the constant pi (Π), the ratio of any circle's circumference to its diameter in Euclidean geometry. The return type is DOUBLE PRECISION.

Behavior Type

Immutable

Syntax

PI()

Examples

```
SELECT PI();  
pi  
-----  
3.14159265358979  
(1 row)
```

POWER (or POW)

Returns a DOUBLE PRECISION value representing one number raised to the power of another number. You can use either POWER or POW as the function name.

Behavior Type

Immutable

Syntax

```
POWER ( expression1, expression2 )
```

Parameters

<i>expression1</i>	Is an expression of type DOUBLE PRECISION that represents the base
<i>expression2</i>	Is an expression of type DOUBLE PRECISION that represents the exponent

Example

```
SELECT POWER(9.0, 3.0);
power
-----
    729
(1 row)
```

RADIANS

Returns a DOUBLE PRECISION value representing an angle expressed in radians. You can express the input angle in [DEGREES](#), and optionally include minutes and seconds.

Behavior Type

Immutable

Syntax

RADIANS (*degrees* [, *minutes*, *seconds*])

Parameters

<i>degrees</i>	A unit of angular measurement, representing 1/360 of a full rotation.
<i>minutes</i>	A unit of angular measurement, representing 1/60 of a degree.
<i>seconds</i>	A unit of angular measurement, representing 1/60 of a minute.

Examples

```
SELECT RADIANS(45);
       RADIANS
-----
0.785398163397448
(1 row)

SELECT RADIANS (1,2,3);
       RADIANS
-----
0.018049613347708
(1 row)
```

RANDOM

Returns a uniformly-distributed random number x , where $0 \leq x < 1$.

Typical pseudo-random generators accept a seed, which is set to generate a reproducible pseudo-random sequence. Vertica, however, distributes SQL processing over a cluster of nodes, where each node generates its own independent random sequence.

Results depending on RANDOM are not reproducible because the work might be divided differently across nodes. Therefore, Vertica automatically generates truly random seeds for each node each time a request is executed and does not provide a mechanism for forcing a specific seed.

Behavior Type

Volatile

Syntax

```
RANDOM()
```

Parameters

RANDOM has no arguments. Its result is a FLOAT8 data type (also called [DOUBLE PRECISION](#)).

Examples

In the following example, the result is a float, which is ≥ 0 and < 1.0 :

```
SELECT RANDOM();
       random
-----
0.211625560652465
(1 row)
```

RANDOMINT

Accepts and returns an INT8 value. `RANDOMINT(n)` returns one of the *n* integers from 0 through *n* - 1.

Typical pseudo-random generators accept a seed, which is set to generate a reproducible pseudo-random sequence. Vertica, however, distributes SQL processing over a cluster of nodes, where each node generates its own independent random sequence.

Results depending on RANDOM are not reproducible because the work might be divided differently across nodes. Therefore, Vertica automatically generates truly random seeds for each node each time a request is executed and does not provide a mechanism for forcing a specific seed.

Behavior Type

Volatile

Syntax

```
RANDOMINT ( n )
```

Parameters

The value accepted is any positive integer (*n*) between the values 1 and 9,223,372,036,854,775,807.

For general information on integer data types, refer to the section, [INTEGER](#).

Restrictions

If you provide a negative value, or if you exceed the maximum value, Vertica returns an error.

Example

In the following example, the result is an INT8, which is ≥ 0 and $< n$, randomly chosen from the set {0,1,2,3,4}.

```
=> SELECT RANDOMINT(5);
RANDOMINT
-----
          3
(1 row)
```

RANDOMINT_crypto

Accepts and returns an INT8 value. `RANDOMINT_crypto (n)` returns one of the *n* integers from 0 through *n* - 1. For this cryptographic random number generator, Vertica uses `RAND_` bytes to provide the random value.

Behavior Type

Volatile

Syntax

```
RANDOMINT_crypto ( n )
```

Parameters

The value accepted is any positive integer (n) between the values 1 and 9,223,372,036,854,775,807.

For general information on integer data types, see [INTEGER](#).

Restrictions

If you provide a negative value, or if you exceed the maximum value, Vertica returns an error.

Examples

In the following example, notice that the result is an INT8, which is ≥ 0 and $< n$, randomly chosen from the set {0,1,2,3,4}.

```
=> SELECT RANDOMINT_crypto(5);
RANDOMINT_crypto
-----
                3
(1 row)
```

ROUND

Rounds a value to a specified number of decimal places, retaining the original precision and scale. Fractions greater than or equal to .5 are rounded up. Fractions less than .5 are rounded down (truncated).

Behavior Type

Immutable

Syntax

```
ROUND ( expression [ , places ] )
```

Parameters

<i>expression</i>	Is an expression of type NUMERIC or DOUBLE PRECISION (FLOAT).
<i>places</i>	An INTEGER value. When places is a positive integer, Vertica rounds the value to the right of the decimal point. When places is a negative integer, Vertica rounds the value on the left side of the decimal point.

Notes

Using ROUND with a NUMERIC datatype returns NUMERIC, retaining the original precision and scale.

```
=> SELECT ROUND(3.5);  
ROUND  
-----  
    4.0  
(1 row)
```

Examples

```
=> SELECT ROUND(2.0, 1.0) FROM dual;  
ROUND  
-----  
    2.0  
(1 row)  
  
=> SELECT ROUND(12.345, 2.0);  
ROUND  
-----  
   12.350  
(1 row)  
  
=> SELECT ROUND(3.4444444444444444);  
ROUND  
-----  
  3.0000000000000000  
(1 row)  
  
=> SELECT ROUND(3.14159, 3);  
ROUND
```

```

-----
 3.14200
(1 row)

=> SELECT ROUND(1234567, -3);
      ROUND
-----
1235000
(1 row)

=> SELECT ROUND(3.4999, -1);
      ROUND
-----
 0.0000
(1 row)

```

The following example creates a table with two columns, adds one row of values, and shows sample rounding to the left and right of a decimal point.

```

=> CREATE TABLE sampleround (roundcol1 NUMERIC, roundcol2 NUMERIC);
CREATE TABLE

=> INSERT INTO sampleround VALUES (1234567, .1234567);
      OUTPUT
-----
          1
(1 row)

=> SELECT ROUND(roundcol1,-3) AS pn3, ROUND(roundcol1,-4) AS pn4, ROUND(roundcol1,-5) AS pn5 FROM
sampleround;

          pn3          |          pn4          |          pn5
-----+-----+-----
1235000.00000000000000 | 1230000.00000000000000 | 1200000.00000000000000
(1 row)

=> SELECT ROUND(roundcol2,3) AS p3, ROUND(roundcol2,4) AS p4, ROUND(roundcol2,5) AS p5 FROM
sampleround;

          p3          |          p4          |          p5
-----+-----+-----
 0.1230000000000000 | 0.1235000000000000 | 0.1234600000000000
(1 row)

```

SIGN

Returns a DOUBLE PRECISION value of -1, 0, or 1 representing the arithmetic sign of the argument.

Behavior Type

Immutable

Syntax

`SIGN (expression)`

Parameters

<i>expression</i>	Is an expression of type DOUBLE PRECISION
-------------------	---

Examples

```
SELECT SIGN(-8.4);
 sign
-----
   -1
(1 row)
```

SIN

Returns a DOUBLE PRECISION value that represents the trigonometric sine of the passed parameter.

Behavior Type

Immutable

Syntax

`SIN (expression)`

Parameters

<i>expression</i>	An expression of type DOUBLE PRECISION
-------------------	--

Example

```
SELECT SIN(30 * 2 * 3.14159 / 360);
      SIN
-----
0.4999999616987256
(1 row)
```

SINH

Returns a DOUBLE PRECISION value that represents the hyperbolic sine of the passed parameter.

Behavior Type

Immutable

Syntax

`SINH (expression)`

Parameters

<i>expression</i>	An expression of type DOUBLE PRECISION
-------------------	--

Example

```
=> SELECT SINH(30 * 2 * 3.14159 / 360);
      SINH
-----
0.547852969600632
```

SQRT

Returns a DOUBLE PRECISION value representing the arithmetic square root of the argument.

Behavior Type

Immutable

Syntax

`SQRT (expression)`

Parameters

<i>expression</i>	Is an expression of type DOUBLE PRECISION
-------------------	---

Examples

```
SELECT SQRT(2);
       sqrt
-----
1.4142135623731
(1 row)
```

TAN

Returns a DOUBLE PRECISION value that represents the trigonometric tangent of the passed parameter.

Behavior Type

Immutable

Syntax

`TAN (expression)`

Parameters

<i>expression</i>	An expression of type DOUBLE PRECISION
-------------------	--

Example

```
=> SELECT TAN(30);  
      TAN  
-----  
-6.40533119664628  
(1 row)
```

TANH

Returns a DOUBLE PRECISION value that represents the hyperbolic tangent of the passed parameter.

Behavior Type

Immutable

Syntax

```
TANH ( expression )
```

Parameters

<i>expression</i>	An expression of type DOUBLE PRECISION
-------------------	--

Example

```
=> SELECT TANH(-1);  
      TANH  
-----
```

```
-0.761594155955765
```

TRUNC

Returns the *expression* value fully truncated (toward zero). Supplying a *places* argument truncates the expression to the number of decimal places you indicate.

Behavior Type

Immutable

Syntax

```
TRUNC ( expression [ , places ] )
```

Parameters

<i>expression</i>	Is an expression of type NUMERIC or DOUBLE PRECISION (FLOAT).
<i>places</i>	An INTEGER value. When places is a positive integer, Vertica truncates the value to the right of the decimal point. When places is a negative integer, Vertica truncates the value on the left side of the decimal point.

Notes

Using TRUNC with a NUMERIC datatype returns NUMERIC, retaining the original precision and scale.

```
=> SELECT TRUNC(3.5);  
TRUNC  
-----  
3.0  
(1 row)
```

Examples

```
=> SELECT TRUNC(42.8);
TRUNC
-----
 42.0
(1 row)

=> SELECT TRUNC(42.4382, 2);
TRUNC
-----
42.4300
(1 row)
```

The following example creates a table with two columns, adds one row of values, and shows sample truncating to the left and right of a decimal point.

```
=> CREATE TABLE sampletrunc (truncol1 NUMERIC, truncol2 NUMERIC);
CREATE TABLE

=> INSERT INTO sampletrunc VALUES (1234567, .1234567);
OUTPUT
-----
      1
(1 row)

=> SELECT TRUNC(truncol1,-3) AS p3, TRUNC(truncol1,-4) AS p4, TRUNC(truncol1,-5) AS p5 FROM
sampletrunc;

      p3          |          p4          |          p5
-----+-----+-----
1234000.00000000000000 | 1230000.00000000000000 | 1200000.00000000000000
(1 row)

=> SELECT TRUNC(truncol2,3) AS p3, TRUNC(truncol2,4) AS p4, TRUNC(truncol2,5) AS p5 FROM sampletrunc;

      p3          |          p4          |          p5
-----+-----+-----
0.1230000000000000 | 0.1234000000000000 | 0.1234500000000000
(1 row)
```

WIDTH_BUCKET

Constructs equiwidth histograms, in which the histogram range is divided into intervals (buckets) of identical sizes. In addition, values below the low bucket return 0, and values above the high bucket return bucket_count +1. Returns an integer value.

Behavior Type

Immutable

Syntax

```
WIDTH_BUCKET ( expression, hist_min, hist_max, bucket_count )
```

Parameters

<i>expression</i>	The expression for which the histogram is created. This expression must evaluate to a numeric or datetime value or to a value that can be implicitly converted to a numeric or datetime value. If <i>expression</i> evaluates to null, then the <i>expression</i> returns null.
<i>hist_min</i>	An expression that resolves to the low boundary of bucket 1. Must also evaluate to numeric or datetime values and cannot evaluate to null.
<i>hist_max</i>	An expression that resolves to the high boundary of bucket <i>bucket_count</i> . Must also evaluate to a numeric or datetime value and cannot evaluate to null.
<i>bucket_count</i>	An expression that resolves to a constant, indicating the number of buckets. This expression always evaluates to a positive INTEGER.

Notes

- WIDTH_BUCKET divides a data set into buckets of equal width. For example, Age = 0–20, 20–40, 40–60, 60–80. This is known as an equiwidth histogram.
- When using WIDTH_BUCKET pay attention to the minimum and maximum boundary values. Each bucket contains values equal to or greater than the base value of that bucket, so that age ranges of 0–20, 20–40, and so on, are actually 0–19.99 and 20–39.999.
- WIDTH_BUCKET accepts the following data types: (FLOAT and/or INT), (TIMESTAMP and/or DATE and/or TIMESTAMPTZ), or (INTERVAL and/or TIME).

Examples

The following example returns five possible values and has three buckets: 0 [Up to 100), 1 [100–300), 2 [300–500), 3 [500–700), and 4 [700 and up):

```
SELECT product_description, product_cost, WIDTH_BUCKET(product_cost, 100, 700, 3);
```

The following example creates a nine-bucket histogram on the `annual_income` column for customers in Connecticut who are female doctors. The results return the bucket number to an “Income” column, divided into eleven buckets, including an underflow and an overflow. Note that if customers had an annual incomes greater than the maximum value, they would be assigned to an overflow bucket, 10:

```
SELECT customer_name, annual_income, WIDTH_BUCKET (annual_income, 100000, 1000000, 9) AS "Income"  
FROM public.customer_dimension WHERE customer_state='CT'  
AND title='Dr.' AND customer_gender='Female' AND household_id < '1000'  
ORDER BY "Income";
```

In the following result set, the reason there is a bucket 0 is because buckets are numbered from 1 to `bucket_count`. Anything less than the given value of `hist_min` goes in bucket 0, and anything greater than the given value of `hist_max` goes in the bucket `bucket_count+1`. In this example, bucket 9 is empty, and there is no overflow. The value 12,283 is less than 100,000, so it goes into the underflow bucket.

customer_name	annual_income	Income
Joanna A. Nguyen	12283	0
Amy I. Nguyen	109806	1
Juanita L. Taylor	219002	2
Carla E. Brown	240872	2
Kim U. Overstreet	284011	2
Tiffany N. Reyes	323213	3
Rebecca V. Martin	324493	3
Betty . Roy	476055	4
Midori B. Young	462587	4
Martha T. Brown	687810	6
Julie D. Miller	616509	6
Julie Y. Nielson	894910	8
Sarah B. Weaver	896260	8
Jessica C. Nielson	861066	8

NULL-handling Functions

NULL-handling functions take arguments of any type, and their return type is based on their argument types.

COALESCE

Returns the value of the first non-null expression in the list. If all expressions evaluate to null, then COALESCE returns null.

COALESCE conforms to the ANSI SQL-92 standard.

Behavior Type

Immutable

Syntax

```
COALESCE ( expression[,...] );
```

Example

```
=> SELECT product_description, COALESCE(
       lowest_competitor_price, highest_competitor_price, average_competitor_price) AS price
   FROM product_dimension LIMIT 10;
 product_description | price
-----+-----
Brand #313 corn muffins | 565
Brand #591 hot dogs | 323
Brand #1247 american cheese | 263
Brand #1510 whole milk | 183
Brand #2549 vegetable soup | 491
Brand #4520 catfish | 113
Brand #4684 onions | 56
Brand #6078 salmon | 195
Brand #6924 bananas | 80
Brand #7912 green peppers | 180
(10 rows)
```

See Also

- [ISNULL](#)

IFNULL

Returns the value of the first non-null expression in the list.

IFNULL is an alias of [NVL](#).

Behavior Type

Immutable

Syntax

```
IFNULL ( expression1 , expression2 );
```

Parameters

- If *expression1* is null, then IFNULL returns *expression2*.
- If *expression1* is not null, then IFNULL returns *expression1*.

Notes

- [COALESCE](#) is the more standard, more general function.
- IFNULL is equivalent to ISNULL.
- IFNULL is equivalent to COALESCE except that IFNULL is called with only two arguments.
- ISNULL(*a*, *b*) is different from *x* IS NULL.
- The arguments can have any data type supported by Vertica.

- Implementation is equivalent to the CASE expression. For example:

```
CASE WHEN expression1 IS NULL THEN expression2  
ELSE expression1 END;
```

- The following statement returns the value 140:

```
SELECT IFNULL(NULL, 140) FROM employee_dimension;
```

- The following statement returns the value 60:

```
SELECT IFNULL(60, 90) FROM employee_dimension;
```

Examples

```
=> SELECT IFNULL (SCORE, 0.0) FROM TESTING;  
IFNULL  
-----  
100.0  
87.0  
.0  
.0  
.0  
(5 rows)
```

- [ISNULL](#)

ISNULL

Returns the value of the first non-null expression in the list.

ISNULL is an alias of [NVL](#).

Behavior Type

Immutable

Syntax

```
ISNULL ( expression1 , expression2 );
```

Parameters

- If *expression1* is null, then ISNULL returns *expression2*.
- If *expression1* is not null, then ISNULL returns *expression1*.

Notes

- [COALESCE](#) is the more standard, more general function.
- ISNULL is equivalent to COALESCE except that ISNULL is called with only two arguments.
- ISNULL(*a*, *b*) is different from *x* IS NULL.
- The arguments can have any data type supported by Vertica.
- Implementation is equivalent to the CASE expression. For example:

```
CASE WHEN expression1 IS NULL THEN expression2  
ELSE expression1 END;
```

- The following statement returns the value 140:

```
SELECT ISNULL(NULL, 140) FROM employee_dimension;
```

- The following statement returns the value 60:

```
SELECT ISNULL(60, 90) FROM employee_dimension;
```

Examples

```
SELECT product_description, product_price,  
ISNULL(product_cost, 0.0) AS cost  
FROM product_dimension;
```

product_description	product_price	cost
Brand #59957 wheat bread	405	207
Brand #59052 blueberry muffins	211	140
Brand #59004 english muffins	399	240
Brand #53222 wheat bread	323	94
Brand #52951 croissants	367	121
Brand #50658 croissants	100	94
Brand #49398 white bread	318	25
Brand #46099 wheat bread	242	3
Brand #45283 wheat bread	111	105
Brand #43503 jelly donuts	259	19

NULLIF

Compares two expressions. If the expressions are not equal, the function returns the first expression (expression1). If the expressions are equal, the function returns null.

Behavior Type

Immutable

Syntax

```
NULLIF( expression1, expression2 )
```

Parameters

<i>expression1</i>	Is a value of any data type.
<i>expression2</i>	Must have the same data type as <i>expr1</i> or a type that can be implicitly cast to match <i>expression1</i> . The result has the same type as <i>expression1</i> .

Examples

The following series of statements illustrates one simple use of the NULLIF function.

Creates a single-column table `t` and insert some values:

```
CREATE TABLE t (x TIMESTAMPTZ);
INSERT INTO t VALUES('2009-09-04 09:14:00-04');
INSERT INTO t VALUES('2010-09-04 09:14:00-04');
```

Issue a select statement:

```
SELECT x, NULLIF(x, '2009-09-04 09:14:00 EDT') FROM t;
      x      |      nullif
-----+-----
2009-09-04 09:14:00-04 |
2010-09-04 09:14:00-04 | 2010-09-04 09:14:00-04
SELECT NULLIF(1, 2);
NULLIF
-----
      1
(1 row)
SELECT NULLIF(1, 1);
NULLIF
-----
(1 row)
SELECT NULLIF(20.45, 50.80);
NULLIF
-----
    20.45
(1 row)
```

NULLIFZERO

Evaluates to NULL if the value in the column is 0.

Syntax

`NULLIFZERO(expression)`

Parameters

<i>expression</i>	(INTEGER, DOUBLE PRECISION, INTERVAL, or NUMERIC) Is the string to evaluate for 0 values.
-------------------	---

Example

The TESTING table below shows the test scores for 5 students. Note that test scores are missing for S. Robinson and K. Johnson (NULL values appear in the Score column.)

```
=> SELECT * FROM TESTING;
  Name      | Score
-----+-----
 J. Doe     |    100
 R. Smith   |     87
 L. White   |     0
 S. Robinson |
 K. Johnson |
(5 rows)
```

The SELECT statement below specifies that Vertica should return any 0 values in the Score column as Null. In the results, you can see that Vertica returns L. White's 0 score as Null.

```
=> SELECT Name, NULLIFZERO(Score) FROM TESTING;
  Name      | NULLIFZERO
-----+-----
 J. Doe     |    100
 R. Smith   |     87
 L. White   |
 S. Robinson |
 K. Johnson |
(5 rows)
```

NVL

Returns the value of the first non-null expression in the list.

Behavior Type

Immutable

Syntax

```
NVL ( expression1 , expression2 );
```

Parameters

- If *expression1* is null, then NVL returns *expression2*.
- If *expression1* is not null, then NVL returns *expression1*.

Notes

- [COALESCE](#) is the more standard, more general function.
- NVL is equivalent to COALESCE except that NVL is called with only two arguments.
- The arguments can have any data type supported by Vertica.
- Implementation is equivalent to the CASE expression:

```
CASE WHEN expression1 IS NULL THEN expression2  
ELSE expression1 END;
```

Examples

expression1 is not null, so NVL returns *expression1*:

```
SELECT NVL('fast', 'database');  
nvl  
-----  
fast  
(1 row)
```

expression1 is null, so NVL returns *expression2*:

```
SELECT NVL(null, 'database');
nvl
-----
database
(1 row)
```

expression2 is null, so NVL returns expression1:

```
SELECT NVL('fast', null);
nvl
-----
fast
(1 row)
```

In the following example, expression1 (title) contains nulls, so NVL returns expression2 and substitutes 'Withheld' for the unknown values:

```
SELECT customer_name, NVL(title, 'Withheld') as title
FROM customer_dimension
ORDER BY title;
customer_name | title
-----+-----
Alexander I. Lang | Dr.
Steve S. Harris | Dr.
Daniel R. King | Dr.
Luigi I. Sanchez | Dr.
Duncan U. Carcetti | Dr.
Meghan K. Li | Dr.
Laura B. Perkins | Dr.
Samantha V. Robinson | Dr.
Joseph P. Wilson | Mr.
Kevin R. Miller | Mr.
Lauren D. Nguyen | Mrs.
Emily E. Goldberg | Mrs.
Darlene K. Harris | Ms.
Meghan J. Farmer | Ms.
Bettercare | Withheld
Ameristar | Withheld
Initech | Withheld
(17 rows)
```

See Also

- [CASE Expressions](#)
- [COALESCE](#)
- [ISNULL](#)
- [NVL2](#)

NVL2

Takes three arguments. If the first argument is not NULL, it returns the second argument, otherwise it returns the third argument. The data types of the second and third arguments are implicitly cast to a common type if they don't agree, similar to [COALESCE](#).

Behavior Type

Immutable

Syntax

```
NVL2 ( expression1 , expression2 , expression3 );
```

Parameters

- If *expression1* is not null, then NVL2 returns *expression2*.
- If *expression1* is null, then NVL2 returns *expression3*.

Notes

Arguments two and three can have any data type supported by Vertica.

Implementation is equivalent to the CASE expression:

```
CASE WHEN expression1 IS NOT NULL THEN expression2 ELSE expression3 END;
```

Examples

In this example, *expression1* is not null, so NVL2 returns *expression2*:

```
SELECT NVL2('very', 'fast', 'database');
nv12
-----
fast
(1 row)
```

In this example, *expression1* is null, so NVL2 returns *expression3*:

```
SELECT NVL2(null, 'fast', 'database');
nvl2
-----
database
(1 row)
```

In the following example, expression1 (title) contains nulls, so NVL2 returns expression3 ('Withheld') and also substitutes the non-null values with the expression 'Known':

```
SELECT customer_name, NVL2(title, 'Known', 'Withheld')
as title
FROM customer_dimension
ORDER BY title;
customer_name | title
-----+-----

ZEROIFNULL

Evaluates to 0 if the column is NULL.

Syntax

ZEROIFNULL(*expression*)

Parameters

<i>expression</i>	(INTEGER, DOUBLE PRECISION, INTERVAL, or NUMERIC) Is the string to evaluate for NULL values.
-------------------	--

Example

The TESTING table below shows the test scores for 5 students. Note that L. White's score is 0, and that scores are missing for S. Robinson and K. Johnson.

```
=> SELECT * FROM TESTING;
  Name  | Score
-----+-----
 J. Doe |   100
 R. Smith |    87
 L. White |     0
 S. Robinson |
 K. Johnson |
(5 rows)
```

The next SELECT statement specifies that Vertica should return any Null values in the Score column as 0s. In the results, you can see that Vertica returns a 0 score for S. Robinson and K. Johnson.

```
=> SELECT Name, ZEROIFNULL (Score) FROM TESTING;
  Name  | ZEROIFNULL
-----+-----
 J. Doe |       100
 R. Smith |        87
 L. White |         0
 S. Robinson |         0
 K. Johnson |         0
(5 rows)
```

Pattern Matching Functions

Used with the [MATCH Clause](#), the Vertica pattern matching functions return additional data about the patterns found/output. For example, you can use these functions to return values representing the name of the event or pattern that matched the input row, the sequential number of the match, or a partition-wide unique identifier for the instance of the pattern that matched.

Pattern matching is particularly useful for clickstream analysis where you might want to identify users' actions based on their Web browsing behavior (page clicks). A typical online clickstream funnel is:

Company home page -> product home page -> search -> results -> purchase online

Using the above clickstream funnel, you can search for a match on the user's sequence of web clicks and identify that the user:

- Landed on the company home page.
- Navigated to the product page.
- Ran a search.
- Clicked a link from the search results.
- Made a purchase.

For examples that use this clickstream model, see [Event Series Pattern Matching](#) in Analyzing Data.

- [MATCH Clause](#)
- [Event Series Pattern Matching](#)

EVENT_NAME

Returns a VARCHAR value representing the name of the event that matched the row.

Syntax

EVENT_NAME()

Notes

Pattern matching functions must be used in [MATCH Clause](#) syntax; for example, if you call EVENT_NAME() on its own, Vertica returns the following error message:

```
=> SELECT event_name();  
ERROR: query with pattern matching function event_name must include a MATCH clause
```

Example

Note: This example uses the schema defined in [Event Series Pattern Matching](#) in Analyzing Data. For a more detailed example, see that topic.

The following statement analyzes users' browsing history on `website2.com` and identifies patterns where the user landed on `website2.com` from another Web site (Entry) and browsed to any number of other pages (Onsite) before making a purchase (Purchase). The query also outputs the values for EVENT_NAME(), which is the name of the event that matched the row.

```
SELECT uid,  
       sid,  
       ts,  
       refurl,  
       pageurl,  
       action,  
       event_name()  
FROM clickstream_log  
MATCH  
  (PARTITION BY uid, sid ORDER BY ts  
  DEFINE  
    Entry AS RefURL NOT ILIKE '%website2.com%' AND PageURL ILIKE '%website2.com%',  
    Onsite AS PageURL ILIKE '%website2.com%' AND Action='V',  
    Purchase AS PageURL ILIKE '%website2.com%' AND Action = 'P'  
  PATTERN  
    P AS (Entry Onsite* Purchase)  
  ROWS MATCH FIRST EVENT);
```

uid	sid	ts	refurl	pageurl	action	event_name
1	100	12:00:00	website1.com	website2.com/home	V	Entry
1	100	12:01:00	website2.com/home	website2.com/floby	V	Onsite
1	100	12:02:00	website2.com/floby	website2.com/shamwow	V	Onsite
1	100	12:03:00	website2.com/shamwow	website2.com/buy	P	Purchase

```
2 | 100 | 12:10:00 | website1.com | website2.com/home | V | Entry
2 | 100 | 12:11:00 | website2.com/home | website2.com/forks | V | Onsite
2 | 100 | 12:13:00 | website2.com/forks | website2.com/buy | P | Purchase
(7 rows)
```

- [MATCH Clause](#)
- [MATCH_ID](#)
- [PATTERN_ID](#)
- [Event Series Pattern Matching](#)

MATCH_ID

Returns a successful pattern match as an INTEGER value. The returned value is the ordinal position of a match within a partition.

Syntax

```
MATCH_ID()
```

Notes

Pattern matching functions must be used in [MATCH Clause](#) syntax; for example, if you call `MATCH_ID()` on its own, Vertica returns the following error message:

```
=> SELECT match_id();
ERROR: query with pattern matching function match_id must include a MATCH clause
```

Example

Note: This example uses the schema defined in [Event Series Pattern Matching](#) in Analyzing Data. For a more detailed example, see that topic.

The following statement analyzes users' browsing history on a site called `website2.com` and identifies patterns where the user reached `website2.com` from another Web site (Entry in

the MATCH clause) and browsed to any number of other pages (Onsite) before making a purchase (Purchase). The query also outputs values for the MATCH_ID(), which represents a sequential number of the match.

```
SELECT uid,
       sid,
       ts,
       refurl,
       pageurl,
       action,
       match_id()
FROM clickstream_log
MATCH
(PARTITION BY uid, sid ORDER BY ts
DEFINE
  Entry AS RefURL NOT ILIKE '%website2.com%' AND PageURL ILIKE '%website2.com%',
  Onsite AS PageURL ILIKE '%website2.com%' AND Action='V',
  Purchase AS PageURL ILIKE '%website2.com%' AND Action = 'P'
PATTERN
  P AS (Entry Onsite* Purchase)
ROWS MATCH FIRST EVENT);
```

uid	sid	ts	refurl	pageurl	action	match_id
1	100	12:00:00	website1.com	website2.com/home	V	1
1	100	12:01:00	website2.com/home	website2.com/floby	V	2
1	100	12:02:00	website2.com/floby	website2.com/shamwow	V	3
1	100	12:03:00	website2.com/shamwow	website2.com/buy	P	4
2	100	12:10:00	website1.com	website2.com/home	V	1
2	100	12:11:00	website2.com/home	website2.com/forks	V	2
2	100	12:13:00	website2.com/forks	website2.com/buy	P	3

(7 rows)

- [Event Series Pattern Matching](#)

PATTERN_ID

Returns an integer value that is a partition-wide unique identifier for the instance of the pattern that matched.

Syntax

PATTERN_ID()

Notes

Pattern matching functions must be used in [MATCH Clause](#) syntax; for example, if call PATTERN_ID() on its own, Vertica returns the following error message:

```
=> SELECT pattern_id();  
ERROR: query with pattern matching function pattern_id must include a MATCH clause
```

Example

Note: This example uses the schema defined in [Event Series Pattern Matching](#) in Analyzing Data. For a more detailed example, see that topic.

The following statement analyzes users' browsing history on website2.com and identifies patterns where the user landed on website2.com from another Web site (Entry) and browsed to any number of other pages (Onsite) before making a purchase (Purchase). The query also outputs values for PATTERN_ID(), which represents the partition-wide identifier for the instance of the pattern that matched.

```
SELECT uid,  
       sid,  
       ts,  
       refurl,  
       pageurl,  
       action,  
       pattern_id()  
FROM clickstream_log  
MATCH  
  (PARTITION BY uid, sid ORDER BY ts  
  DEFINE  
    Entry AS RefURL NOT ILIKE '%website2.com%' AND PageURL ILIKE '%website2.com%',  
    Onsite AS PageURL ILIKE '%website2.com%' AND Action='V',  
    Purchase AS PageURL ILIKE '%website2.com%' AND Action = 'P'  
  PATTERN  
    P AS (Entry Onsite* Purchase)  
  ROWS MATCH FIRST EVENT);
```

```
uid | sid | ts | refurl | pageurl | action | pattern_id  
----+-----+----+-----+-----+-----+-----  
1 | 100 | 12:00:00 | website1.com | website2.com/home | V | 1
```

```
1 | 100 | 12:01:00 | website2.com/home | website2.com/floby | V | 1
1 | 100 | 12:02:00 | website2.com/floby | website2.com/shamwow | V | 1
1 | 100 | 12:03:00 | website2.com/shamwow | website2.com/buy | P | 1
2 | 100 | 12:10:00 | website1.com | website2.com/home | V | 1
2 | 100 | 12:11:00 | website2.com/home | website2.com/forks | V | 1
2 | 100 | 12:13:00 | website2.com/forks | website2.com/buy | P | 1
(7 rows)
```

Regular Expression Functions

A regular expression lets you perform pattern matching on strings of characters. The regular expression syntax allows you to precisely define the pattern used to match strings, giving you much greater control than wildcard matching used in the [LIKE](#) predicate. The Vertica regular expression functions let you perform tasks such as determining if a string value matches a pattern, extracting a portion of a string that matches a pattern, or counting the number of times a pattern occurs within a string.

Vertica uses the [Perl Compatible Regular Expression \(PCRE\)](#) library to evaluate regular expressions. As its name implies, PCRE's regular expression syntax is compatible with the syntax used by the Perl 5 programming language. You can read [PCRE's documentation](#) about its library. However, if you are unfamiliar with using regular expressions, the [Perl Regular Expressions Documentation](#) is a good introduction.

Note: The regular expression functions only operate on valid UTF-8 strings. If you try using a regular expression function on a string that is not valid UTF-8, the query fails with an error. To prevent an error from occurring, use the [ISUTF8](#) function as an initial clause to ensure the strings you pass to the regular expression functions are valid UTF-8 strings. Alternatively, or you can use the 'b' argument to treat the strings as binary octets, rather than UTF-8 encoded strings.

ISUTF8

Tests whether a string is a valid UTF-8 string. Returns true if the string conforms to UTF-8 standards, and false otherwise. This function is useful to test strings for UTF-8 compliance before passing them to one of the regular expression functions, such as [REGEXP_LIKE](#), which expect UTF-8 characters by default.

ISUTF8 checks for invalid UTF8 byte sequences, according to UTF-8 rules:

- invalid bytes
- an unexpected continuation byte
- a start byte not followed by enough continuation bytes
- an Overload Encoding

The presence of an invalid UTF8 byte sequence results in a return value of false.

Syntax

```
ISUTF8( string );
```

Parameters

<i>string</i>	The string to test for UTF-8 compliance.
---------------	--

Examples

```
=> SELECT ISUTF8(E'\xC2\xBF'); -- UTF-8 INVERTED QUESTION MARK ISUTF8
-----
t
(1 row)
=> SELECT ISUTF8(E'\xC2\xC0'); -- UNDEFINED UTF-8 CHARACTER
ISUTF8
-----
f
(1 row)
```

REGEXP_COUNT

Returns the number times a regular expression matches a string.

Syntax

```
REGEXP_COUNT( string, pattern [, position [, regex_modifier ] ] )
```

Parameters

<i>string</i>	The VARCHAR or LONG VARCHAR string to search for a regular expression pattern match. If <i>string</i> exists in a <code>__raw__</code> column of a flex or columnar table, cast <i>string</i> to a LONG VARCHAR before searching for <i>pattern</i> .
<i>pattern</i>	The regular expression to search for within <i>string</i> . The syntax of the regular expression is compatible with the Perl 5 regular expression syntax. See the Perl Regular Expressions Documentation for details.

<i>position</i>	<p>[Optional] The number of characters from the start of the string where the function should start searching for matches. By default, the function begins searching for a match at the first (leftmost) character. Setting this parameter to a value greater than 1 begins searching for a match at the <i>n</i>th character you specify.</p> <p>Default value: 1</p>												
<i>regexp_modifier</i>	<p>[Optional] One or more single-character flags that modify how the regular expression finds matches in <i>string</i>:</p> <table border="1" data-bbox="440 619 1408 1493"> <tr> <td data-bbox="440 619 511 688">b</td> <td data-bbox="511 619 1408 688">Treat strings as binary octets, rather than UTF-8 characters.</td> </tr> <tr> <td data-bbox="440 688 511 758">c</td> <td data-bbox="511 688 1408 758">Force the match to be case sensitive (the default).</td> </tr> <tr> <td data-bbox="440 758 511 827">i</td> <td data-bbox="511 758 1408 827">Force the match to be case insensitive.</td> </tr> <tr> <td data-bbox="440 827 511 1066">m</td> <td data-bbox="511 827 1408 1066">Treat the string to match as multiple lines. Using this modifier, the start of line (^) and end of line (\$) regular expression operators match line breaks (\n) within the string. Without the m modifier, the start and end of line operators match only the start and end of the string.</td> </tr> <tr> <td data-bbox="440 1066 511 1220">n</td> <td data-bbox="511 1066 1408 1220">Allow the single character regular expression operator (.) to match a newline (\n). Without the n modifier, the . operator matches any character except a newline.</td> </tr> <tr> <td data-bbox="440 1220 511 1493">x</td> <td data-bbox="511 1220 1408 1493">Add comments to your regular expressions. Using the x modifier causes the function to ignore all unescaped space characters and comments in the regular expression. Comments start with a hash (#) character and end with a newline (\n). All spaces in the regular expression that you want to be matched in strings must be escaped with a backslash (\) character.</td> </tr> </table>	b	Treat strings as binary octets, rather than UTF-8 characters.	c	Force the match to be case sensitive (the default).	i	Force the match to be case insensitive.	m	Treat the string to match as multiple lines. Using this modifier, the start of line (^) and end of line (\$) regular expression operators match line breaks (\n) within the string. Without the m modifier, the start and end of line operators match only the start and end of the string.	n	Allow the single character regular expression operator (.) to match a newline (\n). Without the n modifier, the . operator matches any character except a newline.	x	Add comments to your regular expressions. Using the x modifier causes the function to ignore all unescaped space characters and comments in the regular expression. Comments start with a hash (#) character and end with a newline (\n). All spaces in the regular expression that you want to be matched in strings must be escaped with a backslash (\) character.
b	Treat strings as binary octets, rather than UTF-8 characters.												
c	Force the match to be case sensitive (the default).												
i	Force the match to be case insensitive.												
m	Treat the string to match as multiple lines. Using this modifier, the start of line (^) and end of line (\$) regular expression operators match line breaks (\n) within the string. Without the m modifier, the start and end of line operators match only the start and end of the string.												
n	Allow the single character regular expression operator (.) to match a newline (\n). Without the n modifier, the . operator matches any character except a newline.												
x	Add comments to your regular expressions. Using the x modifier causes the function to ignore all unescaped space characters and comments in the regular expression. Comments start with a hash (#) character and end with a newline (\n). All spaces in the regular expression that you want to be matched in strings must be escaped with a backslash (\) character.												

Notes

This function operates on UTF-8 strings using the default locale, even if the locale has been set to something else.

If you are porting a regular expression query from an Oracle database, remember that Oracle considers a zero-length string to be equivalent to NULL, while Vertica does not.

Examples

Count the number of occurrences of the substring *an* in the string "a man, a plan, a canal, Panama."

```
=> SELECT REGEXP_COUNT('a man, a plan, a canal: Panama', 'an');
REGEXP_COUNT
-----
                4
(1 row)
```

Find the number of occurrences of the substring *an* in the string "a man, a plan, a canal: Panama" starting with the fifth character.

```
=> SELECT REGEXP_COUNT('a man, a plan, a canal: Panama', 'an',5);
REGEXP_COUNT
-----
                3
(1 row)
```

Find the number of occurrences of a substring containing a lower-case character followed by *an*. In the first example, do not use a modifier. In the second example, use the *i* modifier to force the regular expression to ignore case.

```
=> SELECT REGEXP_COUNT('a man, a plan, a canal: Panama', '[a-z]an');
REGEXP_COUNT
-----
                3
(1 row)

=> SELECT REGEXP_COUNT('a man, a plan, a canal: Panama', '[a-z]an', 1, 'i');

REGEXP_COUNT
-----
                4
```

REGEXP_ILIKE

Returns true if the string contains a match for the regular expression. This function is similar to the [LIKE-predicate](#), except that it uses a case insensitive regular expression, rather than simple wildcard character matching.

Syntax

```
REGEXP_ILIKE( string, pattern )
```

Parameters

<i>string</i>	The VARCHAR or LONG VARCHAR string to search for a regular expression pattern match. If string exists in a <code>__raw__</code> column of a flex or columnar table, cast string to a LONG VARCHAR before searching for <i>pattern</i> .
<i>pattern</i>	A string containing the regular expression to match against the string. The syntax of the regular expression is compatible with the Perl 5 regular expression syntax. See the Perl Regular Expressions Documentation for details.

Notes

This function operates on UTF-8 strings using the default locale, even if the locale has been set to something else.

If you are porting a regular expression query from an Oracle database, remember that Oracle considers a zero-length string to be equivalent to NULL, while Vertica does not.

Examples

This example creates a table containing several strings to demonstrate regular expressions.

1. Create a table (`longvc`) with a single, long varchar column (`body`) and insert data with some distinct characters:

```
=> CREATE table longvc(body long varchar (1048576));
CREATE TABLE

=> insert into longvc values ('На берегу пустынных волн');
=> insert into longvc values ('Voin syödä lasia, se ei vahingoita minua');
=> insert into longvc values ('私はガラスを食べられます。それは私を傷つけません。');
=> insert into longvc values ('Je peux manger du verre, ça ne me fait pas mal. ');
=> insert into longvc values ('zésbaésbaa');

=> SELECT * FROM longvc;
          body
-----
На берегу пустынных волн
Voin syödä lasia, se ei vahingoita minua
私はガラスを食べられます。それは私を傷つけません。
Je peux manger du verre, ça ne me fait pas mal.
zésbaésbaa
(5 rows)
```

2. Pattern match table rows containing a specific character ('ç'), added as part of Step 1:

```
=> SELECT * FROM longvc where regexp_ilike(body, 'c');
      body
-----
Je peux manger du verre, ça ne me fait pas mal.
(1 row)
```

3. Select all rows that contain the substring 'a':

```
=> SELECT * FROM longvc where regexp_ilike(body, 'a');
      body
-----
Je peux manger du verre, ça ne me fait pas mal.
Voin syödä lasia, se ei vahingoita minua
zésbaésbaa
(3 rows)
```

REGEXP_INSTR

Returns the starting or ending position in a string where a regular expression matches. This function returns 0 if no match for the regular expression is found in the string.

Syntax

```
REGEXP_INSTR( string, pattern [, position [, occurrence ... [, return_position [, regexp_modifier ]
... [, captured_subexp ] ] ] )
```

Parameters

<i>string</i>	The VARCHAR or LONG VARCHAR string to search for a regular expression pattern match. If string exists in a <code>__raw__</code> column of a flex or columnar table, cast string to a LONG VARCHAR before searching for <i>pattern</i> .
<i>pattern</i>	The regular expression to search for within the string. The syntax of the regular expression is compatible with the Perl 5 regular expression syntax. See the Perl Regular Expressions Documentation for details.
<i>position</i>	[Optional] The number of characters from the start of the string where the function should start searching for matches. By default, the function begins searching for a match at the first (leftmost) character. Setting this parameter to a value greater than 1 begins searching for a match at the <i>n</i> th character you specify.

	Default value: 1												
<i>occurrence</i>	<p>[Optional] Controls which occurrence of a pattern match in the string to return. By default, the function returns the position of the first matching substring. Use this parameter to find the position of subsequent matching substrings. For example, setting this parameter to 3 returns the position of the third substring that matches the pattern.</p> <p>Default value: 1</p>												
<i>return_position</i>	<p>[Optional] Sets the position within the string to return. Using the default position (0), the function returns the string position of the first character of the substring that matches the pattern. If you set <i>return_position</i> to 1, the function returns the position of the first character after the end of the matching substring.</p> <p>Default value: 0</p>												
<i>regexp_modifier</i>	<p>[Optional] One or more single-character flags that modify how the regular expression finds matches in <i>string</i>:</p> <table border="1"> <tr> <td>b</td> <td>Treat strings as binary octets, rather than UTF-8 characters.</td> </tr> <tr> <td>c</td> <td>Force the match to be case sensitive (the default).</td> </tr> <tr> <td>i</td> <td>Force the match to be case insensitive.</td> </tr> <tr> <td>m</td> <td>Treat the string to match as multiple lines. Using this modifier, the start of line (^) and end of line (\$) regular expression operators match line breaks (\n) within the string. Without the m modifier, the start and end of line operators match only the start and end of the string.</td> </tr> <tr> <td>n</td> <td>Allow the single character regular expression operator (.) to match a newline (\n). Without the n modifier, the . operator matches any character except a newline.</td> </tr> <tr> <td>x</td> <td>Add comments to your regular expressions. Using the x modifier causes the function to ignore all unescaped space characters and comments in the regular expression. Comments start with a hash (#) character and end with a newline (\n). All spaces in the regular expression that you want to be matched in strings must be escaped with a backslash (\) character.</td> </tr> </table>	b	Treat strings as binary octets, rather than UTF-8 characters.	c	Force the match to be case sensitive (the default).	i	Force the match to be case insensitive.	m	Treat the string to match as multiple lines. Using this modifier, the start of line (^) and end of line (\$) regular expression operators match line breaks (\n) within the string. Without the m modifier, the start and end of line operators match only the start and end of the string.	n	Allow the single character regular expression operator (.) to match a newline (\n). Without the n modifier, the . operator matches any character except a newline.	x	Add comments to your regular expressions. Using the x modifier causes the function to ignore all unescaped space characters and comments in the regular expression. Comments start with a hash (#) character and end with a newline (\n). All spaces in the regular expression that you want to be matched in strings must be escaped with a backslash (\) character.
b	Treat strings as binary octets, rather than UTF-8 characters.												
c	Force the match to be case sensitive (the default).												
i	Force the match to be case insensitive.												
m	Treat the string to match as multiple lines. Using this modifier, the start of line (^) and end of line (\$) regular expression operators match line breaks (\n) within the string. Without the m modifier, the start and end of line operators match only the start and end of the string.												
n	Allow the single character regular expression operator (.) to match a newline (\n). Without the n modifier, the . operator matches any character except a newline.												
x	Add comments to your regular expressions. Using the x modifier causes the function to ignore all unescaped space characters and comments in the regular expression. Comments start with a hash (#) character and end with a newline (\n). All spaces in the regular expression that you want to be matched in strings must be escaped with a backslash (\) character.												

<i>captured_subexp</i>	<p>[Optional] The captured subexpression whose position to return. By default, the function returns the position of the first character in <i>string</i> that matches the regular expression. If you set this value from 1 – 9, the function returns the subexpression captured by the corresponding set of parentheses in the regular expression. For example, setting this value to 3 returns the substring captured by the third set of parentheses in the regular expression.</p> <p>Default value: 0</p> <p>Note: The subexpressions are numbered left to right, based on the appearance of opening parenthesis, so nested regular expressions . For example, in the regular expression <code>\s*(\w+\s+(\w+))</code>, subexpression 1 is the one that captures everything but any leading whitespaces.</p>
------------------------	--

Notes

This function operates on UTF-8 strings using the default locale, even if the locale has been set to something else.

If you are porting a regular expression query from an Oracle database, remember that Oracle considers a zero-length string to be equivalent to NULL, while Vertica does not.

Examples

Find the first occurrence of a sequence of letters starting with the letter e and ending with the letter y in the phrase "easy come, easy go."

```
=> SELECT REGEXP_INSTR('easy come, easy go','e\w*y');
REGEXP_INSTR
-----
                1
(1 row)
```

Find the first sequence of letters starting with the letter e and ending with the letter y in the string "easy come, easy go" starting at the second character (2) ."

```
=> SELECT REGEXP_INSTR('easy come, easy go','e\w*y',2);
REGEXP_INSTR
-----
                12
(1 row)
```

Find the second sequence of letters starting with the letter e and ending with the letter y in the string "easy come, easy go" starting at the first character.

```
=> SELECT REGEXP_INSTR('easy come, easy go', 'e\w*y', 1, 2);
   REGEXP_INSTR
-----
                12
(1 row)
```

Find the position of the first character after the first whitespace in the string "easy come, easy go."

```
=> SELECT REGEXP_INSTR('easy come, easy go', '\s', 1, 1, 1);
   REGEXP_INSTR
-----
                6
(1 row)
```

Find the position of the start of the third word in a string by capturing each word as a subexpression, and returning the third subexpression's start position.

```
=> SELECT REGEXP_INSTR('one two three', '(\w+)\s+(\w+)\s+(\w+)', 1, 1, 0, '', 3);
   REGEXP_INSTR
-----
                9
(1 row)
```

REGEXP_LIKE

Returns true if the string matches the regular expression. This function is similar to the [LIKE-predicate](#), except that it uses regular expressions rather than simple wildcard character matching.

Syntax

```
REGEXP_LIKE( string, pattern [, modifiers ] )
```

Parameters

<i>string</i>	The VARCHAR or LONG VARCHAR string to search for a regular expression pattern match. If string exists in a <code>__raw__</code> column of a flex or columnar table, cast string to a LONG VARCHAR before searching for <i>pattern</i> .
<i>pattern</i>	A string containing the regular expression to match against the string. The

	<p>syntax of the regular expression is compatible with the Perl 5 regular expression syntax. See the Perl Regular Expressions Documentation for details.</p>												
<i>modifiers</i>	<p>[Optional] One or more single-character flags that modify how the regular expression finds matches in <i>string</i>:</p> <table border="1"> <tr> <td>b</td> <td>Treat strings as binary octets, rather than UTF-8 characters.</td> </tr> <tr> <td>c</td> <td>Force the match to be case sensitive (the default).</td> </tr> <tr> <td>i</td> <td>Force the match to be case insensitive.</td> </tr> <tr> <td>m</td> <td>Treat the string to match as multiple lines. Using this modifier, the start of line (^) and end of line (\$) regular expression operators match line breaks (\n) within the string. Without the m modifier, the start and end of line operators match only the start and end of the string.</td> </tr> <tr> <td>n</td> <td>Allow the single character regular expression operator (.) to match a newline (\n). Without the n modifier, the . operator matches any character except a newline.</td> </tr> <tr> <td>x</td> <td>Add comments to your regular expressions. Using the x modifier causes the function to ignore all unescaped space characters and comments in the regular expression. Comments start with a hash (#) character and end with a newline (\n). All spaces in the regular expression that you want to be matched in strings must be escaped with a backslash (\) character.</td> </tr> </table>	b	Treat strings as binary octets, rather than UTF-8 characters.	c	Force the match to be case sensitive (the default).	i	Force the match to be case insensitive.	m	Treat the string to match as multiple lines. Using this modifier, the start of line (^) and end of line (\$) regular expression operators match line breaks (\n) within the string. Without the m modifier, the start and end of line operators match only the start and end of the string.	n	Allow the single character regular expression operator (.) to match a newline (\n). Without the n modifier, the . operator matches any character except a newline.	x	Add comments to your regular expressions. Using the x modifier causes the function to ignore all unescaped space characters and comments in the regular expression. Comments start with a hash (#) character and end with a newline (\n). All spaces in the regular expression that you want to be matched in strings must be escaped with a backslash (\) character.
b	Treat strings as binary octets, rather than UTF-8 characters.												
c	Force the match to be case sensitive (the default).												
i	Force the match to be case insensitive.												
m	Treat the string to match as multiple lines. Using this modifier, the start of line (^) and end of line (\$) regular expression operators match line breaks (\n) within the string. Without the m modifier, the start and end of line operators match only the start and end of the string.												
n	Allow the single character regular expression operator (.) to match a newline (\n). Without the n modifier, the . operator matches any character except a newline.												
x	Add comments to your regular expressions. Using the x modifier causes the function to ignore all unescaped space characters and comments in the regular expression. Comments start with a hash (#) character and end with a newline (\n). All spaces in the regular expression that you want to be matched in strings must be escaped with a backslash (\) character.												

Notes

This function operates on UTF-8 strings using the default locale, even if the locale has been set to something else.

If you are porting a regular expression query from an Oracle database, remember that Oracle considers a zero-length string to be equivalent to NULL, while Vertica does not.

Examples

This example creates a table containing several strings to demonstrate regular expressions.

```
=> CREATE TABLE t (v VARCHAR);
CREATE TABLE
=> CREATE PROJECTION t1 AS SELECT * FROM t;
CREATE PROJECTION
=> COPY t FROM stdin;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> aaa
>> Aaa
>> abc
>> abc1
>> 123
>> \.
=> SELECT * FROM t;
   v
-----
aaa
Aaa
abc
abc1
123
(5 rows)
```

Select all records in the table that contain the letter "a."

```
=> SELECT v FROM t WHERE REGEXP_LIKE(v, 'a');
   v
-----
Aaa
aaa
abc
abc1
(4 rows)
```

Select all of the rows in the table that start with the letter "a."

```
=> SELECT v FROM t WHERE REGEXP_LIKE(v, '^a');
   v
-----
aaa
abc
abc1
(3 rows)
```

Select all rows that contain the substring "aa."

```
=> SELECT v FROM t WHERE REGEXP_LIKE(v, 'aa');
   v
-----
Aaa
aaa
(2 rows)
```

Select all rows that contain a digit.

```
=> SELECT v FROM t WHERE REGEXP_LIKE(v, '\d');
v
-----
123
abc1
(2 rows)
```

Select all rows that contain the substring "aaa."

```
=> SELECT v FROM t WHERE REGEXP_LIKE(v, 'aaa');
v
-----
aaa
(1 row)
```

Select all rows that contain the substring "aaa" using case insensitive matching.

```
=> SELECT v FROM t WHERE REGEXP_LIKE(v, 'aaa', 'i');
v
-----
Aaa
aaa
(2 rows)
```

Select rows that contain the substring "a b c."

```
=> SELECT v FROM t WHERE REGEXP_LIKE(v, 'a b c');
v
---
(0 rows)
```

Select rows that contain the substring "a b c" ignoring space within the regular expression.

```
=> SELECT v FROM t WHERE REGEXP_LIKE(v, 'a b c', 'x');
v
-----
abc
abc1
(2 rows)
```

Add multi-line rows to demonstrate using the "m" modifier.

```
=> COPY t FROM stdin RECORD TERMINATOR '!';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> Record 1 line 1
>> Record 1 line 2
>> Record 1 line 3!
>> Record 2 line 1
>> Record 2 line 2
>> Record 2 line 3!
>> \.
```

Select rows that start with the substring "Record" and end with the substring "line 2."

```
=> SELECT v from t WHERE REGEXP_LIKE(v, '^Record.*line 2$');
v
---
(0 rows)
```

Select rows that start with the substring "Record" and end with the substring "line 2," treating multiple lines as separate strings.

```
=> SELECT v from t WHERE REGEXP_LIKE(v, '^Record.*line 2$', 'm');
v
-----
Record 2 line 1
Record 2 line 2
Record 2 line 3
Record 1 line 1
Record 1 line 2
Record 1 line 3
(2 rows)
```

REGEXP_NOT_ILIKE

Returns true if the string does not match the case-insensitive regular expression.

Syntax

```
REGEXP_NOT_ILIKE( string, pattern )
```

Parameters

<i>string</i>	The VARCHAR or LONG VARCHAR string to search for a regular expression pattern match. If string exists in a <code>__raw__</code> column of a flex or columnar table, cast string to a LONG VARCHAR before searching for <i>pattern</i> .
<i>pattern</i>	A string containing the regular expression to match against the string. The syntax of the regular expression is compatible with the Perl 5 regular expression syntax. See the Perl Regular Expressions Documentation for details.

Notes

This function operates on UTF-8 strings using the default locale, even if the locale has been set to something else.

If you are porting a regular expression query from an Oracle database, remember that Oracle considers a zero-length string to be equivalent to NULL, while Vertica does not.

Examples

This example creates a table containing strings to demonstrate regular expressions.

1. Create a table (`longvc`) with a single, long varchar column (`body`). Then, insert data with some distinct characters, and query the table contents:

```
=> CREATE table longvc(body long varchar (1048576));
CREATE TABLE

=> insert into longvc values ('На берегу пустынных волн');
=> insert into longvc values ('Voin syödä lasia, se ei vahingoita minua');
=> insert into longvc values ('私はガラスを食べられます。それは私を傷つけません。');
=> insert into longvc values ('Je peux manger du verre, ça ne me fait pas mal. ');
=> insert into longvc values ('zésbaésbaa');

=> SELECT * FROM longvc;
           body
-----
На берегу пустынных волн
Voin syödä lasia, se ei vahingoita minua
私はガラスを食べられます。それは私を傷つけません。
Je peux manger du verre, ça ne me fait pas mal.
zésbaésbaa
(5 rows)
```

2. Use `REGEXP_NOT_ILIKE` to return rows that do not contain a specific character ('ç'):

```
=> SELECT * FROM longvc where regexp_not_ilike(body, 'ç');
           body
-----
Voin syödä lasia, se ei vahingoita minua
zésbaésbaa
На берегу пустынных волн
私はガラスを食べられます。それは私を傷つけません。
(4 rows)
```

3. Pattern match all rows that do not contain the substring 'a':

```
=> SELECT * FROM longvc where regexp_not_ilike(body, 'a');
           body
-----
На берегу пустынных волн
私はガラスを食べられます。それは私を傷つけません。
(2 rows)
```

REGEXP_NOT_LIKE

Returns true if the string does not contain a match for the regular expression. This function is a case sensitive regular expression.

Syntax

```
REGEXP_NOT_LIKE( string, pattern modifiers ] )
```

Parameters

<i>string</i>	The VARCHAR or LONG VARCHAR string to search for a regular expression pattern match. If string exists in a <code>__raw__</code> column of a flex or columnar table, cast string to a LONG VARCHAR before searching for <i>pattern</i> .												
<i>pattern</i>	A string containing the regular expression to match against the string. The syntax of the regular expression is compatible with the Perl 5 regular expression syntax. See the Perl Regular Expressions Documentation for details.												
<i>modifiers</i>	[Optional] One or more single-character flags that modify how the regular expression finds matches in <i>string</i> : <table border="1"><tr><td>b</td><td>Treat strings as binary octets, rather than UTF-8 characters.</td></tr><tr><td>c</td><td>Force the match to be case sensitive (the default).</td></tr><tr><td>i</td><td>Force the match to be case insensitive.</td></tr><tr><td>m</td><td>Treat the string to match as multiple lines. Using this modifier, the start of line (^) and end of line (\$) regular expression operators match line breaks (\n) within the string. Without the m modifier, the start and end of line operators match only the start and end of the string.</td></tr><tr><td>n</td><td>Allow the single character regular expression operator (.) to match a newline (\n). Without the n modifier, the . operator matches any character except a newline.</td></tr><tr><td>x</td><td>Add comments to your regular expressions. Using the x modifier causes the function to ignore all unescaped space characters and comments in</td></tr></table>	b	Treat strings as binary octets, rather than UTF-8 characters.	c	Force the match to be case sensitive (the default).	i	Force the match to be case insensitive.	m	Treat the string to match as multiple lines. Using this modifier, the start of line (^) and end of line (\$) regular expression operators match line breaks (\n) within the string. Without the m modifier, the start and end of line operators match only the start and end of the string.	n	Allow the single character regular expression operator (.) to match a newline (\n). Without the n modifier, the . operator matches any character except a newline.	x	Add comments to your regular expressions. Using the x modifier causes the function to ignore all unescaped space characters and comments in
b	Treat strings as binary octets, rather than UTF-8 characters.												
c	Force the match to be case sensitive (the default).												
i	Force the match to be case insensitive.												
m	Treat the string to match as multiple lines. Using this modifier, the start of line (^) and end of line (\$) regular expression operators match line breaks (\n) within the string. Without the m modifier, the start and end of line operators match only the start and end of the string.												
n	Allow the single character regular expression operator (.) to match a newline (\n). Without the n modifier, the . operator matches any character except a newline.												
x	Add comments to your regular expressions. Using the x modifier causes the function to ignore all unescaped space characters and comments in												

the regular expression. Comments start with a hash (#) character and end with a newline (\n). All spaces in the regular expression that you want to be matched in strings must be escaped with a backslash (\) character.

Notes

This function operates on UTF-8 strings using the default locale, even if the locale has been set to something else.

If you are porting a regular expression query from an Oracle database, remember that Oracle considers a zero-length string to be equivalent to NULL, while Vertica does not.

Examples

These examples demonstrate the REGEXP_NOT_LIKE regular expression function.

1. Create a table (longvc) with a single, long varchar column (body). Then, insert data with some distinct characters, and query the table contents:

```
=> CREATE table longvc(body long varchar (1048576));
CREATE TABLE

=> insert into longvc values ('На берегу пустынных волн');
=> insert into longvc values ('Voin syödä lasia, se ei vahingoita minua');
=> insert into longvc values ('私はガラスを食べられます。それは私を傷つけません。');
=> insert into longvc values ('Je peux manger du verre, ça ne me fait pas mal. ');
=> insert into longvc values ('zésbaésbaa');

=> SELECT * FROM longvc;
          body
-----
На берегу пустынных волн
Voin syödä lasia, se ei vahingoita minua
私はガラスを食べられます。それは私を傷つけません。
Je peux manger du verre, ça ne me fait pas mal.
zésbaésbaa
(5 rows)
```

2. Use REGEXP_NOT_LIKE to return rows that do not contain a specific character ('ç'):

```
=> SELECT * FROM longvc where regexp_not_like(body, 'ç');
          body
-----
Voin syödä lasia, se ei vahingoita minua
zésbaésbaa
```

```
На берегу пустынных волн  
私はガラスを食べられます。それは私を傷つけません。  
(4 rows)
```

3. Return all rows that do not contain these characters ('.*ö.*ä'):

```
=> SELECT * FROM longvc where regexp_not_like(body, '.*ö.*ä');  
body  
-----  
Je peux manger du verre, ça ne me fait pas mal.  
zésbaésbaa  
На берегу пустынных волн  
私はガラスを食べられます。それは私を傷つけません。  
(4 rows)
```

4. Pattern match all rows that do not contain these specific characters ('z.*eśbaa'):

```
=> SELECT * FROM longvc where regexp_not_like(body, 'z.*eśbaa');  
body  
-----  
Je peux manger du verre, ça ne me fait pas mal.  
Voin syödä lasia, se ei vahingoita minua  
zésbaésbaa  
На берегу пустынных волн  
私はガラスを食べられます。それは私を傷つけません。  
(5 rows)
```

REGEXP_REPLACE

Replace all occurrences of a substring that match a regular expression with another substring. It is similar to the [REPLACE](#) function, except it uses a regular expression to select the substring to be replaced.

Syntax

```
REGEXP_REPLACE( string, target [, replacement [, position [, occurrence ... [, regexp_modifiers ] ] ] )
```

Parameters

<i>string</i>	The VARCHAR or LONG VARCHAR string to search for a regular expression pattern match. If string exists in a <code>__raw__</code> column of a flex or columnar table, cast string to a LONG VARCHAR before searching for <i>pattern</i> .
<i>target</i>	The regular expression to search for within the string. The syntax of the regular expression is compatible with the Perl 5 regular expression syntax. See the Perl Regular Expressions Documentation for details.

<i>replacement</i>	<p>The string to replace matched substrings. If you do not supply a <i>replacement</i>, the function deletes matched substrings. The replacement string can contain backreferences for substrings captured by the regular expression. The first captured substring is inserted into the replacement string using \1, the second \2, and so on.</p>												
<i>position</i>	<p>[Optional] The number of characters from the start of the string where the function should start searching for matches. By default, the function begins searching for a match at the first (leftmost) character. Setting this parameter to a value greater than 1 begins searching for a match at the <i>n</i>th character you specify.</p> <p>Default value: 1</p>												
<i>occurrence</i>	<p>[Optional] Controls which occurrence of a pattern match in the string to return. By default, the function returns the position of the first matching substring. Use this parameter to find the position of subsequent matching substrings. For example, setting this parameter to 3 returns the position of the third substring that matches the pattern.</p> <p>Default value: 1</p>												
<i>regexp_modifier</i>	<p>[Optional] One or more single-character flags that modify how the regular expression finds matches in <i>string</i>:</p> <table border="1" data-bbox="440 1150 1409 1864"> <tr> <td data-bbox="440 1150 509 1220">b</td> <td data-bbox="509 1150 1409 1220">Treat strings as binary octets, rather than UTF-8 characters.</td> </tr> <tr> <td data-bbox="440 1220 509 1289">c</td> <td data-bbox="509 1220 1409 1289">Force the match to be case sensitive (the default).</td> </tr> <tr> <td data-bbox="440 1289 509 1358">i</td> <td data-bbox="509 1289 1409 1358">Force the match to be case insensitive.</td> </tr> <tr> <td data-bbox="440 1358 509 1598">m</td> <td data-bbox="509 1358 1409 1598">Treat the string to match as multiple lines. Using this modifier, the start of line (^) and end of line (\$) regular expression operators match line breaks (\n) within the string. Without the m modifier, the start and end of line operators match only the start and end of the string.</td> </tr> <tr> <td data-bbox="440 1598 509 1751">n</td> <td data-bbox="509 1598 1409 1751">Allow the single character regular expression operator (.) to match a newline (\n). Without the n modifier, the . operator matches any character except a newline.</td> </tr> <tr> <td data-bbox="440 1751 509 1864">x</td> <td data-bbox="509 1751 1409 1864">Add comments to your regular expressions. Using the x modifier causes the function to ignore all unescaped space characters and</td> </tr> </table>	b	Treat strings as binary octets, rather than UTF-8 characters.	c	Force the match to be case sensitive (the default).	i	Force the match to be case insensitive.	m	Treat the string to match as multiple lines. Using this modifier, the start of line (^) and end of line (\$) regular expression operators match line breaks (\n) within the string. Without the m modifier, the start and end of line operators match only the start and end of the string.	n	Allow the single character regular expression operator (.) to match a newline (\n). Without the n modifier, the . operator matches any character except a newline.	x	Add comments to your regular expressions. Using the x modifier causes the function to ignore all unescaped space characters and
b	Treat strings as binary octets, rather than UTF-8 characters.												
c	Force the match to be case sensitive (the default).												
i	Force the match to be case insensitive.												
m	Treat the string to match as multiple lines. Using this modifier, the start of line (^) and end of line (\$) regular expression operators match line breaks (\n) within the string. Without the m modifier, the start and end of line operators match only the start and end of the string.												
n	Allow the single character regular expression operator (.) to match a newline (\n). Without the n modifier, the . operator matches any character except a newline.												
x	Add comments to your regular expressions. Using the x modifier causes the function to ignore all unescaped space characters and												

comments in the regular expression. Comments start with a hash (#) character and end with a newline (\n). All spaces in the regular expression that you want to be matched in strings must be escaped with a backslash (\) character.

Notes

This function operates on UTF-8 strings using the default locale, even if the locale has been set to something else.

If you are porting a regular expression query from an Oracle database, remember that Oracle considers a zero-length string to be equivalent to NULL, while Vertica does not.

Another key difference between Oracle and Vertica is that Vertica can handle an unlimited number of captured subexpressions, while Oracle is limited to nine.

In Vertica, you can use `\10` in the replacement pattern to access the substring captured by the tenth set of parentheses in the regular expression. In Oracle, `\10` is treated as the substring captured by the first set of parentheses, followed by a zero. To force this Oracle behavior in Vertica, use the `\g` back reference and enclose the number of the captured subexpression in curly braces. For example, `\g{1}0` is the substring captured by the first set of parentheses followed by a zero.

You can also name captured subexpressions to make your regular expressions less ambiguous. See the [PCRE](#) documentation for details.

Examples

Find groups of "word characters" (letters, numbers and underscore) ending with "thy" in the string "healthy, wealthy, and wise" and replace them with nothing.

```
=> SELECT REGEXP_REPLACE('healthy, wealthy, and wise','\w+thy');
   REGEXP_REPLACE
-----
, , and wise
(1 row)
```

Find groups of word characters ending with "thy" and replace with the string "something."

```
=> SELECT REGEXP_REPLACE('healthy, wealthy, and wise','\w+thy', 'something');
   REGEXP_REPLACE
-----
something, something, and wise
(1 row)
```

Find groups of word characters ending with "thy" and replace with the string "something" starting at the third character in the string.

```
=> SELECT REGEXP_REPLACE('healthy, wealthy, and wise','\w+thy', 'something', 3);
       REGEXP_REPLACE
-----
hesomething, something, and wise
(1 row)
```

Replace the second group of word characters ending with "thy" with the string "something."

```
=> SELECT REGEXP_REPLACE('healthy, wealthy, and wise','\w+thy', 'something', 1, 2);
       REGEXP_REPLACE
-----
healthy, something, and wise
(1 row)
```

Find groups of word characters ending with "thy" capturing the letters before the "thy", and replace with the captured letters plus the letters "ish."

```
=> SELECT REGEXP_REPLACE('healthy, wealthy, and wise','(\w+)thy', '\1ish');
       REGEXP_REPLACE
-----
healish, wealish, and wise
(1 row)
```

Create a table to demonstrate replacing strings in a query.

```
=> CREATE TABLE customers (name varchar(50), phone varchar(11));
CREATE TABLE
=> CREATE PROJECTION customers1 AS SELECT * FROM customers;
CREATE PROJECTION
=> COPY customers FROM stdin;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> Able,Adam|17815551234
>> Baker,Bob|18005551111
>> Chu,Cindy|16175559876
>> Dodd,Dinara|15083452121
>> \.
```

Query the customers, using REGEXP_REPLACE to format the phone numbers.

```
=> SELECT name, REGEXP_REPLACE(phone, '(\d)(\d{3})(\d{3})(\d{4})',
'\1-(\2) \3-\4') as phone FROM customers;
   name      |      phone
-----+-----
Able, Adam   | 1-(781) 555-1234
Baker,Bob    | 1-(800) 555-1111
Chu,Cindy    | 1-(617) 555-9876
Dodd,Dinara  | 1-(508) 345-2121
(4 rows)
```

REGEXP_SUBSTR

Returns the substring that matches a regular expression within a string. If no matches are found, this function returns NULL. This is different from an empty string, which the function can return if the regular expression matches a zero-length string.

Syntax

```
REGEXP_SUBSTR( string, pattern [, position [, occurrence [, regexp_modifier... [, captured_subexp ] ] ] )
```

Parameters

<i>string</i>	The VARCHAR or LONG VARCHAR string to search for a regular expression pattern match. If string exists in a <code>__raw__</code> column of a flex or columnar table, cast string to a LONG VARCHAR before searching for <i>pattern</i> .
<i>pattern</i>	The regular expression to find a substring to extract. The syntax of the regular expression is compatible with the Perl 5 regular expression syntax. See the Perl Regular Expressions Documentation for details.
<i>position</i>	[Optional] The number of characters from the start of the string where the function should start searching for matches. By default, the function begins searching for a match at the first (leftmost) character. Setting this parameter to a value greater than 1 begins searching for a match at the <i>n</i> th character you specify. Default value: 1
<i>occurrence</i>	[Optional] Controls which occurrence of a pattern match in the string to return. By default, the function returns the position of the first matching substring. Use this parameter to find the position of subsequent matching substrings. For example, setting this parameter to 3 returns the position of the third substring that matches the pattern. Default value: 1
<i>regexp_modifier</i>	[Optional] One or more single-character flags that modify how the regular expression finds matches in <i>string</i> :

	<table border="1"> <tr> <td data-bbox="440 212 509 279">b</td> <td data-bbox="509 212 1408 279">Treat strings as binary octets, rather than UTF-8 characters.</td> </tr> <tr> <td data-bbox="440 279 509 346">c</td> <td data-bbox="509 279 1408 346">Force the match to be case sensitive (the default).</td> </tr> <tr> <td data-bbox="440 346 509 413">i</td> <td data-bbox="509 346 1408 413">Force the match to be case insensitive.</td> </tr> <tr> <td data-bbox="440 413 509 653">m</td> <td data-bbox="509 413 1408 653">Treat the string to match as multiple lines. Using this modifier, the start of line (^) and end of line (\$) regular expression operators match line breaks (\n) within the string. Without the m modifier, the start and end of line operators match only the start and end of the string.</td> </tr> <tr> <td data-bbox="440 653 509 808">n</td> <td data-bbox="509 653 1408 808">Allow the single character regular expression operator (.) to match a newline (\n). Without the n modifier, the . operator matches any character except a newline.</td> </tr> <tr> <td data-bbox="440 808 509 1085">x</td> <td data-bbox="509 808 1408 1085">Add comments to your regular expressions. Using the x modifier causes the function to ignore all unescaped space characters and comments in the regular expression. Comments start with a hash (#) character and end with a newline (\n). All spaces in the regular expression that you want to be matched in strings must be escaped with a backslash (\) character.</td> </tr> </table>	b	Treat strings as binary octets, rather than UTF-8 characters.	c	Force the match to be case sensitive (the default).	i	Force the match to be case insensitive.	m	Treat the string to match as multiple lines. Using this modifier, the start of line (^) and end of line (\$) regular expression operators match line breaks (\n) within the string. Without the m modifier, the start and end of line operators match only the start and end of the string.	n	Allow the single character regular expression operator (.) to match a newline (\n). Without the n modifier, the . operator matches any character except a newline.	x	Add comments to your regular expressions. Using the x modifier causes the function to ignore all unescaped space characters and comments in the regular expression. Comments start with a hash (#) character and end with a newline (\n). All spaces in the regular expression that you want to be matched in strings must be escaped with a backslash (\) character.
b	Treat strings as binary octets, rather than UTF-8 characters.												
c	Force the match to be case sensitive (the default).												
i	Force the match to be case insensitive.												
m	Treat the string to match as multiple lines. Using this modifier, the start of line (^) and end of line (\$) regular expression operators match line breaks (\n) within the string. Without the m modifier, the start and end of line operators match only the start and end of the string.												
n	Allow the single character regular expression operator (.) to match a newline (\n). Without the n modifier, the . operator matches any character except a newline.												
x	Add comments to your regular expressions. Using the x modifier causes the function to ignore all unescaped space characters and comments in the regular expression. Comments start with a hash (#) character and end with a newline (\n). All spaces in the regular expression that you want to be matched in strings must be escaped with a backslash (\) character.												
<p><i>captured_subexp</i></p>	<p>[Optional] The captured subexpression whose position to return. By default, the function returns the position of the first character in <i>string</i> that matches the regular expression. If you set this value from 1 – 9, the function returns the subexpression captured by the corresponding set of parentheses in the regular expression. For example, setting this value to 3 returns the substring captured by the third set of parentheses in the regular expression.</p> <p>Default value: 0</p> <div style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p>Note: The subexpressions are numbered left to right, based on the appearance of opening parenthesis, so nested regular expressions. For example, in the regular expression <code>\s*(\w+\s+(\w+))</code>, subexpression 1 is the one that captures everything but any leading whitespaces.</p> </div>												

Notes

This function operates on UTF-8 strings using the default locale, even if the locale has been set to something else.

If you are porting a regular expression query from an Oracle database, remember that Oracle considers a zero-length string to be equivalent to NULL, while Vertica does not.

Examples

Select the first substring of letters that end with "thy."

```
=> SELECT REGEXP_SUBSTR('healthy, wealthy, and wise', '\w+thy');
REGEXP_SUBSTR
-----
healthy
(1 row)
```

Select the first substring of letters that ends with "thy" starting at the second character in the string.

```
=> SELECT REGEXP_SUBSTR('healthy, wealthy, and wise', '\w+thy', 2);
REGEXP_SUBSTR
-----
ealthy
(1 row)
```

Select the second substring of letters that ends with "thy."

```
=> SELECT REGEXP_SUBSTR('healthy, wealthy, and wise', '\w+thy', 1, 2);
REGEXP_SUBSTR
-----
wealthy
(1 row)
```

Return the contents of the third captured subexpression, which captures the third word in the string.

```
=> SELECT REGEXP_SUBSTR('one two three', '(\w+)\s+(\w+)\s+(\w+)', 1, 1, ' ', 3);
REGEXP_SUBSTR
-----
three
(1 row)
```

Sequence Functions

The sequence functions provide simple, multiuser-safe methods for obtaining successive sequence values from sequence objects.

NEXTVAL

Returns the next value in a sequence. NEXTVAL is used in INSERT, COPY, and SELECT statements to create unique column values.

Call NEXTVAL after creating a sequence to initialize the sequence with its default value. Thereafter, call NEXTVAL to increment the sequence value for ascending sequences, or decrement its value for descending sequences.

Behavior Type

Volatile

Syntax

```
NEXTVAL(' [schema . ]sequence-name' )
```

Parameters

<i>schema</i>	<p>Specifies a schema. If multiple schemas are defined in the database, include the schema name. For example:</p> <pre>myschema.thisDBObject</pre>
<i>sequence-name</i>	Identifies the target sequence.

Privileges

- SELECT privilege on sequence
- USAGE privilege on sequence schema

Examples

The following example creates an ascending sequence called `my_seq`, starting at 101:

```
=> CREATE SEQUENCE my_seq START 101;
```

The following command generates the first number in the sequence:

```
=> SELECT NEXTVAL('my_seq');
nextval
-----
      101
(1 row)
```

The following command generates the next number in the sequence:

```
=> SELECT NEXTVAL('my_seq');
nextval
-----
      102
(1 row)
```

The following command illustrates how `NEXTVAL` is evaluated on a per-row basis, so in this example, both calls to `NEXTVAL` yield the same result:

```
=> SELECT NEXTVAL('my_seq'), NEXTVAL('my_seq');
nextval | nextval
-----+-----
      103 |      103
(1 row)
```

The following example illustrates how the `NEXTVAL` is always evaluated first (and here, increments the `my_seq` sequence from its previous value), even when `CURRVAL` precedes `NEXTVAL`:

```
=> SELECT CURRVAL('my_seq'), NEXTVAL('my_seq');
currval | nextval
-----+-----
      104 |      104
(1 row)
```

The following example shows how to use NEXTVAL in a table SELECT statement. Notice that the nextval column is incremented by 1 again:

```
=> SELECT NEXTVAL('my_seq'), product_description FROM product_dimension LIMIT 10;
nextval |      product_description
-----+-----
    105 | Brand #2 bagels
    106 | Brand #1 butter
    107 | Brand #6 chicken noodle soup
    108 | Brand #5 golf clubs
    109 | Brand #4 brandy
    110 | Brand #3 lamb
    111 | Brand #11 vanilla ice cream
    112 | Brand #10 ground beef
    113 | Brand #9 camera case
    114 | Brand #8 halibut
(10 rows)
```

- [CURRVAL](#)
- [DROP SEQUENCE](#)
- [Working with Sequence Types](#)
- [Sequence Privileges](#)

CURRVAL

Returns the last value across all nodes that was set by [NEXTVAL](#) on this sequence in the current session. If NEXTVAL was never called on this sequence since its creation, Vertica returns an error.

Behavior Type

Volatile

Syntax

```
CURRVAL(['schema.'sequence-name')
```

Parameters

<i>schema</i>	Specifies a schema . If multiple schemas are defined in the database, include the schema name. For example: <pre>myschema.thisDBObject</pre>
<i>sequence-name</i>	The target sequence

Privileges

- SELECT privilege on sequence
- USAGE privilege on sequence schema

Examples

The following example creates an ascending sequence called sequential, starting at 101:

```
=> CREATE SEQUENCE seq2 START 101;
```

You can call CURRVAL only after you initiate the sequence with NEXTVAL; otherwise, Vertica returns an error:

```
=> SELECT CURRVAL('seq2');  
ERROR: Sequence seq2 has not been accessed in the session
```

Use NEXTVAL to generate the first number for this sequence:

```
=> SELECT NEXTVAL('seq2');  
nextval  
-----  
101  
(1 row)
```

Now you can use CURRVAL to return the current number from this sequence:

```
=> SELECT CURRVAL('seq2');
currval
-----
      101
(1 row)
```

The following command shows how to use CURRVAL in a SELECT statement:

```
=> CREATE TABLE customer3 (
  lname VARCHAR(25),
  fname VARCHAR(25),
  membership_card INTEGER,
  ID INTEGER
);
INSERT INTO customer3 VALUES ('Brown' , 'Sabra' , 072753, CURRVAL('my_seq'));
SELECT CURRVAL('seq2'), lname FROM customer3;
CURRVAL | lname
-----+-----
      101 | Brown
(1 row)
```

The following example illustrates how the NEXTVAL is always evaluated first (and here, increments the my_seq sequence from its previous value), even when CURRVAL precedes NEXTVAL:

```
=> SELECT CURRVAL('my_seq'), NEXTVAL('my_seq');
currval | nextval
-----+-----
      102 |      102
(1 row)
```

LAST_INSERT_ID

Returns the last value of a column whose value is automatically incremented through AUTO_INCREMENT or IDENTITY [column constraints](#). If multiple sessions concurrently load the same table, the returned value is the last value generated for an AUTO_INCREMENT column by an insert in that session.

Behavior Type

Volatile

Syntax

```
LAST_INSERT_ID()
```

Privileges

- Table owner
- USAGE privileges on schema

Restrictions

- This function works only with AUTO_INCREMENT and IDENTITY columns. See [column constraints](#) for [CREATE TABLE](#).
- LAST_INSERT_ID does not work with sequence generators created through [CREATE SEQUENCE](#).

Examples

1. Create table customer4:

```
=> CREATE TABLE customer4(  
    ID IDENTITY(2,2),  
    lname VARCHAR(25),  
    fname VARCHAR(25),  
    membership_card INTEGER  
);  
=> INSERT INTO customer4(lname, fname, membership_card) VALUES ('Gupta', 'Saleem', 475987);
```

The IDENTITY column has a seed of 2, which specifies the value for the first row loaded into the table, and an increment of 2, which specifies the value that is added to the IDENTITY value of the previous row.

2. Query the table you just created:

```
=> SELECT * FROM customer4;  
ID | lname | fname | membership_card  
-----+-----+-----+-----  
2 | Gupta | Saleem | 475987  
(1 row)
```

3. Insert additional values:

```
=> INSERT INTO customer4(lname, fname, membership_card) VALUES ('Lee', 'Chen', 598742);
```

4. Call LAST_INSERT_ID:

```
=> SELECT LAST_INSERT_ID();
LAST_INSERT_ID
-----
                4
(1 row)
```

5. Query the table again:

```
=> SELECT * FROM customer4;
ID | lname | fname | membership_card
-----+-----+-----+-----
 2 | Gupta | Saleem |          475987
 4 | Lee   | Chen   |          598742
(2 rows)
```

6. Add another row:

```
=> INSERT INTO customer4(lname, fname, membership_card) VALUES ('Davis', 'Bill', 469543);
```

7. Call LAST_INSERT_ID:

```
=> SELECT LAST_INSERT_ID();
LAST_INSERT_ID
-----
                6
(1 row)
```

8. Query the table again:

```
=> SELECT * FROM customer4;
ID | lname | fname | membership_card
-----+-----+-----+-----
 2 | Gupta | Saleem |          475987
 4 | Lee   | Chen   |          598742
 6 | Davis | Bill   |          469543
(3 rows)
```

String Functions

String functions perform conversion, extraction, or manipulation operations on strings, or return information about strings.

This section describes functions and operators for examining and manipulating string values. Strings in this context include values of the types CHAR, VARCHAR, BINARY, and VARBINARY.

Unless otherwise noted, all of the functions listed in this section work on all four data types. As opposed to some other SQL implementations, Vertica keeps CHAR strings unpadded internally, padding them only on final output. So converting a CHAR(3) 'ab' to VARCHAR(5) results in a VARCHAR of length 2, not one with length 3 including a trailing space.

Some of the functions described here also work on data of non-string types by converting that data to a string representation first. Some functions work only on character strings, while others work only on binary strings. Many work for both. BINARY and VARBINARY functions ignore multibyte UTF-8 character boundaries.

Non-binary character string functions handle normalized multibyte UTF-8 characters, as specified by the Unicode Consortium. Unless otherwise specified, those character string functions for which it matters can optionally specify whether VARCHAR arguments should be interpreted as octet (byte) sequences, or as (locale-aware) sequences of UTF-8 characters. This is accomplished by adding "USING OCTETS" or "USING CHARACTERS" (default) as a parameter to the function.

Some character string functions are stable because in general UTF-8 case-conversion, searching and sorting can be locale dependent. Thus, LOWER is stable, while LOWERB is immutable. The USING OCTETS clause converts these functions into their "B" forms, so they become immutable. If the locale is set to collation=binary, which is the default, all string functions—except CHAR_LENGTH/CHARACTER_LENGTH, LENGTH, SUBSTR, and OVERLAY—are converted to their "B" forms and so are immutable.

BINARY implicitly converts to VARBINARY, so functions that take VARBINARY arguments work with BINARY.

ASCII

Converts the first character of a VARCHAR datatype to an INTEGER.

Behavior Type

Immutable

Syntax

ASCII (*expression*)

Parameters

<i>expression</i>	(VARCHAR) is the string to convert.
-------------------	-------------------------------------

Notes

- ASCII is the opposite of the [CHR](#) function.
- ASCII operates on UTF-8 characters, not only on single-byte ASCII characters. It continues to get the same results for the ASCII subset of UTF-8.

Examples

This example returns employees whose last name begins with M. The ASCII equivalent of M is 77:

```
=> SELECT employee_last_name FROM employee_dimension
      WHERE ASCII(SUBSTR(employee_last_name, 1, 1)) = 76
      LIMIT 5;
employee_last_name
-----
Lewis
Lewis
Lampert
Lampert
Li
(5 rows)
```

BIT_LENGTH

Returns the length of the string expression in bits (bytes * 8) as an INTEGER.

Behavior Type

Immutable

Syntax

```
BIT_LENGTH ( expression )
```

Parameters

<i>expression</i>	(CHAR or VARCHAR or BINARY or VARBINARY) is the string to convert.
-------------------	--

Notes

BIT_LENGTH applies to the contents of VARCHAR and VARBINARY fields.

Examples

Expression	Result
SELECT BIT_LENGTH('abc'::varbinary);	24
SELECT BIT_LENGTH('abc'::binary);	8
SELECT BIT_LENGTH(' '::varbinary);	0
SELECT BIT_LENGTH(' '::binary);	8
SELECT BIT_LENGTH(null::varbinary);	
SELECT BIT_LENGTH(null::binary);	
SELECT BIT_LENGTH(VARCHAR 'abc');	24
SELECT BIT_LENGTH(CHAR 'abc');	24
SELECT BIT_LENGTH(CHAR(6) 'abc');	48
SELECT BIT_LENGTH(VARCHAR(6) 'abc');	24
SELECT BIT_LENGTH(BINARY(6) 'abc');	48
SELECT BIT_LENGTH(BINARY 'abc');	24

SELECT BIT_LENGTH(VARBINARY 'abc');	24
SELECT BIT_LENGTH(VARBINARY(6) 'abc');	24

See Also

- [CHARACTER_LENGTH](#)
- [LENGTH](#)
- [OCTET_LENGTH](#)

BITCOUNT

Returns the number of one-bits (sometimes referred to as set-bits) in the given VARBINARY value. This is also referred to as the population count.

Behavior Type

Immutable

Syntax

```
BITCOUNT ( expression )
```

Parameters

<i>expression</i>	(BINARY or VARBINARY) is the string to return.
-------------------	--

Examples

```
=> SELECT BITCOUNT(HEX_TO_BINARY('0x10'));
   BITCOUNT
-----
           1
(1 row)
```

```
=> SELECT BITCOUNT(HEX_TO_BINARY('0xF0'));
   BITCOUNT
-----
          4
(1 row)

=> SELECT BITCOUNT(HEX_TO_BINARY('0xAB'));
   BITCOUNT
-----
          5
(1 row)
```

BITSTRING_TO_BINARY

Translates the given VARCHAR bitstring representation into a VARBINARY value. This function is the inverse of [TO_BITSTRING](#).

Behavior Type

Immutable

Syntax

```
BITSTRING_TO_BINARY ( expression )
```

Parameters

<i>expression</i>	The VARCHAR string to process.
-------------------	--------------------------------

Examples

If there are an odd number of characters in the hex value, the first character is treated as the low nibble of the first (furthest to the left) byte.

```
=> SELECT BITSTRING_TO_BINARY('0110000101100010');
   BITSTRING_TO_BINARY
-----
          ab
(1 row)
```

BTRIM

Removes the longest string consisting only of specified characters from the start and end of a string.

Behavior Type

Immutable

Syntax

```
BTRIM ( expression [ , characters-to-remove ] )
```

Parameters

<i>expression</i>	(CHAR or VARCHAR) is the string to modify
<i>characters-to-remove</i>	(CHAR or VARCHAR) specifies the characters to remove. The default is the space character.

Example

```
=> SELECT BTRIM('yxtrimyx', 'xy');  
BTRIM  
-----  
trim  
(1 row)
```

See Also

- [LTRIM](#)
- [RTRIM](#)
- [TRIM](#)

CHARACTER_LENGTH

The CHARACTER_LENGTH() function:

- Returns the string length in UTF-8 characters for CHAR and VARCHAR columns
- Returns the string length in bytes (octets) for BINARY and VARBINARY columns
- Strips the padding from CHAR expressions but not from VARCHAR expressions
- Is identical to [LENGTH\(\)](#) for CHAR and VARCHAR. For binary types, CHARACTER_LENGTH() is identical to [OCTET_LENGTH\(\)](#).

Behavior Type

Immutable if USING OCTETS, stable otherwise.

Syntax

```
[ CHAR_LENGTH | CHARACTER_LENGTH ] ( expression ... [ USING { CHARACTERS | OCTETS } ] )
```

Parameters

<i>expression</i>	(CHAR or VARCHAR) is the string to measure
USING CHARACTERS OCTETS	Determines whether the character length is expressed in characters (the default) or octets.

Examples

```
=> SELECT CHAR_LENGTH('1234 '::CHAR(10) USING OCTETS);
   octet_length
-----
           4
(1 row)

=> SELECT CHAR_LENGTH('1234 '::VARCHAR(10));
   char_length
-----
```

```
        6  
(1 row)  
=> SELECT CHAR_LENGTH(NULL::CHAR(10)) IS NULL;  
?column?  
-----  
t  
(1 row)
```

See Also

- [BIT_LENGTH](#)

CHR

Converts the first character of an INTEGER datatype to a VARCHAR.

Behavior Type

Immutable

Syntax

CHR (*expression*)

Parameters

<i>expression</i>	(INTEGER) is the string to convert and is masked to a single character.
-------------------	---

Notes

- CHR is the opposite of the [ASCII](#) function.
- CHR operates on UTF-8 characters, not only on single-byte ASCII characters. It continues to get the same results for the ASCII subset of UTF-8.

Examples

This example returns the VARCHAR datatype of the CHR expressions 65 and 97 from the employee table:

```
=> SELECT CHR(65), CHR(97) FROM employee;
CHR | CHR
-----+-----
A   | a
A   | a
A   | a
A   | a
A   | a
A   | a
A   | a
A   | a
A   | a
A   | a
A   | a
A   | a
(12 rows)
```

COLLATION

Applies a collation to two or more strings. Use COLLATION with ORDER BY, GROUP BY, and equality clauses.

Syntax

```
COLLATION ( 'expression' [ , 'locale_or_collation_name' ] )
```

Parameters

'expression'	Any expression that evaluates to a column name or to two or more values of type CHAR or VARCHAR.
'locale_or_collation_name'	The ICU (International Components for Unicode) locale or collation name to use when collating the string. If you omit this parameter, COLLATION uses the collation associated with the session locale. To determine the current session locale, enter the vsql meta-command <code>\locale</code> :

```
=> \locale
en_US@collation=binary
```

To set the locale and collation, use `\locale` as follows:

```
=> \locale en_US@collation=binary
INFO 2567: Canonical locale: 'en_US'
Standard collation: 'LEN_KBINARY'
English (United States)
```

Locales

The locale used for COLLATION can be one of the following:

- The default locale
- A session locale
- A locale that you specify when you call COLLATION. If you specify the locale, Vertica applies the collation associated with that locale to the data. COLLATION does not modify the collation for any other columns in the table.

For a list of valid ICU locales, go to [Locale Explorer \(ICU\)](#).

Binary and Non-Binary Collations

The Vertica default locale is `en_US@collation=binary`, which uses *binary collation*. Binary collation compares binary representations of strings. Binary collation is fast, but it can result in a sort order where K precedes c because the binary representation of K is lower than c.

For non-binary collation, Vertica transforms the data according to the rules of the locale or the specified collation, and then applies the sorting rules. Suppose the locale collation is non-binary and you request a GROUP BY on string data. In this case, Vertica calls COLLATION, whether or not you specify the function in your query.

For information about collation naming, see [Collator Naming Scheme](#).

Examples

Collating GROUP BY Results

The following examples are based on a `Premium_Customer` table that contains the following data:

```
=> SELECT * FROM Premium_Customer;
ID | LName | FName
----+-----+-----
 1 | Mc Coy | Bob
 2 | Mc Coy | Janice
 3 | McCoy | Jody
 4 | McCoy | Peter
 5 | McCoy | Brendon
 6 | Mccoy | Cameron
 7 | Mccoy | Lisa
```

The first statement shows how COLLATION applies the collation for the EN_US locale to the LName column for the locale EN_US. Vertica sorts the GROUP BY output as follows:

- Last names with spaces
- Last names where "coy" starts with a lowercase letter
- Last names where "Coy" starts with an uppercase letter

```
=> SELECT * FROM Premium_Customer ORDER BY COLLATION(LName, 'EN_US'), FName;
ID | LName | FName
----+-----+-----
 1 | Mc Coy | Bob
 2 | Mc Coy | Janice
 6 | Mccoy | Cameron
 7 | Mccoy | Lisa
 5 | McCoy | Brendon
 3 | McCoy | Jody
 4 | McCoy | Peter
```

The next statement shows how COLLATION collates the LName column for the locale LEN_AS:

- LEN indicates the language (L) is English (EN).
- AS (Alternate Shifted) instructs COLLATION that lowercase letters come before uppercase (shifted) letters.

In the results, the last names in which "coy" starts with a lowercase letter precede the last names where "Coy" starts with an uppercase letter.

```
=> SELECT * FROM Premium_Customer ORDER BY COLLATION(LName, 'LEN_AS'), FName;
ID | LName | FName
----+-----+-----
 6 | Mccoy | Cameron
 7 | Mccoy | Lisa
 1 | Mc Coy | Bob
 5 | McCoy | Brendon
 2 | Mc Coy | Janice
 3 | McCoy | Jody
 4 | McCoy | Peter
```

Comparing Strings with an Equality Clause

In the following query, COLLATION removes spaces and punctuation when comparing two strings in English. It then determines whether the two strings still have the same value after the punctuation has been removed:

```
=> SELECT COLLATION ('U.S.A', 'LEN_AS') = COLLATION('USA', 'LEN_AS');
?column?
-----
t
```

Sorting Strings in Non-English Languages

The following table contains data that uses the German character eszett, ß:

```
=> SELECT * FROM t1;
   a      | b | c
-----+-----+-----
ßstringß | 1 | 10
SSstringSS | 2 | 20
random1   | 3 | 30
random1   | 4 | 40
random2   | 5 | 50
```

When you specify the collation LDE_S1:

- LDE indicates the language (L) is German (DE).
- S1 indicates the strength (S) of 1 (primary). This value indicates that the collation does not need to consider accents and case.

The query returns the data in the following order:

```
=> SELECT a FROM t1 ORDER BY COLLATION(a, 'LDE_S1');
a
-----
random1
random1
random2
SSstringSS
ßstringß
```

CONCAT

Used to concatenate two strings.

Syntax

```
CONCAT ('string1','string2')
```

Behavior Type

Immutable

Parameters

'string1'	Can be any datatype.
'string2'	

Restrictions

Varbinary and long varbinary types cannot be mixed with other types. These types return varbinary and long varbinary, respectively.

Similarly, long varchar types return long varchar.

Otherwise, the result is varchar.

Note: If either argument is null, concat returns null.

Example

The following simple examples use a sample table named `alphabet`, which contains two rows, `letter1` and `letter2`. The contents are as follows.

```
=> CREATE TABLE alphabet (letter1 varchar(2), letter2 varchar(2));
CREATE TABLE
=> COPY alphabet FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> A|B
>> C|D
>> \.
=> SELECT * FROM alphabet;
 letter1 | letter2
-----+-----
 C      | D
 A      | B
(2 rows)
```

The following example concatenates the contents of the first column with a character string.

```
=> SELECT CONCAT(letter1, ' is a letter') FROM alphabet;
      CONCAT
-----
A is a letter
C is a letter
(2 rows)
```

The following example nests the CONCAT function.

```
=> SELECT CONCAT(CONCAT(letter1, ' and '), CONCAT(letter2, ' are both letters')) FROM alphabet;
      CONCAT
-----
C and D are both letters
A and B are both letters
(2 rows)
```

DECODE

Compares *expression* to each search value one by one. If *expression* is equal to a search, the function returns the corresponding result. If no match is found, the function returns default. If default is omitted, the function returns null.

DECODE is similar to the IF-THEN-ELSE and [CASE](#) expression:

```
CASE expression WHEN search THEN result
[WHEN search THEN result]
[ELSE default];
```

The arguments can have any data type supported by Vertica. The result types of individual results are promoted to the least common type that can be used to represent all of them. This leads to a character string type, an exact numeric type, an approximate numeric type, or a DATETIME type, where all the various result arguments must be of the same type grouping.

Behavior Type

Immutable

Syntax

```
DECODE ( expression, search, result [ , search, result ]...[, default ] )
```

Parameters

<i>expression</i>	The value to compare.
<i>search</i>	The value compared against <i>expression</i> .
<i>result</i>	The value returned, if <i>expression</i> is equal to search.
<i>default</i>	Optional. If no matches are found, DECODE returns default. If default is omitted, then DECODE returns NULL (if no matches are found).

Example

The following example converts numeric values in the weight column from the product_ dimension table to descriptive values in the output.

```
=> SELECT product_description, DECODE(weight,
    2, 'Light',
    50, 'Medium',
    71, 'Heavy',
    99, 'Call for help',
    'N/A')
FROM product_dimension
WHERE category_description = 'Food'
AND department_description = 'Canned Goods'
AND sku_number BETWEEN 'SKU-#49750' AND 'SKU-#49999'
LIMIT 15;
```

product_description	case
Brand #499 canned corn	N/A
Brand #49900 fruit cocktail	Medium
Brand #49837 canned tomatoes	Heavy
Brand #49782 canned peaches	N/A
Brand #49805 chicken noodle soup	N/A
Brand #49944 canned chicken broth	N/A
Brand #49819 canned chili	N/A
Brand #49848 baked beans	N/A
Brand #49989 minestrone soup	N/A
Brand #49778 canned peaches	N/A
Brand #49770 canned peaches	N/A
Brand #4977 fruit cocktail	N/A
Brand #49933 canned olives	N/A
Brand #49750 canned olives	Call for help
Brand #49777 canned tomatoes	N/A

(15 rows)

GREATEST

Returns the largest value in a list of expressions.

Behavior Type

Stable

Syntax

```
GREATEST ( expression1, expression2, ... expression-n )
```

Parameters

expression1, *expression2*, and *expression-n* are the expressions to be evaluated.

Notes

- Works for all data types, and implicitly casts similar types. See Examples.
- A NULL value in any one of the expressions returns NULL.
- Depends on the collation setting of the locale.

Examples

This example returns 9 as the greatest in the list of expressions:

```
=> SELECT GREATEST(7, 5, 9);
GREATEST
-----
          9
(1 row)
```

Note that putting quotes around the integer expressions returns the same result as the first example:

```
=> SELECT GREATEST('7', '5', '9');
GREATEST
-----
9
(1 row)
```

The next example returns FLOAT 1.5 as the greatest because the integer is implicitly cast to float:

```
=> SELECT GREATEST(1, 1.5);
GREATEST
-----
1.5
(1 row)
```

The following example returns 'vertica' as the greatest:

```
=> SELECT GREATEST('vertica', 'analytic', 'database');
GREATEST
-----
vertica
(1 row)
```

Notice this next command returns NULL:

```
=> SELECT GREATEST('vertica', 'analytic', 'database', null);
GREATEST
-----
(1 row)
```

And one more:

```
=> SELECT GREATEST('sit', 'site', 'sight');
GREATEST
-----
site
(1 row)
```

See Also

- [LEAST](#)

GREATESTB

Returns its greatest argument, using binary ordering, not UTF-8 character ordering.

Behavior Type

Immutable

Syntax

```
GREATESTB ( expression1, expression2, ... expression-n )
```

Parameters

expression1, *expression2*, and *expression-n* are the expressions to be evaluated.

Notes

- Works for all data types, and implicitly casts similar types. See Examples.
- A NULL value in any one of the expressions returns NULL.
- Depends on the collation setting of the locale.

Examples

The following command selects *straße* as the greatest in the series of inputs:

```
=> SELECT GREATESTB('straße', 'strasse');
GREATESTB
-----
straße
(1 row)
```

This example returns 9 as the greatest in the list of expressions:

```
=> SELECT GREATESTB(7, 5, 9);
GREATESTB
-----
          9
(1 row)
```

Note that putting quotes around the integer expressions returns the same result as the first example:

```
=> SELECT GREATESTB('7', '5', '9');
GREATESTB
-----
9
(1 row)
```

The next example returns FLOAT 1.5 as the greatest because the integer is implicitly cast to float:

```
=> SELECT GREATESTB(1, 1.5);
GREATESTB
-----
1.5
(1 row)
```

The following example returns `vertica` as the greatest:

```
=> SELECT GREATESTB('vertica', 'analytic', 'database');
GREATESTB
-----
vertica
(1 row)
```

Notice this next command returns NULL:

```
=> SELECT GREATESTB('vertica', 'analytic', 'database', null);
GREATESTB
-----
(1 row)
```

And one more:

```
=> SELECT GREATESTB('sit', 'site', 'sight');
GREATESTB
-----
site
(1 row)
```

- [LEASTB](#)

HEX_TO_BINARY

Translates the given VARCHAR hexadecimal representation into a VARBINARY value.

Behavior Type

Immutable

Syntax

```
HEX_TO_BINARY ( [ 0x ] expression )
```

Parameters

<i>expression</i>	(BINARY or VARBINARY) String to translate.
0x	Optional prefix.

Notes

VARBINARY HEX_TO_BINARY(VARCHAR) converts data from character type in hexadecimal format to binary type. This function is the inverse of [TO_HEX](#).

```
HEX_TO_BINARY(TO_HEX(x)) = x  
TO_HEX(HEX_TO_BINARY(x)) = x
```

If there are an odd number of characters in the hexadecimal value, the first character is treated as the low nibble of the first (furthest to the left) byte.

Examples

If the given string begins with "0x" the prefix is ignored. For example:

```
=> SELECT HEX_TO_BINARY('0x6162') AS hex1, HEX_TO_BINARY('6162') AS hex2;  
hex1 | hex2  
-----+-----  
ab   | ab  
(1 row)
```

If an invalid hex value is given, Vertica returns an "invalid binary representation" error; for example:

```
=> SELECT HEX_TO_BINARY('0xffgf');  
ERROR:  invalid hex string "0xffgf"
```

See Also

- [TO_HEX](#)

HEX_TO_INTEGER

Translates the given VARCHAR hexadecimal representation into an INTEGER value.

Vertica completes this conversion as follows:

- Adds the 0x prefix if it is not specified in the input
- Casts the VARCHAR string to a NUMERIC
- Casts the NUMERIC to an INTEGER

Behavior Type

Immutable

Syntax

```
HEX_TO_INTEGER ( [ 0x ] expression )
```

Parameters

<i>expression</i>	VARCHAR is the string to translate.
0x	Is the optional prefix.

Examples

You can enter the string with or without the 0x prefix. For example:

```
=> SELECT HEX_TO_INTEGER ('0aedic')
      AS hex1,HEX_TO_INTEGER ('aedic') AS hex2;
hex1  | hex2
-----+-----
44764 | 44764
(1 row)
```

If you pass the function an invalid hex value, Vertica returns an `invalid input syntax` error; for example:

```
=> SELECT HEX_TO_INTEGER ('0xffgf');
ERROR 3691: Invalid input syntax for numeric: "0xffgf"
```

See Also

- [TO_HEX](#)
- [HEX_TO_BINARY](#)

INET_ATON

Returns an integer that represents the value of the address in host byte order, given the dotted-quad representation of a network address as a string.

Behavior Type

Immutable

Syntax

```
INET_ATON ( expression )
```

Parameters

<i>expression</i>	(VARCHAR) is the string to convert.
-------------------	-------------------------------------

Notes

The following syntax converts an IPv4 address represented as the string *A* to an integer *I*. `INET_ATON` trims any spaces from the right of *A*, calls the Linux function `inet_pton`, and converts the result from network byte order to host byte order using `ntohl`.

```
=> INET_ATON(VARCHAR A) -> INT8 I
```

If *A* is NULL, too long, or `inet_pton` returns an error, the result is NULL.

Examples

The generated number is always in host byte order. In the following example, the number is calculated as $209 \times 256^3 + 207 \times 256^2 + 224 \times 256 + 40$.

```
=> SELECT INET_ATON('209.207.224.40');
inet_aton
-----
3520061480
(1 row)

=> SELECT INET_ATON('1.2.3.4');
inet_aton
-----
16909060
(1 row)

=> SELECT TO_HEX(INET_ATON('1.2.3.4'));
to_hex
-----
1020304
(1 row)
```

See Also

- [INET_NTOA](#)

INET_NTOA

Returns the dotted-quad representation of the address as a VARCHAR, given a network address as an integer in network byte order.

Behavior Type

Immutable

Syntax

```
INET_NTOA ( expression )
```

Parameters

<i>expression</i>	(INTEGER) is the network address to convert.
-------------------	--

Notes

The following syntax converts an IPv4 address represented as integer I to a string A.

INET_NTOA converts I from host byte order to network byte order using [htonl](#), and calls the Linux function [inet_ntop](#).

```
=> INET_NTOA(INT8 I) -> VARCHAR A
```

If I is NULL, greater than 2^{32} or negative, the result is NULL.

Examples

```
=> SELECT INET_NTOA(16909060);
inet_ntoa
-----
1.2.3.4
(1 row)

=> SELECT INET_NTOA(03021962);
inet_ntoa
-----
0.46.28.138
(1 row)
```

See Also

- [INET_ATON](#)

INITCAP

Capitalizes first letter of each alphanumeric word and puts the rest in lowercase.

Behavior Type

Immutable

Syntax

INITCAP (*expression*)

Parameters

<i>expression</i>	(VARCHAR) is the string to format.
-------------------	------------------------------------

Notes

- Depends on collation setting of the locale.
- INITCAP is restricted to 32750 octet inputs, since it is possible for the UTF-8 representation of result to double in size.

Examples

Expression	Result
SELECT INITCAP('high speed database');	High Speed Database
SELECT INITCAP('LINUX TUTORIAL');	Linux Tutorial

SELECT INITCAP('abc DEF 123aVc 124Btd,1AsT');	Abc Def 123Avc 124Btd,Last
SELECT INITCAP('');	
SELECT INITCAP(null);	

INITCAPB

Capitalizes first letter of each alphanumeric word and puts the rest in lowercase. Multibyte characters are not converted and are skipped.

Behavior Type

Immutable

Syntax

INITCAPB (*expression*)

Parameters

<i>expression</i>	(VARCHAR) is the string to format.
-------------------	------------------------------------

Notes

Depends on collation setting of the locale.

Examples

Expression	Result
SELECT INITCAPB('étudiant');	éTudiant
SELECT INITCAPB('high speed database');	High Speed Database
SELECT INITCAPB('LINUX TUTORIAL');	Linux Tutorial
SELECT INITCAPB('abc DEF 123aVc 124Btd,1AsT');	Abc Def 123Avc 124Btd,Last

SELECT INITCAPB('');	
SELECT INITCAPB(null);	

INSERT

Inserts a character string into a specified location in another character string.

Syntax

```
INSERT( 'string1', n, m, 'string2' )
```

Behavior Type

Immutable

Parameters

<i>string1</i>	(VARCHAR) Is the string in which to insert the new string.
<i>n</i>	A character of type INTEGER that represents the starting point for the insertion within <i>string1</i> . You specify the number of characters from the first character in <i>string1</i> as the starting point for the insertion. For example, to insert characters before "c", in the string "abcdef," enter 3.
<i>m</i>	A character of type INTEGER that represents the number of characters in <i>string1</i> (if any) that should be replaced by the insertion. For example, if you want the insertion to replace the letters "cd" in the string "abcdef, " enter 2.
<i>string2</i>	(VARCHAR) Is the string to be inserted.

Example

The following example changes the string Warehouse to Storehouse using the INSERT function:

```
=> SELECT INSERT ('Warehouse',1,3,'Stor');  
      INSERT  
-----
```

Storehouse
(1 row)

INSTR

Searches *string* for *substring* and returns an integer indicating the position of the character in *string* that is the first character of this *occurrence*. The return value is based on the character position of the identified character.

Behavior Type

Immutable

Syntax

```
INSTR ( string , substring [, position [, occurrence ] ] )
```

Parameters

<i>string</i>	(CHAR or VARCHAR, or BINARY or VARBINARY) Text expression to search.
<i>substring</i>	(CHAR or VARCHAR, or BINARY or VARBINARY) String to search for.
<i>position</i>	Nonzero integer indicating the character of string where Vertica begins the search. If position is negative, then Vertica counts backward from the end of string and then searches backward from the resulting position. The first character of string occupies the default position 1, and position cannot be 0.
<i>occurrence</i>	Integer indicating which occurrence of string Vertica searches. The value of occurrence must be positive (greater than 0), and the default is 1.

Notes

Both *position* and *occurrence* must be of types that can resolve to an integer. The default values of both parameters are 1, meaning Vertica begins searching at the first character of string for the first occurrence of substring. The return value is relative to the beginning of string, regardless of the value of position, and is expressed in characters.

If the search is unsuccessful (that is, if substring does not appear *occurrence* times after the *position* character of *string*, the return value is 0.

Examples

The first example searches forward in string 'abc' for substring 'b'. The search returns the position in 'abc' where 'b' occurs, or position 2. Because no position parameters are given, the default search starts at 'a', position 1.

```
=> SELECT INSTR('abc', 'b');
INSTR
-----
      2
(1 row)
```

The following three examples use character position to search backward to find the position of a substring.

Note: Although it might seem intuitive that the function returns a negative integer, the position of *n* occurrence is read left to right in the sting, even though the search happens in reverse (from the end—or right side—of the string).

In the first example, the function counts backward one character from the end of the string, starting with character 'c'. The function then searches backward for the first occurrence of 'a', which it finds it in the first position in the search string.

```
=> SELECT INSTR('abc', 'a', -1);
INSTR
-----
      1
(1 row)
```

In the second example, the function counts backward one byte from the end of the string, starting with character 'c'. The function then searches backward for the first occurrence of 'a', which it finds it in the first position in the search string.

```
=> SELECT INSTR(VARBINARY 'abc', VARBINARY 'a', -1);
INSTR
-----
      1
(1 row)
```

In the third example, the function counts backward one character from the end of the string, starting with character 'b', and searches backward for substring 'bc', which it finds in the second position of the search string.

```
=> SELECT INSTR('abcb', 'bc', -1);
INSTR
-----
      2
(1 row)
```

In the fourth example, the function counts backward one character from the end of the string, starting with character 'b', and searches backward for substring 'bcef', which it does not find. The result is 0.

```
=> SELECT INSTR('abcb', 'bcef', -1);
INSTR
-----
      0
(1 row)
```

In the fifth example, the function counts backward one byte from the end of the string, starting with character 'b', and searches backward for substring 'bcef', which it does not find. The result is 0.

```
=> SELECT INSTR(VARBINARY 'abcb', VARBINARY 'bcef', -1);
INSTR
-----
      0
(1 row)
```

Multibyte characters are treated as a single character:

```
=> SELECT INSTR('aébc', 'b');
INSTR
-----
      3
(1 row)
```

Use INSTRB to treat multibyte characters as binary:

```
=> SELECT INSTRB('aébc', 'b');
INSTRB
-----
      4
(1 row)
```

INSTRB

Searches *string* for *substring* and returns an integer indicating the octet position within string that is the first *occurrence*. The return value is based on the octet position of the identified byte.

Behavior Type

Immutable

Syntax

```
INSTRB ( string , substring [, position [, occurrence ] ] )
```

Parameters

<i>string</i>	Is the text expression to search.
<i>substring</i>	Is the string to search for.
<i>position</i>	Is a nonzero integer indicating the character of string where Vertica begins the search. If position is negative, then Vertica counts backward from the end of string and then searches backward from the resulting position. The first byte of string occupies the default position 1, and position cannot be 0.
<i>occurrence</i>	Is an integer indicating which occurrence of string Vertica searches. The value of occurrence must be positive (greater than 0), and the default is 1.

Notes

Both *position* and *occurrence* must be of types that can resolve to an integer. The default values of both parameters are 1, meaning Vertica begins searching at the first byte of string for the first occurrence of substring. The return value is relative to the beginning of string, regardless of the value of position, and is expressed in octets.

If the search is unsuccessful (that is, if substring does not appear *occurrence* times after the *position* character of *string*, then the return value is 0.

Example

```
=> SELECT INSTRB('straße', 'ß');  
INSTRB  
-----  
5
```

(1 row)

See Also

- [INSTR](#)

ISUTF8

Tests whether a string is a valid UTF-8 string. Returns true if the string conforms to UTF-8 standards, and false otherwise. This function is useful to test strings for UTF-8 compliance before passing them to one of the regular expression functions, such as [REGEXP_LIKE](#), which expect UTF-8 characters by default.

ISUTF8 checks for invalid UTF8 byte sequences, according to UTF-8 rules:

- invalid bytes
- an unexpected continuation byte
- a start byte not followed by enough continuation bytes
- an Overload Encoding

The presence of an invalid UTF8 byte sequence results in a return value of false.

Syntax

```
ISUTF8( string );
```

Parameters

<i>string</i>	The string to test for UTF-8 compliance.
---------------	--

Examples

```
=> SELECT ISUTF8(E'\xC2\xBF'); -- UTF-8 INVERTED QUESTION MARK ISUTF8  
-----
```

```
t
(1 row)
=> SELECT ISUTF8(E'\xC2\xC0'); -- UNDEFINED UTF-8 CHARACTER
ISUTF8
-----
f
(1 row)
```

LEAST

Returns the smallest value in a list of expressions.

Behavior Type

Stable

Syntax

```
LEAST ( expression1, expression2, ... expression-n )
```

Parameters

expression1, *expression2*, and *expression-n* are the expressions to be evaluated.

Notes

- Works for all data types, and implicitly casts similar types. See Examples below.
- A NULL value in any one of the expressions returns NULL.

Examples

This example returns 5 as the least:

```
=> SELECT LEAST(7, 5, 9);
LEAST
-----
5
(1 row)
```

Putting quotes around the integer expressions returns the same result as the first example:

```
=> SELECT LEAST('7', '5', '9');
LEAST
-----
5
(1 row)
```

In the above example, the values are being compared as strings, so '10' would be less than '2'.

The next example returns 1.5, as INTEGER 2 is implicitly cast to FLOAT:

```
=> SELECT LEAST(2, 1.5);
LEAST
-----
1.5
(1 row)
```

The following example returns 'analytic' as the least:

```
=> SELECT LEAST('vertica', 'analytic', 'database');
LEAST
-----
analytic
(1 row)
```

Notice this next command returns NULL:

```
=> SELECT LEAST('vertica', 'analytic', 'database', null);
LEAST
-----

(1 row)
```

And one more:

```
=> SELECT LEAST('sit', 'site', 'sight');
LEAST
-----
sight
(1 row)
```

See Also

- [GREATEST](#)

LEASTB

Returns the function's least argument, using binary ordering, not UTF-8 character ordering.

Behavior Type

Immutable

Syntax

```
LEASTB ( expression1, expression2, ... expression-n )
```

Parameters

expression1, *expression2*, and *expression-n* are the expressions to be evaluated.

Notes

- Works for all data types, and implicitly casts similar types. See Examples below.
- A NULL value in any one of the expressions returns NULL.

Examples

The following command selects *strasse* as the least in the series of inputs:

```
=> SELECT LEASTB('straße', 'strasse');
LEASTB
-----
strasse
(1 row)
```

This example returns 5 as the least:

```
==> SELECT LEASTB(7, 5, 9);
LEASTB
-----
5
(1 row)
```

Putting quotes around the integer expressions returns the same result as the first example:

```
=> SELECT LEASTB('7', '5', '9');
LEASTB
-----
5
```

```
(1 row)
```

In the above example, the values are being compared as strings, so '10' would be less than '2'.

The next example returns 1.5, as INTEGER 2 is implicitly cast to FLOAT:

```
=> SELECT LEASTB(2, 1.5);
LEASTB
-----
      1.5
(1 row)
```

The following example returns 'analytic' as the least in the series of inputs:

```
=> SELECT LEASTB('vertica', 'analytic', 'database');
LEASTB
-----
analytic
(1 row)
```

Notice this next command returns NULL:

```
=> SELECT LEASTB('vertica', 'analytic', 'database', null);
LEASTB
-----

(1 row)
```

See Also

- [GREATESTB](#)

LEFT

Returns the specified characters from the left side of a string.

Behavior Type

Immutable

Syntax

```
LEFT ( string , Length )
```

Parameters

<i>string</i>	(CHAR or VARCHAR) is the string to return.
<i>length</i>	Is an INTEGER value that specifies the count of characters to return.

Examples

```
=> SELECT LEFT('vertica', 3);
LEFT
-----
ver
(1 row)

=> SELECT LEFT('straße', 5);
LEFT
-----
straß
(1 row)
```

See Also

- [SUBSTR](#)

LENGTH

Returns the length of a string. The behavior of LENGTH varies according to the input data type:

- CHAR and VARCHAR: Identical to [CHARACTER_LENGTH](#), returns the string length in UTF-8 characters, .
- CHAR: Strips padding.
- BINARY and VARBINARY: Identical to [OCTET_LENGTH](#), returns the string length in bytes (octets).

Behavior Type

Immutable

Syntax

LENGTH (*expression*)

Parameters

<i>expression</i>	String to evaluate, one of the following: CHAR, VARCHAR, BINARY or VARBINARY.
-------------------	---

Examples

Statement	Returns
SELECT LENGTH('1234 '::CHAR(10));	4
SELECT LENGTH('1234 '::VARCHAR(10));	6
SELECT LENGTH('1234 '::BINARY(10));	10
SELECT LENGTH('1234 '::VARBINARY(10));	6
SELECT LENGTH(NULL::CHAR(10)) IS NULL;	t

See Also

[BIT_LENGTH](#)

LOWER

Returns a VARCHAR value containing the argument converted to lowercase letters.

LOWER treats the `string` argument as a UTF-8 encoded string, rather than depending on the collation setting of the locale (for example, `collation=binary`) to identify the encoding.

Behavior Type

stable

Syntax

`LOWER (expression)`

Parameters

<i>expression</i>	CHAR or VARCHAR string to convert
-------------------	-----------------------------------

Notes

LOWER is restricted to 32500 octet inputs, since it is possible for the UTF-8 representation of result to double in size.

Examples

```
=> SELECT LOWER('AbCdEfg');
      LOWER
-----
abcdefg
(1 row)

=> SELECT LOWER('The Bat In The Hat');
      LOWER
-----
the bat in the hat
(1 row)

=> SELECT LOWER('ÉTUDIANT');
      LOWER
-----
étudiant
(1 row)
```

LOWERRB

Returns a character string with each ASCII character converted to lowercase. Multi-byte characters are skipped and not converted.

Behavior Type

Immutable

Syntax

`LOWERB (expression)`

Parameters

<i>expression</i>	CHAR or VARCHAR string to convert
-------------------	-----------------------------------

Examples

In the following example, the multi-byte UTF-8 character É is not converted to lowercase:

```
=> SELECT LOWERB('ÉTUDIANT');
      LOWERB
-----
Étudiant
(1 row)

=> SELECT LOWER('ÉTUDIANT');
      LOWER
-----
étudiant
(1 row)

=> SELECT LOWERB('AbCdEfg');
      LOWERB
-----
abcdefg
(1 row)

=> SELECT LOWERB('The Vertica Database');
      LOWERB
-----
the vertica database
(1 row)
```

LPAD

Returns a VARCHAR value representing a string of a specific length filled on the left with specific characters.

Behavior Type

Immutable

Syntax

`LPAD (expression , Length [, fill])`

Parameters

<i>expression</i>	(CHAR OR VARCHAR) specifies the string to fill
<i>Length</i>	(INTEGER) specifies the number of characters to return
<i>fill</i>	(CHAR OR VARCHAR) specifies the repeating string of characters with which to fill the output string. The default is the space character.

Examples

```
=> SELECT LPAD('database', 15, 'xzy');
      LPAD
-----
 xzyxzyxdatabase
(1 row)
```

If the string is already longer than the specified length it is truncated on the right:

```
=> SELECT LPAD('establishment', 10, 'abc');
      LPAD
-----
 establishm
(1 row)
```

LTRIM

Returns a VARCHAR value representing a string with leading blanks removed from the left side (beginning).

Behavior Type

Immutable

Syntax

`LTRIM (expression [, characters])`

Parameters

<i>expression</i>	(CHAR or VARCHAR) is the string to trim
<i>characters</i>	(CHAR or VARCHAR) specifies the characters to remove from the left side of <i>expression</i> . The default is the space character.

Examples

```
=> SELECT LTRIM('zzzyyyyyxxxxxxxxtrim', 'xyz');
   LTRIM
-----
trim
(1 row)
```

See Also

- [BTRIM](#)
- [RTRIM](#)
- [TRIM](#)

MD5

Calculates the MD5 hash of string, returning the result as a VARCHAR string in hexadecimal.

Behavior Type

Immutable

Syntax

MD5 (*string*)

Parameters

<i>string</i>	Is the argument string.
---------------	-------------------------

Examples

```
=> SELECT MD5('123');
      MD5
-----
202cb962ac59075b964b07152d234b70
(1 row)

=> SELECT MD5('Vertica'::bytea);
      MD5
-----
fc45b815747d8236f9f6fdb9c2c3f676
(1 row)
```

See Also

- [SHA1](#)
- [SHA224](#)
- [SHA256](#)
- [SHA384](#)
- [SHA512](#)

OCTET_LENGTH

Takes one argument as an input and returns the string length in octets for all string types.

Behavior Type

Immutable

Syntax

```
OCTET_LENGTH ( expression )
```

Parameters

<i>expression</i>	(CHAR or VARCHAR or BINARY or VARBINARY) is the string to measure.
-------------------	--

Notes

- If the data type of *expression* is a CHAR, VARCHAR or VARBINARY, the result is the same as the actual length of *expression* in octets. For CHAR, the length does not include any trailing spaces.
- If the data type of *expression* is BINARY, the result is the same as the fixed-length of *expression*.
- If the value of *expression* is NULL, the result is NULL.

Examples

Expression	Result
SELECT OCTET_LENGTH(CHAR(10) '1234 ');	4
SELECT OCTET_LENGTH(CHAR(10) '1234');	4
SELECT OCTET_LENGTH(CHAR(10) ' 1234');	6
SELECT OCTET_LENGTH(VARCHAR(10) '1234 ');	6
SELECT OCTET_LENGTH(VARCHAR(10) '1234');	5
SELECT OCTET_LENGTH(VARCHAR(10) '1234');	4
SELECT OCTET_LENGTH(VARCHAR(10) ' 1234');	7

SELECT OCTET_LENGTH('abc'::VARBINARY);	3
SELECT OCTET_LENGTH(VARBINARY 'abc');	3
SELECT OCTET_LENGTH(VARBINARY 'abc ');	5
SELECT OCTET_LENGTH(BINARY(6) 'abc');	6
SELECT OCTET_LENGTH(VARBINARY '');	0
SELECT OCTET_LENGTH('':BINARY);	1
SELECT OCTET_LENGTH(null::VARBINARY);	
SELECT OCTET_LENGTH(null::BINARY);

- [LENGTH](#)

OVERLAY

Returns a VARCHAR value representing a string having had a substring replaced by another string.

Behavior Type

Immutable if using OCTETS, Stable otherwise

Syntax

```
OVERLAY ( expression1 PLACING expression2 FROM position  
... [ FOR extent ]  
... [ USING { CHARACTERS | OCTETS } ] )
```

Parameters

<i>expression1</i>	(CHAR or VARCHAR) is the string to process
<i>expression2</i>	(CHAR or VARCHAR) is the substring to overlay
<i>position</i>	(INTEGER) is the character or octet position (counting from one) at which to begin the overlay
<i>extent</i>	(INTEGER) specifies the number of characters or octets to replace with the overlay
USING CHARACTERS OCTETS	Determines whether OVERLAY uses characters (the default) or octets

Examples

```
=> SELECT OVERLAY('123456789' PLACING 'xxx' FROM 2);
  overlay
-----
1xxx56789
(1 row)

=> SELECT OVERLAY('123456789' PLACING 'XXX' FROM 2 USING OCTETS);
  overlayb
-----
1XXX56789
(1 row)

=> SELECT OVERLAY('123456789' PLACING 'xxx' FROM 2 FOR 4);
  overlay
-----
1xxx6789
(1 row)

=> SELECT OVERLAY('123456789' PLACING 'xxx' FROM 2 FOR 5);
  overlay
-----
1xxx789
(1 row)

=> SELECT OVERLAY('123456789' PLACING 'xxx' FROM 2 FOR 6);
  overlay
-----
1xxx89
(1 row)
```

OVERLAYB

Returns an octet value representing a string having had a substring replaced by another string.

Behavior Type

Immutable

Syntax

```
OVERLAYB ( expression1, expression2, position [ , extent ] )
```

Parameters

<i>expression1</i>	(CHAR or VARCHAR) is the string to process
<i>expression2</i>	(CHAR or VARCHAR) is the substring to overlay
<i>position</i>	(INTEGER) is the octet position (counting from one) at which to begin the overlay
<i>extent</i>	(INTEGER) specifies the number of octets to replace with the overlay

Notes

The OVERLAYB function treats the multibyte character string as a string of octets (bytes) and use octet numbers as incoming and outgoing position specifiers and lengths. The strings themselves are type VARCHAR, but they treated as if each byte was a separate character.

Examples

```
=> SELECT OVERLAYB('123456789', 'ééé', 2);
OVERLAYB
-----
1ééé89
(1 row)
```

```
=> SELECT OVERLAYB('123456789', 'BBB', 2);
OVERLAYB
-----
1BBB89
(1 row)

=> SELECT OVERLAYB('123456789', 'xxx', 2);
OVERLAYB
-----
1xxx56789
(1 row)

=> SELECT OVERLAYB('123456789', 'xxx', 2, 4);
OVERLAYB
-----
1xxx6789
(1 row)

=> SELECT OVERLAYB('123456789', 'xxx', 2, 5);
OVERLAYB
-----
1xxx789
(1 row)

=> SELECT OVERLAYB('123456789', 'xxx', 2, 6);
OVERLAYB
-----
1xxx89
(1 row)
```

POSITION

Returns an INTEGER value representing the character location of a specified substring with a string (counting from one).

Behavior Type

Immutable

Syntax 1

```
POSITION ( substring IN string [ USING { CHARACTERS | OCTETS } ] )
```

Parameters

<i>substring</i>	(CHAR or VARCHAR) is the substring to locate
------------------	--

<i>string</i>	(CHAR or VARCHAR) is the string in which to locate the substring
USING CHARACTERS OCTETS	Determines whether the position is reported by using characters (the default) or octets.

Syntax 2

POSITION (*substring* IN *string*)

Parameters

<i>substring</i>	(VARBINARY) is the substring to locate
<i>string</i>	(VARBINARY) is the string in which to locate the substring

Notes

- When the string and substring are CHAR or VARCHAR, the return value is based on either the character or octet position of the substring.
- When the string and substring are VARBINARY, the return value is always based on the octet position of the substring.
- The string and substring must be consistent. Do not mix VARBINARY with CHAR or VARCHAR.
- POSITION is similar to [STRPOS](#) although POSITION allows finding by characters and by octet.
- If the string is not found, the return value is zero.

Examples

```
=> SELECT POSITION('é' IN 'étudiant' USING CHARACTERS);
position
-----
         1
(1 row)

=> SELECT POSITION('ß' IN 'straße' USING OCTETS);
positionb
```

```

-----
      5
(1 row)
=> SELECT POSITION('c' IN 'abcd' USING CHARACTERS);
   position
-----
      3
(1 row)
=> SELECT POSITION(VARBINARY '456' IN VARBINARY '123456789');
   position
-----
      4
(1 row)
SELECT POSITION('n' in 'León') as 'default',
       POSITIONB('León', 'n') as 'POSITIONB',
       POSITION('n' in 'León' USING CHARACTERS) as 'pos_chars',
       POSITION('n' in 'León' USING OCTETS) as 'pos_oct', INSTR('León', 'n'),
       INSTRB('León', 'n'), REGEXP_INSTR('León', 'n');
 default | POSITIONB | pos_chars | pos_oct | INSTR | INSTRB | REGEXP_INSTR
-----+-----+-----+-----+-----+-----+-----
      4 |         |      5 |      4 |      5 |      4 |           4
(1 row)

```

POSITIONB

Returns an INTEGER value representing the octet location of a specified substring with a string (counting from one).

Behavior Type

Immutable

Syntax

POSITIONB (*string*, *substring*)

Parameters

<i>string</i>	(CHAR or VARCHAR) is the string in which to locate the substring
<i>substring</i>	(CHAR or VARCHAR) is the substring to locate

Examples

```
=> SELECT POSITIONB('straße', 'ße');
POSITIONB
-----
          5
(1 row)

=> SELECT POSITIONB('étudiant', 'é');
POSITIONB
-----
          1
(1 row)
```

QUOTE_IDENT

Returns the given string, suitably quoted, to be used as an [identifier](#) in a SQL statement string. Quotes are added only if necessary; that is, if the string contains non-identifier characters, is a SQL [keyword](#), such as '1time', 'Next week' and 'Select'. Embedded double quotes are doubled.

Behavior Type

Immutable

Syntax

```
QUOTE_IDENT( string )
```

Parameters

<i>string</i>	String to quote.
---------------	------------------

Notes

- SQL identifiers, such as table and column names, are stored as created, and references to them are resolved using case-insensitive compares. Thus, you do not need to double-quote

mixed-case identifiers.

- Vertica quotes all currently-reserved keywords, even those not currently being used.

Examples

Quoted identifiers are case-insensitive, and Vertica does not supply the quotes:

```
=> SELECT QUOTE_IDENT('VErtIcA');
QUOTE_IDENT
-----
VErtIcA
(1 row)

=> SELECT QUOTE_IDENT('Vertica database');
QUOTE_IDENT
-----
"Vertica database"
(1 row)
```

Embedded double quotes are doubled:

```
=> SELECT QUOTE_IDENT('Vertica "!" database');
QUOTE_IDENT
-----
"Vertica ""!"" database"
(1 row)
```

The following example uses the SQL keyword, SELECT; results are double quoted:

```
=> SELECT QUOTE_IDENT('select');
QUOTE_IDENT
-----
"select"
(1 row)
```

QUOTE_LITERAL

Returns the given string, suitably quoted, to be used as a string literal in a SQL statement string. Embedded single quotes and backslashes are doubled.

Behavior Type

Immutable

Syntax

QUOTE_LITERAL (*string*)

Parameters

<i>string</i>	String to convert to a string literal.
---------------	--

Notes

Vertica recognizes two consecutive single quotes within a string literal as one single quote character. For example, 'You''re here!'. This is the SQL standard representation and is preferred over the form, 'You\'re here!', as backslashes are not parsed as before.

Examples

```
=> SELECT QUOTE_LITERAL('You''re here!');
   QUOTE_LITERAL
-----
'You''re here!'
(1 row)
```

See Also

- [Character String Literals](#)

REPEAT

Replicates a string the specified number of times, and concatenates the replicated values as a single string. The return value can be up to 65000 bytes in length. If the length of *string* * *count* is greater than 65000 bytes, Vertica silently truncates the results.

Behavior Type

Immutable

Syntax

```
REPEAT ( 'string', count )
```

Parameters

<i>string</i>	The string to repeat, one of the following: CHAR, VARCHAR, BINARY or VARBINARY.
<i>count</i>	An integer expression that specifies how many times to repeat <i>string</i> .

Examples

The following example repeats `vmart` three times:

```
=> SELECT REPEAT ('vmart', 3);
      REPEAT
-----
vmartvmartvmart
(1 row)
```

REPLACE

Replaces all occurrences of characters in a string with another set of characters.

Behavior Type

Immutable

Syntax

```
REPLACE ('string', 'target', 'replacement' )
```

Parameters

<i>string</i>	The string to modify.
<i>target</i>	The characters in <i>string</i> to replace.
<i>replacement</i>	The characters to replace <i>target</i> .

Examples

```
=> SELECT REPLACE('Documentation%20Library', '%20', ' ');
      REPLACE
-----
Documentation Library
(1 row)

=> SELECT REPLACE('This & That', '&', 'and');
      REPLACE
-----
This and That
(1 row)

=> SELECT REPLACE('straße', 'ß', 'ss');
      REPLACE
-----
strasse
(1 row)
```

RIGHT

Returns the specified characters from the right side of a string.

Behavior Type

Immutable

Syntax

```
RIGHT ( string , length )
```

Parameters

<i>string</i>	(CHAR or VARCHAR) is the string to return.
<i>length</i>	Is an INTEGER value that specifies the count of characters to return.

Examples

The following command returns the last three characters of the string 'vertica':

```
=> SELECT RIGHT('vertica', 3);
RIGHT
-----
ica
(1 row)
```

The following command returns the last two characters of the string 'straße':

```
=> SELECT RIGHT('straße', 2);
RIGHT
-----
ße
(1 row)
```

See Also

- [SUBSTR](#)

RPAD

Returns a VARCHAR value representing a string of a specific length filled on the right with specific characters.

Behavior Type

Immutable

Syntax

`RPAD (expression , Length [, fill])`

Parameters

<i>expression</i>	(CHAR OR VARCHAR) specifies the string to fill
<i>Length</i>	(INTEGER) specifies the number of characters to return
<i>fill</i>	(CHAR OR VARCHAR) specifies the repeating string of characters with which to fill the output string. The default is the space character.

Examples

```
=> SELECT RPAD('database', 15, 'xzy');
      RPAD
-----
databasexzyxzyx
(1 row)
```

If the string is already longer than the specified length it is truncated on the right:

```
=> SELECT RPAD('database', 6, 'xzy');
      RPAD
-----
databa
(1 row)
```

RTRIM

Returns a VARCHAR value representing a string with trailing blanks removed from the right side (end).

Behavior Type

Immutable

Syntax

```
RTRIM ( expression [ , characters ] )
```

Parameters

<i>expression</i>	(CHAR or VARCHAR) is the string to trim
<i>characters</i>	(CHAR or VARCHAR) specifies the characters to remove from the right side of <i>expression</i> . The default is the space character.

Examples

```
=> SELECT RTRIM('trimzzzyyyyyxxxxxxxx', 'yz');  
RTRIM  
-----  
trim  
(1 row)
```

See Also

- [BTRIM](#)
- [LTRIM](#)
- [TRIM](#)

SHA1

Uses the US Secure Hash Algorithm 1 to calculate the SHA1 hash of string. Returns the result as a VARCHAR string in hexadecimal.

Behavior Type

Immutable

Syntax

SHA1 (*string*)

Parameters

<i>string</i>	The VARCHAR or VARBINARY string to be calculated.
---------------	---

Examples

The following examples calculate the SHA1 hash of the provided strings:

```
=> SELECT SHA1('123');
           SHA1
-----
40bd001563085fc35165329ea1ff5c5ecbdbbbeeef
(1 row)
```

```
=> SELECT SHA1('Vertica'::bytea);
           SHA1
-----
ee2cff8d3444995c6c301546c4fc5ee152d77c11
(1 row)
```

See Also

SHA224

Uses the US Secure Hash Algorithm 2 to calculate the SHA224 hash of string. Returns the result as a VARCHAR string in hexadecimal.

Behavior Type

Immutable

Syntax

```
SHA224 ( string )
```

Parameters

<i>string</i>	The VARCHAR or VARBINARY string to be calculated.
---------------	---

Examples

The following examples calculate the SHA224 hash of the provided strings:

```
=> SELECT SHA224('abc');
           SHA224
-----
78d8045d684abd2eece923758f3cd781489df3a48e1278982466017f
(1 row)
```

```
=> SELECT SHA224('Vertica'::bytea);
           SHA224
-----
135ac268f64ff3124aeceb3cc0af0a29fd600a3be8e29ed97e45e25
(1 row)
```

```
=> SELECT sha224(' '::varbinary) = 'd14a028c2a3a2bc9476102bb288234c415a2b01f828ea62ac5b3e42f' AS
"TRUE";
           TRUE
-----
t
(1 row)
```

- [SHA384\(\)](#)
- [SHA512\(\)](#)

SHA256

Uses the US Secure Hash Algorithm 2 to calculate the SHA256 hash of string. Returns the result as a VARCHAR string in hexadecimal.

Behavior Type

Immutable

Syntax

SHA256 (*string*)

Parameters

<i>string</i>	The VARCHAR or VARBINARY string to be calculated.
---------------	---

Examples

The following examples calculate the SHA256 hash of the provided strings:

```
=> SELECT SHA256('abc');  
SHA256
```

```
-----  
a665a45920422f9d417e4867efdc4fb8a04a1f3fff1fa07e998e86f7f7a27ae3  
(1 row)
```

```
=> SELECT SHA256('Vertica'::bytea);  
          SHA256
```

```
-----  
9981b0b7df9f5be06e9e1a7f4ae2336a7868d9ab522b9a6ca6a87cd9ed95ba53  
(1 row)
```

```
=> SELECT sha256('') = 'e3b0c44298fc1c149afb4c8996fb92427ae41e4649b934ca495991b7852b855' AS "TRUE";  
TRUE
```

```
-----  
t  
(1 row)
```

- [SHA384](#)
- [SHA512](#)

SHA384

Uses the US Secure Hash Algorithm 2 to calculate the SHA384 hash of string. Returns the result as a VARCHAR string in hexadecimal.

Behavior Type

Immutable

Syntax

```
SHA384 ( string )
```

Parameters

<i>string</i>	The VARCHAR or VARBINARY string to be calculated.
---------------	---

Examples

The following examples calculate the SHA384 hash of the provided strings:

```
=> SELECT SHA384('123');
                                     SHA384
-----
9a0a82f0c0cf31470d7affede3406cc9aa8410671520b727044eda15b4c25532a9b5cd8aaf9cec4919d76255b6bf00f
(1 row)
```

```
=> SELECT SHA384('Vertica'::bytea);
                                     SHA384
-----
3431a717dc3289862bbd636a064d26980b47ebe4684b800cff4756f0c24985866ef97763eafd548fedb0ce28722c96bb
(1 row)
```

See Also

- [MD5](#)

SHA512

Uses the US Secure Hash Algorithm 2 to calculate the SHA512 hash of string. Returns the result as a VARCHAR string in hexadecimal.

Behavior Type

Immutable

Syntax

SHA512 (*string*)

Parameters

<i>string</i>	The VARCHAR or VARBINARY string to be calculated.
---------------	---

Examples

The following examples calculate the SHA512 hash of the provided strings:

```
=> SELECT SHA512('123');
                                     SHA512
-----
3c9909afec25354d551dae21590bb26e38d53f2173b8d3dc3eee4c047e7ab1c1eb8b85103e3be7ba613b31bb5c9c36214dc9f
14a42fd7a2fdb84856bca5c44c2
(1 row)
```

```
=> SELECT SHA512('Vertica'::bytea);
                                     SHA512
-----
c4ee2b2d17759226a3897c9c30d7c6df1145c4582849bb5191ee140bce05b83d3d869890cc3619b534fea6f97ff28a739d8b5
68a5ade66e756b3243ef97d3f00
(1 row)
```

See Also

- [SHA1](#)
- [SHA224](#)
- [SHA256](#)
- [SHA384](#)

SPACE

Returns the specified number of blank spaces, typically for insertion into a character string.

Behavior Type

Immutable

Syntax

`SPACE(n)`

Parameters

<i>n</i>	An integer argument that specifies how many spaces to insert.
----------	---

Example

The following example concatenates strings *x* and *y* with 10 spaces inserted between them:

```
=> SELECT 'x' || SPACE(10) || 'y' AS Ten_spaces;
   Ten_spaces
-----
x          y
(1 row)
```

SPLIT_PART

Splits string on the delimiter and returns the location of the beginning of the given field (counting from one).

Behavior Type

Immutable

Syntax

```
SPLIT_PART ( string , delimiter , field )
```

Parameters

<i>string</i>	Is the argument string.
<i>delimiter</i>	Is the given delimiter.
<i>field</i>	(INTEGER) is the number of the part to return.

Notes

Use this with the character form of the subfield.

Examples

The specified integer of 2 returns the second string, or def.

```
=> SELECT SPLIT_PART('abc~@~def~@~ghi', '~@~', 2);
   SPLIT_PART
-----
      def
(1 row)
```

In the next example, specify 3, which returns the third string, or 789.

```
=> SELECT SPLIT_PART('123~|~456~|~789', '~|~', 3);
   SPLIT_PART
-----
      789
(1 row)
```

The tildes are for readability only. Omitting them returns the same results:

```
=> SELECT SPLIT_PART('123|456|789', '|', 3);
   SPLIT_PART
-----
      789
(1 row)
```

See what happens if you specify an integer that exceeds the number of strings: No results.

```
=> SELECT SPLIT_PART('123|456|789', '|', 4);
   SPLIT_PART
-----

(1 row)
```

The previous result is not null, it is an empty string.

```
=> SELECT SPLIT_PART('123|456|789', '|', 4) IS NULL;
   ?column?
-----
         f
(1 row)
```

If `SPLIT_PART` had returned `NULL`, `LENGTH` would have returned null.

```
=> SELECT LENGTH (SPLIT_PART('123|456|789', '|', 4));
   LENGTH
-----
         0
(1 row)
```

SPLIT_PARTB

Splits string on the delimiter and returns the location of the beginning of the given field (counting from one). The `VARCHAR` arguments are treated as octets rather than UTF-8 characters.

Behavior Type

Immutable

Syntax

`SPLIT_PARTB (string , delimiter , field)`

Parameters

<i>string</i>	(VARCHAR) Is the argument string.
<i>delimiter</i>	(VARCHAR) Is the given delimiter.
<i>field</i>	(INTEGER) is the number of the part to return.

Notes

Use this function with the character form of the subfield.

Examples

The specified integer of 3 returns the third string, or `souçon`.

```
=> SELECT SPLIT_PARTB('straße~@~café~@~souçon', '~@~', 3);
   SPLIT_PARTB
-----
   souçon
(1 row)
```

The tildes are for readability only. Omitting them returns the same results:

```
=> SELECT SPLIT_PARTB('straße @ café @ souçon', '@', 3);
   SPLIT_PARTB
-----
   souçon
(1 row)
```

See what happens if you specify an integer that exceeds the number of strings: No results.

```
=> SELECT SPLIT_PARTB('straße @ café @ souçon', '@', 4);
   SPLIT_PARTB
-----
(1 row)
```

The above result is not null, it is an empty string.

```
=> SELECT SPLIT_PARTB('straße @ café @ soupçon', '@', 4) IS NULL;  
?column?  
-----  
f  
(1 row)
```

STRPOS

Returns an INTEGER value representing the character location of a specified substring within a string (counting from one).

Behavior Type

Immutable

Syntax

```
STRPOS ( string , substring )
```

Parameters

<i>string</i>	(CHAR or VARCHAR) is the string in which to locate the substring
<i>substring</i>	(CHAR or VARCHAR) is the substring to locate

Notes

STRPOS is similar to [POSITION](#) although POSITION allows finding by characters and by octet.

If the string is not found, the return value is zero.

Examples

```
=> SELECT STRPOS('abcd', 'c');  
STRPOS  
-----  
3  
(1 row)
```

STRPOSB

Returns an INTEGER value representing the location of a specified substring within a string, counting from one, where each octet in the string is counted (as opposed to characters).

Behavior Type

Immutable

Syntax

`STRPOSB (string , substring)`

Parameters

<i>string</i>	(CHAR or VARCHAR) is the string in which to locate the substring
<i>substring</i>	(CHAR or VARCHAR) is the substring to locate

Notes

STRPOSB is identical to [POSITIONB](#) except for the order of the arguments.

Examples

```
=> SELECT STRPOSB('straße', 'e');
   STRPOSB
-----
         7
(1 row)

=> SELECT STRPOSB('étudiant', 'tud');
   STRPOSB
-----
         3
(1 row)
```

SUBSTR

Returns VARCHAR or VARBINARY value representing a substring of a specified string.

Behavior Type

Immutable

Syntax

```
SUBSTR ( string , position [ , extent ] )
```

Parameters

<i>string</i>	(CHAR/VARCHAR or BINARY/VARBINARY) is the string from which to extract a substring.
<i>position</i>	(INTEGER or DOUBLE PRECISION) is the starting position of the substring (counting from one by characters).
<i>extent</i>	(INTEGER or DOUBLE PRECISION) is the length of the substring to extract (in characters). The default is the end of the string.

Notes

SUBSTR truncates DOUBLE PRECISION input values.

Examples

```
=> SELECT SUBSTR('abc'::binary(3),1);
 substr
-----
 abc
(1 row)

=> SELECT SUBSTR('123456789', 3, 2);
 substr
```

```
-----  
34  
(1 row)  
=> SELECT SUBSTR('123456789', 3);  
substr  
-----  
3456789  
(1 row)  
=> SELECT SUBSTR(TO_BITSTRING(HEX_TO_BINARY('0x10')), 2, 2);  
substr  
-----  
00  
(1 row)  
=> SELECT SUBSTR(TO_HEX(10010), 2, 2);  
substr  
-----  
71  
(1 row)
```

SUBSTRB

Returns an octet value representing the substring of a specified string.

Behavior Type

Immutable

Syntax

```
SUBSTRB ( string , position [ , extent ] )
```

Parameters

<i>string</i>	(CHAR/VARCHAR) is the string from which to extract a substring.
<i>position</i>	(INTEGER or DOUBLE PRECISION) is the starting position of the substring (counting from one in octets).
<i>extent</i>	(INTEGER or DOUBLE PRECISION) is the length of the substring to extract (in octets). The default is the end of the string

Notes

- This function treats the multibyte character string as a string of octets (bytes) and uses octet numbers as incoming and outgoing position specifiers and lengths. The strings themselves are type VARCHAR, but they are treated as if each octet were a separate character.
- SUBSTRB truncates DOUBLE PRECISION input values.

Examples

```
=> SELECT SUBSTRB('soupçon', 5);
SUBSTRB
-----
çon
(1 row)

=> SELECT SUBSTRB('soupçon', 5, 2);
SUBSTRB
-----
ç
(1 row)
```

Vertica returns the following error message if you use BINARY/VARBINARY:

```
=>SELECT SUBSTRB('abc'::binary(3),1);
ERROR: function substrb(binary, int) does not exist, or permission is denied for substrb(binary, int)
HINT: No function matches the given name and argument types. You may need to add explicit type casts.
```

SUBSTRING

Returns a value representing a substring of the specified string at the given position, given a value, a position, and an optional length. SUBSTRING truncates DOUBLE PRECISION input values.

Behavior Type

Immutable if USING OCTETS, stable otherwise.

Syntax

```
SUBSTRING ( string , position [ , length ]
... [USING {CHARACTERS | OCTETS } ] )
```

```
SUBSTRING ( string FROM position [ FOR length ]
... [USING { CHARACTERS | OCTETS } ] )
```

Parameters

<i>string</i>	(CHAR/VARCHAR or BINARY/VARBINARY) is the string from which to extract a substring
<i>position</i>	(INTEGER or DOUBLE PRECISION) is the starting position of the substring (counting from one by either characters or octets). (The default is characters.) If position is greater than the length of the given value, an empty value is returned.
<i>length</i>	(INTEGER or DOUBLE PRECISION) is the length of the substring to extract in either characters or octets. (The default is characters.) The default is the end of the string. If a length is given the result is at most that many bytes. The maximum length is the length of the given value less the given position. If no length is given or if the given length is greater than the maximum length then the length is set to the maximum length.
USING CHARACTERS OCTETS	Determines whether the value is expressed in characters (the default) or octets.

Examples

```
=> SELECT SUBSTRING('abc'::binary(3),1);
  substring
-----
  abc
(1 row)

=> SELECT SUBSTRING('soupçon', 5, 2 USING CHARACTERS);
  substring
-----
  çö
(1 row)

=> SELECT SUBSTRING('soupçon', 5, 2 USING OCTETS);
  substring
-----
  ç
(1 row)
```

If you use a negative position, then the functions starts at a non-existent position. In this example, that means counting eight characters starting at position -4. So the function starts at the empty position -4 and counts five characters, including a position for zero which is also empty. This returns three characters.

```
=> SELECT SUBSTRING('1234567890', -4, 8);
 substring
-----
123
(1 row)
```

TO_BITSTRING

Returns a VARCHAR that represents the given VARBINARY value in bitstring format. This function is the inverse of [BITSTRING_TO_BINARY](#).

Behavior Type

Immutable

Syntax

```
TO_BITSTRING ( expression )
```

Parameters

<i>expression</i>	The VARCHAR string to process.
-------------------	--------------------------------

Examples

```
=> SELECT TO_BITSTRING('ab'::BINARY(2));
 to_bitstring
-----
0110000101100010
(1 row)

=> SELECT TO_BITSTRING(HEX_TO_BINARY('0x10'));
 to_bitstring
-----
00010000
(1 row)
```

```
=> SELECT TO_BITSTRING(HEX_TO_BINARY('0xF0'));
   to_bitstring
-----
11110000
(1 row)
```

See Also

[BITCOUNT](#)

TO_HEX

Returns a VARCHAR or VARBINARY representing the hexadecimal equivalent of a number. This function is the inverse of [HEX_TO_BINARY](#).

Behavior Type

Immutable

Syntax

```
TO_HEX ( number )
```

Parameters

<i>number</i>	An INTEGER or VARBINARY value to convert to hexadecimal. If you supply a VARBINARY argument, the function's return value is not preceded by 0x.
---------------	---

Examples

```
=> SELECT TO_HEX(123456789);
   TO_HEX
-----
75bcd15
(1 row)
```

For VARBINARY inputs, the returned value is not preceded by 0x. For example:

```
=> SELECT TO_HEX('ab'::binary(2));
   TO_HEX
-----
   6162
(1 row)
```

TRANSLATE

Replaces individual characters in *string_to_replace* with other characters.

Behavior Type

Immutable

Syntax

```
TRANSLATE ( string_to_replace , from_string , to_string );
```

Parameters

<i>string_to_replace</i>	String to be translated.
<i>from_string</i>	Contains characters that should be replaced in <i>string_to_replace</i> .
<i>to_string</i>	Any character in <i>string_to_replace</i> that matches a character in <i>from_string</i> is replaced by the corresponding character in <i>to_string</i> .

Example

```
=> SELECT TRANSLATE('straße', 'ß', 'ss');
   TRANSLATE
-----
   strase
(1 row)
```

TRIM

Combines the BTRIM, LTRIM, and RTRIM functions into a single function.

Behavior Type

Immutable

Syntax

```
TRIM ( [ [ LEADING | TRAILING | BOTH ] characters FROM ] expression )
```

Parameters

LEADING	Removes the specified characters from the left side of the string
TRAILING	Removes the specified characters from the right side of the string
BOTH	Removes the specified characters from both sides of the string (default)
<i>characters</i>	(CHAR or VARCHAR) specifies the characters to remove from <i>expression</i> . The default is the space character.
<i>expression</i>	(CHAR or VARCHAR) is the string to trim

Examples

```
=> SELECT '-' || TRIM(LEADING 'x' FROM 'xxdatabasexx') || '-';
?column?
-----
-databasexx-
(1 row)

=> SELECT '-' || TRIM(TRAILING 'x' FROM 'xxdatabasexx') || '-';
?column?
-----
-xxdatabase-
(1 row)

=> SELECT '-' || TRIM(BOTH 'x' FROM 'xxdatabasexx') || '-';
?column?
-----
-database-
(1 row)

=> SELECT '-' || TRIM('x' FROM 'xxdatabasexx') || '-';
?column?
-----
```

```
-database-
(1 row)
=> SELECT '-' || TRIM(LEADING FROM ' database ' ) || '-';
?column?
-----
-database -
(1 row)
=> SELECT '-' || TRIM(' database ') || '-'; ?column?
-----
-database-
(1 row)
```

See Also

- [BTRIM](#)
- [LTRIM](#)
- [RTRIM](#)

UPPER

Returns a VARCHAR value containing the argument converted to uppercase letters.

Starting in Release 5.1, this function treats the `string` argument as a UTF-8 encoded string, rather than depending on the collation setting of the locale (for example, `collation=binary`) to identify the encoding.

Behavior Type

stable

Syntax

```
UPPER ( expression )
```

Parameters

<i>expression</i>	CHAR or VARCHAR containing the string to convert
-------------------	--

Notes

UPPER is restricted to 32500 octet inputs, since it is possible for the UTF-8 representation of result to double in size.

Examples

```
=> SELECT UPPER('AbCdEFG');
      UPPER
-----
ABCDEF
(1 row)
=> SELECT UPPER('étudiant');
      UPPER
-----
ÉTUDIANT
(1 row)
```

UPPERB

Returns a character string with each ASCII character converted to uppercase. Multibyte characters are not converted and are skipped.

Behavior Type

Immutable

Syntax

```
UPPERB ( expression )
```

Parameters

<i>expression</i>	(CHAR or VARCHAR) is the string to convert
-------------------	--

Examples

In the following example, the multibyte UTF-8 character é is not converted to uppercase:

```
=> SELECT UPPERB('étudiant');
      UPPERB
-----
     étUDIANT
(1 row)

=> SELECT UPPERB('AbCdEfG');
      UPPERB
-----
     ABCDEFG
(1 row)

=> SELECT UPPERB('The Vertica Database');
      UPPERB
-----
     THE VERTICA DATABASE
(1 row)
```

V6_ATON

Converts an IPv6 address represented as a character string to a binary string.

Behavior Type

Immutable

Syntax

V6_ATON (*expression*)

Parameters

<i>expression</i>	(VARCHAR) is the string to convert.
-------------------	-------------------------------------

Notes

The following syntax converts an IPv6 address represented as the character string A to a binary string B.

V6_ATON trims any spaces from the right of A and calls the Linux function [inet_pton](#).

```
=> V6_ATON(VARCHAR A) -> VARBINARY(16) B
```

If A has no colons it is prepended with '::ffff:'. If A is NULL, too long, or if `inet_pton` returns an error, the result is NULL.

Examples

```
=> SELECT V6_ATON('2001:DB8::8:800:200C:417A');
           v6_aton
-----
\001\015\270\000\000\000\000\000\000\010\010\000 \014Az
(1 row)

=> SELECT V6_ATON('1.2.3.4');
           v6_aton
-----
\000\000\000\000\000\000\000\000\000\000\000\000\377\377\001\002\003\004
(1 row)
SELECT TO_HEX(V6_ATON('2001:DB8::8:800:200C:417A'));
           to_hex
-----
20010db800000000000000800200c417a
(1 row)

=> SELECT V6_ATON('::1.2.3.4');
           v6_aton
-----
\000\000\000\000\000\000\000\000\000\000\000\000\000\000\001\002\003\004
(1 row)
```

See Also

- [V6_NTOA](#)

V6_NTOA

Converts an IPv6 address represented as varbinary to a character string.

Behavior Type

Immutable

Syntax

V6_NTOA (*expression*)

Parameters

<i>expression</i>	(VARBINARY) is the binary string to convert.
-------------------	--

Notes

The following syntax converts an IPv6 address represented as VARBINARY B to a string A.

V6_NTOA right-pads B to 16 bytes with zeros, if necessary, and calls the Linux function [inet_ntop](#).

```
=> V6_NTOA(VARBINARY B) -> VARCHAR A
```

If B is NULL or longer than 16 bytes, the result is NULL.

Vertica automatically converts the form '::ffff:1.2.3.4' to '1.2.3.4'.

Examples

```
=> SELECT V6_NTOA(' \001\015\270\000\000\000\000\000\010\010\000 \014Az');
      v6_ntoa
-----
2001:db8::8:800:200c:417a
(1 row)

=> SELECT V6_NTOA(V6_ATON('1.2.3.4'));
      v6_ntoa
-----
1.2.3.4
(1 row)

=> SELECT V6_NTOA(V6_ATON('::1.2.3.4'));
      v6_ntoa
-----
```

```
:::1.2.3.4  
(1 row)
```

See Also

- [V6_ATON](#)

V6_SUBNETA

Calculates a subnet address in CIDR (Classless Inter-Domain Routing) format from a binary or alphanumeric IPv6 address.

Behavior Type

Immutable

Syntax

```
V6_SUBNETA ( expression1, expression2 )
```

Parameters

<i>expression1</i>	(VARBINARY or VARCHAR) is the string to calculate.
<i>expression2</i>	(INTEGER) is the size of the subnet.

Notes

The following syntax calculates a subnet address in CIDR format from a binary or varchar IPv6 address.

V6_SUBNETA masks a binary IPv6 address B so that the N leftmost bits form a subnet address, while the remaining rightmost bits are cleared. It then converts to an alphanumeric IPv6 address, appending a slash and N.

```
=> V6_SUBNETA(BINARY B, INT8 N) -> VARCHAR C
```

The following syntax calculates a subnet address in CIDR format from an alphanumeric IPv6 address.

```
=> V6_SUBNETA(VARCHAR A, INT8 N) -> V6_SUBNETA(V6_ATON(A), N) -> VARCHAR C
```

Examples

```
=> SELECT V6_SUBNETA(V6_ATON('2001:db8::8:800:200c:417a'), 28);
   v6_subneta
-----
2001:db8::/28
(1 row)
```

See Also

- [V6_SUBNETN](#)

V6_SUBNETN

Calculates a subnet address in CIDR (Classless Inter-Domain Routing) format from a varbinary or alphanumeric IPv6 address.

Behavior Type

Immutable

Syntax

```
V6_SUBNETN ( expression1, expression2 )
```

Parameters

<i>expression1</i>	(VARBINARY or VARCHAR) is the string to calculate. Notes: <ul style="list-style-type: none">• V6_SUBNETN(<VARBINARY>, <INTEGER>) returns VARBINARY.
--------------------	---

	<p>OR</p> <ul style="list-style-type: none"> • <code>V6_SUBNETN(<VARCHAR>, <INTEGER>)</code> returns <code>VARBINARY</code>, after using <code>V6_ATON</code> to convert the <code><VARCHAR></code> string to <code><VARBINARY></code>.
<i>expression2</i>	<code>(INTEGER)</code> is the size of the subnet.

Notes

The following syntax masks a `BINARY` IPv6 address `B` so that the `N` left-most bits of `S` form a subnet address, while the remaining right-most bits are cleared.

`V6_SUBNETN` right-pads `B` to 16 bytes with zeros, if necessary and masks `B`, preserving its `N`-bit subnet prefix.

```
=> V6_SUBNETN(VARBINARY B, INT8 N) -> VARBINARY(16) S
```

If `B` is `NULL` or longer than 16 bytes, or if `N` is not between 0 and 128 inclusive, the result is `NULL`.

`S` = `[B]/N` in [Classless Inter-Domain Routing](#) notation (CIDR notation).

The following syntax masks an alphanumeric IPv6 address `A` so that the `N` leftmost bits form a subnet address, while the remaining rightmost bits are cleared.

```
=> V6_SUBNETN(VARCHAR A, INT8 N) -> V6_SUBNETN(V6_ATON(A), N) -> VARBINARY(16) S
```

Example

This example returns `VARBINARY`, after using `V6_ATON` to convert the `VARCHAR` string to `VARBINARY`:

```
=> SELECT V6_SUBNETN(V6_ATON('2001:db8::8:800:200c:417a'), 28);
           v6_subnetn
-----
\001\015\260\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000
```

See Also

- [V6_ATON](#)
- [V6_SUBNETA](#)

V6_TYPE

Characterizes a binary or alphanumeric IPv6 address B as an integer type.

Behavior Type

Immutable

Syntax

```
V6_TYPE ( expression )
```

Parameters

<i>expression</i>	(VARBINARY or VARCHAR) is the type to convert.
-------------------	--

Notes

V6_TYPE(VARBINARY B) returns INT8 T.

```
=> V6_TYPE(VARCHAR A) -> V6_TYPE(V6_ATON(A)) -> INT8 T
```

The IPv6 types are defined in the Network Working Group's [IP Version 6 Addressing Architecture memo](#).

GLOBAL = 0	Global unicast addresses
LINKLOCAL = 1	Link-Local unicast (and Private-Use) addresses
LOOPBACK = 2	Loopback
UNSPECIFIED = 3	Unspecified
MULTICAST = 4	Multicast

IPv4-mapped and IPv4-compatible IPv6 addresses are also interpreted, as specified in [IPv4 Global Unicast Address Assignments](#).

- For IPv4, Private-Use is grouped with Link-Local.
- If B is VARBINARY, it is right-padded to 16 bytes with zeros, if necessary.
- If B is NULL or longer than 16 bytes, the result is NULL.

Details

IPv4 (either kind):

0.0.0.0/8	UNSPECIFIED	10.0.0.0/8	LINKLOCAL
127.0.0.0/8	LOOPBACK		
169.254.0.0/16	LINKLOCAL		
172.16.0.0/12	LINKLOCAL		
192.168.0.0/16	LINKLOCAL		
224.0.0.0/4	MULTICAST		
others	GLOBAL		

IPv6:

::0/128	UNSPECIFIED	::1/128	LOOPBACK
fe80::/10	LINKLOCAL		
ff00::/8	MULTICAST		
others	GLOBAL		

Examples

```
=> SELECT V6_TYPE(V6_ATON('192.168.2.10'));
v6_type
-----
      1
(1 row)

=> SELECT V6_TYPE(V6_ATON('2001:db8::8:800:200c:417a'));
v6_type
-----
      0
(1 row)
```

System Information Functions

These functions provide system information regarding user sessions. A superuser has unrestricted access to all system information, but users can view only information about their own, current sessions.

CURRENT_DATABASE

Returns a VARCHAR value containing the name of the database to which you are connected.

Behavior Type

Immutable

Syntax

```
CURRENT_DATABASE()
```

Notes

- The parentheses following the CURRENT_DATABASE function are optional.
- This function is equivalent to DBNAME.

Examples

```
SELECT CURRENT_DATABASE();  
CURRENT_DATABASE  
-----  
VMart  
(1 row)
```

The following command returns the same results without the parentheses:

```
SELECT CURRENT_DATABASE;  
CURRENT_DATABASE  
-----
```

```
VMart  
(1 row)
```

CURRENT_SCHEMA

Returns the name of the current schema.

Behavior Type

Stable

Syntax

```
CURRENT_SCHEMA()
```

Note: You can call this function without parentheses.

Privileges

None

Examples

The following command returns the name of the current schema:

```
=> SELECT CURRENT_SCHEMA();  
current_schema  
-----  
public  
(1 row)
```

The following command returns the same results without the parentheses:

```
=> SELECT CURRENT_SCHEMA;  
current_schema  
-----  
public  
(1 row)
```

The following command shows the current schema, listed after the [current user](#), in the search path:

```
=> SHOW SEARCH_PATH;
   name      |          setting
-----+-----
 search_path | "$user", public, v_catalog, v_monitor, v_internal
(1 row)
```

See Also

- [SET SEARCH_PATH](#)

CURRENT_USER

Returns a VARCHAR containing the name of the user who initiated the current database connection.

Behavior Type

Stable

Syntax

```
CURRENT_USER()
```

Notes

- The CURRENT_USER function does not require parentheses.
- This function is useful for permission checking.
- CURRENT_USER is equivalent to [SESSION_USER](#), [USER](#), and [USERNAME](#).

Examples

```
SELECT CURRENT_USER();
CURRENT_USER
-----
dbadmin
(1 row)
```

The following command returns the same results without the parentheses:

```
SELECT CURRENT_USER;  
CURRENT_USER  
-----  
dbadmin  
(1 row)
```

DBNAME (function)

Returns a VARCHAR value containing the name of the database to which you are connected. DBNAME is equivalent to [CURRENT_DATABASE](#).

Behavior Type

Immutable

Syntax

```
DBNAME()
```

Examples

```
SELECT DBNAME();  
dbname  
-----  
VMart  
(1 row)
```

HAS_TABLE_PRIVILEGE

Indicates whether a user can access a table in a particular way. The function returns a true (t) or false (f) value.

Behavior Type

Stable

Syntax

```
HAS_TABLE_PRIVILEGE ( [ user, ] [schema-name.]table , privilege )
```

Parameters

<i>user</i>	Specifies the name or OID of a database user. The default is the CURRENT_USER .
<i>schema</i>	Specifies a schema . If multiple schemas are defined in the database, include the schema name. For example: <pre>myschema.thisDBObject</pre>
<i>table</i>	Specifies the name or OID of a table in the logical schema. If necessary, specify the database and schema, as noted above.
<i>privilege</i>	<ul style="list-style-type: none">• SELECT Allows the user to SELECT from any column of the specified table.• INSERT Allows the user to INSERT records into the specified table and to use the COPY command to load the table.• UPDATE Allows the user to UPDATE records in the specified table.• DELETE Allows the user to delete a row from the specified table.• REFERENCES Allows the user to create a foreign key constraint (privileges required on both the referencing and referenced tables).

Privileges

A superuser can check all other user's table privileges.

Users without superuser privileges can use `HAS_TABLE_PRIVILEGE` to check:

- Any tables they own.
- Tables in a schema to which they have been granted **USAGE** privileges, and at least one other table privilege, as described in [GRANT \(Table\)](#).

Examples

```
SELECT HAS_TABLE_PRIVILEGE('store.store_dimension', 'SELECT');
HAS_TABLE_PRIVILEGE
-----
t
(1 row)

SELECT HAS_TABLE_PRIVILEGE('release', 'store.store_dimension', 'INSERT');
HAS_TABLE_PRIVILEGE
-----
t
(1 row)

SELECT HAS_TABLE_PRIVILEGE('store.store_dimension', 'UPDATE');
HAS_TABLE_PRIVILEGE
-----
t
(1 row)

SELECT HAS_TABLE_PRIVILEGE('store.store_dimension', 'REFERENCES');
HAS_TABLE_PRIVILEGE
-----
t
(1 row)

SELECT HAS_TABLE_PRIVILEGE(45035996273711159, 45035996273711160, 'select');

HAS_TABLE_PRIVILEGE
-----
t
(1 row)
```

LIST_ENABLED_CIPHERS

Returns a list of ciphers enabled on your server.

Syntax

```
list_enabled_ciphers()
```

Example

```
=> list_enabled_ciphers()
SSL_RSA_WITH_RC4_128_MD5
SSL_RSA_WITH_RC4_128_SHA
TLS_RSA_WITH_AES_128_CBC_SHA
```

SESSION_USER

Returns a VARCHAR containing the name of the user who initiated the current database session.

Behavior Type

Stable

Syntax

```
SESSION_USER()
```

Notes

- The SESSION_USER function does not require parentheses.
- SESSION_USER is equivalent to [CURRENT_USER](#), [USER](#), and [USERNAME](#).

Examples

```
SELECT SESSION_USER();
 session_user
-----
 dbadmin
(1 row)
```

The following command returns the same results without the parentheses:

```
SELECT SESSION_USER;
 session_user
-----
 dbadmin
(1 row)
```

USER

Returns a VARCHAR containing the name of the user who initiated the current database connection.

Behavior Type

Stable

Syntax

```
USER()
```

Notes

- The USER function does not require parentheses.
- USER is equivalent to [CURRENT_USER](#), [SESSION_USER](#), and [USERNAME](#).

Examples

```
=> SELECT USER();
current_user
-----
dbadmin
(1 row)
```

The following command returns the same results without the parentheses:

```
=> SELECT USER;
current_user
-----
dbadmin
(1 row)
```

USERNAME

Returns a VARCHAR containing the name of the user who initiated the current database connection.

Behavior Type

Stable

Syntax

```
USERNAME()
```

Notes

- This function is useful for permission checking.
- USERNAME is equivalent to [CURRENT_USER](#), [SESSION_USER](#) and [USER](#).

Examples

```
=> SELECT USERNAME();
  username
-----
  dbadmin
(1 row)
```

VERSION

Returns a VARCHAR containing an Vertica node's version information.

Behavior Type

Stable

Syntax

VERSION()

Examples

```
SELECT VERSION();
          VERSION
-----
Vertica Analytic Database v4.0.12-20100513010203
(1 row)
```

The parentheses are required. If you omit them, the system returns an error:

```
SELECT VERSION;
ERROR: column "version" does not exist
```

Timeseries Functions

Timeseries aggregate functions evaluate the values of a given set of variables over time and group those values into a window for analysis and aggregation.

One output row is produced per time slice—or per partition per time slice—if partition expressions are present.

TS_FIRST_VALUE

Processes the data that belongs to each time slice. A time series aggregate (TSA) function, `TS_FIRST_VALUE` returns the value at the start of the time slice, where an interpolation scheme is applied if the timeslice is missing, in which case the value is determined by the values corresponding to the previous (and next) timeslices based on the interpolation scheme of `const` (linear). There is one value per time slice per partition.

Behavior Type

Immutable

Syntax

```
TS_FIRST_VALUE ( expression [ IGNORE NULLS ]  
... [, { 'CONST' | 'LINEAR' } ] )
```

Parameters

<i>expression</i>	Argument expression on which to aggregate and interpolate. <i>expression</i> is data type INTEGER or FLOAT.
IGNORE NULLS	The IGNORE NULLS behavior changes depending on a CONST or LINEAR interpolation scheme. See When Time Series Data Contains Nulls in Analyzing Data for details.
'CONST' 'LINEAR'	(Default CONST) Optionally specifies the interpolation value as either constant or linear.

- **CONST**—New value are interpolated based on previous input records.
- **LINEAR**—Values are interpolated in a linear slope based on the specified time slice.

Notes

- The function returns one output row per time slice or one output row per partition per time slice if partition expressions are specified.
- Multiple time series aggregate functions can exists in the same query. They share the same gap-filling policy as defined by the [TIMESERIES Clause](#); however, each time series aggregate function can specify its own interpolation policy. For example:

```
=> SELECT slice_time, symbol,  
       TS_FIRST_VALUE(tid, 'const') fv_c,  
       TS_FIRST_VALUE(tid, 'linear') fv_l,  
       TS_LAST_VALUE(tid, 'const') lv_c  
FROM TickStore  
TIMESERIES slice_time AS '3 seconds'  
OVER(PARTITION BY symbol ORDER BY ts);
```

- You must use an **ORDER BY** clause with a **TIMESTAMP** column.

Example

For detailed examples, see [Gap Filling and Interpolation](#) in Analyzing Data.

See Also

- [TIMESERIES Clause](#)
- [TS_LAST_VALUE](#)
- [Time Series Analytics](#)

TS_LAST_VALUE

Processes the data that belongs to each time slice. A time series aggregate (TSA) function, `TS_LAST_VALUE` returns the value at the end of the time slice, where an interpolation scheme is applied if the timeslice is missing, in which case the value is determined by the values corresponding to the previous (and next) timeslices based on the interpolation scheme of `const` (linear). There is one value per time slice per partition.

Behavior Type

Immutable

Syntax

```
TS_LAST_VALUE ( expression [ IGNORE NULLS ]  
... [, { 'CONST' | 'LINEAR' } ] )
```

Parameters

<i>expression</i>	Argument expression on which to aggregate and interpolate. <i>expression</i> is data type INTEGER or FLOAT.
IGNORE NULLS	The IGNORE NULLS behavior changes depending on a CONST or LINEAR interpolation scheme. See When Time Series Data Contains Nulls in Analyzing Data for details.
'CONST' 'LINEAR'	(Default CONST) Optionally specifies the interpolation value as either constant or linear. <ul style="list-style-type: none">• CONST—New value are interpolated based on previous input records.• LINEAR—Values are interpolated in a linear slope based on the specified time slice.

Notes

- The function returns one output row per time slice or one output row per partition per time slice if partition expressions are specified.
- Multiple time series aggregate functions can exist in the same query. They share the same gap-filling policy as defined by the [TIMESERIES Clause](#); however, each time series aggregate function can specify its own interpolation policy. For example:

```
=> SELECT slice_time, symbol,  
       TS_FIRST_VALUE(bid, 'const') fv_c,  
       TS_FIRST_VALUE(bid, 'linear') fv_l,  
       TS_LAST_VALUE(bid, 'const') lv_c  
FROM TickStore  
TIMESERIES slice_time AS 3 seconds  
OVER(PARTITION BY symbol ORDER BY ts);
```

- You must use the `ORDER BY` clause with a `TIMESTAMP` column.

Example

For detailed examples, see [Gap Filling and Interpolation](#) in Analyzing Data.

URI Encode/Decode Functions

The functions in this section follow the RFC 3986 standard for percent-encoding a Universal Resource Identifier (URI).

URI_PERCENT_DECODE

Decodes a percent-encoded Universal Resource Identifier (URI) according to the RFC 3986 standard.

Syntax

```
URI_PERCENT_DECODE (expression)
```

Behavior Type

Immutable

Parameters

<i>expression</i>	(VARCHAR) is the string to convert.
-------------------	-------------------------------------

Examples

The following example invokes `uri_percent_decode` on the `Websites` column of the `URI` table and returns a decoded URI:

```
=> SELECT URI_PERCENT_DECODE(Websites) from URI;
      URI_PERCENT_DECODE
-----
http://www.faqs.org/rfcs/rfc3986.html x xj%a%
(1 row)
```

The following example returns the original URI in the `Websites` column and its decoded version:

```
=> SELECT Websites, URI_PERCENT_DECODE (Websites) from URI;

-----+-----
      Websites                |                URI_PERCENT_DECODE
-----+-----
http://www.faqs.org/rfcs/rfc3986.html+x%20x%6a%a%a% | http://www.faqs.org/rfcs/rfc3986.html x xj%a%

(1 row)
```

URI_PERCENT_ENCODE

Encodes a Universal Resource Identifier (URI) according to the RFC 3986 standard for percent encoding. In addition, for compatibility with older encoders this function converts '+' to space; space is converted to %20 by `uri_percent_encode`.

Syntax

`URI_PERCENT_ENCODE (expression)`

Behavior Type

Immutable

Parameters

<i>expression</i>	(VARCHAR) is the string to convert.
-------------------	-------------------------------------

Examples

The following example shows how the `uri_percent_encode` function is invoked on a the `Websites` column of the `URI` table and returns an encoded URI:

```
=> SELECT URI_PERCENT_ENCODE(Websites) from URI;

-----+-----
      URI_PERCENT_ENCODE
-----+-----
http%3A%2F%2Fexample.com%2F%3F%3D11%2F15

(1 row)
```

The following example returns the original URI in the `Websites` column and it's encoded form:

```
=> SELECT Websites, URI_PERCENT_ENCODE(Websites) from URI;      Websites      |
URI_PERCENT_ENCODE
-----+-----
http://example.com/?=11/15 | http%3A%2F%2Fexample.com%2F%3F%3D11%2F15
(1 row)
```

Vertica Meta-Functions

Vertica built-in (meta) functions access the internal state of Vertica and are used in SELECT queries with the function name and an argument (where required). These functions are not part of the SQL standard and take the following form:

```
SELECT <meta-function-name>(<args>);
```

Note: The query cannot contain other clauses, such as FROM or WHERE.

The behavior type of Vertica meta-functions is immutable.

Alphabetical List of Vertica Meta-Functions

The following list shows all of the Vertica meta-functions in alphabetical order.

Jump to letter: [A](#) - [B](#) - [C](#) - [D](#) - [E](#) - [F](#) - [G](#) - [H](#) - [I](#) - [K](#) - [L](#) - [M](#) - [N](#) - [P](#) - [R](#) - [S](#) - [V](#)

[ADVANCE_EPOCH](#)

Manually closes the current epoch and begins a new epoch.

[ALTER_LOCATION_LABEL](#)

Alters the location label.

[ALTER_LOCATION_USE](#)

Alters the type of files that can be stored at the specified storage location.

[ANALYZE_CONSTRAINTS](#)

Analyzes and reports on constraint violations within the specified scope.

[ANALYZE_CORRELATIONS](#)

Analyzes the specified tables for pairs of columns that are strongly correlated.

[ANALYZE_EXTERNAL_ROW_COUNT](#)

Calculates the exact number of rows in an external table.

[ANALYZE_STATISTICS](#)

Collects and aggregates data samples and storage information from all nodes that store projections associated with the specified table.

[ANALYZE_WORKLOAD](#)

Runs the Workload Analyzer (WLA), a utility that analyzes system information held in system tables .

AUDIT

Estimates the raw data size of a database, schema, or table as it is counted in an audit of the database size.

AUDIT_FLEX

Estimates the ROS size of one or more flexible tables contained in a database, schema, or projection.

AUDIT_LICENSE_SIZE

Triggers an immediate audit of the database size to determine if it is in compliance with the raw data storage allowance included in your licenses.

AUDIT_LICENSE_TERM

Triggers an immediate audit to determine if the license has expired.

AWS_GET_CONFIG

Returns the current Amazon Web Services (AWS) credentials set by `AWS_SET_CONFIG` or `ALTER SESSION`.

AWS_SET_CONFIG

Gets the values from a table with your Amazon Web Services (AWS) credentials and passes them to session parameters.

BUILD_FLEXTABLE_VIEW

Creates, or re-creates, a view for a default or user-defined `_keys` table, ignoring any empty keys.

CANCEL_REBALANCE_CLUSTER

Stops any rebalance task that is currently in progress or is waiting to execute.

CANCEL_REFRESH

Cancels refresh-related internal operations initiated by `START_REFRESH` and `REFRESH`.

CHANGE_CURRENT_STATEMENT_RUNTIME_PRIORITY

Changes the run-time priority of an active query.

CHANGE_RUNTIME_PRIORITY

Changes the run-time priority of a query that is actively running.

CLEAR_CACHES

Clears the internal cache files.

CLEAR_DATA_COLLECTOR

Clears all memory and disk records on the Data Collector tables and functions and resets collection statistics in the system table `DATA_COLLECTOR`.

CLEAR_HDFS_CACHES

Clears the configuration information copied from HDFS and any cached connections.

CLEAR_OBJECT_STORAGE_POLICY

Removes an existing storage policy.

[CLEAR_PROFILING](#)

Clears from memory data for the specified profiling type.

[CLEAR_PROJECTION_REFRESHES](#)

Triggers to clear information about refresh operations for projections immediately.

[CLEAR_RESOURCE_REJECTIONS](#)

Clears the content of the RESOURCE_REJECTIONS and DISK_RESOURCE_REJECTIONS system tables.

[CLOSE_ALL_RESULTSETS](#)

Closes all result set sessions within Multiple Active Result Sets (MARS) and frees the MARS storage for other result sets.

[CLOSE_ALL_SESSIONS](#)

Closes all external sessions except the one that issues this function.

[CLOSE_RESULTSET](#)

Closes a specific result set within Multiple Active Result Sets (MARS) and frees the MARS storage for other result sets.

[CLOSE_SESSION](#)

Interrupts the specified external session, rolls back the current transaction if any, and closes the socket.

[CLOSE_USER_SESSIONS](#)

Stops the session for a user, rolls back any transaction currently running, and closes the connection.

[COMPACT_STORAGE](#)

Bundles existing data (.fdb) and index (.pidx) files into the .gt file format.

[COMPUTE_FLEXTABLE_KEYS](#)

Computes the virtual columns (keys and values) from the flex table VMap data.

[COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW](#)

Combines the functionality of BUILD_FLEXTABLE_VIEW and COMPUTE_FLEXTABLE_KEYS to compute virtual columns (keys) from the VMap data of a flex table and construct a view.

[COPY_PARTITIONS_TO_TABLE](#)

Copies partitions from one table to another.

[COPY_TABLE](#)

Copies one table to another.

[CURRENT_SCHEMA](#)

Returns the name of the current schema.

[DATA_COLLECTOR_HELP](#)

Returns online usage instructions about the Data Collector, the V_MONITOR.DATA_COLLECTOR system table, and the Data Collector control functions.

DELETE_COMMUNITY_KEY

Removes the security key from the database DFS.

DELETE_TOKENIZER_CONFIG_FILE

Deletes a tokenizer configuration file.

DESCRIBE_COMMUNITY_KEY

Retrieves the value of the security key so you can use it in a query.

DESIGNER_ADD_DESIGN_QUERIES

Reads and evaluates queries from an input file, and adds the queries that it accepts to the specified design.

DESIGNER_ADD_DESIGN_QUERIES_FROM_RESULTS

Executes the specified query and evaluates results in the following columns:

DESIGNER_ADD_DESIGN_QUERY

Reads and parses the specified query, and if accepted, adds it to the design.

DESIGNER_ADD_DESIGN_TABLES

Adds the specified tables to a design.

DESIGNER_CANCEL_POPULATE_DESIGN

Cancels population or deployment operation for the specified design if it is currently running.

DESIGNER_CREATE_DESIGN

Creates a design with the specified name.

DESIGNER_DESIGN_PROJECTION_ENCODINGS

Analyzes encoding in the specified projections, creates a script to implement encoding recommendations, and optionally deploys the recommendations.

DESIGNER_DROP_ALL_DESIGNS

Removes all -related schemas associated with the current user.

DESIGNER_DROP_DESIGN

Removes the schema associated with the specified design and all its contents.

DESIGNER_OUTPUT_ALL_DESIGN_PROJECTIONS

Displays the DDL statements that define the design projections to standard output.

DESIGNER_OUTPUT_DEPLOYMENT_SCRIPT

Displays the deployment script for the specified design to standard output.

DESIGNER_RESET_DESIGN

Discards all run-specific information of the previous build or deployment of the specified design but keeps its configuration.

DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY

Populates the design and creates the design and deployment scripts.

DESIGNER_SET_ANALYZE_CORRELATIONS_MODE

Specifies how handles column correlations in a design.

DESIGNER_SET_DESIGN_KSAFETY

Sets K-safety for a comprehensive design and stores the K-safety value in the DESIGNS table.

DESIGNER_SET_DESIGN_TYPE

Specifies whether should create a comprehensive or incremental design.

DESIGNER_SET_OPTIMIZATION_OBJECTIVE

Valid only for comprehensive database designs, specifies the optimization objective uses.

DESIGNER_SET_PROPOSE_UNSEGMENTED_PROJECTIONS

Specifies whether a design can include unsegmented projections .

DESIGNER_WAIT_FOR_DESIGN

Waits for completion of operations that are populating and deploying the design.

DISABLE_DUPLICATE_KEY_ERROR

Disables error messaging when finds duplicate primary or unique key values at run time (for use with key constraints that are not automatically enabled).

DISABLE_ELASTIC_CLUSTER

Disables elastic cluster scaling, which prevents from bundling data into chunks that are easily transportable to other nodes when performing cluster resizing.

DISABLE_LOCAL_SEGMENTS

Disables local data segmentation, which breaks projections segments on nodes into containers that can be easily moved to other nodes.

DISABLE_PROFILING

Disables profiling for the specified profiling type.

DISPLAY_LICENSE

Returns the terms of your license.

DO_TM_TASK

Runs a Tuple Mover operation on the specified table or projection and commits any current transaction.

DROP_EXTERNAL_ROW_COUNT

Removes external table row count statistics compiled by ANALYZE_EXTERNAL_ROW_COUNT .

DROP_LICENSE

Drops a license key from the global catalog.

DROP_LOCATION

Removes the specified storage location.

DROP_PARTITION

Drops the specified partition.

DROP_STATISTICS

Removes statistical data on database projections previously generated by ANALYZE_STATISTICS .

DUMP_CATALOG

Returns an internal representation of the catalog.

DUMP_LOCKTABLE

Returns information about deadlocked clients and the resources they are waiting for.

DUMP_PARTITION_KEYS

Dumps the partition keys of all projections in the system.

DUMP_PROJECTION_PARTITION_KEYS

Dumps the partition keys of the specified projection.

DUMP_TABLE_PARTITION_KEYS

Dumps the partition keys of all projections for the specified table.

EMPTYMAP

Constructs a new VMap with one row but without keys or data.

ENABLE_ELASTIC_CLUSTER

Enables elastic cluster scaling, which makes enlarging or reducing the size of your database cluster more efficient by segmenting a node's data into chunks that can be easily moved to other hosts.

ENABLE_LOCAL_SEGMENTS

Enables local storage segmentation, which breaks projections segments on nodes into containers that can be easily moved to other nodes.

ENABLE_PROFILING

Enables profiling for the specified profiling type.

ENFORCE_OBJECT_STORAGE_POLICY

Applies object storage policies immediately, instead of waiting for the Tuple Mover to perform the next moveout.

EVALUATE_DELETE_PERFORMANCE

Evaluates projections for potential DELETE performance issues.

EXPORT_CATALOG

Generates a SQL script for recreating a physical schema design on another cluster.

EXPORT_DIRECTED_QUERIES

Generates SQL for creating directed queries from a set of input queries, and writes the SQL to the specified file or to standard output.

EXPORT_OBJECTS

Generates a SQL script you can use to recreate non-virtual catalog objects on another cluster.

EXPORT_STATISTICS

Generates database statistics in XML format from data previously collected by ANALYZE_STATISTICS .

EXPORT_TABLES

Generates a SQL script that can be used to recreate a logical schema—schemas, tables, constraints, and views—on another cluster.

FLUSH_DATA_COLLECTOR

Waits until memory logs are moved to disk and then flushes the Data Collector, synchronizing the log with the disk storage.

GET_AHM_EPOCH

Returns the number of the epoch in which the Ancient History Mark is located.

GET_AHM_TIME

Returns a TIMESTAMP value representing the Ancient History Mark .

GET_AUDIT_TIME

Reports the time when the automatic audit of database size occurs.

GET_CLIENT_LABEL

Returns the client connection label for the current session.

GET_COMPLIANCE_STATUS

Displays whether your database is in compliance with your license agreement.

GET_CURRENT_EPOCH

The epoch into which data (COPY, INSERT, UPDATE, and DELETE operations) is currently being written.

GET_DATA_COLLECTOR_POLICY

Retrieves a brief statement about the retention policy for the specified component.

GET_LAST_GOOD_EPOCH

Returns the last good epoch number.

GET_NUM_ACCEPTED_ROWS

Returns the number of rows loaded into the database for the last completed load for the current session.

GET_NUM_REJECTED_ROWS

Returns the number of rows that were rejected during the last completed load for the current session.

GET_PROJECTIONS

Returns information about projections that are anchored to the specified table, as follows:.

GET_PROJECTION_STATUS

Returns information relevant to the status of a projection :.

GET_TOKENIZER_PARAMETER

Returns the configuration parameter for a given tokenizer.

HAS_ROLE

Indicates, with a Boolean value, whether a role has been assigned to a user.

IDOL_CHECK_ACL

Checks the access control list to verify that the user has permissions to access the data in the IDOL flex table and any views created from the table.

IMPORT_DIRECTED_QUERIES

Imports to the database catalog directed queries from a SQL file that was generated by EXPORT_DIRECTED_QUERIES .

IMPORT_STATISTICS

Imports statistics from the XML file that was generated by EXPORT_STATISTICS .

INSTALL_COMMUNITY_KEY

Stores the Connector Framework Service security key in the Distributed File System (DFS).

INSTALL_LICENSE

Installs the license key in the global catalog.

INTERRUPT_STATEMENT

Interrupts the specified statement in a user session, rolls back the current transaction, and writes a success or failure message to the log file.

KERBEROS_CONFIG_CHECK

Tests the Kerberos configuration of a cluster.

KERBEROS_HDFS_CONFIG_CHECK

Tests the Kerberos configuration of a cluster that uses HDFS.

LAST_INSERT_ID

Returns the last value of a column whose value is automatically incremented through AUTO_INCREMENT or IDENTITY column constraints .

MAKE_AHM_NOW

Sets the Ancient History Mark (AHM) to the greatest allowable value.

MAPAGGREGATE

Returns a LONG VARBINARY VMap with keys and value pairs supplied from two VARCHAR input columns of an existing columnar table.

MAPCONTAINSKEY

Determines whether a VMap contains a virtual column (key).

MAPCONTAINSVALUE

Determines whether a VMap contains a specific value.

MAPDELIMITEDEXTRACTOR

Extracts data with a delimiter character, and other optional arguments, returning a single VMap value.

MAPITEMS

Returns information about items in a VMap.

MAPJSONEXTRACTOR

Extracts content of repeated JSON data objects, including nested maps, or data with an outer list of JSON elements.

MAPKEYS

Returns the virtual columns (and values) present in any VMap data.

MAPKEYSINFO

Returns virtual column information from a given map.

MAPLOOKUP

Returns single-key values from VMAP data.

MAPPUT

Accepts a VMap and one or more key/value pairs and returns a new VMap with the key/value pairs added.

MAPREGEXEXTRACTOR

Extracts data from a regular expression and returns the results as a VMap.

MAPSIZE

Returns the number of virtual columns present in any VMap data.

MAPTOSTRING

Recursively builds a string representation VMap data, including nested JSON maps.

MAPVALUES

Returns a string representation of the top-level values from a VMap.

MAPVERSION

Returns the version or invalidity of any map data.

MARK_DESIGN_KSAFE

Enables or disables high availability in your environment, in case of a failure.

MATERIALIZE_FLEXTABLE_COLUMNS

Materializes virtual columns listed as key_names in the flextable_keys table you compute using either COMPUTE_FLEXTABLE_KEYS or COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW

.

MEASURE_LOCATION_PERFORMANCE

Measures disk performance for the location specified.

MOVE_PARTITIONS_TO_TABLE

Moves partitions from one table to another.

MOVE_RETIRED_LOCATION_DATA

Moves all data from either a single retired storage location or all retired storage locations in the database.

MOVE_STATEMENT_TO_RESOURCE_POOL

Attempts to move the specified query to the specified target pool.

NOTIFY

Specifies the text message to include with a notification.

PARTITION_PROJECTION

Splits ROS containers for a specified projection.

PARTITION_TABLE

Forces the database to split ROS containers in the specified table that contain multiple distinct values of the partitioning expression.

PURGE

Permanently removes delete vectors from ROS storage containers so disk space can be reused.

PURGE_PARTITION

Purges a table partition of deleted rows.

PURGE_PROJECTION

Permanently removes deleted data from physical storage so disk space can be reused.

PURGE_TABLE

Permanently removes deleted data from physical storage so disk space can be reused.

READ_CONFIG_FILE

Reads and returns the key-value pairs of all the parameters of a given tokenizer.

REALIGN_CONTROL_NODES

Chooses control nodes (spread hosts) from all cluster nodes and assigns the rest of the nodes in the cluster to a control node.

REBALANCE_CLUSTER

Rebalances the database cluster synchronously as a session foreground task.

REBALANCE_TABLE

Synchronously rebalances data in the specified table.

REENABLE_DUPLICATE_KEY_ERROR

Restores the default behavior of error reporting by reversing the effects of `DISABLE_DUPLICATE_KEY_ERROR`.

REFRESH

Performs a synchronous, optionally-targeted refresh of a specified table's projections.

REFRESH_COLUMNS

Refreshes table columns that are defined with the constraint `SET USING`.

RELEASE_ALL_JVM_MEMORY

Forces all sessions to release the memory consumed by their Java Virtual Machines (JVM).

RELEASE_JVM_MEMORY

Terminates a Java Virtual Machine (JVM), making available the memory the JVM was using.

RELOAD_SPREAD

Updates cluster changes to the catalog's spread configuration file.

RESERVE_SESSION_RESOURCE

Reserves memory resources from the general resource pool for the exclusive use of the backup and restore process.

RESET_LOAD_BALANCE_POLICY

Resets the counter each host in the cluster maintains, to track which host it will refer a client to when the native connection load balancing scheme is set to ROUNDROBIN .

RESET_SESSION

Applies your default connection string configuration settings to your current session.

RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW

Restores the `_keys` table and the `_view` .

RESTORE_LOCATION

Restores a storage location that was previously retired with `RETIRE_LOCATION` .

RETIRE_LOCATION

Makes the specified storage location inactive.

S3

Identifies the source location of files in an Amazon S3 bucket.

S3EXPORT

Exports data to an Amazon S3 bucket from your cluster.

SET_AHM_EPOCH

Sets the Ancient History Mark (AHM) to the specified epoch.

SET_AHM_TIME

Sets the Ancient History Mark (AHM) to the epoch corresponding to the specified time on the initiator node.

SET_AUDIT_TIME

Sets the time that performs automatic database size audit to determine if the size of the database is compliant with the raw data allowance in your license.

SET_CLIENT_LABEL

Assigns a label to a client connection for the current session.

SET_CONFIG_PARAMETER

Specifies the value of a configuration parameter at the database level, or for a specific node.

SET_CONTROL_SET_SIZE

Specifies the number of cluster nodes on which to deploy control messaging (spread).

SET_DATA_COLLECTOR_POLICY

Sets a size restraint (memory and disk space in kilobytes) for the specified Data Collector table on all nodes.

SET_DATA_COLLECTOR_TIME_POLICY

Sets a time capacity for individual Data Collector tables on all nodes.

SET_LOAD_BALANCE_POLICY

Sets how native connection load balancing chooses a host to handle a client connection.

SET_LOCATION_PERFORMANCE

Sets disk performance for the location specified.

SET_OBJECT_STORAGE_POLICY

Creates or changes an object storage policy by associating a database object with a labeled storage location.

SET_SCALING_FACTOR

Sets the scaling factor that determines the number of storage containers used when rebalancing the database and when using local data segmentation is enabled.

SET_TOKENIZER_PARAMETER

Configures the tokenizer parameters.

SHOW_PROFILING_CONFIG

Shows whether profiling is enabled.

SHUTDOWN

Forces a database to shut down, even if there are users connected.

SLEEP

Waits a specified number of seconds before executing another statement or command.

START_REBALANCE_CLUSTER

Asynchronously rebalances the database cluster as a background task.

START_REFRESH

For the current schema, transfers data to projections that are not able to participate in query execution due to missing or out-of-date data.

SWAP_PARTITIONS_BETWEEN_TABLES

Swaps partitions between two tables.

SYNC_WITH_HCATALOG_SCHEMA

Copies the structure of a Hive database schema available through the HCatalog Connector to a schema.

SYNC_WITH_HCATALOG_SCHEMA_TABLE

Copies the structure of a single table in a Hive database schema available through the HCatalog Connector to a table.

VALIDATE_STATISTICS

Validates statistics in the XML file generated by the EXPORT_STATISTICS command.

[VERIFY_HADOOP_CONF_DIR](#)

Verifies that the Hadoop configuration that is used to access HDFS is valid on all nodes.

AWS Library Functions

This section contains the functions associated with the Vertica library for Amazon Web Services (AWS).

AWS_GET_CONFIG

Returns the current Amazon Web Services (AWS) credentials set by [AWS_SET_CONFIG](#) or ALTER SESSION.

Syntax

```
AWS_GET_CONFIG( 'parameter' )
```

parameter

aws_id
aws_secret
aws_region
aws_ca_path
aws_ca_bundle
aws_proxy
aws_verbose
aws_max_send_speed
aws_max_recv_speed

Parameters

aws_id	Retrieves the value for the 20-character AWS access key used to authenticate your account
aws_secret	Retrieves the value for the 40-character AWS secret access key used to authenticate your account
aws_region	Retrieves the region where your AWS bucket is located. See the AWS Documentation for the full list of values. Default value: us-east-1
aws_ca_path	Retrieves the path Vertica uses to look up SSL server certificates..

<code>aws_ca_bundle</code>	Retrieves the path Vertica uses to look up an SSL server certificate bundle.
<code>aws_proxy</code>	A string value that lets you set an HTTP/HTTPS proxy for the AWS library.
<code>aws_verbose</code>	When enabled, logs libcurl debug messages to dbLog.
<code>aws_max_send_speed</code>	Retrieves the value for the maximum transfer speed when sending data to AWS S3, in bytes per second.
<code>aws_max_recv_speed</code>	Retrieves the value for the maximum transfer speed for receiving data to AWS S3, in bytes per second.

Examples

This example retrieves a stored AWS access key in a session.

```
=> SELECT AWS_GET_CONFIG('aws_id');
   aws_get_config
-----
AKABCOEXAMPLEPKPXYZQ
(1 row)
```

See Also

- [AWS Library Parameters](#)
- [Vertica AWS Library](#)

AWS_SET_CONFIG

Gets the values from a table with your Amazon Web Services (AWS) credentials and passes them to session parameters.

Syntax

```
AWS_SET_CONFIG( 'parameter' = 'value')
```

parameter

```
aws_id
aws_secret
```

aws_region
aws_ca_path
aws_ca_bundle
aws_proxy
aws_verbose
aws_max_send_speed
aws_max_recv_speed

Parameters

aws_id	Specifies the 20-character AWS access key used to authenticate your account.
aws_secret	Specifies the 40-character AWS secret access key used to authenticate your account.
aws_region	<p>Specifies the region where your AWS bucket is located. See the AWS Documentation for the full list of values.</p> <p>You can configure <code>aws_region</code> with only one region. To access buckets in multiple regions, reset the parameter each time you change regions.</p> <p>Default value: <code>us-east-1</code></p>
aws_ca_path	<p>The path Vertica uses to look up SSL server certificates.</p> <p>Default value: System-dependent</p>
aws_ca_bundle	<p>The path Vertica uses to look up an SSL server certificate bundle.</p> <p>Default value: System-dependent</p>
aws_proxy	A string value that lets you set an HTTP/HTTPS proxy for the AWS library.
aws_verbose	<p>When enabled, logs libcurl debug messages to dbLog.</p> <p>Default value: <code>false</code></p>
aws_max_send_speed	<p>Sets the maximum transfer speed for sending data to AWS S3, in bytes per second.</p> <p>Default value: unlimited</p>
aws_max_recv_speed	<p>Sets the maximum transfer speed when receiving data to AWS S3, in bytes per second.</p> <p>Default value: unlimited</p>

Examples

Configure session parameters for an AWS access key and secret access key with credentials in table `keychain`:

```
=> SELECT AWS_SET_CONFIG('aws_id', accesskey), AWS_SET_CONFIG('aws_secret', secretaccesskey) FROM
keychain;
aws_set_config | aws_set_config
-----+-----
aws_id        | aws_secret
(1 row)
```

See Also

- [AWS_GET_CONFIG](#)
- [AWS Library Parameters](#)
- [Vertica AWS Library](#)

S3

Identifies the source location of files in an Amazon S3 bucket. Use the `S3` function in conjunction with a `COPY` statement to import data into a Vertica cluster from an S3 object.

Syntax

```
S3( url='object-url'[, delimiter='char' ] | bucket='objecturl' )
```

Parameters

<code>url[, delimiter='char']</code>	<p>Specifies the URLs of one or more S3 objects to import, either the HTTPS URL or the S3 URL.</p> <p>URLs should contain only ASCII characters, 0x01 to 0x7F.</p> <p>If you specify multiple URLs, you can optionally qualify this parameter by specifying a delimiter character, by default (vertical bar). Do not use one of the following characters:</p> <ul style="list-style-type: none">• : (colon)
--	---

	<ul style="list-style-type: none">• - (hyphen)• , (comma)• / (slash)• null
bucket	URL of the bucket when importing multiple files using glob expansion.

Privileges

Write privileges on the table you are copying to.

Examples

The following statement specifies to import multiple files. Object URLs are delimited by vertical bars, the default delimiter:

```
=> COPY exampleTable SOURCE s3(url='s3://exampleBucket/object1|S3://exampleBucket/object2');
```

Import all files in a bucket using glob expansion:

```
=> COPY table1 WITH SOURCE S3(bucket='S3://exampleBucket/*');
```

```
=> COPY exampleTable SOURCE S3(bucket='s3://exampleBucket/');
```

```
=> COPY exampleTable SOURCE S3(bucket='s3://exampleBucket');
```

- [AWS_SET_CONFIG](#)
- [AWS_GET_CONFIG](#)
- [AWS Library Parameters](#)
- [Vertica AWS Library](#)

S3EXPORT

Exports data to an Amazon S3 bucket from your Vertica cluster.

If your bucket name contains a period, you must specify a file extension in your export syntax or enable the `prepend_hash` parameter in `s3export`.

Syntax

```
S3EXPORT( expression USING PARAMETERS { parameter=setting }[,...]
```

parameter=setting

```
url='object-url'  
delimiter='char'  
multipart='char'  
chunksize=integer  
record_terminator='char'  
from_charset='varchar'  
to_charset='varchar'  
prepend_hash='boolean'
```

Parameters

<i>expression</i>	Specifies the source of the export operation.
<code>url</code>	The URL of the S3 bucket and object base name. This value can be either the HTTPS URL or the S3 URL. URL length is limited to a maximum of 236 characters. URLs should contain only ASCII characters, 0x01 to 0x7F.
<code>delimiter</code>	Specifies the column delimiter character. Default value: (vertical bar)
<code>multipart</code>	Specifies a Boolean value to enable (true) or disable (false) multipart upload. Default value: true
<code>chunksize</code>	Specifies in bytes the maximum size of each part. Valid settings can range between 5 MB and 5 GB. The maximum number of chunks allowed in an export is 10000. Default value: 10485760

<code>record_terminator</code>	Specifies what character marks the end of a record. Default value: <code>\n</code>
<code>from_charset</code>	Specifies the character set in which your data is currently encoded.
<code>to_charset</code>	Specifies the character set in which you want to encode your export.
<code>prepend_hash</code>	Prepends the unique hash values assigned to exported objects instead of the standard appendation. If your S3 bucket contains a period in its path, set the <code>prepend_hash</code> parameter to <code>true</code> . Default value: <code>false</code>

`from_charset` and `to_charset` values are system-dependent. Refer to your operating system documentation for more details.

Examples

Export `column1` data from `exampleTable`:

```
=> SELECT s3export(column1 USING PARAMETERS
  url='s3://exampleBucket/object',
  delimiter=',',
  multipart='true',
  chunksize='10485760',
  record_terminator='\n',
  from_charset='ASCII',
  to_charset='UTF-8',
  prepend_hash='true')
OVER () FROM exampleTable;
```

S3EXPORT_PARTITION

The S3EXPORT_PARTITION function allows Vertica output to be used by Amazon's Elastic MapReduce (EMR) feature. Since EMR stores and consumes data from S3 using the partition key included in the key of the S3 file, S3EXPORT_PARTITION exports data by adding the partition key in the url/filename.

Syntax

S3EXPORT_PARTITION (*expression* USING PARAMETERS { *parameter=setting*} [,...])

<i>expression</i>	Specifies the source of the export operation.
<i>url</i>	<p>The URL of the S3 bucket and object base name. Also include the partition key as part of the URL to export data so it is usable by EMR.</p> <p>The URL can be either the HTTPS URL or the S3 URL. URL length is limited to a maximum of 236 characters.</p> <p>URLs should contain only ASCII characters, 0x01 to 0x7F.</p>
<i>delimiter</i>	<p>Specifies the column delimiter character.</p> <p>Default value: (vertical bar)</p>
<i>chunksize</i>	<p>Determines the buffer size used to send bytes to S3. Valid settings can range between 5 MB and 5 GB.</p> <p>The maximum number of chunks allowed in an export is 10000.</p> <p>Default value: 10485760</p>
<i>record_terminator</i>	<p>Specifies what character marks the end of a record.</p> <p>Default value: \n</p>
<i>from_charset</i>	Specifies the character set in which your data is currently encoded.
<i>to_charset</i>	Specifies the character set in which you want to encode your export.
<i>prepend_hash</i>	Prepends the unique hash values assigned to exported objects instead of the standard appendation.

	If your S3 bucket contains a period in its path, set the <code>prepend_hash</code> parameter to true. Default value: false
<i>expression</i>	Specifies the source of the export operation.

`from_charset` and `to_charset` values are system-dependent. Refer to your operating system documentation for more details.

Examples

In the following example, `st` and `yr` are the partition keys:

```
=> select s3export_partition (* using parameters url='https://s3.amazonaws.com/db001/bystate.date;')
OVER (PARTITION by st, yr) from T;

rows | url
-----
184647| https://s3.amazonaws.com/db001/st=MA/yr=2005/bystate.77fcab9836b93a04.dat
282633| https://s3.amazonaws.com/db001/st=VA/yr=2007/bystate.77fcab9836b93a05.dat
282633| https://s3.amazonaws.com/db001/st=VA/yr=2009/bystate.77fcab9836b93a05.dat
(3 rows)
```

Catalog Management Functions

This section contains catalog management functions specific to Vertica.

DROP_LICENSE

Drops a license key from the global catalog.

Syntax

```
DROP_LICENSE( 'license-name' )
```

Parameters

<i>license-name</i>	The name of the license to drop. Use the name (or long license key) in the NAME column of system table LICENSES .
---------------------	---

Privileges

Superuser

Examples

```
=> SELECT DROP_LICENSE( '9b2d81e2-aab1-4cfb-bc07-fa9a696e8f5e' );
```

See Also

[Managing Licenses](#)

DUMP_CATALOG

Returns an internal representation of the Vertica catalog. This function is used for diagnostic purposes.

DUMP_CATALOG returns only the objects that are visible to the user.

Syntax

```
DUMP_CATALOG()
```

Privileges

None

Examples

The following query obtains an internal representation of the Vertica catalog:

```
=> SELECT DUMP_CATALOG();
```

The output is written to the specified file:

```
\o /tmp/catalog.txtSELECT DUMP_CATALOG();  
\o
```

EXPORT_CATALOG

Generates a SQL script for recreating a physical schema design on another cluster. This function always attempts to recreate projection statements with KSAFE clauses, if they exist in the original definitions, or OFFSET clauses if they do not.

Syntax

```
EXPORT_CATALOG ( '[destination]' [, 'scope' ] )
```

Parameters

If you omit all parameters, EXPORT_CATALOG exports to standard output all schemas, tables, constraints, views, and projections to which the user has access.

<i>destination</i>	Specifies where to send output, one of the following: <ul style="list-style-type: none">• An empty string (' ') writes the script to standard output.• The path and name of a SQL output file. This option is valid only for superusers. If you specify a file that does not exist, the function creates one. If you specify only a file name, Vertica creates it in the catalog directory. If the file already exists, the function silently overwrites its contents.
<i>scope</i>	Determines what to export:

	<ul style="list-style-type: none">• DESIGN (default): Exports schemas, tables, constraints, views, projections, and SQL macros to which the user has access. See also EXPORT_OBJECTS.• DESIGN_ALL: Exports all design objects plus system objects created in Database Designer—for example, design contexts and their tables. Exported objects are those to which the user has access.• TABLES: Exports all tables and constraints for which the user has access. See also EXPORT_TABLES.• DIRECTED_QUERIES: Exports all directed queries that are stored in the database. For more information, see Managing Directed Queries in the Administrator's Guide.
--	---

Privileges

None

Example

See [Exporting the Catalog](#).

See Also

- [EXPORT_OBJECTS](#)
- [EXPORT_TABLES](#)
- [Exporting the Catalog](#)

EXPORT_OBJECTS

Generates a SQL script you can use to recreate non-virtual catalog objects on another cluster. The following requirements apply:

- **EXPORT_OBJECTS** only exports objects to which the user has access.

- EXPORT_OBJECTS exports objects in order dependency for correct recreation. When you run the script on another cluster, Vertica creates all referenced objects before their dependent objects.
- EXPORT_OBJECTS always tries to recreate projection statements with their KSAFE clause, if any, otherwise with their OFFSET clause.

Syntax

```
EXPORT_OBJECTS( '[destination]' [, 'scope' ] [, 'ksafe' ] )
```

Parameters

<i>destination</i>	<p>Specifies where to send output, one of the following:</p> <ul style="list-style-type: none"> • An empty string (' ') writes the script to standard output. • The path and name of a SQL output file. This option is valid only for superusers. If you specify a file that does not exist, the function creates one. If you specify only a file name, Vertica creates it in the catalog directory. If the file already exists, the function silently overwrites its contents.
<i>scope</i>	<p>Specifies one or more objects to export, as follows:</p> <p><i>schema</i>[.<i>object</i>][, ...]</p> <p>If set to an empty string, Vertica exports all objects to which the user has access, including constraints.</p> <p>If you specify a schema, Vertica exports all objects in that schema.</p>
<i>ksafe</i>	<p>Specifies whether to include a MARK_DESIGN_KSAFE statement in the generated script with the correct K-safe value for the database:</p> <ul style="list-style-type: none"> • true (default): Include the MARK_DESIGN_KSAFE statement at the end of the output script. • false: Omit the MARK_DESIGN_KSAFE statement from the script.

Privileges

None

Example

See [Exporting Objects](#).

See Also

- [EXPORT_CATALOG](#)
- [EXPORT_TABLES](#)

EXPORT_TABLES

Generates a SQL script that can be used to recreate a logical schema—schemas, tables, constraints, and views—on another cluster. `EXPORT_OBJECTS` only exports objects to which the user has access.

Syntax

```
EXPORT_TABLES( '[destination]' [, 'scope' ] )
```

Parameters

<i>destination</i>	<p>Specifies where to send output, one of the following:</p> <ul style="list-style-type: none">• An empty string (' ') writes the script to standard output.• The path and name of a SQL output file. This option is valid only for superusers. If you specify a file that does not exist, the function creates one. If you specify only a file name, Vertica creates it in the catalog directory. If the file already exists, the function silently overwrites its contents.
<i>scope</i>	<p>Specifies one or more tables to export, as follows:</p> <p><i>schema</i>[.<i>table</i>][,...]</p> <p>If set to an empty string, Vertica exports all non-virtual table objects to which the user has access, including table schemas, sequences, and constraints.</p> <p>If you specify a schema, Vertica exports all non-virtual table objects in that schema.</p>

Privileges

None

Example

See [Exporting Tables](#).

The following example exports to standard output all tables in the store schema:

```
=> SELECT EXPORT_TABLES('', 'store');
                                EXPORT_TABLES
-----
CREATE SCHEMA store;

CREATE TABLE store.store_dimension
(
  store_key int NOT NULL,
  store_name varchar(64),
  store_number int,
  store_address varchar(256),
  store_city varchar(64),
  store_state char(2),
  store_region varchar(64),
  floor_plan_type varchar(32),
  photo_processing_type varchar(32),
  financial_service_type varchar(32),

    order_number int NOT NULL,
    date_ordered date,
    date_shipped date,
    expected_delivery_date date,
    date_delivered date,
    quantity_ordered int,
    quantity_delivered int,
    shipper_name varchar(32),
    unit_price int,
    shipping_cost int,
    total_order_cost int,
    quantity_in_stock int,
    reorder_level int,
    overstock_ceiling int
);

ALTER TABLE store.store_sales_fact ADD CONSTRAINT fk_store_sales_date FOREIGN KEY (date_key)
references public.date_dimension (date_key);
ALTER TABLE store.store_sales_fact ADD CONSTRAINT fk_store_sales_product FOREIGN KEY (product_key,
product_version) references public.product_dimension (product_key, product_version);
ALTER TABLE store.store_sales_fact ADD CONSTRAINT fk_store_sales_store FOREIGN KEY (store_key)
references store.store_dimension (store_key);
ALTER TABLE store.store_sales_fact ADD CONSTRAINT fk_store_sales_promotion FOREIGN KEY (promotion_
key) references public.promotion_dimension (promotion_key);
ALTER TABLE store.store_sales_fact ADD CONSTRAINT fk_store_sales_customer FOREIGN KEY (customer_key)
references public.customer_dimension (customer_key);
ALTER TABLE store.store_sales_fact ADD CONSTRAINT fk_store_sales_employee FOREIGN KEY (employee_key)
references public.employee_dimension (employee_key);
ALTER TABLE store.store_orders_fact ADD CONSTRAINT fk_store_orders_product FOREIGN KEY (product_key,
product_version) references public.product_dimension (product_key, product_version);
ALTER TABLE store.store_orders_fact ADD CONSTRAINT fk_store_orders_store FOREIGN KEY (store_key)
references store.store_dimension (store_key);
ALTER TABLE store.store_orders_fact ADD CONSTRAINT fk_store_orders_vendor FOREIGN KEY (vendor_key)
references public.vendor_dimension (vendor_key);
ALTER TABLE store.store_orders_fact ADD CONSTRAINT fk_store_orders_employee FOREIGN KEY (employee_
key) references public.employee_dimension (employee_key);

(1 row)
```

See Also

- [EXPORT_CATALOG](#)
- [EXPORT_OBJECTS](#)

INSTALL_LICENSE

Installs the license key in the global catalog.

Syntax

```
INSTALL_LICENSE( 'filename' )
```

Parameters

<i>filename</i>	The absolute path name of a valid license file.
-----------------	---

Privileges

Superuser

Examples

```
=> SELECT INSTALL_LICENSE('/tmp/vlicense.dat');
```

See Also

[Managing Licenses](#)

MARK_DESIGN_KSAFE

Enables or disables high availability in your environment, in case of a failure. Before enabling recovery, MARK_DESIGN_KSAFE queries the catalog to determine whether a cluster's physical schema design meets the following requirements:

- Small, unsegmented tables are replicated on all nodes.
- Large table superprojections are segmented with each segment on a different node.
- Each large table projection has at least one buddy projection for K-safety=1 (or two buddy projections for K-safety=2).

Buddy projections are also segmented across database nodes, but the distribution is modified so segments that contain the same data are distributed to different nodes. See [High Availability With Projections](#) in Vertica Concepts.

MARK_DESIGN_KSAFE does not change the physical schema.

Syntax

```
MARK_DESIGN_KSAFE ( k )
```

Parameters

<i>k</i>	<p>Specifies the level of K-safety, one of the following:</p> <ul style="list-style-type: none">• 2: Enables high availability if the schema design meets requirements for K-safety=2• 1: Enables high availability if the schema design meets requirements for K-safety=1• 0: Disables high availability
----------	---

Return Messages

If you specify a *k* value of 1 or 2, Vertica returns one of the following messages.

Success:

```
Marked design n-safe
```

Failure:

```
The schema does not meet requirements for K=n.  
Fact table projection projection-name  
has insufficient "buddy" projections.
```

where *n* is a K-safety setting.

Privileges

Superuser

Notes

- The database's internal recovery state persists across database restarts but it is not checked at startup time.
- When one node fails on a system marked K-safe=1, the remaining nodes are available for DML operations.

Examples

```
=> SELECT MARK_DESIGN_KSAFE(1);
   mark_design_ksafe
-----
Marked design 1-safe
(1 row)
```

If the physical schema design is not K-safe, messages indicate which projections do not have a buddy:

```
=> SELECT MARK_DESIGN_KSAFE(1);
The given K value is not correct;
the schema is 0-safe
Projection pp1 has 0 buddies,
which is smaller that the given K of 1
Projection pp2 has 0 buddies,
which is smaller that the given K of 1
.
.
.
(1 row)
```

See Also

- [Identical Segmentation](#)
- [Failure Recovery](#)

CFS Security Functions

This section describes functions you can use with the Connector Framework Services (CFS) security features.

These functions reside in the `v_idol` schema in the `idollib` library that is installed with CFS. When you run one of these functions, you must qualify its name with the `v_idol` schema. For example:

```
=> SELECT v_idol.DELETE_COMMUNITY_KEY();
```

DELETE_COMMUNITY_KEY

Removes the security key from the Vertica database DFS.

Syntax

```
V_IDOL.DELETE_COMMUNITY_KEY()
```

Privileges

Superuser

Examples

```
=> SELECT V_IDOL.DELETE_COMMUNITY_KEY();  
DELETE_COMMUNITY_KEY  
-----  
key successfully deleted
```

DESCRIBE_COMMUNITY_KEY

Retrieves the value of the security key so you can use it in a query.

Syntax

```
V_IDOL.DESCRIBE_COMMUNITY_KEY()
```

Example

This example retrieves the security key stored in the the Vertica database DFS:

```
=> SELECT V_IDOL.DESCRIBE_COMMUNITY_KEY();  
describe_community_key  
-----
```

```
123.144,564,231  
(1 row)
```

IDOL_CHECK_ACL

Checks the access control list to verify that the user has permissions to access the data in the IDOL flex table and any views created from the table.

Syntax

```
v_idol.idol_check_acl(autonomymetadata,securitysection, securitytype using parameters  
sis='MTMyfNudFzPXVB5rX2dLnU89CQo+B668H6iNiHr14KPC+ptoA4x80KzeFmme/y3QNYzQs+QVMd7nmvPc4CaT9qxNr3t2EMgr8YN  
GJ5KKnE61YN4BixkKd241tEN1LZ08c  
CJXiQaTppIqayD8UI9aC+JVvtGxeyc003cqrVQiMMqxzmrHEQfw==' ) from v_idol.idolsecurity;
```

You can also use the session parameter as part of the syntax:

```
Alter session set UDPARAMETER FOR v_idol.IdolLib IdolSecurityInfo ='MTMyf ... <encrypted SIS> ...BCmky';  
SELECT v_idol.idol_check_acl(acl, security_section, security_type) from v_idol.t;
```

Privileges

To run `idol_check_acl` on a view, you must be granted access to the view by the database administration user. This example creates a table, creates a view from the table, and grants access to the view to user1:

```
=> CREATE TABLE idoldata_base(...);  
=> CREATE VIEW idoldata as select * from idoldata_base where idol_  
check_acl(...);  
=> GRANT SELECT ON idoldata to user1;
```

Returns

This function returns one of the following:

- t - indicates the user has permission to access the data.
- f - indicates the user does not have permission to access the data.

INSTALL_COMMUNITY_KEY

Stores the Connector Framework Service security key in the Vertica Distributed File System (DFS).

Syntax

```
V_IDOL.INSTALL_COMMUNITY_KEY(USING PARAMETERS file_path='keyfile-path');
```

Parameters

file_path	Specifies the location of key file from which the key is copied to DFS.
-----------	---

Privileges

You must be a dbadmin user.

Example

Store the CFS security key that is in btea . key:

```
=> SELECT v_idol.install_community_key(  
    USING PARAMETERS file_path='/home/release/IDOL/test-data/btea.key');
```

Client Connection Management Functions

This section contains client connection management functions specific to Vertica.

GET_CLIENT_LABEL

Returns the client connection label for the current session.

Syntax

```
GET_CLIENT_LABEL()
```

Privileges

None

Examples

Return the current client connection label:

```
=> SELECT GET_CLIENT_LABEL();
      GET_CLIENT_LABEL
-----
data_load_application
(1 row)
```

See Also

[Setting a Client Connection Label](#)

RESET_LOAD_BALANCE_POLICY

Resets the counter each host in the cluster maintains, to track which host it will refer a client to when the native [connection load balancing scheme](#) is set to ROUNDROBIN. To reset the counter, run this function on all cluster nodes.

Syntax

```
RESET_LOAD_BALANCE_POLICY()
```

Privileges

Superuser

Example

```
=> SELECT RESET_LOAD_BALANCE_POLICY();
      RESET_LOAD_BALANCE_POLICY
-----
Successfully reset stateful client load balance policies: "roundrobin".
(1 row)
```

SET_CLIENT_LABEL

Assigns a label to a client connection for the current session. You can use this label to distinguish client connections.

Labels appear in the `v_monitor.sessions` table. However, they are not updated in Data Collector tables because the change occurs after Vertica makes the connection.

Syntax

```
SET_CLIENT_LABEL('Label-name')
```

Parameters

<i>Label-name</i>	VARCHAR name assigned to the client connection label.
-------------------	---

Privileges

None

Examples

Assign label `data_load_application` to the current client connection:

```
=> SELECT SET_CLIENT_LABEL('data_load_application');
       SET_CLIENT_LABEL
-----
client_label set to data_load_application
(1 row)
```

See Also

[Setting a Client Connection Label](#)

SET_LOAD_BALANCE_POLICY

Sets how native connection load balancing chooses a host to handle a client connection.

Syntax

```
SET_LOAD_BALANCE_POLICY(policy)
```

Parameters

<i>policy</i>	<p>The name of the load balancing policy to use, one of the following:</p> <ul style="list-style-type: none">• NONE (default): Disables native connection load balancing.• ROUNDROBIN: Chooses the next host from a circular list of hosts in the cluster that are up—for example, in a three-node cluster, iterates over node1, node2, and node3, then wraps back to node1. Each host in the cluster maintains its own pointer to the next host in the circular list, rather than there being a single cluster-wide state.• RANDOM: Randomly chooses a host from among all hosts in the cluster that are up. <p>Note: Even if the load balancing policy is set on the server to something other than NONE, clients must indicate they want their connections to be load balanced by setting a connection property.</p>
---------------	---

Privileges

Superuser

Example

The following example demonstrates enabling native connection load balancing on the server by setting the load balancing scheme to ROUNDROBIN:

```
=> SELECT SET_LOAD_BALANCE_POLICY('ROUNDROBIN');
          SET_LOAD_BALANCE_POLICY
-----
Successfully changed the client initiator load balancing policy to: roundrobin
(1 row)
```

See Also

[About Native Connection Load Balancing](#)

Cluster Management Functions

This section contains functions that manage spread deployment on large, distributed database clusters.

REALIGN_CONTROL_NODES

Chooses control nodes (spread hosts) from all cluster nodes and assigns the rest of the nodes in the cluster to a control node. Calling this function respects existing [fault groups](#), which you can view by querying the [V_CATALOG.CLUSTER_LAYOUT](#) system table. This view also lets you see the proposed new layout for nodes in the cluster.

Syntax

```
REALIGN_CONTROL_NODES()
```

Privileges

Superuser

Example

Choose control nodes from all cluster nodes and assign the remaining nodes to a control node:

```
=> SELECT REALIGN_CONTROL_NODES;
```

See Also

[Defining and Realigning Control Nodes on an Existing Cluster](#)

REBALANCE_CLUSTER

Rebalances the database cluster synchronously as a session foreground task. `REBALANCE_CLUSTER` returns only after the rebalance operation is complete. If the current session ends, the operation immediately aborts. To rebalance the cluster as a background task, call [START_REBALANCE_CLUSTER](#).

On large cluster arrangements, you typically call `REBALANCE_CLUSTER` in a flow (see [Defining and Realigning Control Nodes](#) in the Administrator's Guide). After you change the number and distribution of control nodes (spread hosts), you must run `REBALANCE_CLUSTER()` for fault tolerance to be realized.

For detailed information about rebalancing tasks, see [Rebalancing Data Across Nodes](#).

Tip: By default, before performing a rebalance, Vertica queries system tables to compute the size of all projections involved in the rebalance task. This query can add significant overhead to the rebalance operation. To disable this query, set projection configuration parameter `RebalanceQueryStorageContainers` to 0.

Syntax

```
REBALANCE_CLUSTER()
```

Privileges

Superuser

Example

```
=> SELECT REBALANCE_CLUSTER();
REBALANCE_CLUSTER
-----
REBALANCED
(1 row)
```

RELOAD_SPREAD

Updates cluster changes to the catalog's spread configuration file. These changes include:

- New or realigned control nodes
- New spread hosts or fault group
- New or dropped cluster nodes

This function is often used in a multi-step process for large and elastic cluster arrangements. Calling it might require you to restart the database. You must then rebalance the cluster to realize fault tolerance. For details, see [Defining and Realigning Control Nodes](#) in the Administrator's Guide.

Syntax

```
RELOAD_SPREAD( true )
```

Parameters

<i>true</i>	Updates cluster changes related to control message responsibilities to the spread configuration file.
-------------	---

Privileges

Superuser

Example

Update the cluster with changes to control messaging:

```
=> SELECT reload_spread(true);
 reload_spread
-----
reloaded
(1 row)
```

See Also

[REBALANCE_CLUSTER](#)

SET_CONTROL_SET_SIZE

Specifies the number of cluster nodes on which to deploy control messaging (spread). You can call this function only on a running database.

To determine whether the current spread hosts and the control designations in the catalog match, query system table [LARGE_CLUSTER_CONFIGURATION_STATUS](#)

Note: This function is equivalent to:

```
install_vertica --large cluster integer
```

For details, see [Installing a Large Cluster](#) in the Administrator's Guide.

Syntax

```
SET_CONTROL_SET_SIZE( integer )
```

Parameters

<i>integer</i>	The number of cluster hosts from the database cluster on which spread runs.
----------------	---

Privileges

Superuser

Example

Run spread on two cluster nodes:

```
=> SELECT set_control_set_size(2);
   SET_CONTROL_SET_SIZE
-----
Control size set
(1 row)
```

See Also

[Defining and Realigining Control Nodes on an Existing Cluster](#)

Cluster Scaling Functions

This section contains functions that control how the cluster organizes data for rebalancing.

CANCEL_REBALANCE_CLUSTER

Stops any rebalance task that is currently in progress or is waiting to execute.

Syntax

```
CANCEL_REBALANCE_CLUSTER()
```

Privileges

Superuser

Example

```
=> SELECT CANCEL_REBALANCE_CLUSTER();
CANCEL_REBALANCE_CLUSTER
-----
CANCELED
(1 row)
```

See Also

- [START_REBALANCE_CLUSTER](#)
- [REBALANCE_CLUSTER](#)

DISABLE_ELASTIC_CLUSTER

Disables elastic cluster scaling, which prevents Vertica from bundling data into chunks that are easily transportable to other nodes when performing cluster resizing. The main reason to disable elastic clustering is if you find that the slightly unequal data distribution in your cluster caused by grouping data into discrete blocks results in performance issues.

Syntax

```
DISABLE_ELASTIC_CLUSTER()
```

Privileges

Superuser

Example

```
=> SELECT DISABLE_ELASTIC_CLUSTER();
DISABLE_ELASTIC_CLUSTER
-----
DISABLED
(1 row)
```

See Also

- [ENABLE_ELASTIC_CLUSTER](#)

DISABLE_LOCAL_SEGMENTS

Disables local data segmentation, which breaks projections segments on nodes into containers that can be easily moved to other nodes. See [Local Data Segmentation](#) in the Administrator's Guide for details.

Syntax

```
DISABLE_LOCAL_SEGMENTS()
```

Privileges

Superuser

Example

```
=> SELECT DISABLE_LOCAL_SEGMENTS();
DISABLE_LOCAL_SEGMENTS
-----
DISABLED
```

```
(1 row)
```

ENABLE_ELASTIC_CLUSTER

Enables elastic cluster scaling, which makes enlarging or reducing the size of your database cluster more efficient by segmenting a node's data into chunks that can be easily moved to other hosts.

Syntax

```
ENABLE_ELASTIC_CLUSTER()
```

Privileges

Superuser

Example

```
=> SELECT ENABLE_ELASTIC_CLUSTER();
ENABLE_ELASTIC_CLUSTER
-----
ENABLED
(1 row)
```

See Also

- [DISABLE_ELASTIC_CLUSTER](#)

ENABLE_LOCAL_SEGMENTS

Enables local storage segmentation, which breaks projections segments on nodes into containers that can be easily moved to other nodes. See [Local Data Segmentation](#) in the Administrator's Guide for more information.

Syntax

```
ENABLE_LOCAL_SEGMENTS()
```

Privileges

Superuser

Example

```
=> SELECT ENABLE_LOCAL_SEGMENTS();
   ENABLE_LOCAL_SEGMENTS
-----
   ENABLED
(1 row)
```

SET_SCALING_FACTOR

Sets the scaling factor that determines the number of storage containers used when rebalancing the database and when using local data segmentation is enabled. See [Cluster Scaling](#) for details.

Syntax

```
SET_SCALING_FACTOR( factor )
```

Parameters

<i>factor</i>	An integer value between 1 and 32. Vertica uses this value to calculate the number of storage containers each projection is broken into when rebalancing or when local data segmentation is enabled.
---------------	--

Privileges

Superuser

Best Practices

The scaling factor determines the number of storage containers that Vertica uses to store each projection across the database during rebalancing when local segmentation is enabled. When setting the scaling factor, follow these guidelines:

- The number of storage containers should be greater than or equal to the number of partitions multiplied by the number of local segments:

$$\text{num-storage-containers} \geq (\text{num-partitions} * \text{num-local-segments})$$

- Set the scaling factor high enough so rebalance can transfer local segments to satisfy the skew threshold, but small enough so the number of storage containers does not result in too many ROS containers, and cause ROS *pushback*. The maximum number of ROS containers is 1024.

Example

```
=> SELECT SET_SCALING_FACTOR(12);
   SET_SCALING_FACTOR
-----
SET
(1 row)
```

START_REBALANCE_CLUSTER

Asynchronously rebalances the database cluster as a background task. This function returns immediately after the rebalancing operation is complete. Rebalancing persists until the operation is complete, even if you close the current session or the database shuts down. In the case of shutdown, rebalancing resumes after the cluster restarts. To stop the rebalance operation, call [CANCEL_REBALANCE_CLUSTER](#).

For detailed information about rebalancing tasks, see [Rebalancing Data Across Nodes](#).

Syntax

```
START_REBALANCE_CLUSTER()
```

Privileges

Superuser

Example

```
=> SELECT START_REBALANCE_CLUSTER();
   START_REBALANCE_CLUSTER
-----
```

```
REBALANCING  
(1 row)
```

See Also

[REBALANCE_CLUSTER](#)

Communications Functions

This section contains communication functions specific to Vertica.

NOTIFY

Specifies the text message to include with a notification.

Syntax

```
NOTIFY ( 'message', 'notifier', 'target-topic' )
```

Parameters

<i>message</i>	The message to send to the end point.
<i>notifier</i>	The name of the notifier used to deliver the message.
<i>target-topic</i>	The name of the destination Kafka topic for the message.

Privileges

Superuser

Examples

Send a message to confirm that an ETL job is complete:

```
=> SELECT NOTIFY('ETL Done!', 'my_notifier', 'DB_activity_topic');
```

Constraint Management Functions

This section contains constraint management functions specific to Vertica.

See also SQL system table [V_CATALOG.TABLE_CONSTRAINTS](#).

ANALYZE_CONSTRAINTS

Analyzes and reports on constraint violations within the specified scope

You can enable automatic enforcement of primary key, unique key, and check constraints when INSERT, UPDATE, MERGE, or COPY statements execute. Alternatively, you can use ANALYZE_CONSTRAINTS to validate constraints after issuing these statements. Refer to [Enforcing Primary Key, Unique Key, and Check Constraints Automatically](#) for more information.

ANALYZE_CONSTRAINTS performs a lock in the same way that SELECT * FROM t1 holds a lock on table t1. See [LOCKS](#) for additional information.

Syntax

```
ANALYZE_CONSTRAINTS ('[ schema.]table ' [, 'column[,...]')
```

Parameters

<i>schema</i>	Specifies a schema . If multiple schemas are defined in the database, include the schema name. For example: <pre>myschema.thisDBObject</pre>
<i>table-name</i>	Identifies the table to analyze. If you omit specifying a schema, Vertica uses the current schema search path. If set to an empty string, Vertica analyzes all tables in the current schema.
<i>column</i>	The column in <i>table</i> to analyze. You can specify multiple comma-delimited columns. Vertica narrows the scope of the analysis to the specified columns. If you omit specifying a column, Vertica analyzes all columns in <i>table</i> .

Privileges

- SELECT privilege on table
- USAGE privilege on schema

Detecting Constraint Violations During a Load Process

Vertica checks for constraint violations when queries are run, not when data is loaded. To detect constraint violations as part of the load process, use a [COPY](#) statement with the NO COMMIT option. By loading data without committing it, you can run a post-load check of your data using the ANALYZE_CONSTRAINTS function. If the function finds constraint violations, you can roll back the load because you have not committed it.

If ANALYZE_CONSTRAINTS finds violations, such as when you insert a duplicate value into a primary key, you can correct errors using the following functions. Effects last until the end of the session only:

- [DISABLE_DUPLICATE_KEY_ERROR](#)
- [REENABLE_DUPLICATE_KEY_ERROR](#)

Important: If a check constraint SQL expression evaluates to an unknown for a given row because a column within the expression contains a null, the row passes the constraint condition.

Return Values

ANALYZE_CONSTRAINTS returns results in a structured set (see table below) that lists the schema name, table name, column name, constraint name, constraint type, and the column values that caused the violation.

If the result set is empty, then no constraint violations exist; for example:

```
> SELECT ANALYZE_CONSTRAINTS ('public.product_dimension', 'product_key');
Schema Name | Table Name | Column Names | Constraint Name | Constraint Type | Column Values
-----+-----+-----+-----+-----+-----
(0 rows)
```

The following result set shows a primary key violation, along with the value that caused the violation ('10'):

```
=> SELECT ANALYZE_CONSTRAINTS ('');
Schema Name | Table Name | Column Names | Constraint Name | Constraint Type | Column Values
-----+-----+-----+-----+-----+-----
store       | t1         | c1           | pk_t1          | PRIMARY        | ('10')
```

(1 row)

The result set columns are described in further detail in the following table:

Column Name	Data Type	Description
Schema Name	VARCHAR	The name of the schema.
Table Name	VARCHAR	The name of the table, if specified.
Column Names	VARCHAR	A list of comma-delimited columns that contain constraints.
Constraint Name	VARCHAR	The given name of the primary key, foreign key, unique, check, or not null constraint, if specified.
Constraint Type	VARCHAR	Identified by one of the following strings: <ul style="list-style-type: none"> • PRIMARY KEY • FOREIGN KEY • UNIQUE • CHECK • NOT NULL
Column Values	VARCHAR	Value of the constraint column, in the same order in which Column Names contains the value of that column in the violating row. When interpreted as SQL, the value of this column forms a list of values of the same type as the columns in Column Names; for example: ('1'), ('1', 'z')

Examples

See [Detecting Constraint Violations with ANALYZE_CONSTRAINTS](#) in the Administrator's Guide.

ANALYZE_CORRELATIONS

Analyzes the specified tables for pairs of columns that are strongly correlated. ANALYZE_CORRELATIONS stores the 20 pairs with the strongest correlation. ANALYZE_CORRELATIONS also analyzes statistics.

ANALYZE_CORRELATIONS analyzes only pairwise single-column correlations.

For example, state name and country name columns are strongly correlated because the city name usually, but perhaps not always, identifies the state name. The city of Conshohocken is uniquely associated with Pennsylvania, while the city of Boston exists in Georgia, Indiana, Kentucky, New York, Virginia, and Massachusetts. In this case, city name is strongly correlated with state name.

Behavior Type

Immutable

Syntax

```
ANALYZE_CORRELATIONS ('[ [schema.]table ]' [, 'recalculate' ] )
```

Parameters

<i>schema</i>	<p>Specifies a schema. If multiple schemas are defined in the database, include the schema name. For example:</p> <pre>myschema.thisDBObject</pre>
<i>table-name</i>	<p>Identifies the table to analyze. If you omit specifying a schema, Vertica uses the current schema search path. If set to an empty string, Vertica analyzes all tables in the current schema.</p>
<i>recalculate</i>	<p>Boolean that specifies whether to analyze correlated columns that were previously analyzed.</p> <p>Note: Column correlation analysis typically needs to be done only once.</p> <p>Default: false</p>

Privileges

One of the following:

- Superuser
- User with USAGE privilege on the design schema

Analysis Follow-Up

To take advantage of the correlations that ANALYZE_CORRELATIONS discovers, run Database Designer programmatically. Run [DESIGNER_SET_ANALYZE_CORRELATIONS_MODE](#) to specify that Database Designer consider existing column correlations. Be sure to specify that Database Designer not analyze statistics so it does not override existing statistics.

Example

In the following example, ANALYZE_CORRELATIONS analyzes column correlations for all tables in the public schema, even if they currently exist. The correlations that ANALYZE_CORRELATIONS finds are saved, so Database Designer can use them the next time it runs on the VMart database:

```
=> SELECT ANALYZE_CORRELATIONS ('public.*', 'true');
ANALYZE_CORRELATIONS
-----
0
(1 row)
```

DISABLE_DUPLICATE_KEY_ERROR

Disables error messaging when Vertica finds duplicate primary or unique key values at run time (for use with key constraints that are not automatically enabled). Queries execute as though no constraints are defined on the schema. Effects are session scoped.

Syntax

```
DISABLE_DUPLICATE_KEY_ERROR();
```

Privileges

Superuser

Examples

When you call `DISABLE_DUPLICATE_KEY_ERROR`, Vertica issues warnings letting you know that duplicate values will be ignored, and incorrect results are possible. `DISABLE_DUPLICATE_KEY_ERROR` is for use only for key constraints that are not automatically enabled.

```
=> select DISABLE_DUPLICATE_KEY_ERROR();
WARNING 3152: Duplicate values in columns marked as UNIQUE will now be ignored for the remainder of
your session or until reenable_duplicate_key_error() is called
WARNING 3539: Incorrect results are possible. Please contact Vertica Support if unsure
  disable_duplicate_key_error
-----
Duplicate key error disabled
(1 row)
```

See Also

[ANALYZE_CONSTRAINTS](#)

LAST_INSERT_ID

Returns the last value of a column whose value is automatically incremented through `AUTO_INCREMENT` or `IDENTITY` [column constraints](#). If multiple sessions concurrently load the same table, the returned value is the last value generated for an `AUTO_INCREMENT` column by an insert in that session.

Behavior Type

Volatile

Syntax

```
LAST_INSERT_ID()
```

Privileges

- Table owner
- `USAGE` privileges on schema

Restrictions

- This function works only with AUTO_INCREMENT and IDENTITY columns. See [column constraints](#) for [CREATE TABLE](#).
- LAST_INSERT_ID does not work with sequence generators created through [CREATE SEQUENCE](#).

Examples

1. Create table customer4:

```
=> CREATE TABLE customer4(  
    ID IDENTITY(2,2),  
    lname VARCHAR(25),  
    fname VARCHAR(25),  
    membership_card INTEGER  
);  
=> INSERT INTO customer4(lname, fname, membership_card) VALUES ('Gupta', 'Saleem', 475987);
```

The IDENTITY column has a seed of 2, which specifies the value for the first row loaded into the table, and an increment of 2, which specifies the value that is added to the IDENTITY value of the previous row.

2. Query the table you just created:

```
=> SELECT * FROM customer4;  
ID | lname | fname | membership_card  
-----+-----+-----+-----  
  2 | Gupta | Saleem |          475987  
(1 row)
```

3. Insert additional values:

```
=> INSERT INTO customer4(lname, fname, membership_card) VALUES ('Lee', 'Chen', 598742);
```

4. Call LAST_INSERT_ID:

```
=> SELECT LAST_INSERT_ID();  
LAST_INSERT_ID  
-----  
                4  
(1 row)
```

5. Query the table again:

```
=> SELECT * FROM customer4;
ID | lname | fname | membership_card
-----+-----+-----+-----
 2 | Gupta | Saleem |          475987
 4 | Lee   | Chen   |          598742
(2 rows)
```

6. Add another row:

```
=> INSERT INTO customer4(lname, fname, membership_card) VALUES ('Davis', 'Bill', 469543);
```

7. Call LAST_INSERT_ID:

```
=> SELECT LAST_INSERT_ID();
LAST_INSERT_ID
-----
              6
(1 row)
```

8. Query the table again:

```
=> SELECT * FROM customer4;
ID | lname | fname | membership_card
-----+-----+-----+-----
 2 | Gupta | Saleem |          475987
 4 | Lee   | Chen   |          598742
 6 | Davis | Bill   |          469543
(3 rows)
```

See Also

- [Working with Sequence Types](#)
- [Sequence Privileges](#)

REENABLE_DUPLICATE_KEY_ERROR

Restores the default behavior of error reporting by reversing the effects of [DISABLE_DUPLICATE_KEY_ERROR](#). Effects are session scoped.

Syntax

```
REENABLE_DUPLICATE_KEY_ERROR();
```

Privileges

Superuser

Examples

```
=> SELECT REENABLE_DUPLICATE_KEY_ERROR();
reenable_duplicate_key_error
-----
Duplicate key error enabled
(1 row)
```

[ANALYZE_CONSTRAINTS](#)

Data Collector Functions

The Vertica Data Collector is a utility that extends [system table](#) functionality by providing a framework for recording events. It gathers and retains monitoring information about your database cluster and makes that information available in system tables, requiring few configuration parameter tweaks, and having negligible impact on performance.

Collected data is stored on disk in the `DataCollector` directory under the Vertica `/catalog` path. You can use the information the Data Collector retains to query the past state of system tables and extract aggregate information, as well as do the following:

- See what actions users have taken
- Locate performance bottlenecks
- Identify potential improvements to Vertica configuration

Data Collector works in conjunction with an advisor tool called Workload Analyzer, which intelligently monitors the performance of SQL queries and workloads and recommends tuning actions based on observations of the actual workload history.

By default, Data Collector is on and retains information for all sessions. If performance issues arise, a superuser can disable DC. See [Data Collector Parameters](#) and [Enabling and Disabling Data Collector](#) in the Administrator's Guide.

This section describes the Data Collection control functions.

Related Topics

[V_MONITOR.DATA_COLLECTOR](#)

[Retaining Monitoring Information](#) and [Analyzing Workloads](#) in the Administrator's Guide

CLEAR_DATA_COLLECTOR

Clears all memory and disk records on the Data Collector tables and functions and resets collection statistics in the system table [DATA_COLLECTOR](#). A superuser can clear Data Collector data for all components or specify an individual component

After you clear the Data Collector log, the information is no longer available for querying.

Syntax

```
CLEAR_DATA_COLLECTOR( [ 'component' ] )
```

Parameters

<i>component</i>	<p>Clears memory and disk records for the specified component only. If you provide no argument, the function clears all Data Collector memory and disk records for all components.</p> <p>For the current list of component names, query the system table DATA_COLLECTOR.</p>
------------------	---

Privileges

Superuser

Examples

The following command clears memory and disk records for the ResourceAcquisitions component:

```
=> SELECT clear_data_collector('ResourceAcquisitions');
clear_data_collector
-----
CLEAR
(1 row)
```

The following command clears data collection for all components on all nodes:

```
=> SELECT clear_data_collector();
clear_data_collector
-----
CLEAR
(1 row)
```

See Also

- [DATA_COLLECTOR](#)
- [Retaining Monitoring Information](#)

DATA_COLLECTOR_HELP

Returns online usage instructions about the Data Collector, the [DATA_COLLECTOR](#) system table, and the Data Collector control functions.

Syntax

```
DATA_COLLECTOR_HELP()
```

Privileges

None

Returns

The `DATA_COLLECTOR_HELP()` function returns the following information:

```
=> SELECT DATA_COLLECTOR_HELP();

-----
Usage Data Collector
The data collector retains history of important system activities.
  This data can be used as a reference of what actions have been taken
  by users, but it can also be used to locate performance bottlenecks,
  or identify potential improvements to the Vertica configuration.
  This data is queryable via Vertica system tables.

Access a list of data collector components, and some statistics, by running:
SELECT * FROM v_monitor.data_collector;

The amount of data retained by size and time can be controlled with several
functions.
  To just set the size amount:
      set_data_collector_policy(<component>,
                              <memory retention (KB)>,
                              <disk retention (KB)>);

  To set both the size and time amounts (the smaller one will dominate):
      set_data_collector_policy(<component>,
                              <memory retention (KB)>,
                              <disk retention (KB)>,
                              <interval>);

  To set just the time amount:
      set_data_collector_time_policy(<component>,
                                     <interval>);

  To set the time amount for all tables:
      set_data_collector_time_policy(<interval>);
```

The current retention policy for a component can be queried with:
`get_data_collector_policy(<component>);`

Data on disk is kept in the "DataCollector" directory under the Vertica \catalog path. This directory also contains instructions on how to load the monitoring data into another Vertica database.

To move the data collector logs and instructions to other storage locations, create labeled storage locations using `add_location` and then use:

```
set_data_collector_storage_location(<storage_label>);
```

Additional commands can be used to configure the data collection logs.

The log can be cleared with:

```
clear_data_collector([<optional component>]);
```

The log can be synchronized with the disk storage using:

```
flush_data_collector([<optional component>]);
```

See Also

- [DATA_COLLECTOR](#)
- [TUNING_RECOMMENDATIONS](#)
- [Analyzing Workloads](#)
- [Retaining Monitoring Information](#)

FLUSH_DATA_COLLECTOR

Waits until memory logs are moved to disk and then flushes the Data Collector, synchronizing the log with the disk storage. A superuser can flush Data Collector information for an individual component or for all components.

Syntax

```
FLUSH_DATA_COLLECTOR( [ 'component' ] )
```

Parameters

<i>component</i>	Flushes the specified component. If you provide no argument, the function flushes the Data Collector in full. For the current list of component names, query the V_MONITOR.DATA_
------------------	---

	COLLECTOR system table.
--	-------------------------

Privileges

Superuser

Examples

The following command flushes the Data Collector for the ResourceAcquisitions component:

```
=> SELECT flush_data_collector('ResourceAcquisitions');
flush_data_collector
-----
FLUSH
(1 row)
```

The following command flushes data collection for all components:

```
=> SELECT flush_data_collector();
flush_data_collector
-----
FLUSH
(1 row)
```

See Also

- [DATA_COLLECTOR](#)
- [Retaining Monitoring Information](#)

GET_DATA_COLLECTOR_POLICY

Retrieves a brief statement about the retention policy for the specified component.

Syntax

```
GET_DATA_COLLECTOR_POLICY( 'component' )
```

Parameters

<i>component</i>	Returns the retention policy for the specified component.
------------------	---

	For a current list of component names, query the V_MONITOR.DATA_COLLECTOR system table
--	--

Privileges

None

Example

The following query returns the history of all resource acquisitions by specifying the ResourceAcquisitions component:

```
=> SELECT get_data_collector_policy('ResourceAcquisitions');
       get_data_collector_policy
-----
1000KB kept in memory, 10000KB kept on disk.
(1 row)
```

See Also

- [DATA_COLLECTOR](#)
- [Retaining Monitoring Information](#)

SET_DATA_COLLECTOR_POLICY

Sets a size restraint (memory and disk space in kilobytes) for the specified Data Collector table on all nodes. If nodes are down, the failed nodes receive the setting when they rejoin the cluster.

You can use this function to set a size restraint only, or you can include the optional *interval* argument to set disk capacity for both size and time in a single command.

If you specify *interval*, Vertica enforces the setting that is exceeded first (size or time). Before you include a time restraint, verify that the disk size capacity is sufficiently large.

If you want to specify just a time restraint, or you want to turn off a time restraint you set using this function, see [SET_DATA_COLLECTOR_TIME_POLICY\(\)](#).

Syntax

```
SET_DATA_COLLECTOR_POLICY('component', 'memoryKB', 'diskKB' [, 'interval'] )
```

Parameters

<i>component</i>	Configures the retention policy for the specified component.
<i>memoryKB</i>	Specifies the memory size to retain in kilobytes.
<i>diskKB</i>	Specifies the disk size in kilobytes.
<i>interval</i>	[Default off] Takes an optional <i>interval</i> argument to specify how long to retain the specified component on disk. To disable a time restraint, set <i>interval</i> to -1. Note: Any negative input will turn off the time restraint

Privileges

Superuser

Notes

- Before you change a retention policy, view its current setting by calling the `GET_DATA_COLLECTOR_POLICY()` function.
- If you don't know the name of a component, query the `V_MONITOR.DATA_COLLECTOR` system table for a list; for example:

```
=> SELECT DISTINCT component, description FROM data_collector  
ORDER BY 1 ASC;
```

Examples

The following command returns the retention policy for the `ResourceAcquisitions` component:

```
=> SELECT get_data_collector_policy('ResourceAcquisitions');  
get_data_collector_policy  
-----  
1000KB kept in memory, 10000KB kept on disk.  
(1 row)
```

This command changes the memory and disk setting for `ResourceAcquisitions` from its current setting of 1,000 KB memory and 10,000 KB disk space to 1500 KB and 25000 KB, respectively:

```
=> SELECT set_data_collector_policy('ResourceAcquisitions', '1500', '25000');
       set_data_collector_policy
-----
      SET
(1 row)
```

This command sets the `RequestsIssued` component to 1500 KB memory and 11000 KB on disk, and includes a 3-minute time restraint:

```
=> SELECT set_data_collector_policy('RequestsIssued', '1500', '11000', '3 minutes'::interval);
       set_data_collector_policy
-----
      SET
(1 row)
```

The following command disables the 3-minute retention policy for the `RequestsIssued` component, using [SET_DATA_COLLECTOR_TIME_POLICY](#):

```
=> SELECT set_data_collector_time_policy('RequestsIssued', '-1');
       set_data_collector_time_policy
-----
      SET
(1 row)
```

See Also

- [GET_DATA_COLLECTOR_POLICY](#)
- [SET_DATA_COLLECTOR_TIME_POLICY\(\)](#)
- [DATA_COLLECTOR](#)
- [Retaining Monitoring Information](#) in the *Administrator's Guide*

SET_DATA_COLLECTOR_TIME_POLICY

Sets a time capacity for individual Data Collector tables on all nodes. If nodes are down, the failed nodes receive the setting when they rejoin the cluster.

If you specify *interval*, Vertica enforces the setting that is exceeded first (size or time). Before you include a time restraint, verify that the disk size capacity is sufficiently large.

If you want to configure both time and size restraints at the same time, see [SET_DATA_COLLECTOR_POLICY](#).

Syntax

```
SET_DATA_COLLECTOR_TIME_POLICY( [component'], interval' )
```

Parameters

<i>component</i>	[Optional] Configures the time retention policy for the specified component. If you omit the <i>component</i> argument, Vertica sets the specified time capacity for all Data Collector tables.
<i>interval</i>	Specifies the time restraint on disk using an INTERVAL type. To disable a time restraint, set <i>interval</i> to -1. Note: Any negative input turns off the time restraint

Privileges

Superuser

Usage Considerations

- Before you change a retention policy, view its current setting by calling the [GET_DATA_COLLECTOR_POLICY](#) function.
- If you don't know the name of a component, query the V_MONITOR.DATA_COLLECTOR system table for a list. For example:

```
=> SELECT DISTINCT component, description FROM data_collector  
ORDER BY 1 ASC;
```

Setting the Time Interval for System Tables

You can also use the *interval* argument to query system tables the same way you query Data Collector tables; for example:

```
set_data_collector_time_policy('<system-table>', <'interval'>);
```

To illustrate, the following command in the left column is equivalent to running the series of commands on the right:

Run one command	Instead of a series of commands
<pre>SELECT set_data_collector_time_policy ('v_monitor.query_requests', '3 minutes'::interval);</pre>	<pre>SELECT set_data_collector_time_policy ('RequestsIssued', '3 minutes'::interval); SELECT set_data_collector_time_policy ('RequestsCompleted', '3 minutes'::interval); SELECT set_data_collector_time_policy ('Errors', '3 minutes'::interval); SELECT set_data_collector_time_policy ('ResourceAcquisitions', '3 minutes'::interval);</pre>

The [SET_DATA_COLLECTOR_TIME_POLICY](#) function updates the time capacity for all Data Collector tables in the V_MONITOR.QUERY_REQUESTS view. The new setting overrides any previous settings for every Data Collector table in that view.

Examples

The following command configures the Backups component to be retained on disk for 1 day:

```
=> SELECT set_data_collector_time_policy('Backups', '1 day'::interval);
set_data_collector_time_policy
-----
SET
(1 row)
```

This command disables the 1-day restraint for the Backups component:

```
=> SELECT set_data_collector_time_policy('Backups', '-1');
set_data_collector_time_policy
-----
SET
(1 row)
```

This command sets a 30-minute time capacity for all Data Collector tables in a single command:

```
=> SELECT set_data_collector_time_policy('30 minutes'::interval);
set_data_collector_time_policy
-----
SET
(1 row)
```

To view current retention policy settings for each Data Collector table, call the [GET_DATA_COLLECTION_POLICY\(\)](#) function. In the next example, the time restraint is included.

```
=> SELECT get_data_collector_policy('RequestsIssued');
           get_data_collector_policy
-----
2000KB kept in memory, 50000KB kept on disk. 2 years 3 days 15:08 hours kept
on disk.
(1 row)
```

If the time policy setting is disabled, the output of `GET_DATA_COLLECTION_POLICY()` returns "Time based retention disabled."

```
2000KB kept in memory, 50000KB kept on disk. Time based retention disabled.
```

- [DATA_COLLECTOR](#)

Database Designer Functions

Database Designer functions provide programmatic access to Database Designer functionality. For information on required privileges, see [Privileges for Running Database Designer Functions](#) in the Administrator's Guide

Database Designer functions perform the following operations, generally performed in the following order:

1. [Create a design.](#)
2. [Set design properties.](#)
3. [Populate a design.](#)
4. [Create design and deployment scripts.](#)
5. [Get design data.](#)
6. [Clean up.](#)

For detailed information, see [Workflow for Running Database Designer Programmatically.](#)

Create a design

[DESIGNER_CREATE_DESIGN](#) directs Database Designer to create a design.

Set design properties

The following functions let you specify properties of a particular design:

DESIGNER_SET_DESIGN_TYPE	Specifies whether the design is comprehensive or incremental.
DESIGNER_DESIGN_PROJECTION_ENCODINGS	Analyzes encoding in the specified projections and creates a script that implements encoding recommendations.
DESIGNER_SET_DESIGN_KSAFETY	Sets the K-safety value for a comprehensive design.
DESIGNER_SET_	Specifies whether the design optimizes for query or load

OPTIMIZATION_OBJECTIVE	performance.
DESIGNER_SET_PROPOSE_UNSEGMENTED_PROJECTIONS	Enables inclusion of unsegmented projections in the design.
DESIGNER_SET_ANALYZE_CORRELATIONS_MODE	Determines how the design handles column correlations.

Populate a design

The following functions let you add tables and queries to your Database Designer design:

DESIGNER_ADD_DESIGN_TABLES	Adds the specified tables to a design.
DESIGNER_ADD_DESIGN_QUERY	Adds queries to the design and weights them.
DESIGNER_ADD_DESIGN_QUERIES	
DESIGNER_ADD_DESIGN_QUERIES_FROM_RESULTS	

Create design and deployment scripts

The following functions populate the Database Designer workspace and create design and deployment scripts. You can also analyze statistics, deploy the design automatically, and drop the workspace after the deployment:

DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY	Populates the design and creates design and deployment scripts.
DESIGNER_WAIT_FOR_DESIGN	Waits for a currently running design to complete.

Reset a design

[DESIGNER_RESET_DESIGN](#) discards all the run-specific information of the previous Database Designer build or deployment of the specified design but retains its configuration.

Get design data

The following functions display information about projections and scripts that the Database Designer created:

DESIGNER_OUTPUT_ALL_DESIGN_PROJECTIONS	Sends to standard output DDL statements that define design projections.
DESIGNER_OUTPUT_DEPLOYMENT_SCRIPT	Sends to standard output a design's deployment script.

Clean up

The following functions cancel any running Database Designer operation or drop a Database Designer design and all its contents:

DESIGNER_CANCEL_POPULATE_DESIGN	Cancels population or deployment operation for the specified design if it is currently running.
DESIGNER_DROP_DESIGN	Removes the schema associated with the specified design and all its contents.
DESIGNER_DROP_ALL_DESIGNS	Removes all Database Designer-related schemas associated with the current user.

DESIGNER_ADD_DESIGN_QUERIES

Reads and evaluates queries from an input file, and adds the queries that it accepts to the specified design. All accepted queries are assigned a weight of 1 (see [DESIGNER_ADD_DESIGN_QUERIES](#)).

The following requirements apply:

- All queried tables must previously be added to the design with [DESIGNER_ADD_DESIGN_TABLES](#).
- If the [design type](#) is incremental, the Database Designer reads only the first 100 queries in the input file, and ignores all queries beyond that number.

All accepted queries are added to the system table [DESIGN_QUERIES](#).

Behavior Type

Immutable

Syntax

```
DESIGNER_ADD_DESIGN_QUERIES ( 'design-name', 'input-file' [, return-results] )
```

Parameters

<i>design-name</i>	Name of the target design.
<i>input-file</i>	Absolute path to the queries file.
<i>return-results</i>	Boolean, optionally specifies whether to return results of the add operation to standard output. If set to true, Database Designer returns the following results: <ul style="list-style-type: none">• Number of accepted queries• Number of queries referencing non-design tables• Number of unsupported queries• Number of illegal queries

Privileges

Read access to the input file, and one of the following:

- Superuser
- Design creator with all privileges that pertain to the input file queries (see [Privileges Required for Common Database Operations](#)).

Errors

Database Designer returns an error in the following cases:

- The query contains illegal syntax.
- The query references:
 - External or system tables only
 - Local temporary or other non-design tables
- DELETE or UPDATE query has one or more subqueries.
- INSERT query does not include a SELECT clause.
- Database Designer cannot optimize the query.

Examples

The following example adds queries from `vmart_queries.sql` to the `VMART_DESIGN` design. This file contains nine queries. The statement includes a third argument of `true`, so Database Designer returns results of the add operation:

```
=> SELECT DESIGNER_ADD_DESIGN_QUERIES ('VMART_DESIGN', '/tmp/examples/vmart_queries.sql', 'true');
...
DESIGNER_ADD_DESIGN_QUERIES
-----
Number of accepted queries          =9
Number of queries referencing non-design tables =0
Number of unsupported queries       =0
Number of illegal queries           =0
(1 row)
```

See Also

[Running Database Designer Programmatically](#)

DESIGNER_ADD_DESIGN_QUERIES_FROM_RESULTS

Executes the specified query and evaluates results in the following columns:

- `QUERY_TEXT` (required): Text of potential design queries.
- `QUERY_WEIGHT` (optional): The weight assigned to each query that indicates its importance relative to other queries, a real number >0 and ≤ 1 . Database Designer uses this setting when creating the design to prioritize the query. If `DESIGNER_ADD_DESIGN_QUERIES_FROM_RESULTS` returns any results that omit this value, Database Designer sets their weight to 1.

After evaluating the queries in `QUERY_TEXT`, `DESIGNER_ADD_DESIGN_QUERIES_FROM_RESULTS` adds all accepted queries to the design. An unlimited number of queries can be added to the design.

Before you add queries to a design, you must add the queried tables with [DESIGNER_ADD_DESIGN_TABLES](#).

Behavior Type

Immutable

Syntax

```
DESIGNER_ADD_DESIGN_QUERIES_FROM_RESULTS ( 'design-name', 'query' )
```

Parameters

<i>design-name</i>	Name of the target design.
<i>query</i>	A valid SQL query whose results contain columns named <code>QUERY_TEXT</code> and, optionally, <code>QUERY_WEIGHT</code> .

Privileges

- Superuser
- Design creator with all privileges that pertain to the specified query and all queries that this function returns (see [Privileges Required for Common Database Operations](#)).

Errors

Database Designer returns an error in the following cases:

- The query contains illegal syntax.
- The query references:
 - External or system tables only
 - Local temporary or other non-design tables
- DELETE or UPDATE query has one or more subqueries.

- INSERT query does not include a SELECT clause.
- Database Designer cannot optimize the query.

Example

The following example queries the system table [QUERY_REQUESTS](#) for all long-running queries (> 1 million microseconds) and adds them to the VMART_DESIGN design. The query returns no information on query weights, so all queries are assigned a weight of 1:

```
=> SELECT DESIGNER_ADD_DESIGN_QUERIES_FROM_RESULTS ( 'VMART_DESIGN',  
  'SELECT request as query_text FROM query_requests where request_duration_ms > 1000000 AND request_  
type =  
  'QUERY' );
```

See Also

[Running Database Designer Programmatically](#)

DESIGNER_ADD_DESIGN_QUERY

Reads and parses the specified query, and if accepted, adds it to the design. Before you add queries to a design, you must add the queried tables with [DESIGNER_ADD_DESIGN_TABLES](#).

All accepted queries are added to the system table [DESIGN_QUERIES](#).

Behavior Type

Immutable

Syntax

```
DESIGNER_ADD_DESIGN_QUERY ( 'design-name', 'design-query' [, query-weight] )
```

Parameters

<i>design-name</i>	Name of the target design.
<i>design-query</i>	Executable SQL query.
<i>query-weight</i>	Optionally assigns a weight to each query that indicates its importance

	<p>relative to other queries, a real number >0 and ≤ 1. Database Designer uses this setting to prioritize queries in the design .</p> <p>If you omit this parameter, Database Designer assigns a weight of 1.</p>
--	---

Privileges

One of the following:

- Superuser
- Design creator with all privileges that pertain to the specified query (see [Privileges Required for Common Database Operations](#)).

Errors

Database Designer returns an error in the following cases:

- The query contains illegal syntax.
- The query references:
 - External or system tables only
 - Local temporary or other non-design tables
- DELETE or UPDATE query has one or more subqueries.
- INSERT query does not include a SELECT clause.
- Database Designer cannot optimize the query.

Examples

The following example adds the specified query to the VMART_DESIGN design and assigns that query a weight of 0.5:

```
=> SELECT DESIGNER_ADD_DESIGN_QUERY (  
    'VMART_DESIGN',  
    'SELECT customer_name, customer_type FROM customer_dimension ORDER BY customer_name ASC;', 0.5  
);
```

See Also

[Running Database Designer Programmatically](#)

DESIGNER_ADD_DESIGN_TABLES

Adds the specified tables to a design. You must run `DESIGNER_ADD_DESIGN_TABLES` before adding design queries to the design. If no tables are added to the design, Vertica does not accept design queries.

Behavior Type

Immutable

Syntax

```
DESIGNER_ADD_DESIGN_TABLES ( 'design-name', '[ table-spec[,...] ]' [, 'analyze-statistics' ] )
```

Parameters

<i>design-name</i>	Name of the Database Designer design.
<i>table-spec</i> [, ...]	<p>One or more comma-delimited arguments that specify which tables to add to the design, where each <i>table-spec</i> argument can specify tables as follows:</p> <ul style="list-style-type: none">• <i>[schema.]table</i> Add <i>table</i> to the design.• <i>schema.*</i> Add all tables in <i>schema</i>. <p>If set to an empty string, Vertica adds all tables in the database to which the user has access.</p>
<i>analyze-statistics</i>	<p>Boolean that optionally specifies whether to run ANALYZE_STATISTICS after adding the specified tables to the design, by default set to <code>false</code>.</p> <p>Accurate statistics help Database Designer optimize compression and query performance. Updating statistics takes time and resources.</p>

Privileges

One of the following:

- Superuser
- DBDUSER who created the design, has USAGE privilege on the design table schema, and owns the design table.

Examples

The following example adds to design VMART_DESIGN all tables from schemas `online_sales` and `store`, and analyzes statistics for those tables:

```
=> SELECT DESIGNER_ADD_DESIGN_TABLES('VMART_DESIGN', 'online_sales.*', 'store.*','true');
DESIGNER_ADD_DESIGN_TABLES
-----
                          7
(1 row)
```

See Also

[Running Database Designer Programmatically](#)

DESIGNER_CANCEL_POPULATE_DESIGN

Cancels population or deployment operation for the specified design if it is currently running. When you cancel a deployment, the Database Designer cancels the projection refresh operation. It does not roll back projections that it already deployed and refreshed.

Behavior Type

Immutable

Syntax

```
DESIGNER_CANCEL_POPULATE_DESIGN ( 'design-name' )
```

Parameters

<i>design-name</i>	Name of the design operation to cancel.
--------------------	---

Privileges

One of the following:

- Superuser
- Design creator

Examples

The following example cancels a currently running design for VMART_DESIGN and then drops the design:

```
=> SELECT DESIGNER_CANCEL_POPULATE_DESIGN ('VMART_DESIGN');  
=> SELECT DESIGNER_DROP_DESIGN ('VMART_DESIGN', 'true');
```

See Also

[Running Database Designer Programmatically](#)

DESIGNER_CREATE_DESIGN

Creates a design with the specified name.

Note: Be sure to back up the current design using the function [EXPORT_CATALOG](#) before running the Database Designer functions on an existing schema. You must explicitly back up the existing design when using Database Designer programmatically.

If any of the following [V_MONITOR](#) tables do not already exist from previous designs, DESIGNER_CREATE_DESIGN creates them:

- [DESIGNS](#)
- [DESIGN_TABLES](#)
- [DEPLOYMENT_PROJECTIONS](#)
- [DEPLOYMENT_PROJECTION_STATEMENTS](#)
- [DESIGN_QUERIES](#)

- [OUTPUT_DEPLOYMENT_STATUS](#)
- [OUTPUT_EVENT_HISTORY](#)

Behavior Type

Immutable

Syntax

```
DESIGNER_CREATE_DESIGN ( 'design-name' )
```

Parameters

<i>design-name</i>	Name of the design to create, can contain only alphanumeric and underscore (<code>_</code>) characters. Two users cannot have designs with the same name at the same time.
--------------------	---

Privileges

One of the following:

- Superuser
- DBDUSER

Examples

The following example creates the design VMART_DESIGN:

```
=> SELECT DESIGNER_CREATE_DESIGN('VMART_DESIGN');  
DESIGNER_CREATE_DESIGN  
-----  
0  
(1 row)
```

See Also

[Running Database Designer Programmatically](#)

DESIGNER_DESIGN_PROJECTION_ENCODINGS

Analyzes encoding in the specified projections, creates a script to implement encoding recommendations, and optionally deploys the recommendations.

Behavior Type

Immutable

Syntax

```
DESIGNER_DESIGN_PROJECTION_ENCODINGS ( '[ proj-spec[,... ] ]', '[destination]' [, 'deploy'] [, 'reanalyze-encodings' ] )
```

Parameters

<code><i>proj-spec</i>[, ...]</code>	<p>One or more comma-delimited projections to add to the design. Each projection can be specified in one of the following ways:</p> <ul style="list-style-type: none">• <code>[[<i>schema</i>.]<i>table</i>.]<i>projection</i></code> Specifies to analyze <i>projection</i>.• <code><i>schema</i>.*</code> Specifies to analyze all projections in the named schema.• <code>[[<i>schema</i>.]<i>table</i></code> Specifies to analyze all projections of the named table. <p>If set to an empty string, Vertica analyzes all projections in the database to which the user has access.</p> <p>For example, the following statement specifies to analyze all projections in schema <code>private</code>, and send the results to the file <code>encodings.sql</code>:</p> <pre>=> SELECT DESIGNER_DESIGN_PROJECTION_ENCODINGS ('mydb.private.*', 'encodings.sql');</pre>
<code><i>destination</i></code>	<p>Specifies where to send output, one of the following:</p> <ul style="list-style-type: none">• An empty string (' ') writes the script to standard output.

	<ul style="list-style-type: none"> The path and name of a SQL output file. If you specify a file that does not exist, the function creates one. If you specify only a file name, Vertica creates it in the catalog directory. If the file already exists, the function silently overwrites its contents.
<i>deploy</i>	Boolean that optionally specifies whether to deploy encoding changes, by default set to <code>false</code> .
<i>reanalyze-encodings</i>	<p>Boolean that optionally specifies whether <code>DESIGNER_DESIGN_PROJECTION_ENCODINGS</code> analyzes encodings in a projection where all columns are already encoded:</p> <ul style="list-style-type: none"> <code>false</code> (default): Analyzes no columns and generates no recommendations if all columns are encoded. <code>true</code>: Ignores existing encodings and generates recommendations.

Privileges

The following requirements pertain to the target projections:

- OWNER of all projections to analyze
- USAGE privilege on the schema for the specified projections

Examples

The following example requests that Database Designer analyze encodings of all projections in the schema `online_sales`, and save output to the file `encodings.sql`. The last parameter is omitted, so Database Designer does not execute the script:

```
=> SELECT DESIGNER_DESIGN_PROJECTION_ENCODINGS ('online_sales.*', 'encodings.sql');
DESIGNER_DESIGN_PROJECTION_ENCODINGS
-----
(1 row)
```

See Also

[Running Database Designer Programmatically](#)

DESIGNER_DROP_ALL_DESIGNS

Removes all Database Designer-related schemas associated with the current user. Use this function to remove database objects after one or more Database Designer sessions complete execution.

Behavior Type

Immutable

Syntax

```
DESIGNER_DROP_ALL_DESIGNS()
```

Parameters

None.

Privileges

One of the following:

- Superuser : Drops all designs.
- Design creator: Drops all designs created by this user.

Example

The following example removes all schema and their contents associated with the current user. `DESIGNER_DROP_ALL_DESIGNS` returns the number of designs dropped:

```
=> SELECT DESIGNER_DROP_ALL_DESIGNS();  
DESIGNER_DROP_ALL_DESIGNS  
-----  
2  
(1 row)
```

See Also

- [DESIGNER_CANCEL_POPULATE_DESIGN](#)
- [DESIGNER_DROP_DESIGN](#)

DESIGNER_DROP_DESIGN

Removes the schema associated with the specified design and all its contents. Use `DESIGNER_DROP_DESIGN` after a Database Designer design or deployment completes successfully. You must also use it to drop a design before creating another one under the same name.

To drop all designs that you created, use [DESIGNER_DROP_ALL_DESIGNS](#).

Behavior Type

Immutable

Syntax

```
DESIGNER_DROP_DESIGN ( 'design-name' [, force-drop ] )
```

Parameters

<i>design-name</i>	Name of the design to drop.
<i>force-drop</i>	Boolean that overrides any dependencies that otherwise prevent Vertica from executing this function—for example, the design is in use or is currently being deployed. If you omit this parameter, Vertica sets it to false.

Privileges

One of the following:

- Superuser
- Design creator

Example

The following example deletes the Database Designer design VMART_DESIGN and all its contents:

```
=> SELECT DESIGNER_DROP_DESIGN ('VMART_DESIGN');
```

See Also

[Running Database Designer Programmatically](#)

DESIGNER_OUTPUT_ALL_DESIGN_PROJECTIONS

Displays the DDL statements that define the design projections to standard output.

Behavior Type

Immutable

Syntax

```
DESIGNER_OUTPUT_ALL_DESIGN_PROJECTIONS ( 'design-name' )
```

Parameters

<i>design-name</i>	Name of the target design.
--------------------	----------------------------

Privileges

One of the following:

- Superuser
- DBDUSER role

Examples

The following example returns the design projection DDL statements for vmart_design:

```
=> SELECT DESIGNER_OUTPUT_ALL_DESIGN_PROJECTIONS('vmart_design');
CREATE PROJECTION customer_dimension_DBD_1_rep_VMART_DESIGN /*+createtype(D)*/
(
  customer_key ENCODING DELTAVAL,
  customer_type ENCODING AUTO,
  customer_name ENCODING AUTO,
  customer_gender ENCODING REL,
  title ENCODING AUTO,
  household_id ENCODING DELTAVAL,
  customer_address ENCODING AUTO,
  customer_city ENCODING AUTO,
  customer_state ENCODING AUTO,
  customer_region ENCODING AUTO,
  marital_status ENCODING AUTO,
  customer_age ENCODING DELTAVAL,
  number_of_children ENCODING BLOCKDICT_COMP,
  annual_income ENCODING DELTARANGE_COMP,
  occupation ENCODING AUTO,
  largest_bill_amount ENCODING DELTAVAL,
  store_membership_card ENCODING BLOCKDICT_COMP,
  customer_since ENCODING DELTAVAL,
  deal_stage ENCODING AUTO,
  deal_size ENCODING DELTARANGE_COMP,
  last_deal_update ENCODING DELTARANGE_COMP
)
AS
SELECT customer_key,
       customer_type,
       customer_name,
       customer_gender,
       title,
       household_id,
       customer_address,
       customer_city,
       customer_state,
       customer_region,
       marital_status,
       customer_age,
       number_of_children,
       annual_income,
       occupation,
       largest_bill_amount,
       store_membership_card,
       customer_since,
       deal_stage,
       deal_size,
       last_deal_update
FROM public.customer_dimension
ORDER BY customer_gender,
        annual_income
UNSEGMENTED ALL NODES;
CREATE PROJECTION product_dimension_DBD_2_rep_VMART_DESIGN /*+createtype(D)*/
(
  ...
```

See Also

[DESIGNER_OUTPUT_DEPLOYMENT_SCRIPT](#)

DESIGNER_OUTPUT_DEPLOYMENT_SCRIPT

Displays the deployment script for the specified design to standard output. If the design is already deployed, Vertica ignores this function.

To output only the CREATE PROJECTION commands in a design script, use [DESIGNER_OUTPUT_ALL_DESIGN_PROJECTIONS](#).

Behavior Type

Immutable

Syntax

```
DESIGNER_OUTPUT_DEPLOYMENT_SCRIPT ( 'design-name' )
```

Parameters

<i>design-name</i>	Name of the target design.
--------------------	----------------------------

Privileges

One of the following:

- Superuser
- Design creator

Examples

The following example displays the deployment script for VMART_DESIGN:

```
=> SELECT DESIGNER_OUTPUT_DEPLOYMENT_SCRIPT('VMART_DESIGN');  
CREATE PROJECTION customer_dimension_DBD_1_rep_VMART_DESIGN /*+createtype(D)*/  
...  
CREATE PROJECTION product_dimension_DBD_2_rep_VMART_DESIGN /*+createtype(D)*/  
...  
select refresh('public.customer_dimension,  
              public.product_dimension,  
              public.promotion.dimension,  
              public.date_dimension');  
select make_ahm_now();
```

```
DROP PROJECTION public.customer_dimension_super CASCADE;  
DROP PROJECTION public.product_dimension_super CASCADE;  
...
```

See Also

[DESIGNER_OUTPUT_ALL_DESIGN_PROJECTIONS](#)

DESIGNER_RESET_DESIGN

Discards all run-specific information of the previous Database Designer build or deployment of the specified design but keeps its configuration. You can make changes to the design as needed, for example, by changing parameters or adding additional tables and/or queries, before running the design again.

Behavior Type

Immutable

Syntax

```
DESIGNER_RESET_DESIGN ( 'design-name' )
```

Parameters

<i>design-name</i>	Name of the design to reset.
--------------------	------------------------------

Privileges

- Superuser
- Design creator

Example

The following example resets the Database Designer design VMART_DESIGN:

```
=> SELECT DESIGNER_RESET_DESIGN ('VMART_DESIGN');
```

DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY

Populates the design and creates the design and deployment scripts. `DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY` can also analyze statistics, deploy the design, and drop the workspace after the deployment.

Caution: `DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY` does not create a backup copy of the current design before deploying the new design. Before running this function, back up the existing schema design with [EXPORT_CATALOG](#).

Behavior Type

Immutable

Syntax

```
DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY (  
  'design-name',  
  'output-design-file',  
  'output-deployment-file',  
  [ 'analyze-statistics', ]  
  [ 'deploy', ]  
  [ 'drop-design-workspace', ]  
  [ 'continue-after-error', ]  
)
```

Parameters

<i>design-name</i>	Name of the design to populate and deploy.
<i>output-design-file</i>	Specifies where to save the file with DDL statements to create design projections, where <i>output-design-file</i> is an absolute path to the node where the session is connected.
<i>output-deployment-file</i>	Specifies where to save the file that contains the deployment script, where <i>output-deployment-file</i> is an absolute path to the node where the session is connected.
<i>analyze-statistics</i>	Specifies whether to collect or refresh statistics for the tables before populating the design. If set to true, Vertica

	<p>Invokes ANALYZE_STATISTICS. Accurate statistics help Database Designer optimize compression and query performance. However, updating statistics requires time and resources.</p> <p>Default: false</p>
<i>deploy</i>	<p>Specifies whether to deploy the Database Designer design using the deployment script created by this function.</p> <p>Default: true</p>
<i>drop-design-workspace</i>	<p>Specifies whether to drop the design workspace after the design is deployed.</p> <p>Default: true</p>
<i>continue-after-error</i>	<p>Specifies whether DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY continues to run after an error occurs. By default, an error causes this function to terminate.</p> <p>Default: false</p>

Privileges

- Superuser
- Design creator with WRITE privileges on storage locations of design and deployment scripts; otherwise DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY cannot save the design and deployment scripts.

Requirements

Before calling this function, you must:

- Create a design, a logical schema with tables.
- Associate tables with the design.
- Load queries to the design.
- Set design properties (K-safety level, mode, and policy).

Examples

The following example creates projections for and deploys the VMART_DESIGN design, and analyzes statistics about the design tables.

```
=> SELECT DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY (  
    'VMART_DESIGN',  
    '/tmp/examples/vmart_design_files/vmart_design_DDL',  
    '/tmp/examples/vmart_design_files/vmart_design_deployment_scripts',  
    'true',  
    'false',  
    'false',  
    'false'  
);
```

See Also

[Running Database Designer Programmatically](#)

DESIGNER_SET_ANALYZE_CORRELATIONS_MODE

Specifies how Database Designer handles column correlations in a design. A design's mode determines whether Database Designer analyzes or re-analyzes existing column correlations and considers them in the design that it creates.

The following recommendations apply:

- You typically need to analyze column correlations only once.
- Analyze correlations when the table row count is at least [DBDCorrelationSampleRowCount](#)—by default, 4000.

Important: Database Designer analyzes column correlations for a design only if you enable analysis with this function.

Behavior Type

Immutable

Syntax

```
DESIGNER_SET_ANALYZE_CORRELATIONS_MODE ( 'design-name', mode )
```

Parameters

<i>design-name</i>	Name of the design that specifies how Database Designer handles correlated columns.								
<i>mode</i>	<p>Specifies how to handle correlations in the design tables, one of the following integer settings:</p> <table border="1"> <tr> <td>0</td> <td>Ignore column correlations in the design tables.</td> </tr> <tr> <td>1</td> <td>Consider existing correlations in tables when creating the design. If no existing correlations exist, Database Designer sets none in the design.</td> </tr> <tr> <td>2</td> <td>Analyze column correlations on tables where correlation analysis was not previously performed. When creating the design, consider all column correlations, new and existing.</td> </tr> <tr> <td>3</td> <td>Analyze all tables for column correlations and consider them when creating the design. If correlations already exist for a table, ignore them and re-analyze the table.</td> </tr> </table> <p>Setting the correlation analysis mode does not affect whether Database Designer analyzes statistics when creating a design.</p>	0	Ignore column correlations in the design tables.	1	Consider existing correlations in tables when creating the design. If no existing correlations exist, Database Designer sets none in the design.	2	Analyze column correlations on tables where correlation analysis was not previously performed. When creating the design, consider all column correlations, new and existing.	3	Analyze all tables for column correlations and consider them when creating the design. If correlations already exist for a table, ignore them and re-analyze the table.
0	Ignore column correlations in the design tables.								
1	Consider existing correlations in tables when creating the design. If no existing correlations exist, Database Designer sets none in the design.								
2	Analyze column correlations on tables where correlation analysis was not previously performed. When creating the design, consider all column correlations, new and existing.								
3	Analyze all tables for column correlations and consider them when creating the design. If correlations already exist for a table, ignore them and re-analyze the table.								

Privileges

One of the following:

- Superuser
- DBDUSER role with USAGE privilege on the design schema.

Example

The following example specifies that Database Designer analyze all tables for correlated columns and consider them when creating a design:

```
=> SELECT DESIGNER_SET_ANALYZE_CORRELATIONS_MODE ('VMART_DESIGN', 3);
DESIGNER_SET_ANALYZE_CORRELATIONS_MODE
```

3

(1 row)

See Also

- [ANALYZE_CORRELATIONS](#)
- [Running Database Designer Programmatically](#)

DESIGNER_SET_DESIGN_KSAFETY

Sets [K-safety](#) for a comprehensive design and stores the K-safety value in the [DESIGNS](#) table. Database Designer ignores this function for incremental designs.

Behavior Type

Immutable

Syntax

```
DESIGNER_SET_DESIGN_KSAFETY ( 'design-name' [, k-Level ]  
)
```

Parameters

<i>design-name</i>	Name of the design for which you want to set the K-safety value, type VARCHAR.
<i>k-Level</i>	<p>An integer between 0 and 2 that specifies the level of K-safety for the target design. This value must be compatible with the number of nodes in the database cluster:</p> <ul style="list-style-type: none">• <i>k-Level</i> = 0: ≥ 1 nodes• <i>k-Level</i> = 1: ≥ 3 nodes• <i>k-Level</i> = 2: ≥ 5 nodes <p>If you omit this parameter, Vertica sets K-safety for this design to 0 or 1, according to the number of nodes: 1 if the cluster contains ≥ 3 nodes, otherwise 0.</p>

	<p>If you are a DBADMIN user and <i>k-Level</i> differs from system K-safety, Vertica changes system K-safety as follows:</p> <ul style="list-style-type: none">• If <i>k-Level</i> is less than system K-safety, Vertica changes system K-safety to the lower level after the design is deployed.• If <i>k-Level</i> is greater than system K-safety and is valid for the database cluster, Vertica creates the required number of buddy projections for the tables in this design. If the design applies to all database tables, or all tables in the database have the required number of buddy projections, Database Designer changes system K-safety to <i>k-Level</i>. <p>If the design excludes some database tables and the number of their buddy projections is less than <i>k-Level</i>, Database Designer leaves system K-safety unchanged. Instead, it returns a warning and indicates which tables need new buddy projections in order to adjust system K-safety.</p> <p>If you are a DBDUSER, Vertica ignores this parameter.</p>
--	--

Privileges

One of the following:

- Superuser
- Design creator

Examples

The following example set K-safety for the VMART_DESIGN design to 1:

```
=> SELECT DESIGNER_SET_DESIGN_KSAFETY('VMART_DESIGN', 1);
```

See Also

[Running Database Designer Programmatically](#)

DESIGNER_SET_DESIGN_TYPE

Specifies whether Database Designer should create a comprehensive or incremental design. `DESIGNER_SET_DESIGN_TYPE` stores the design mode in the [DESIGNS](#) table.

If you do not explicitly set a design mode with this function, Database Designer creates a comprehensive design.

Behavior Type

Immutable

Syntax

```
DESIGNER_SET_DESIGN_TYPE ( 'design-name', 'mode' )
```

Parameters

<i>design-name</i>	Name of the target design.
<i>mode</i>	<p>Name of the mode that Database Designer should use when designing the database, one of the following:</p> <ul style="list-style-type: none">• COMPREHENSIVE: Creates an initial or replacement design for all tables in the specified schemas. You typically create a comprehensive design for a new database.• INCREMENTAL: Modifies an existing design with additional projection that are optimized for new or modified queries. <p>For more information, see Design Types in the Administrator's Guide.</p>

Privileges

One of the following:

- Superuser
- Design creator

Notes

Incremental designs always inherit the K-safety value of the database.

Examples

The following examples show the two design mode options for the VMART_DESIGN design:

```
=> SELECT DESIGNER_SET_DESIGN_TYPE(  
    'VMART_DESIGN',  
    'COMPREHENSIVE');  
DESIGNER_SET_DESIGN_TYPE  
-----  
                                0  
(1 row)  
=> SELECT DESIGNER_SET_DESIGN_TYPE(  
    'VMART_DESIGN',  
    'INCREMENTAL');  
DESIGNER_SET_DESIGN_TYPE  
-----  
                                0  
(1 row)
```

See Also

[Running Database Designer Programmatically](#)

DESIGNER_SET_OPTIMIZATION_OBJECTIVE

Valid only for comprehensive database designs, specifies the optimization objective Database Designer uses. Database Designer ignores this function for incremental designs.

DESIGNER_SET_OPTIMIZATION_OBJECTIVE stores the optimization objective in the [DESIGNS](#) table.

Behavior Type

Immutable

Syntax

```
DESIGNER_SET_OPTIMIZATION_OBJECTIVE ( 'design-name', 'policy' )
```

Parameters

<i>design-name</i>	Name of the target design.
<i>policy</i>	Specifies the design's optimization policy, one of the following: <ul style="list-style-type: none">• QUERY: Optimize for query performance. This can result in a larger database storage footprint because additional projections might be created.• LOAD: Optimize for load performance so database size is minimized. This can result in slower query performance.• BALANCED: Balance the design between query performance and database size.

Privileges

One of the following:

- Superuser
- Design creator

Examples

The following example sets the optimization objective option for the VMART_DESIGN design: to QUERY:

```
=> SELECT DESIGNER_SET_OPTIMIZATION_OBJECTIVE( 'VMART_DESIGN', 'QUERY');
DESIGNER_SET_OPTIMIZATION_OBJECTIVE
-----
                                0
(1 row)
```

See Also

[Running Database Designer Programmatically](#)

DESIGNER_SET_PROPOSE_UNSEGMENTED_PROJECTIONS

Specifies whether a design can include [unsegmented projections](#). Vertica ignores this function on a one-node cluster, where all projections must be unsegmented.

Behavior Type

Immutable

Syntax

```
DESIGNER_SET_PROPOSE_UNSEGMENTED_PROJECTIONS ( 'design-name', unsegmented )
```

Parameters

<i>design-name</i>	Name of the target design.
<i>unsegmented</i>	Boolean that specifies whether Database Designer can propose unsegmented projections for tables in this design. When you create a design, the <code>propose_unsegmented_projections</code> value in system table DESIGNS for this design is set to <code>true</code> . If <code>DESIGNER_SET_PROPOSE_UNSEGMENTED_PROJECTIONS</code> sets this value to <code>false</code> , Database Designer only proposes segmented projections for the design.

Privileges

One of the following:

- Superuser
- Design creator

Example

The following example specifies that Database Designer can propose only segmented projections for tables in the design `VMART_DESIGN`:

```
=> SELECT DESIGNER_SET_PROPOSE_UNSEGMENTED_PROJECTIONS('VMART_DESIGN', false);
```

See Also

[Running Database Designer Programmatically](#)

DESIGNER_WAIT_FOR_DESIGN

Waits for completion of operations that are populating and deploying the design. Ctrl+C cancels this operation and returns control to the user.

Behavior Type

Immutable

Syntax

```
DESIGNER_WAIT_FOR_DESIGN ( 'design-name' )
```

Parameters

<i>design-name</i>	Name of the running design.
--------------------	-----------------------------

Privileges

Privileges

One of the following:

- Superuser
- DBDUSER role with USAGE privilege on the design schema.

Examples

The following example requests to wait for the currently running design of VMART_DESIGN to complete:

```
=> SELECT DESIGNER_WAIT_FOR_DESIGN ('VMART_DESIGN');
```

See Also

- [DESIGNER_CANCEL_POPULATE_DESIGN](#)
- [DESIGNER_DROP_ALL_DESIGNS](#)
- [DESIGNER_DROP_DESIGN](#)

Database Management Functions

This section contains the database management functions specific to Vertica.

CLEAR_RESOURCE_REJECTIONS

Clears the content of the [RESOURCE_REJECTIONS](#) and [DISK_RESOURCE_REJECTIONS](#) system tables. Normally, these tables are only cleared during a node restart. This function lets you clear the tables whenever you need. For example, you might want to clear the system tables after you resolved a disk space issue that was causing disk resource rejections.

Syntax

```
CLEAR_RESOURCE_REJECTIONS();
```

Privileges

Superuser

Example

The following command clears the content of the `RESOURCE_REJECTIONS` and `DISK_RESOURCE_REJECTIONS` system tables:

```
=> SELECT clear_resource_rejections();
clear_resource_rejections
-----
OK
(1 row)
```

See Also

- [DISK_RESOURCE_REJECTIONS](#)
- [RESOURCE_REJECTIONS](#)

CURRENT_SCHEMA

Returns the name of the current schema.

Behavior Type

Stable

Syntax

```
CURRENT_SCHEMA()
```

Note: You can call this function without parentheses.

Privileges

None

Examples

The following command returns the name of the current schema:

```
=> SELECT CURRENT_SCHEMA();
current_schema
-----
public
(1 row)
```

The following command returns the same results without the parentheses:

```
=> SELECT CURRENT_SCHEMA;
current_schema
-----
public
(1 row)
```

The following command shows the current schema, listed after the [current user](#), in the search path:

```
=> SHOW SEARCH_PATH;
name | setting
-----+-----
search_path | "$user", public, v_catalog, v_monitor, v_internal
(1 row)
```

See Also

- [SET SEARCH_PATH](#)

DUMP_LOCKTABLE

Returns information about deadlocked clients and the resources they are waiting for.

Syntax

```
DUMP_LOCKTABLE()
```

Privileges

None

Notes

Use DUMP_LOCKTABLE if Vertica becomes unresponsive:

1. Open an additional vsql connection.
2. Execute the query:

```
=> SELECT DUMP_LOCKTABLE();
```

The output is written to vsql. See [Monitoring the Log Files](#).

You can also see who is connected using the following command:

```
=> SELECT * FROM SESSIONS;
```

Close all sessions using the following command:

```
=> SELECT CLOSE_ALL_SESSIONS();
```

Close a single session using the following command:

```
=> SELECT CLOSE_SESSION('session_id');
```

You get the session_id value from the [V_MONITOR.SESSIONS](#) system table.

See Also

- [CLOSE_ALL_SESSIONS](#)
- [CLOSE_SESSION](#)
- [LOCKS](#)
- [SESSIONS](#)

DUMP_PARTITION_KEYS

Dumps the partition keys of all projections in the system.

Syntax

```
DUMP_PARTITION_KEYS( )
```

Note: The ROS objects of partitioned tables without partition keys are ignored by the tuple mover and are not merged during automatic tuple mover operations.

Privileges

User must have select privileges on the table or usage privileges on the schema.

Example

```
=> SELECT DUMP_PARTITION_KEYS( );
Partition keys on node v_vmart_node0001
Projection 'states_b0'
Storage [ROS container]
  No of partition keys: 1
  Partition keys: NH
Storage [ROS container]
  No of partition keys: 1
  Partition keys: MA
Projection 'states_b1'
Storage [ROS container]
  No of partition keys: 1
  Partition keys: VT
Storage [ROS container]
  No of partition keys: 1
  Partition keys: ME
Storage [ROS container]
  No of partition keys: 1
```

Partition keys: CT

See Also

- [DO_TM_TASK](#)
- [DROP_PARTITION](#)
- [DUMP_PROJECTION_PARTITION_KEYS](#)
- [DUMP_TABLE_PARTITION_KEYS](#)
- [PARTITION_PROJECTION](#)
- [PARTITION_TABLE](#)
- [PARTITIONS](#)
- [Using Table Partitions](#)

HAS_ROLE

Indicates, with a Boolean value, whether a role has been assigned to a user. This function is useful for letting you check your own role membership.

Behavior Type

Stable

Syntax 1

```
HAS_ROLE( [ 'user_name' ,] 'role_name' );
```

Syntax 2

```
HAS_ROLE( 'role_name' );
```

Parameters

<i>user_name</i>	[Optional] The name of a user to look up. Currently, only a superuser can supply the <code>user_name</code> argument.
------------------	---

<code>role_name</code>	The name of the role you want to verify has been granted.
------------------------	---

Privileges

Users can check their own role membership by calling `HAS_ROLE('role_name')`, but only a superuser can look up other users' memberships using the optional `user_name` parameter.

Notes

You can query `V_CATALOG` system tables [ROLES](#), [GRANTS](#), and [USERS](#) to show any directly-assigned roles; however, these tables do not indicate whether a role is available to a user when roles may be available through other roles (indirectly).

Examples

User Bob wants to see if he has been granted the commentor role:

```
=> SELECT HAS_ROLE('commentor');
```

Output `t` for true indicates that Bob has been assigned the commentor role:

```
HAS_ROLE
-----
t
(1 row)
```

In the following function call, a superuser checks if the logadmin role has been granted to user Bob:

```
=> SELECT HAS_ROLE('Bob', 'logadmin');
HAS_ROLE
-----
t
(1 row)
```

To view the names of all roles users can access, along with any roles that have been assigned to those roles, query the [V_CATALOG.ROLES](#) system table. An asterisk in the output means role granted WITH ADMIN OPTION.

```
=> SELECT * FROM roles;
role_id | name | assigned_roles
-----+-----+-----
45035996273704964 | public |
45035996273704966 | dbduser |
45035996273704968 | dbadmin | dbduser*
45035996273704972 | pseudosuperuser | dbadmin*
```

```
45035996273704974 | logreader      |  
45035996273704976 | logwriter      |  
45035996273704978 | logadmin       | logreader,  
                                     logwriter  
(7 rows)
```

See Also

- [GRANTS](#)
- [ROLES](#)
- [USERS](#)
- [Managing Users and Privileges](#)
- [Viewing a User's Role](#)

KERBEROS_CONFIG_CHECK

Tests the Kerberos configuration of a Vertica cluster. The function performs the following tests, in order:

- Are Kerberos services available?
- Does a keytab file exist and are the Kerberos configuration parameters set in the database?
- Can Vertica read and invoke kinit with the keys?

If any test fails, the function returns a descriptive error message.

Syntax

```
KERBEROS_CONFIG_CHECK( )
```

Parameters

This function has no parameters.

Privileges

This function does not require privileges.

Examples

The following example shows the results when the Kerberos configuration is valid.

```
=> SELECT KERBEROS_CONFIG_CHECK();
ok: kinit exists
ok: klist exists
ok: krb5 exists at [/etc/krb5.conf]
ok: Vertica Keytab file is set to [/scratch_b/qa/vdb.keytab]
ok: Vertica Keytab file exists at [/scratch_b/qa/vdb.keytab]
Kerberos configuration parameters set in the database
KerberosServiceName : [vdb]
KerberosHostname : []
KerberosRealm : [EXAMPLE.COM]
KerberosKeytabFile : [/scratch_b/qa/vdb.keytab]
Vertica Principal: [vdb/engvmqa24.example.com@EXAMPLE.COM]
ok: Can read Vertica keys
ok: Can get tickets for vertica principal
ok: vertica can kinit

(1 row)
```

The following example shows an error report.

```
=> SELECT KERBEROS_CONFIG_CHECK();
WARNING 2807: Could not access file "/etc/krb5.keytab": No such file or directory
ok: kinit exists
ok: klist exists
ok: krb5 exists at [/etc/krb5.conf]
FAILED: Vertica Keytab file is not set
FAILED: Could not find Vertica Keytab file at
Kerberos configuration parameters set in the database
    KerberosServiceName : [vertica]
    KerberosHostname : []
    KerberosRealm : []
    KerberosKeytabFile : []
Vertica Principal: []
FAILED: Command to read Vertica keys did not succeed
FAILED: Command to kinit Vertica keys did not succeed
FAILED: Vertica not 'kinit'ing if krb5 cannot kinit

(1 row)
```

SET_CONFIG_PARAMETER

Specifies the value of a configuration parameter at the database level, or for a specific node.

Important: Vertica encourages use of `ALTER NODE`, `ALTER DATABASE`, and `ALTER SESSION` statements to set and clear configuration parameters. See [Managing Configuration Parameters: VSQL](#) for more information.

Caution: . Vertica is designed to operate with minimal configuration changes, so use this capability sparingly. Carefully follow any documented guidelines for the parameter you wish to configure.

Syntax

```
SET_CONFIG_PARAMETER( 'parameter-name', value, ['node-name'] )
```

Parameters

<i>parameter-name</i>	The parameter value to set. See Configuration Parameters in the Administrator's Guide for a list of supported parameters, their purposes, and usage examples.
<i>value</i>	The value to set for <i>parameter-name</i> . Syntax for this argument varies depending upon the parameter and its expected data type. For strings, enclose the argument in single quotes; integer arguments can be unquoted. If <code>value</code> is specified as <code>NULL</code> , the parameter is cleared.
<i>node-name</i>	The name of the node whose parameter value you wish to set. If you omit this parameter or set it to <code>NULL</code> , the parameter is set at the database level. If a parameter is explicitly set for a node, the node setting supersedes the database-level setting.

Note: Some parameters require restart for the value to take effect.

Privileges

Superuser

Examples

The following examples show how to use `SET_CONFIG_PARAMETER` in various situations.

Set a Configuration Parameter at Database Level

Set the `AnalyzeRowCountInterval` parameter to 3600 at the database level:

```
=> SELECT SET_CONFIG_PARAMETER ('AnalyzeRowCountInterval',3600);
```

Find Details on All Configuration Parameters

Find all configuration parameters and information about them, including their current and default values:

```
=> SELECT * FROM CONFIGURATION_PARAMETERS;
```

See Also

[Managing Configuration Parameters: VSQL](#)

[CONFIGURATION_PARAMETERS](#)

SHUTDOWN

Forces a database to shut down, even if there are users connected.

Syntax

```
SHUTDOWN ( [ 'false' | 'true' ] )
```

Parameters

<i>false</i>	[Default] Returns a message if users are connected. Has the same effect as supplying no parameters.
<i>true</i>	Performs a moveout operation and forces the database to shut down, disallowing further connections.

Privileges

Superuser

Notes

- Quotes around the `true` or `false` arguments are optional.
- Issuing the shutdown command without arguments or with the default (`false`) argument returns a message if users are connected, and the shutdown fails. If no users are connected, the database performs a moveout operation and shuts down.

- Issuing the `SHUTDOWN('true')` command forces the database to shut down whether users are connected or not.
- You can check the status of the shutdown operation in the `vertica.log` file:

```
2010-03-09 16:51:52.625 unknown:0x7fc6d6d2e700  
[Init] <INFO> Shutdown complete. Exiting.
```

- As an alternative to `SHUTDOWN()`, you can also temporarily set `MaxClientSessions` to 0 and then use `CLOSE_ALL_SESSIONS()`. New client connections cannot connect unless they connect using the `dbadmin` account. See [CLOSE_ALL_SESSIONS](#) for details.

Examples

The following command attempts to shut down the database. Because users are connected, the command fails:

```
=> SELECT SHUTDOWN('false');  
NOTICE: Cannot shut down while users are connected  
        SHUTDOWN  
-----  
Shutdown: aborting shutdown  
(1 row)
```

`SHUTDOWN()` and `SHUTDOWN('false')` perform the same operation:

```
=> SELECT SHUTDOWN();  
NOTICE: Cannot shut down while users are connected  
        SHUTDOWN  
-----  
Shutdown: aborting shutdown  
(1 row)
```

Using the `'true'` parameter forces the database to shut down, even though clients might be connected:

```
=> SELECT SHUTDOWN('true');  
        SHUTDOWN  
-----  
Shutdown: moveout complete  
(1 row)
```

See Also

- [SESSIONS](#)

Directed Queries Functions

The following meta-functions let you batch export query plans as directed queries from one Vertica database, and import those directed queries to another database.

EXPORT_DIRECTED_QUERIES

Generates SQL for creating directed queries from a set of input queries, and writes the SQL to the specified file or to standard output.

Syntax

```
EXPORT_DIRECTED_QUERIES('input-file', '[output-file]')
```

Parameters

<i>input-file</i>	A SQL file that contains one or more input queries. See Input Format below for details on format requirements.
<i>output-file</i>	Specifies where to write the generated SQL for creating directed queries. If the file name already exists, EXPORT_DIRECTED_QUERIES returns with an error. If you supply an empty string, Vertica writes the SQL to standard output. See Output Format below for details.

Privileges

Superuser

Input Format

The input file that you supply to EXPORT_DIRECTED_QUERIES contains one or more input queries. For each input query, you can optionally specify two fields that are used in the generated directed query:

- `DirQueryName` provides the directed query's unique identifier, a string that conforms to conventions described in [Identifiers](#).
- `DirQueryComment` specifies a quote-delimited string, up to 128 characters.

You format each input query as follows:

```
--DirQueryName=query-name  
--DirQueryComment='comment'  
input-query
```

Output Format

EXPORT_DIRECTED_QUERIES generates SQL for creating directed queries, and writes the SQL to the specified file or to standard output. In both cases, output conforms to the following format:

```
/* Query: directed-query-name */  
/* Comment: directed-query-comment */  
SAVE QUERY input-query;  
CREATE DIRECTED QUERY CUSTOM 'directed-query-name'  
COMMENT 'directed-query-comment'  
OPTVER 'vertica-release-num'  
PSDATE 'timestamp'  
annotated-query
```

Error Handling

If any errors or warnings occur during EXPORT_DIRECTED_QUERIES execution, it returns with a message like this one:

```
1 queries successfully exported.  
1 warning message was generated.  
Queries exported to /home/dbadmin/outputQueries.  
See error report, /home/dbadmin/outputQueries.err for details.
```

EXPORT_DIRECTED_QUERIES writes all errors and warnings to a file that it creates on the same path as the output file, and uses the output file's base name.

For example:

```
-----  
WARNING: Name field not supplied. Using auto-generated name: 'Autoname:2016-04-25 15:03:32.115317.0'  
Input Query: SELECT employee_dimension.employee_first_name, employee_dimension.employee_last_name,  
employee_dimension.job_title FROM public.employee_dimension WHERE (employee_dimension.employee_city =  
'Boston'::varchar(6)) ORDER BY employee_dimension.job_title;  
END WARNING
```

Examples

See [Batch Query Plan Export](#) in the Administrator's Guide.

See Also

- [Batch Query Plan Export](#)
- [IMPORT_DIRECTED_QUERIES](#)

IMPORT_DIRECTED_QUERIES

Imports to the database catalog directed queries from a SQL file that was generated by [EXPORT_DIRECTED_QUERIES](#). If no directed queries are specified, Vertica lists all directed queries in the SQL file.

Syntax

```
IMPORT_DIRECTED_QUERIES( 'export-file'[, 'directed-query-name[,...]' ] )
```

Parameters

<i>export-file</i>	A SQL file generated by EXPORT_DIRECTED_QUERIES. When you run this file, Vertica creates the specified directed queries in the current database catalog.
<i>directed-query-name</i>	The name of a directed query that is defined in <i>export-file</i> . You can specify multiple comma-delimited directed query names. If you omit this parameter, Vertica lists the names of all directed queries in <i>export-file</i> .

Privileges

Superuser

See Also

- [Batch Query Plan Export](#)
- [EXPORT_DIRECTED_QUERIES](#)

Epoch Management Functions

This section contains the epoch management functions specific to Vertica.

ADVANCE_EPOCH

Manually closes the current epoch and begins a new epoch.

Syntax

```
ADVANCE_EPOCH ( [ integer ] )
```

Parameters

<i>integer</i>	Specifies the number of epochs to advance.
----------------	--

Privileges

Superuser

Notes

This function is primarily maintained for backward compatibility with earlier versions of Vertica.

Example

The following command increments the epoch number by 1:

```
=> SELECT ADVANCE_EPOCH(1);
```

GET_AHM_EPOCH

Returns the number of the epoch in which the Ancient History Mark is located. Data deleted up to and including the AHM epoch can be purged from physical storage.

Syntax

GET_AHM_EPOCH()

Note: The AHM epoch is 0 (zero) by default (purge is disabled).

Privileges

None

Examples

```
=> SELECT GET_AHM_EPOCH();
      GET_AHM_EPOCH
-----
Current AHM epoch: 0
(1 row)
```

GET_AHM_TIME

Returns a `TIMESTAMP` value representing the Ancient History Mark. Data deleted up to and including the AHM epoch can be purged from physical storage.

Syntax

GET_AHM_TIME()

Privileges

None

Examples

```
=> SELECT GET_AHM_TIME();
      GET_AHM_TIME
-----
Current AHM Time: 2010-05-13 12:48:10.532332-04
(1 row)
```

GET_CURRENT_EPOCH

The epoch into which data (COPY, INSERT, UPDATE, and DELETE operations) is currently being written.

Returns the number of the current epoch.

Syntax

```
GET_CURRENT_EPOCH()
```

Privileges

None

Examples

```
=> SELECT GET_CURRENT_EPOCH();
   GET_CURRENT_EPOCH
-----
                   683
(1 row)
```

GET_LAST_GOOD_EPOCH

Returns the last good epoch number. If no database has no projections, the function returns an error.

Syntax

```
GET_LAST_GOOD_EPOCH()
```

Privileges

None

Examples

```
=> SELECT GET_LAST_GOOD_EPOCH();
       GET_LAST_GOOD_EPOCH
-----
                682
(1 row)
```

MAKE_AHM_NOW

Sets the Ancient History Mark (AHM) to the greatest allowable value. This lets you purge all deleted data.

Caution: After running this function, you cannot query historical data that precedes the current epoch. Only database administrators should use this function.

MAKE_AHM_NOW performs the following operations:

- Advances the epoch.
- Performs a [moveout](#) operation on all projections.
- Sets the AHM to the last good epoch (LGE) — at least to the epoch that is current when you execute MAKE_AHM_NOW.

Syntax

```
MAKE_AHM_NOW ( [ true ] )
```

Parameters

<i>true</i>	<p>Allows AHM to advance when one of the conditions is true:</p> <ul style="list-style-type: none">• One or more nodes are down.• One projection is being refreshed from another (retentive refresh). <p>In either case, you must supply this argument to MAKE_AHM_NOW, otherwise Vertica returns an error. If you execute MAKE_AHM_NOW(<i>true</i>) during retentive refresh, Vertica rolls back the refresh operation and advances the AHM.</p>
-------------	--

Privileges

Superuser

Setting AHM When Nodes Are Down

If you run `MAKE_AHM_NOW` while any node is down, you must supply an argument of `true`; otherwise, Vertica returns an error. In the following example, `MAKE_AHM_NOW` advances the AHM even though a node is down:

```
=> SELECT MAKE_AHM_NOW(true);
WARNING: Received no response from v_vmartdb_node0002 in get cluster LGE
WARNING: Received no response from v_vmartdb_node0002 in get cluster LGE
WARNING: Received no response from v_vmartdb_node0002 in set AHM
        MAKE_AHM_NOW
-----
        AHM set (New AHM Epoch: 684)
(1 row)
```

Caution: If the AHM is advanced beyond the last good epoch of the failed nodes, those nodes must recover all data from scratch.

See Also

- [SET_AHM_EPOCH](#)
- [SET_AHM_TIME](#)

SET_AHM_EPOCH

Sets the Ancient History Mark (AHM) to the specified epoch. This function allows deleted data up to and including the AHM epoch to be purged from physical storage.

`SET_AHM_EPOCH` is normally used for testing purposes. Instead, consider using [SET_AHM_TIME](#) which is easier to use.

Syntax

```
SET_AHM_EPOCH ( epoch, [ true ] )
```

Parameters

<i>epoch</i>	<p>Specifies one of the following:</p> <ul style="list-style-type: none"> • The number of the epoch in which to set the AHM • Zero (0) (the default) disables PURGE
<i>true</i>	<p>Allows the AHM to advance when nodes are down.</p> <p>Note: If the AHM is advanced after the last good epoch of the failed nodes, those nodes must recover all data from scratch. Use with care.</p>

Privileges

Superuser

Restrictions

The number of the specified epoch must be:

- Greater than the current AHM epoch
- Less than the current epoch
- Less than or equal to the cluster last good epoch (the minimum of the last good epochs of the individual nodes in the cluster)

Use the [SYSTEM](#) table to see current values of various epochs related to the AHM, For example:

```
=> SELECT * from SYSTEM;
-[ RECORD 1 ]-----+-----
current_timestamp    | 2009-08-11 17:09:54.651413
current_epoch        | 1512
ahm_epoch            | 961
last_good_epoch      | 1510
refresh_epoch        | -1
designed_fault_tolerance | 1
node_count           | 4
node_down_count      | 0
current_fault_tolerance | 1
catalog_revision_number | 1590
wos_used_bytes       | 0
wos_row_count        | 0
```

```
ros_used_bytes      | 41490783
ros_row_count       | 1298104
total_used_bytes    | 41490783
total_row_count     | 1298104
```

All nodes must be up. You cannot use `SET_AHM_EPOCH` when any node in the cluster is down, except by using the optional `true` parameter.

When a node is down and you use `MAKE_AHM_NOW`, the following error is printed to the `vertica.log`:

```
Some nodes were excluded from setAHM. If their LGE is before the AHM they will perform full recovery.
```

Examples

The following command sets the AHM to a specified epoch of 12:

```
=> SELECT SET_AHM_EPOCH(12);
```

The following command sets the AHM to a specified epoch of 2 and allows the AHM to advance despite a failed node:

```
=> SELECT SET_AHM_EPOCH(2, true);
```

See Also

- [MAKE_AHM_NOW](#)
- [SET_AHM_TIME](#)
- [SYSTEM](#)

SET_AHM_TIME

Sets the Ancient History Mark (AHM) to the epoch corresponding to the specified time on the initiator node. This function allows historical data up to and including the AHM epoch to be purged from physical storage.

Syntax

```
SET_AHM_TIME ( time , [ true ] )
```

Parameters

<i>time</i>	Is a TIMESTAMP/TIMESTAMPTZ value that is automatically converted to the appropriate epoch number.
<i>true</i>	[Optional] Allows the AHM to advance when nodes are down. Note: If the AHM is advanced after the last good epoch of the failed nodes, those nodes must recover all data from scratch.

Privileges

Superuser

Notes

- SET_AHM_TIME returns a `TIMESTAMP WITH TIME ZONE` value representing the end point of the AHM epoch.
- You cannot change the AHM when any node in the cluster is down, except by using the optional *true* parameter.
- When a node is down and you issue `SELECT MAKE_AHM_NOW()`, the following error is printed to the `vertica.log`:

```
Some nodes were excluded from setAHM. If their LGE is before the AHM they will perform full recovery.
```

Examples

Epochs depend on a configured epoch advancement interval. If an epoch includes a three-minute range of time, the purge operation is accurate only to within minus three minutes of the specified timestamp:

```
=> SELECT SET_AHM_TIME('2008-02-27 18:13');
       set_ahm_time
-----
AHM set to '2008-02-27 18:11:50-05'
(1 row)
```

Note: The `-05` part of the output string is a time zone value, an offset in hours from UTC (Universal Coordinated Time, traditionally known as Greenwich Mean Time, or GMT).

In the previous example, the actual AHM epoch ends at 18:11:50, roughly one minute before the specified timestamp. This is because `SET_AHM_TIME` selects the epoch that ends at or before the specified timestamp. It does not select the epoch that ends after the specified timestamp because that would purge data deleted as much as three minutes after the AHM.

For example, using only hours and minutes, suppose that epoch 9000 runs from 08:50 to 11:50 and epoch 9001 runs from 11:50 to 15:50. `SET_AHM_TIME('11:51')` chooses epoch 9000 because it ends roughly one minute before the specified timestamp.

In the next example, suppose that a node went down at 11:00:00 AM on January 1st 2017. At noon, you want to advance the AHM to 11:15:00, but the node is still down.

Suppose you try to set the AHM using this command:

```
=> SELECT SET_AHM_TIME('2017-01-01 11:15:00');
```

Then you will receive an error message. Vertica prevents you from moving the AHM past the point where a node went down. Vertica returns this error to prevent the AHM from advancing past the down node's last good epoch. You can force the AHM to advance by supplying the optional second parameter:

```
=> SELECT SET_AHM_TIME('2017-01-01 11:15:00', true);
```

However, if you force the AHM past the last good epoch, the failed node will have to recover from scratch.

Flex Table Functions

This section contains helper functions for use in working with flex tables.

Note: While the functions are available to all users, they are applicable only to flex table, their associated *flex_table_keys* table and *flex_table_view* views. By computing keys and creating views from flex table data, the functions facilitate SELECT queries. One function restores the original keys table and view that were made when you first created the flex table. For more information, see [Using Flex Tables](#).

BUILD_FLEXTABLE_VIEW

Creates, or re-creates, a view for a default or user-defined *_keys* table, ignoring any empty keys.

Syntax

```
build_flextable_view('flex_table' [ [, 'view_name'] [, 'user_keys_
table'] ])
```

Arguments

<i>flex_table</i>	The flex table name. By default, this function builds or rebuilds a view for the input table with the current contents of the associated <i>flex_table_keys</i> table.
<i>view_name</i>	[Optional] A custom view name. Use this option to build a new view for <i>flex_table</i> with the name you specify.
<i>user_keys_table</i>	[Optional] Specifies a keys table from which to create the view. Use this option if you created a custom <i>user_keys</i> table from the flex table map data, rather than from the default <i>flex_table_keys</i> table. The function builds a view from the keys in <i>user_keys</i> table, rather than from the <i>flex_table_keys</i> table.

Examples

The following examples show how to call `build_flextable_view` with 1, 2, or 3 arguments.

Creating a Default View

To create, or re-create, a default view:

1. Call the function with an input flex table, darkdata:

```
=> SELECT build_flextable_view('darkdata');
           build_flextable_view
-----
The view public.darkdata_view is ready for querying
(1 row)
```

The function creates a view with the default name (darkdata_view) from the darkdata_keys table.

2. Query a key name (user.id) from the new or updated view:

```
=> SELECT "user.id" from darkdata_view;
       user.id
-----
340857907
727774963
390498773
288187825
164464905
125434448
601328899
352494946
(12 rows)
```

Creating a Custom Name View

To create, or re-create, a view with a custom name:

1. Call the function with two arguments, an input flex table, darkdata, and the name of the view to create, dd_view:

```
=> SELECT build_flextable_view('darkdata', 'dd_view');
           build_flextable_view
-----
The view public.dd_view is ready for querying
(1 row)
```

2. Query a key name (user.lang) from the new or updated view (dd_view):

```
=> SELECT "user.lang" from dd_view;
       user.lang
-----
tr
en
es
en
en
it
```

```
es
en
(12 rows)
```

Creating a View from a Custom Keys Table

To create a view from a custom `_keys` table with `build_flextable_view`, the custom table must have the same schema and table definition as the default table (`darkdata_keys`).

Create a custom keys table, using any of these three approaches:

1. Create a columnar table with all keys from the default keys table for a flex table (`darkdata_keys`):

```
=> CREATE table new_darkdata_keys as select * from darkdata_keys;
CREATE TABLE
```

2. Create a columnar table without content (`LIMIT 0`) from the default keys table for a flex table (`darkdata_keys`):

```
=> CREATE table new_darkdata_keys as select * from darkdata_keys LIMIT 0;
CREATE TABLE
kdb=> select * from new_darkdata_keys;
 key_name | frequency | data_type_guess
-----+-----+-----
(0 rows)
```

3. Create a columnar table without content (`LIMIT 0`) from the default keys table, and insert two values (`'user.lang'`, `'user.name'`) into the `key_name` column:

```
=> CREATE table dd_keys as select * from darkdata_keys limit 0;
CREATE TABLE
=> insert into dd_keys (key_name) values ('user.lang');
OUTPUT
-----
      1
(1 row)
=> INSERT into dd_keys (key_name) values ('user.name');
OUTPUT
-----
      1
(1 row)
=> SELECT * from dd_keys;
 key_name | frequency | data_type_guess
-----+-----+-----
 user.lang |          | 
 user.name |          | 
(2 rows)
```

4. After creating a custom keys table, call `build_flextable_view` with all arguments (an input flex table, the new view name, the custom keys table):

```
=> SELECT BUILD_FLEXTABLE_VIEW('darkdata', 'dd_view', 'dd_keys');
       build_flextable_view
-----
The view public.dd_view is ready for querying
(1 row)
```

5. Query the new view:

```
=> SELECT * from dd_view;
```

- [COMPUTE_FLEXTABLE_KEYS](#)
- [COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW](#)
- [MATERIALIZED_FLEXTABLE_COLUMNS](#)
- [RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW](#)

COMPUTE_FLEXTABLE_KEYS

Computes the virtual columns (keys and values) from the flex table VMap data. Use this function to compute keys without creating an associated table view. To also build a view, use [COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW](#).

The function stores its results in the associated flex `_keys` table, which has the following columns:

- `key_name`
- `frequency`
- `data_type_guess`

For more information, see [Computing Flex Table Keys](#).

Syntax

```
compute_flextable_keys('flex_table')
```

Arguments

<i>flex_table</i>	The name of a flex table.
-------------------	---------------------------

Using Data Type Guessing

The results of the `flex_keys` table `data_type_guess` column depend on the `EnableBetterFlexTypeGuessing` configuration parameter. By default, the parameter is 1 (ON). This setting results in the function returning all non-string keys in the `data_type_guess` column as one of the following types (and others listed in [SQL Data Types](#)):

- BOOLEAN
- INTEGER
- FLOAT
- TIMESTAMP
- DATE

Setting the configuration parameter to 0 (OFF), results in the function returning only string types (`[LONG]VARCHAR`) or (`[LONG] VARBINARY`) for all values in the `data_type_guess` column of the `flex_keys` table .

Assigning Flex Key Data Types

Use the sample CSV data in this section to compare the results of using or not using the `EnableBetterFlexTypeGuessing` configuration parameter. When the parameter is ON, the function determines key non-string data types in your map data more accurately. The default for the parameter is 1 (ON).

```
Year,Quarter,Region,Species,Grade,Pond Value,Number of Quotes,Available
2015,1,2 - Northwest Oregon & Willamette,Douglas-fir,1P,$615.12 ,12,No
2015,1,2 - Northwest Oregon & Willamette,Douglas-fir,SM,$610.78 ,12,Yes
2015,1,2 - Northwest Oregon & Willamette,Douglas-fir,2S,$596.00 ,20,Yes
2015,1,2 - Northwest Oregon & Willamette,Hemlock,P,$520.00 ,6,Yes
2015,1,2 - Northwest Oregon & Willamette,Hemlock,SM,$510.00 ,6,No
2015,1,2 - Northwest Oregon & Willamette,Hemlock,2S,$490.00 ,14,No
```

To compare the data type assignment results, complete the following steps:

1. Save the CSV data file (here, as `trees.csv`).
2. Create a flex table (`trees`) and load `trees.csv` using the `fcsvparser`:

```
=> CREATE FLEX TABLE trees();  
=> COPY trees FROM '/home/dbadmin/tempdat/trees.csv' PARSER fcsvparser();
```

3. Use `COMPUTE_FLEXTABLE_KEYS` with the `trees` flex table.

```
=> SELECT COMPUTE_FLEXTABLE_KEYS('trees');  
          COMPUTE_FLEXTABLE_KEYS  
-----  
Please see public.trees_keys for updated keys  
(1 row)
```

4. Query the `trees_keys` table output.:

```
=> SELECT * FROM trees_keys;  
   key_name | frequency | data_type_guess  
-----+-----+-----  
Year        |          6 | Integer  
Quarter     |          6 | Integer  
Region      |          6 | Varchar(66)  
Available   |          6 | Boolean  
Number of Quotes |          6 | Integer  
Grade       |          6 | Varchar(20)  
Species     |          6 | Varchar(22)  
Pond Value  |          6 | Numeric(8,3)  
(8 rows)
```

5. Set the `EnableBetterFlexTypeGuessing` parameter to 0 (OFF).
6. Call `COMPUTE_FLEXTABLE_KEYS` with the `trees` flex table again.
7. Query the `trees_keys` table to compare the `data_type_guess` values with the previous results. Without the configuration parameter set, all of the non-string data types are `VARCHARS` of various lengths:

```
=> SELECT * FROM trees_keys;  
   key_name | frequency | data_type_guess  
-----+-----+-----  
Year        |          6 | varchar(20)  
Quarter     |          6 | varchar(20)  
Region      |          6 | varchar(66)  
Available   |          6 | varchar(20)  
Grade       |          6 | varchar(20)  
Number of Quotes |          6 | varchar(20)  
Pond Value  |          6 | varchar(20)  
Species     |          6 | varchar(22)
```

(8 rows)

8. To maintain accurate results for non-string data types, set the `EnableBetterFlexTypeGuessing` parameter back to 1 (ON).

For more information about setting the `EnableBetterFlexTypeGuessing` configuration parameter, see [Setting Flex Table Configuration Parameters](#).

- [COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW](#)
- [MATERIALIZATE_FLEXTABLE_COLUMNS](#)
- [RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW](#)

COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW

Combines the functionality of [BUILD_FLEXTABLE_VIEW](#) and [COMPUTE_FLEXTABLE_KEYS](#) to compute virtual columns (keys) from the VMap data of a flex table and construct a view. Creating a view with this function ignores empty keys. If you do not need to perform both operations together, use one of the single-operation functions instead.

Syntax

```
compute_flextable_keys_and_build_view('flex_table')
```

Arguments

<i>flex_table</i>	The name of a flex table.
-------------------	---------------------------

Examples

This example shows how to call the function for the `darkdata` flex table.

```
=> SELECT compute_flextable_keys_and_build_view('darkdata');  
        compute_flextable_keys_and_build_view  
-----
```

```
Please see public.darkdata_keys for updated keys
The view public.darkdata_view is ready for querying
(1 row)
```

See Also

- [MATERIALIZE_FLEXTABLE_COLUMNS](#)
- [RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW](#)

EMPTYMAP

Constructs a new VMap with one row but without keys or data. Use this transform function to populate a map without using a flex parser. Instead, you use either from SQL queries or from map data present elsewhere in the database.

Syntax

```
emptymap()
```

Arguments

None

Examples

Create an Empty Map

```
=> SELECT emptymap();
           emptymap
-----
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000\000
(1 row)
```

Create an Empty Map from an Existing Flex Table

If you create an empty map from an existing flex table, the new map has the same number of rows as the table from which it was created.

clause for the source table.

Syntax

```
mapaggregate(source_column1, source_column2)
```

Arguments

<code>source_column1</code>	Table column with values to use as the keys of the key/value pair of the returned VMap data.
<code>source_column2</code>	Table column with values to use as the values in the key/value pair of the returned VMap data.

Examples

This example creates a columnar table `btest`, with two VARCHAR columns, named `keys` and `values`, and adds three sets of values:

```
=> CREATE table btest(keys varchar(10), values varchar(10));
CREATE TABLE
=> copy btest from stdin;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> one|1
>> two|2
>> three|3
>> \.
```

After populating the `btest` table, call `mapaggregate()`, using the `over` (`PARTITION BEST`) clause. This call returns the `raw_map` data:

```
=> SELECT mapaggregate(keys, values) over(PARTITION BEST) from btest;
          raw_map
-----
\001\000\000\000\023\000\000\000\003\000\000\000\020\000\000\000\021\000\000\000\022\000\000\000\0132
\003\000\000\000\020\000\000\000\023\000\000\000\030\000\000\000onethreetwo
(1 row)
```

The next example illustrates using `MAPTOSTRING()` with the returned `raw_map` from `mapaggregate()` to see the values:

```
=> SELECT maptostring(raw_map) from (select mapaggregate(keys, values) over(PARTITION BEST) from
btest) bit;
          maptostring
-----
```

```
{
  "one": "1",
  "three": "3",
  "two": "2"
}
(1 row)
```

- [MAPSIZE](#)
- [MAPTOSTRING](#)
- [MAPVALUES](#)
- [MAPVERSION](#)

MAPCONTAINSKEY

Determines whether a VMap contains a virtual column (key). This scalar function returns true (t), if the virtual column exists, or false (f) if it does not. Determining that a key exists before calling `maplookup()` lets you distinguish between NULL returns. The `maplookup()` function uses for both a non-existent key and an existing key with a NULL value.

Syntax

```
mapcontainskey(VMap_data, 'virtual_column_name')
```

Arguments

VMap_data	<p>Any VMap data. The VMap can exist as:</p> <ul style="list-style-type: none"> • The <code>__raw__</code> column of a flex table • Data returned from a map function such as <code>maplookup()</code> • Other database content
virtual_column_name	The name of the key to check.

Examples

This example shows how to use the `mapcontainskey()` functions with `maplookup()`. View the results returned from both functions. Check whether the empty fields that `maplookup()` returns indicate a NULL value for the row (t) or no value (f):

You can use `mapcontainskey()` to determine that a key exists before calling `maplookup()`. The `maplookup()` function uses both NULL returns and existing keys with NULL values to indicate a non-existent key.

```
=> SELECT maplookup(__raw__, 'user.location'), mapcontainskey(__raw__, 'user.location') from darkdata
order by 1;
 maplookup | mapcontainskey
-----+-----
          | t
          | t
          | t
          | t
Chile     | t
Narnia    | t
Uptown.. | t
chicago  | t
          | f
          | f
          | f
          | f
(12 rows)
```

See Also

- [MAPAGGREGATE](#)
- [MAPCONTAINSVALUE](#)
- [MAPITEMS](#)
- [MAPKEYS](#)
- [MAPKEYSINFO](#)
- [MAPLOOKUP](#)
- [MAPSIZE](#)
- [MAPTOSTRING](#)
- [MAPVALUES](#)
- [MAPVERSION](#)

MAPCONTAINSVALUE

Determines whether a VMap contains a specific value. Use this scalar function to return true (t), if the value exists, or false (f), if it does not.

Syntax

```
mapcontainsvalue(VMap_data, 'virtual_column_value')
```

Arguments

VMap_data	Any VMap data. The VMap can exist as: <ul style="list-style-type: none">• The <code>__raw__</code> column of a flex table• Data returned from a map function such as <code>maplookup()</code>• Other database content
-----------	---

virtual_column_value	The value whose existence you want to confirm.
----------------------	--

Examples

This example shows how to use `mapcontainsvalue()` to determine whether or not a virtual column contains a particular value. Create a flex table (`ftest`), and populate it with some virtual columns and values. Name both virtual columns one:

```
=> CREATE flex table ftest();
CREATE TABLE
=> copy ftest from stdin parser fjsonparser();
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> {"one":1, "two":2}
>> {"one":"one", "2":"2"}
>> \.
```

Call `mapcontainsvalue()` on the `ftest` map data. The query returns false (`f`) for the first virtual column, and true (`t`) for the second, which contains the value one:

```
=> SELECT mapcontainsvalue(__raw__, 'one') from ftest;
mapcontainsvalue
-----
f
t
(2 rows)
```

- [MAPTOSTRING](#)

- [MAPVALUES](#)
- [MAPVERSION](#)

MAPDELIMITEDEXTRACTOR

Extracts data with a delimiter character, and other optional arguments, returning a single VMap value. The USING PARAMETERS phrase specifies optional parameters for the function.

Parameters

delimiter	VARCHAR	Single delimiter character. Default value:
header_names	VARCHAR	[Optional] Specifies header names for columns. Default value: uco1n Where <i>n</i> is the column offset number, starting with 0 for the first column. The function uses default values if you do not specify values for the header_names parameter.
trim	BOOLEAN	[Optional] Trims white space from header names and field values. Default value: true
treat_empty_val_as_null	BOOLEAN	[Optional] Specifies that empty fields become NULLs, rather than empty strings (' '). Default value: true

Examples

These examples use a short set of delimited data:

```
Name|CITY|New city|State|zip
Tom|BOSTON|boston|MA|01
Eric|Burlington|BURLINGTON|MA|02
Jamie|cambridge|CAMBRIDGE|MA|08
```

To begin, save this data as `delim.dat`.

1. Create a flex table, `dflex`:

```
=> CREATE flex table dflex();  
CREATE TABLE
```

2. Use `COPY` to load the `delim.dat` file. Use the flex tables `fdelimitedparser` with the `header='false'` option:

```
=> COPY dflex from '/home/release/kmm/flextables/delim.dat' parser fdelimitedparser  
(header='false');  
Rows Loaded  
-----  
4  
(1 row)
```

3. Create a columnar table, `dtab`, with an identity `id` column, a `delim` column, and a column to hold a `VMap`, named `vmap`:

```
=> CREATE table dtab (id IDENTITY(1,1), delim varchar(128), vmap long varbinary(512));  
CREATE TABLE
```

4. Use `COPY` to load the `delim.dat` file into the `dtab` table. For the `mapdelimitedextractor` function, add a header row with `USING PARAMETERS header_names=` option to specify the header row for the sample data, along with `delimiter '!'`:

```
=> COPY dtab(delim, vmap as mapdelimitedextractor(delim  
USING PARAMETERS header_names='Name|CITY|New City|State|Zip')) FROM  
'/home/dbadmin/data/delim.dat' DELIMITER '!';  
Rows Loaded  
-----  
4  
(1 row)
```

5. Use `maptostring` for the flex table `dflex` to view the `__raw__` column contents. Notice the default header names in use (`ucol0 – ucol4`), since you specified `header='false'` when you loaded the flex table:

```
=> SELECT maptostring(__raw__) from dflex limit 10;  
maptostring  
-----  
{  
  "ucol0" : "Jamie",  
  "ucol1" : "cambridge",  
  "ucol2" : "CAMBRIDGE",  
  "ucol3" : "MA",  
  "ucol4" : "08"
```

```
}  
  
{  
  "ucol0" : "Name",  
  "ucol1" : "CITY",  
  "ucol2" : "New city",  
  "ucol3" : "State",  
  "ucol4" : "zip"  
}  
  
{  
  "ucol0" : "Tom",  
  "ucol1" : "BOSTON",  
  "ucol2" : "boston",  
  "ucol3" : "MA",  
  "ucol4" : "01"  
}  
  
{  
  "ucol0" : "Eric",  
  "ucol1" : "Burlington",  
  "ucol2" : "BURLINGTON",  
  "ucol3" : "MA",  
  "ucol4" : "02"  
}  
  
(4 rows)
```

6. Use `maptostring` again, this time with the `dtab` table's `vmap` column. Compare the results of this output to those for the `flex` table. Note that `maptostring` returns the `header_name` parameter values you specified when you loaded the data:

```
=> SELECT maptostring(vmap) from dtab;  
  
                                maptostring  
-----  
  
{  
  "CITY" : "CITY",  
  "Name" : "Name",  
  "New City" : "New city",  
  "State" : "State",  
  "Zip" : "zip"  
}  
  
{  
  "CITY" : "BOSTON",  
  "Name" : "Tom",  
  "New City" : "boston",  
  "State" : "MA",  
  "Zip" : "02121"  
}  
  
{  
  "CITY" : "Burlington",  
  "Name" : "Eric",
```

```
"New City" : "BURLINGTON",  
"State" : "MA",  
"Zip" : "02482"  
}  
  
{  
  "CITY" : "cambridge",  
  "Name" : "Jamie",  
  "New City" : "CAMBRIDGE",  
  "State" : "MA",  
  "Zip" : "02811"  
}  
  
(4 rows)
```

7. Query the `delim` column to view the contents differently:

```
=> SELECT delim from dtab;  
      delim  
-----  
Name|CITY|New city|State|zip  
Tom|BOSTON|boston|MA|02121  
Eric|Burlington|BURLINGTON|MA|02482  
Jamie|cambridge|CAMBRIDGE|MA|02811  
(4 rows)
```

See Also

- [MAPJSONEXTRACTOR](#)
- [MAPREGEXEXTRACTOR](#)

MAPITEMS

Returns information about items in a VMap. Use this transform function with one or more optional arguments to access polystructured values within the VMap data. This function requires an `OVER()` clause.

Syntax

```
mapItems(VMap_data [, passthrough_arg [,... ] ])
```

Arguments

<code>VMap_data</code>	Any VMap data. The VMap can exist as:
------------------------	---------------------------------------

	<ul style="list-style-type: none"> • The <code>__raw__</code> column of a flex table • Data returned from a map function such as <code>maplookup()</code> • Other database content
<code>passthrough_arg</code>	[Optional] One or more arguments indicating keys within the map data in <code>VMap_data</code>

Examples

The following examples illustrate using `mapItems()` with the `over(PARTITION BEST)` clause.

This example determines the number of virtual columns in the map data using a flex table, labeled `darkmountain`. Query using the `count()` function to return the number of virtual columns in the map data:

```
=> SELECT count(keys) FROM (select mapitems(darkmountain.__raw__) over(PARTITION BEST) from
darkmountain) as a;
count
-----
      19
(1 row)
```

The next example determines what items exist in the map data:

```
=> SELECT * FROM (select mapitems(darkmountain.__raw__) over(PARTITION BEST) from darkmountain) as a;
keys      | values
-----+-----
hike_safety | 50.6
name       | Mt Washington
type       | mountain
height    | 17000
hike_safety | 12.2
name       | Denali
type       | mountain
height    | 29029
hike_safety | 34.1

Directly Query a Key Value in a VMap

Review the following JSON input file, `simple.json`. In particular, notice the array called `three_Array`, and its four values:

```
{
  "one": "one",
  "two": 2,
  "three_Array":
  [
    "three_One",
    "three_Two",
    3,
    "three_Four"
  ],
  "four": 4,
  "five_Map":
  {
    "five_One": 51,
    "five_Two": "Fifty-two",
    "five_Three": "fifty three",
    "five_Four": 54,
    "five_Five": "5 x 5"
  },
  "six": 6
}
```

1. Create a flex table, mapper:

```
=> CREATE flex table mapper();
CREATE TABLE
```

1. Load `simple.json` into the flex table mapper:

```
=> COPY mapper from '/home/dbadmin/data/simple.json' parser fjsonparser (flatten_arrays=false,
flatten_maps=false);
Rows Loaded
-----
                1
(1 row)
```

2. Call `mapkeys` on the flex table's `__raw__` column to see the flex table's keys, but not the key submaps. The return values indicate `three_Array` as one of the virtual columns:

```
=> SELECT mapkeys(__raw__) over() from mapper;
keys
-----
five_Map
four
one
six
three_Array
two
(6 rows)
```

3. Call `mapitems` on flex table mapper with `three_Array` as a pass-through argument to the function. The call returns these array values:

```
=> SELECT __identity__, mapitems(three_Array) OVER(PARTITION BY __identity__) from mapper;
__identity__ | keys | values
-----+-----+-----
          1 | 0    | three_One
          1 | 1    | three_Two
          1 | 2    | 3
          1 | 3    | three_Four
(4 rows)
```

MAPJSONEXTRACTOR

Extracts content of repeated JSON data objects, including nested maps, or data with an outer list of JSON elements. The `USING PARAMETERS` phrase specifies optional parameters for the function. Empty input does not generate a Warning or Error.

Note: The function fails if the output size of the function is greater than 65000.

Parameters

<code>flatten_maps</code>	BOOLEAN	[Optional] Flattens sub-maps within the JSON data, separating map levels with a period (.). Default value: true
<code>flatten_arrays</code>	BOOLEAN	[Optional] Converts lists to sub-maps with integer keys. Lists are not flattened by default. Default value: false
<code>reject_on_duplicate</code>	BOOLEAN	[Optional] Specifies whether to ignore duplicate records (false), or to reject duplicates (true). In either case, the load continues. Default value: false
<code>reject_on_empty_key</code>	BOOLEAN	[Optional] Rejects any row containing a key without a value (<code>reject_on_empty_key=true</code>). Default value: false
<code>omit_empty_keys</code>	BOOLEAN	[Optional] Omits any key from the load data that does not have a value (<code>omit_empty_keys=true</code>). Default value: false
<code>start_point</code>	CHAR	[Optional] Specifies the name of a key in the JSON load data at which to begin parsing. The parser ignores all data before the <code>start_point</code> value. The parser processes data after the first instance, and up to the second, ignoring any remaining data. Default value: none

Examples

These examples use the following sample JSON data:

```
{ "id": "5001", "type": "None" }
{ "id": "5002", "type": "Glazed" }
{ "id": "5005", "type": "Sugar" }
{ "id": "5007", "type": "Powdered Sugar" }
{ "id": "5004", "type": "Maple" }
```

Save this example data as `bake_single.json`, and load that file.

1. Create a flex table, flexjson:

```
=> CREATE flex table flexjson();  
CREATE TABLE
```

2. Use COPY to load the bake_single.json file with the fjsonparser parser:

```
=> COPY flexjson from '/home/dbadmin/data/bake_single.json' parser fjsonparser();  
Rows Loaded  
-----  
5  
(1 row)
```

3. Create a columnar table, coljson, with an identity column (id), a json column, and a column to hold a VMap, called vmap:

```
=> CREATE table coljson(id IDENTITY(1,1), json varchar(128), vmap long varbinary(10000));  
CREATE TABLE
```

4. Use COPY to load the bake_single.json file into the coljson table, using the mapjsonextractor function:

```
=> COPY coljson (json, vmap AS MapJSONExtractor(json)) FROM '/home/dbadmin/data/bake_  
single.json';  
Rows Loaded  
-----  
5  
(1 row)
```

5. Use the maptostring function for the flex table flexjson to output the __raw__ column contents as strings:

```
=> SELECT maptostring(__raw__) from flexjson limit 5;  
maptostring  
-----  
{  
  "id" : "5001",  
  "type" : "None"  
}  
  
{  
  "id" : "5002",  
  "type" : "Glazed"  
}  
  
{  
  "id" : "5005",  
  "type" : "Sugar"  
}
```

```
{
  "id" : "5007",
  "type" : "Powdered Sugar"
}

{
  "id" : "5004",
  "type" : "Maple"
}

(5 rows)
```

6. Use the `maptostring` function again, this time with the `coljson` table's `vmap` column and compare the results. The element order differs:

```
=> SELECT maptostring(vmap) from coljson limit 5;
      maptostring
-----
{
  "id" : "5001",
  "type" : "None"
}

{
  "id" : "5002",
  "type" : "Glazed"
}

{
  "id" : "5004",
  "type" : "Maple"
}

{
  "id" : "5005",
  "type" : "Sugar"
}

{
  "id" : "5007",
  "type" : "Powdered Sugar"
}

(5 rows)
```

- [MAPREGEXEXTRACTOR](#)

MAPKEYS

Returns the virtual columns (and values) present in any VMap data. This transform function requires an `over(PARTITION BEST)` clause.

Syntax

```
mapkeys(VMap_data)
```

Arguments

<code>VMap_data</code>	<p>Any VMap data. The VMap can exist as:</p> <ul style="list-style-type: none">• The <code>__raw__</code> column of a flex table• Data returned from a map function such as <code>maplookup()</code>• Other database content
------------------------	--

Examples

Determine Number of Virtual Columns in Map Data

This example shows how to create a query, using an `over(PARTITION BEST)` clause with a flex table, `darkdata` to find the number of virtual column in the map data. The table is populated with JSON tweet data.

```
=> SELECT count(keys) FROM (SELECT mapkeys(darkdata.__raw__) over(PARTITION BEST) from darkdata) as a;  
count  
-----  
550  
(1 row)
```

Query Ordered List of All Virtual Columns in the Map

This example shows a snippet of the return data when you query an ordered list of all virtual columns in the map data:

```
=> SELECT * FROM (SELECT mapkeys(darkdata.__raw__) over(PARTITION BEST) from darkdata) as a;  
keys  
-----
```

```
contributors
coordinates
created_at
delete.status.id
delete.status.id_str
delete.status.user_id
delete.status.user_id_str
entities.hashtags
entities.media
entities.urls
entities.user_mentions
favorited
geo
id
.
.
.
user.statuses_count
user.time_zone
user.url
user.utc_offset
user.verified
(125 rows)
```

- [MAPVALUES](#)
- [MAPVERSION](#)

MAPKEYSINFO

Returns virtual column information from a given map. This transform function requires an `over(PARTITION BEST)` clause.

Syntax

```
mapkeysinfo(VMap_data)
```

Arguments

<code>VMap_data</code>	<p>Any VMap data. The VMap can exist as:</p> <ul style="list-style-type: none">• The <code>__raw__</code> column of a flex table• Data returned from a map function such as <code>maplookup()</code>• Other database content
------------------------	--

Returns

This function is a superset of the [MAPKEYS\(\)](#) function. It returns the following information about each virtual column:

Column	Description
<code>keys</code>	The virtual column names in the raw data.
<code>length</code>	The data length of the key name, which can differ from the actual string length.
<code>type_oid</code>	The OID type into which the value should be converted. Currently, the type is always 116 for a <code>LONG VARCHAR</code> , or 199 for a nested map that is stored as a <code>LONG VARBINARY</code> .
<code>row_num</code>	The number of rows in which the key was found.
<code>field_num</code>	The field number in which the key exists.

Examples

This example shows a snippet of the return data you receive if you query an ordered list of all virtual columns in the map data:

```
=> SELECT * FROM (SELECT mapkeysinfo(darkdata.__raw__) over(PARTITION BEST) from darkdata) as a;
      keys | length | type_oid | row_num | field_num
-----+-----+-----+-----+-----
contributors | 0 | 116 | 1 | 0
coordinates | 0 | 116 | 1 | 1
created_at | 30 | 116 | 1 | 2
entities.hashtags | 93 | 199 | 1 | 3
entities.media | 772 | 199 | 1 | 4
entities.urls | 16 | 199 | 1 | 5
entities.user_mentions | 16 | 199 | 1 | 6
favorited | 1 | 116 | 1 | 7
geo | 0 | 116 | 1 | 8
id | 18 | 116 | 1 | 9
id_str | 18 | 116 | 1 | 10
.
.
.
delete.status.id | 18 | 116 | 11 | 0
delete.status.id_str | 18 | 116 | 11 | 1
delete.status.user_id | 9 | 116 | 11 | 2
delete.status.user_id_str | 9 | 116 | 11 | 3
delete.status.id | 18 | 116 | 12 | 0
delete.status.id_str | 18 | 116 | 12 | 1
delete.status.user_id | 9 | 116 | 12 | 2
delete.status.user_id_str | 9 | 116 | 12 | 3
(550 rows)
```

MAPLOOKUP

Returns single-key values from VMAP data. This scalar function returns a LONG VARCHAR, with values, or NULL if the virtual column does not have a value.

Using `maplookup` is case insensitive to virtual column names. To avoid loading same-name values, set the `fjsonparser parser reject_on_duplicate` parameter to `true` when data loading.

You can control the behavior for non-scalar values in a VMAP (like arrays), when loading data with the `fjsonparser` or `favroparser` parsers and its `flatten-arrays` argument. See [Loading JSON Data](#) and the [FJSONPARSER](#) reference.

For information about using `maplookup()` to access nested JSON data, see [Querying Nested Data](#).

Syntax

```
maplookup (VMap_data, 'virtual_column_name' [USING PARAMETERS [case_sensitive={false | true}] [, buffer_size=n] ] )
```

Parameters

<code>VMap_data</code>	Any VMap data. The VMap can exist as: <ul style="list-style-type: none">• The <code>__raw__</code> column of a flex table• Data returned from a map function such as <code>maplookup()</code>• Other database content
<code>virtual_column_name</code>	The name of the virtual column whose values this function returns.
<code>buffer_size</code>	[Optional parameter] Specifies the maximum length (in bytes) of each value returned for <code>virtual_column_name</code> . To return all values for <code>virtual_column_name</code> , specify a <code>buffer_size</code> equal to or greater than (<code>=></code>) the number of bytes for any returned value. Any returned

	values greater in length than <code>buffer_size</code> are rejected. Default value: 0 (No limit on <code>buffer_size</code>)
<code>case_sensitive</code>	[Optional parameter] Specifies whether to return values for <code>virtual_column_name</code> if keys with different cases exist. Example: (... USING PARAMETERS <code>case_sensitive=true</code>) Default value: false

Examples

This example returns the values of one virtual column, `user.location`:

```
=> SELECT maplookup(__raw__, 'user.location') FROM darkdata order by 1;
maplookup
-----
Chile
Nesnia
Uptown
.
.
chicago
(12 rows)
```

Using `maplookup buffer_size`

Use the `buffer_size=` parameter to indicate the maximum length of any value that `maplookup` returns for the virtual column you specify. If none of the returned key values can be greater than `n` bytes, use this parameter to allocate `n` bytes as the `buffer_size`.

For the next example, save this JSON data to a file, `simple_name.json`:

```
{
  "name": "sierra",
  "age": "63",
  "eyes": "brown",
  "weapon": "doggie"
}
{
  "name": "janis",
  "age": "10",
  "eyes": "blue",
  "weapon": "humor"
}
{
  "name": "ben",
  "age": "43",
```

```
"eyes": "blue",  
"weapon": "sword"  
}  
{  
  "name": "jen",  
  "age": "38",  
  "eyes": "green",  
  "weapon": "shopping"  
}
```

1. Create a flex table, logs.
2. Load the simple_name.json data into logs, using the fjsonparser. Specify the flatten_arrays option as True:

```
=> COPY logs FROM '/home/dbadmin/data/simple_name.json'  
  PARSER fjsonparser(flatten_arrays=True);
```

3. Use maplookup with buffer_size=0 for the logs table name key. This query returns all of the values:

```
=> SELECT MapLookup(__raw__, 'name' USING PARAMETERS buffer_size=0) FROM logs;  
MapLookup  
-----  
sierra  
ben  
janis  
jen  
(4 rows)
```

4. Next, call maplookup() three times, specifying the buffer_size parameter as 3, 5, and 6, respectively. Now, maplookup() returns values with a byte length less than or equal to (<=) buffer_size:

```
=> SELECT MapLookup(__raw__, 'name' USING PARAMETERS buffer_size=3) FROM logs;  
MapLookup  
-----  
  
ben  
  
jen  
(4 rows)  
=> SELECT MapLookup(__raw__, 'name' USING PARAMETERS buffer_size=5) FROM logs;  
MapLookup  
-----  
  
janis  
jen  
ben  
(4 rows)
```

```
=> SELECT MapLookup(__raw__, 'name' USING PARAMETERS buffer_size=6) FROM logs;
MapLookup
-----
sierra
janis
jen
ben
(4 rows)
```

Disambiguate Empty Output Rows

This example shows how to interpret empty rows. Using `maplookup` without first checking whether a key exists can be ambiguous. When you review the following output, 12 empty rows, you cannot determine whether a `user.location` key has:

- A non-NULL value
- A NULL value
- No value

```
=> SELECT maplookup(__raw__, 'user.location') FROM darkdata;
maplookup
-----
(12 rows)
```

To disambiguate empty output rows, use the `mapcontainskey()` function in conjunction with `maplookup()`. When `maplookup` returns an empty field, the corresponding value from `mapcontainskey` indicates `t` for a NULL or other value, or `f` for no value.

The following example output using both functions lists rows with NULL or a name value as `t`, and rows with no value as `f`:

```
=> SELECT maplookup(__raw__, 'user.location'), mapcontainskey(__raw__, 'user.location')
from darkdata order by 1;
maplookup | mapcontainskey
-----+-----
          | t
          | t
          | t
```

```
=> CREATE flex table dupe();  
CREATE TABLE  
dbt=> copy dupe from '/home/release/KData/repeated_key_name.json' parser fjsonparser();  
Rows Loaded  
-----  
                8  
(1 row)
```

MAPPUT

Accepts a VMap and one or more key/value pairs and returns a new VMap with the key/value pairs added. Keys must be set using the auxiliary function `SetMapKeys()`, and can only be constant strings. If the VMap has any of the new input keys, then the original values are replaced by the new ones.

Syntax

`MapPut(VMap_data, value1 [, value2, value3, ...]` using parameters
`keys=SetMapKeys('key1'[, 'key2', 'key3', ...])`

Arguments

<code>VMap_data</code>	Any VMap data. The VMap can exist as: <ul style="list-style-type: none">• The <code>__raw__</code> column of a flex table• Data returned from a map function such as <code>maplookup()</code>• Other database content
<code>value</code>	One or more values to add to the VMap specified in <code>VMap_data</code> .

Parameters

<code>keys</code>	The <code>keys</code> parameter must be the result of <code>SetMapKeys()</code> . <code>SetMapKeys()</code> simply takes one or more constant strings as arguments.
-------------------	---

The following example shows how to create a flex table and use `COPY` to enter some basic JSON data. After creating a second flex table (`vmapdata2`), insert the new vmap results from `mapput()`, with additional key/value pairs.

1. Create sample table:

```
=> CREATE flex table vmapdata1();  
CREATE TABLE
```

2. Load sample JSON data from STDIN:

```
=> COPY vmapdata1 FROM stdin parser fjsonparser();  
Enter data to be copied followed by a newline.  
End with a backslash and a period on a line by itself.  
>> {"aaa": 1, "bbb": 2, "ccc": 3}  
>> \.
```

3. Create another flex table and use the function to insert data into it:

```
=> CREATE flex table vmapdata2();  
=> INSERT into vmapdata2 select mapput(__row__, '7','8','9'  
    using parameters keys=SetMapKeys('xxx','yyy','zzz')) from vmapdata1;
```

4. View the difference between the original and the new flex tables:

```
=> SELECT maptostring(__row__) FROM vmapdata1;  
      maptostring  
-----  
{  
  "aaa" : "1",  
  "bbb" : "2",  
  "ccc" : "3"  
}  
(1 row)  
=> select maptostring(__row__) from vmapdata2;  
      maptostring  
-----  
{  
  "mapput" : {  
    "aaa" : "1",  
    "bbb" : "2",  
    "ccc" : "3",  
    "xxx" : "7",  
    "yyy" : "8",  
    "zzz" : "9"  
  }  
}
```

MAPREGEXEXTRACTOR

Extracts data from a regular expression and returns the results as a VMap. Use the USING PARAMETERS pattern= phrase, followed by the regular expression.

Parameters

pattern=	VARCHAR	The regular expression as a string. Default value: An empty string ("").
use_jit	BOOLEAN	[Optional] Uses just-in-time compiling when parsing the regular expression. Default value: false.
record_terminator	VARCHAR	[Optional] The character used to separate input records. Default value: \n.
logline_column	VARCHAR	[Optional] The destination column containing the full string that the regular expression matched. Default value: An empty string ("").

Examples

These examples use the following regular expression, which searches for information that includes the timestamp, date, thread_name, and thread_id strings.

Caution: For display purposes, this sample regular expression adds new line characters to split long lines of text. To use this expression in a query, first copy and edit the example to remove any new line characters.

This example expression loads any thread_id hex value, regardless of whether it has a 0x prefix, (<thread_id>(?:0x)?[0-9a-f]+).

```
'^(?<time>\d\d\d\d-\d\d-\d\d \d\d:\d\d:\d\d\.\d+)
 (?<thread_name>[A-Za-z ]+):(?<thread_id>(?:0x)?[0-9a-f]+)
 -?(?<transaction_id>[0-9a-f])?(?:[(?<component>\w+)]
 \<(?!<level>\w+)\> )?(?:<(?!<elevel>\w+)\> @[(?!<enode>\w+)\>]? : )
 (?<text>.*).'
```

The following examples may include newline characters for display purposes.

1. Create a flex table, flogs:

```
=> CREATE flex table flogs();
CREATE TABLE
```

2. Use COPY to load a sample log file (vertica.log), using the flex table fregexparser. Note that this example includes added line characters for displaying long text lines.

```
=> COPY flogs FROM '/home/dbadmin/tempdat/vertica.log' PARSER FREGEXPARSER(pattern='
^(?<time>\d\d\d\d-\d\d-\d\d \d\d:\d\d:\d\d\.\d+) (?<thread_name>[A-Za-z ]+):
(?<thread_id>(?:0x)?[0-9a-f])-(?<transaction_id>[0-9a-f])?(?:[(?<component>\w+)]
\<(?!<level>\w+)\> )?(?:<(?!<elevel>\w+)\> @[(?!<enode>\w+)\>]? : )?(?<text>.*)');
Rows Loaded
-----
81399
(1 row)
```

3. Use MapToString to return the results from calling MapRegexExtractor with a regular expression. The output returns the results of the function in string format.

```
=> SELECT maptostring(MapregexExtractor(E'2014-04-02 04:02:51.011
TM Moveout:0x2aab9000f860-a000000002067 [Txn] <INFO>
Begin Txn: a000000002067 'Moveout: Tuple Mover\'' using PARAMETERS
pattern='^(?<time>\d\d\d\d-\d\d-\d\d \d\d:\d\d:\d\d\.\d+)
 (?<thread_name>[A-Za-z ]+):(?<thread_id>(?:0x)?[0-9a-f]+)
 -?(?<transaction_id>[0-9a-f])?(?:[(?<component>\w+)]
 \<(?!<level>\w+)\> )?(?:<(?!<elevel>\w+)\> @[(?!<enode>\w+)\>]? : )
 (?<text>.*)'')) FROM flogs where __identity__=13;

maptostring
-----
--
{
"component" : "Txn",
"level" : "INFO",
"text" : "Begin Txn: a000000002067 'Moveout: Tuple Mover'",
"thread_id" : "0x2aab9000f860",
"thread_name" : "TM Moveout",
"time" : "2014-04-02 04:02:51.011",
"transaction_id" : "a000000002067"
}
(1 row)
```

See Also

- [MAPDELIMITEDEXTRACTOR](#)
- [MAPJSONEXTRACTOR](#)

MAPSIZE

Returns the number of virtual columns present in any VMap data. Use this scalar function to determine the size of keys.

Syntax

```
mapsize(VMap_data)
```

Arguments

VMap_data	<p>Any VMap data. The VMap can exist as:</p> <ul style="list-style-type: none">• The <code>__raw__</code> column of a flex table• Data returned from a map function such as <code>maplookup()</code>• Other database content
-----------	--

Examples

This example shows the returned sizes from the number of keys in the flex table `darkmountain`:

```
=> SELECT mapsize(__raw__) FROM darkmountain;
mapsize
-----
      3
      4
      4
      4
      4
(5 rows)
```

MAPTOSTRING

Recursively builds a string representation VMap data, including nested JSON maps. Use this transform function to display the VMap contents in a readable LONG VARCHAR format. Use `maptostring` to see how map data is nested before querying virtual columns with `mapvalues()`.

Syntax

```
maptostring(VMap_data [using parameters canonical_json={true  
| false}])
```

Arguments

VMap_data	Any VMap data. The VMap can exist as: <ul style="list-style-type: none">• The <code>__raw__</code> column of a flex table
-----------	---

	<ul style="list-style-type: none">• Data returned from a map function such as <code>maplookup()</code>• Other database content
--	---

Parameters

<code>canonical_json</code>	<p><i>=bool</i> [Optional parameter]</p> <p>Produces canonical JSON output by default, using the first instance of any duplicate keys in the map data.</p> <p>Use this parameter as other UDF parameters, preceded by using parameters, as shown in the examples. Setting this argument to <code>false</code> maintains the previous behavior of <code>maptostring()</code> and returns same-name keys and their values.</p> <p>Default value: <code>canonical-json=true</code></p>
-----------------------------	--

Examples

The following example shows how to create a sample flex table, `darkdata` and load JSON data from STDIN. By calling `maptostring()` twice with both values for the `canonical_json` parameter, you can see the different results on the flex table `__raw__` column data.

1. Create sample table:

```
=> CREATE flex table darkdata();  
CREATE TABLE
```

2. Load sample JSON data from STDIN:

```
=> COPY darkdata FROM stdin parser fjsonparser();  
Enter data to be copied followed by a newline.  
End with a backslash and a period on a line by itself.  
>> {"aaa": 1, "aaa": 2, "AAA": 3, "bbb": "aaa\"bbb"}  
>> \.
```

3. Call `maptostring()` with its default behavior using canonical JSON output, and then review the flex table contents. The function returns the first duplicate key and its value (`"aaa": "1"`) but omits remaining duplicate keys (`"aaa": "2"`):

```
=> SELECT maptostring (__raw__) FROM darkdata;  
maptostring
```

```
-----  
{  
  "AAA" : "3",  
  "aaa" : "1",  
  "bbb" : "aaa\"bbb"  
}  
(1 row)
```

4. Next, call `maptostring()` with using parameters `canonical_json=false`). This time, the function returns the first duplicate keys and their values:

```
=> SELECT maptostring(__raw__ using parameters canonical_json=false) FROM darkdata;  
maptostring
```

```
-----  
{  
  "aaa": "1",  
  "aaa": "2",  
  "AAA": "3",  
  "bbb": "aaa\"bbb"  
}  
(1 row)
```

- [MAPVERSION](#)

MAPVALUES

Returns a string representation of the top-level values from a VMap. This transform function requires an `over()` clause.

Syntax

```
mapvalues(VMap_data)
```

Arguments

<code>VMap_data</code>	The VMap from which values should be returned. The VMap can exist as: <ul style="list-style-type: none">• The <code>__raw__</code> column of a flex table• Data returned from a map function such as <code>maplookup()</code>• Other database content
------------------------	---

Examples

The following example shows how to query a `darkmountain` flex table, using an `over()` clause (in this case, the `over(PARTITION BEST)` clause) with `mapvalues()`.

```
=> SELECT * FROM (select mapvalues(darkmountain.__raw__) over(PARTITION BEST) from darkmountain) as  
a;  
  values  
-----  
29029  
34.1  
Everest  
mountain  
29029  
15.4  
Mt St Helens  
volcano  
17000  
12.2  
Denali  
mountain  
14000
```

```
22.8  
Kilimanjaro  
mountain  
50.6  
Mt Washington  
mountain  
(19 rows)
```

- [MAPKEYSINFO](#)
- [MAPLOOKUP](#)
- [MAPSIZE](#)
- [MAPTOSTRING](#)
- [MAPVERSION](#)

MAPVERSION

Returns the version or invalidity of any map data. This scalar function returns the map version (such as 1) or -1, if the map data is invalid.

Syntax

```
mapversion(VMap_data)
```

Arguments

VMap_data	The VMap data either from a <code>__raw__</code> column in a flex table or from the data returned from a map function such as <code>maplookup()</code> .
-----------	--

Examples

The following example shows how to use `mapversion()` with the `darkmountainflex` table, returning `mapversion 1` for the flex table map data:

```
=> SELECT mapversion(__raw__) FROM darkmountain;  
mapversion  
-----  
          1  
          1  
          1  
          1  
          1  
          1  
(5 rows)
```

MATERIALIZED_FLEXTABLE_COLUMNS

Materializes virtual columns listed as *key_names* in the *flextable_keys* table you compute using either [COMPUTE_FLEXTABLE_KEYS](#) or [COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW](#).

Note: Each column that you materialize with this function counts against the data storage limit of your license. To check your Vertica license compliance, call the `AUDIT()` or `AUDIT_FLEX()` functions.

Syntax

```
materialize_flextable_columns('flex_table' [, n-columns [, keys_table_name] ])
```

Arguments

<i>flex_table</i>	<p>The name of the flex table with columns to materialize. Specifying only the flex table name attempts to materialize up to 50 columns of key names in the default <i>flex_table_keys</i> table. When you use this argument, the function:</p> <ul style="list-style-type: none">• Skips any columns already materialized• Ignores any empty keys <p>To materialize a specific number of columns, use the optional parameter <code>n_columns</code>, described next.</p>
<i>n-columns</i>	<p>[Optional] The number of columns to materialize. The function attempts to materialize the number of columns from the <i>flex_table_keys</i> table, skipping any columns already materialized.</p> <p>Vertica tables support a total of 1600 columns, which is the largest value you can specify for <code>n-columns</code>. The function orders the materialized results by frequency, descending, <i>key_name</i> when materializing the first <code>n</code> columns.</p>
<i>keys_table_name</i>	<p>[Optional] The name of a <i>flex_keys_table</i> from which to materialize columns. The function:</p> <ul style="list-style-type: none">• Materializes the number of columns (value of <i>n-columns</i>) from <i>keys_table_name</i>

- Skips any columns already materialized
- Orders the materialized results by frequency, descending, *key_name* when materializing the first n columns.

Examples

The following example shows how to call `materialize_flextable_columns` to materialize columns. First, load a sample file of tweets (`tweets_10000.json`) into the flex table `twitter_r`.

After loading data and computing keys for the sample flex table, call `materialize_flextable_columns` to materialize the first four columns:

```
=> COPY twitter_r FROM '/home/release/KData/tweets_10000.json' parser fjsonparser();
Rows Loaded
-----
      10000
(1 row)

=> SELECT compute_flextable_keys ('twitter_r');
           compute_flextable_keys
-----
Please see public.twitter_r_keys for updated keys
(1 row)

=> select materialize_flextable_columns('twitter_r', 4);
           materialize_flextable_columns
-----
The following columns were added to the table public.twitter_r:
      contributors
      entities.hashtags
      entities.urls
For more details, run the following query:
SELECT * FROM v_catalog.materialize_flextable_columns_results WHERE table_schema = 'public' and
table_name = 'twitter_r';

(1 row)
```

The last message in the example recommends querying the `materialize_flextable_columns_results` system table for the results of materializing the columns, as shown:

```
=> SELECT * FROM v_catalog.materialize_flextable_columns_results WHERE table_schema = 'public' and
table_name = 'twitter_r';
table_id      | table_schema | table_name |      creation_time      |      key_name      |
status |      message
-----+-----+-----+-----+-----+-----
45035996273733172 | public      | twitter_r | 2013-11-20 17:00:27.945484-05 | contributors      |
ADDED | Added successfully
45035996273733172 | public      | twitter_r | 2013-11-20 17:00:27.94551-05 | entities.hashtags |
ADDED | Added successfully
```

```
45035996273733172 | public      | twitter_r | 2013-11-20 17:00:27.945519-05 | entities.urls |
ADDED | Added successfully
45035996273733172 | public      | twitter_r | 2013-11-20 17:00:27.945532-05 | created_at   |
EXISTS | Column of same name already
(4 rows)
```

See the [MATERIALIZE_FLEXTABLE_COLUMNS_RESULTS](#) system table in the SQL Reference Manual.

See Also

- [BUILD_FLEXTABLE_VIEW](#)
- [COMPUTE_FLEXTABLE_KEYS](#)
- [COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW](#)
- [RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW](#)

RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW

Restores the `_keys` table and the `_view`. The function also links the `_keys` table with its associated flex table, in cases where either table is dropped. The function also indicates whether it restored one or both objects.

Syntax

```
RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW('flex_table')
```

Arguments

<i>flex_table</i>	The name of a flex table.
-------------------	---------------------------

Examples

This example shows how to invoke this function with an existing flex table, restoring both the `_keys` table and `_view`:

```
=> SELECT RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW('darkdata');
       RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW
```

```
-----
The keys table public.darkdata_keys was restored successfully.
```

```
The view public.darkdata_view was restored successfully.
(1 row)
```

This example illustrates that the function restored `darkdata_view`, but that `darkdata_keys` did not need restoring:

```
=> SELECT RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW('darkdata');
           RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW
-----
The keys table public.darkdata_keys already exists and is linked to darkdata.
The view public.darkdata_view was restored successfully.
(1 row)
```

After restoring the `_keys` table, there is no content. To populate the flex keys, call the [COMPUTE_FLEXTABLE_KEYS](#) meta function.

```
=> SELECT * FROM darkdata_keys;
 key_name | frequency | data_type_guess
-----+-----+-----
(0 rows)
```

Hadoop Functions

This section contains functions to manage interactions with Hadoop.

CLEAR_HDFS_CACHES

Clears the configuration information copied from HDFS and any cached connections.

This function affects reads using the `hdfs` scheme in the following ways:

- This function flushes information loaded from configuration files copied from Hadoop (such as `core-site.xml`). These files are found on the path set by the `HadoopConfDir` configuration

parameter.

- This function flushes information about which Name Node is active in a High Availability (HA) Hadoop cluster. Therefore, the first request to Hadoop after calling this function is slower than expected.

Vertica maintains a cache of open connections to name nodes to reduce latency. This function flushes that cache.

Syntax

```
CLEAR_HDFS_CACHES ( )
```

Privileges

Superuser

Example

The following example clears the Hadoop configuration information:

```
=> SELECT CLEAR_HDFS_CACHES();
CLEAR_HDFS_CACHES
-----
Cleared
(1 row)
```

See Also

[Hadoop Parameters](#)

KERBEROS_HDFS_CONFIG_CHECK

Tests the Kerberos configuration of a Vertica cluster that uses HDFS. This function is a more specific version of [KERBEROS_CONFIG_CHECK](#).

You can call this function with arguments to specify an HDFS configuration to test, or without arguments. If you call it with no arguments, this function reads the HDFS configuration files and fails if it does not find them. See [Configuring the hdfs Scheme](#). If it finds configuration files, it tests all configured nameservices.

The function performs the following tests, in order:

- Are Kerberos services available?
- Does a keytab file exist and are the Kerberos and HDFS configuration parameters set in the database?
- Can Vertica read and invoke kinit with the keys to authenticate to HDFS and obtain the database Kerberos ticket?
- Can Vertica perform hdfs and webhdfs operations using both the database Kerberos ticket and user-forwardable tickets?
- Can Vertica make unauthenticated WebHCat calls?

If any test fails, the function returns a descriptive error message.

Syntax

```
KERBEROS_HDFS_CONFIG_CHECK( [ 'hdfsHost:hdfsPort',  
                             'webhdfsHost:webhdfsPort', 'webhcatHost:webhcatPort' ] )
```

Arguments

<i>hdfsHost, hdfsPort</i>	The hostname or IP address and port of the HDFS name node. Vertica uses this server to access data that is specified with hdfs URLs. If the value is '', the function skips this part of the check.
<i>webhdfsHost, webhdfsPort</i>	The hostname or IP address and port of the WebHDFS server. Vertica uses this server to access data that is specified with webhdfs URLs. If the value is '', the function skips this part of the check.
<i>webhcatHost, webhcatPort</i>	The hostname or IP address and port of the WebHCat server. The HCatalog Connector uses this server to access data through Hive. If the value is '', the function skips this part of the check.

Privileges

This function does not require privileges.

Examples

The following example shows the results when the function cannot infer the configuration from the HDFS configuration files.

```
=> SELECT KERBEROS_HDFS_CONFIG_CHECK();
-----Checking basic Kerberos configuration-----
ok: kinit exists
ok: klist exists
ok: krb5 exists at [/etc/krb5.conf]

-----Checking basic Hadoop configuration-----
HadoopFSPrincipal: [mydb/server.example.com@EXAMPLE.COM]
HadoopFSAuthentication (default): [/scratch_b/qa/mydb.keytab]
HadoopFSTokenRefreshFrequency: 0
HadoopFSKinitCommand: export KRB5CCNAME=%tmp%; kinit %principal% -k -t %keytab% -c %tmp%; %cmd%; V_
HADOOP_RESULT=$?; rm %tmp%; exit $V_HADOOP_RESULT;
HadoopFSConnectionTimeout: 60
ok: Can read HDFS keys
ok: Can get tickets for hdfs principal
ok: vertica can kinit as HDFS storage

**Inferring HDFS configuration**
Number of HDFS Clusters: 1
Cluster 1 is HA

-----Checking LibHdfs++ configurations-----

**Checking default LibHdfs++ Nameservice**
ok: Vertica can perform LibHdfs++ operations at [hdfs:///]
ok: Can access [hdfs:///] using delegated ticket for [dbuser]

**Checking LibHdfs++ using hdfs configurations found if any**
ok: Vertica can perform LibHdfs++ operations at [hdfs://ns-server1/]
ok: Can access [hdfs://ns-server1/] using delegated ticket for [dbuser]

-----Checking WebHdfs configurations----- Attempt to pull an unauthenticated page from the

FAILED: Could not make external connection to webhcat at
[server1.example.com:14433/templeton/v1/status]

(1 row)
```

SYNC_WITH_HCATALOG_SCHEMA

Copies the structure of a Hive database schema available through the HCatalog Connector to a Vertica schema.

Syntax

```
SYNC_WITH_HCATALOG_SCHEMA( local_schema, hcatalog_schema, [drop_tables] )
```

Parameters

<i>Local_schema</i>	The existing Vertica schema to store the copied HCatalog schema's metadata. This can be the same schema as <i>hcatalog_schema</i> , or it can be a separate one created using CREATE SCHEMA.
<i>hcatalog_schema</i>	The HCatalog schema to copy. This is the schema created using CREATE HCATALOG SCHEMA.
[<i>drop_tables</i>]	If true, drop any tables in <i>Local_schema</i> that do not correspond to a table in <i>hcatalog_schema</i>

Notes

The SYNC_WITH_HCATALOG_SCHEMA function overwrites tables in the Vertica schema whose names match a table in the HCatalog schema. Do not use the Vertica schema to store other data.

Hive STRING and BINARY data types are matched, in Vertica, to VARCHAR(65000) and VARBINARY(65000) types. You can use [ALTER TABLE](#) to adjust these after creating the schema. The maximum size of a VARCHAR or VARBINARY in Vertica is 65000, but you can use LONG VARCHAR and LONG VARBINARY to specify larger values.

Hive and Vertica define string length in different ways. In Hive the length is the number of characters; in Vertica it is the number of bytes. Thus, a character encoding that uses more than one byte, such as Unicode, can result in mismatches between the two. Set values in Vertica based on bytes, not characters, to avoid data truncation.

If the data size exceeds the declared size for the column, Vertica logs an event at read time in the QUERY_EVENTS system table.

This function can synchronize the HCatalog schema directly, in which case you call it with the same schema name for both parameters. It can also synchronize a different schema to the HCatalog schema.

If you change the settings of any HCatalog Connector configuration parameters ([Hadoop Parameters](#)), you must call this function again.

Privileges

The user must have CREATE privileges on *Local_schema* and USAGE permissions on *hcatalog_schema*.

Examples

The following example shows using `SYNC_WITH_HCATALOG_SCHEMA` to synchronize an HCatalog schema named `hcat`:

```
=> CREATE HCATALOG SCHEMA hcat WITH hostname='hcahost' HCATALOG_SCHEMA='default'
-> HCATALOG_USER='hcatuser';
CREATE SCHEMA
=> SELECT sync_with_hcatalog_schema('hcat', 'hcat');
sync_with_hcatalog_schema
-----
Schema hcat synchronized with hcat
tables in hcat = 56
tables altered in hcat = 0
tables created in hcat = 56
stale tables in hcat = 0
table changes erred in hcat = 0
(1 row)

=> -- Use vsql's \d command to describe a table in the synced schema

=> \d hcat.messages
List of Fields by Tables
 Schema | Table | Column | Type | Size | Default | Not Null | Primary Key | Foreign
Key
-----+-----+-----+-----+-----+-----+-----+-----+-----
-----
hcat    | messages | id      | int   | 8    |         | f        | f           |
hcat    | messages | userid  | varchar(65000) | 65000 |         | f        | f           |
hcat    | messages | "time"  | varchar(65000) | 65000 |         | f        | f           |
hcat    | messages | message | varchar(65000) | 65000 |         | f        | f           |
(4 rows)
```

The following example shows using `SYNC_WITH_HCATALOG_SCHEMA` followed by `ALTER TABLE` to adjust a column value:

```
=> CREATE HCATALOG SCHEMA hcat WITH hostname='hcahost' HCATALOG_SCHEMA='default'
-> HCATALOG_USER='hcatuser';
CREATE SCHEMA
=> SELECT sync_with_hcatalog_schema('hcat', 'hcat');
...
=> ALTER TABLE hcat.t ALTER COLUMN a1 SET DATA TYPE long varchar(1000000);
=> ALTER TABLE hcat.t ALTER COLUMN a2 SET DATA TYPE long varbinary(1000000);
```

The following example shows using `SYNC_WITH_HCATALOG_SCHEMA` with a local (non-HCatalog) schema:

```
=> CREATE HCATALOG SCHEMA hcat WITH hostname='hcahost' HCATALOG_SCHEMA='default'
-> HCATALOG_USER='hcatuser';
CREATE SCHEMA
=> CREATE SCHEMA hcat_local;
CREATE SCHEMA
=> SELECT sync_with_hcatalog_schema('hcat_local', 'hcat');
```

SYNC_WITH_HCATALOG_SCHEMA_TABLE

Copies the structure of a single table in a Hive database schema available through the HCatalog Connector to a Vertica table.

Syntax

```
SYNC_WITH_HCATALOG_SCHEMA_TABLE( local_schema, hcatalog_schema, table_name )
```

Parameters

<i>local_schema</i>	The existing Vertica schema to store the copied HCatalog schema's metadata. This can be the same schema as <i>hcatalog_schema</i> , or it can be a separate one created using CREATE SCHEMA.
<i>hcatalog_schema</i>	The HCatalog schema to copy. This is the schema created using CREATE HCATALOG SCHEMA.
<i>table_name</i>	The table in <i>hcatalog_schema</i> to copy.

Notes

If *table_name* does not exist in *hcatalog_schema*, this function returns an error.

If *table_name* already exists in *local_schema*, the SYNC_WITH_HCATALOG_SCHEMA_TABLE function overwrites it.

Hive STRING and BINARY data types are matched, in Vertica, to VARCHAR(65000) and VARBINARY(65000) types. You can use [ALTER TABLE](#) to adjust these after creating the schema. The maximum size of a VARCHAR or VARBINARY in Vertica is 65000, but you can use LONG VARCHAR and LONG VARBINARY to specify larger values.

Hive and Vertica define string length in different ways. In Hive the length is the number of characters; in Vertica it is the number of bytes. Thus, a character encoding that uses more than one byte, such as Unicode, can result in mismatches between the two. Set values in Vertica based on bytes, not characters, to avoid data truncation.

If the data size exceeds the declared size for the column, Vertica logs an event at read time in the QUERY_EVENTS system table.

This function can synchronize the HCatalog schema directly, in which case you call it with the same schema name for both of the *local_schema* and *hcatalog_schema* parameters. It can also synchronize a different schema to the HCatalog schema.

Privileges

The user must have CREATE privileges on *Local_schema* and USAGE permissions on *hcatalog_schema*.

Examples

The following example shows using SYNC_WITH_HCATALOG_SCHEMA_TABLE to synchronize the "nation" table:

```
=> CREATE HCATALOG SCHEMA hcat WITH hostname='hcatost' HCATALOG_SCHEMA='hcat_truth'  
-> HCATALOG_USER='hcatuser';  
CREATE SCHEMA  
=> SELECT sync_with_hcatalog_schema_table('hcat', 'hcat_truth', 'nation');  
sync_with_hcatalog_schema_table  
-----  
Schema hcat synchronized with hcat_truth for table nation  
table nation is created in schema hcat  
(1 row)
```

The following example shows the behavior if the "nation" table already exists in the local schema:

```
=> SELECT sync_with_hcatalog_schema_table('hcat', 'hcat_truth', 'nation');  
sync_with_hcatalog_schema_table  
-----  
Schema hcat synchronized with hcat_truth for table nation  
table nation is altered in schema hcat  
(1 row)
```

VERIFY_HADOOP_CONF_DIR

Verifies that the Hadoop configuration that is used to access HDFS is valid on all Vertica nodes. The configuration is valid if:

- all required configuration files are found on the path defined by the HadoopConfDir configuration parameter
- all properties needed by Vertica are set in those files

This function does not attempt to validate the settings of those properties; it only verifies that they have values.

It is possible for Hadoop configuration to be valid on some nodes and invalid on others. The function reports a validation failure if the value is invalid on any node; the rest of the output reports the details.

Syntax

```
VERIFY_HADOOP_CONF_DIR( )
```

Parameters

This function has no parameters.

Privileges

This function does not require privileges.

Examples

The following example shows the results when the Hadoop configuration is valid.

```
=> SELECT VERIFY_HADOOP_CONF_DIR();
       verify_hadoop_conf_dir
-----
Validation Success
v_vmart_node0001: HadoopConfDir [PG_TESTOUT/config] is valid
v_vmart_node0002: HadoopConfDir [PG_TESTOUT/config] is valid
v_vmart_node0003: HadoopConfDir [PG_TESTOUT/config] is valid
v_vmart_node0004: HadoopConfDir [PG_TESTOUT/config] is valid
(1 row)
```

In the following example, the Hadoop configuration is valid on one node, but on other nodes a needed value is missing.

```
=> SELECT VERIFY_HADOOP_CONF_DIR();
       verify_hadoop_conf_dir
-----
Validation Failure
v_vmart_node0001: HadoopConfDir [PG_TESTOUT/test_configs/config] is valid
v_vmart_node0002: No fs.defaultFS parameter found in config files in [PG_TESTOUT/config]
v_vmart_node0003: No fs.defaultFS parameter found in config files in [PG_TESTOUT/config]
v_vmart_node0004: No fs.defaultFS parameter found in config files in [PG_TESTOUT/config]
(1 row)
```

LDAP Link Functions

This section contains the functions associated with the Vertica [LDAP Link](#) function.

In This Section

LDAP_LINK_SYNC_START

Begins the synchronization between the LDAP server and Vertica immediately rather than waiting for the interval set in LDAPLinkInterval.

Syntax

```
ldap_link_sync_start()
```

Privileges

You must be a dbadmin user.

Example

```
=> SELECT ldap_link_sync_start();
```

See Also

[LDAP Link Parameters](#)

License Management Functions

This section contains function that monitor Vertica license status and compliance.

AUDIT

Estimates the raw data size of a database, schema, or table as it is counted in an audit of the database size.

AUDIT estimates the size using the same data sampling method as Vertica uses, to determine if a database complies with the licensed database size allowance. The results of this function are not considered when Vertica determines whether the size of the database complies with the Vertica license's data allowance. For details, see [Calculating the Database Size](#) in the Administrator's Guide.

Syntax

```
AUDIT('name'[, 'granularity'] [, error-tolerance[, confidence-level] ])
```

Parameters

<i>name</i>	The database, schema, or table to audit. If you supply an empty string (' '), AUDIT audits the database.
<i>granularity</i>	<p>The level at which the audit reports its results, one of the following strings:</p> <ul style="list-style-type: none">• database• schema• table <p>The level of granularity must be equal to or less than the granularity of <i>name</i>. If you omit this parameter, granularity is the same level as <i>name</i>. Thus, if <code>online_sales</code> is a schema, the following statements are identical:</p> <pre>AUDIT('sales', 'schema'); AUDIT('sales');</pre>

	<p>If granularity is less than <i>name</i>, AUDIT returns with a message that refers to system table <code>V_CATALOG.USER_AUDITS</code>. You can query this table to find detailed information on the objects within <i>name</i> at the specified granularity. For example:</p> <pre> => SELECT AUDIT('online_sales','table'); AUDIT ----- See table sizes in v_catalog.user_audits for schema online_sales (1 row) => SELECT * FROM user_audits WHERE object_schema='online_sales'; -[RECORD 1]-----+----- size_bytes 59016 user_id 45035996273704962 user_name dbadmin object_id 45035996273739208 object_type TABLE object_schema online_sales object_name online_page_dimension license_name vertica audit_start_timestamp 2016-06-17 10:37:31.238291-04 audit_end_timestamp 2016-06-17 10:37:31.358232-04 confidence_level_percent 99 error_tolerance_percent 20 used_sampling f confidence_interval_lower_bound_bytes 59016 confidence_interval_upper_bound_bytes 59016 sample_count 0 cell_count 0 -[RECORD 2]-----+----- ... </pre>
<p><i>error-tolerance</i></p>	<p>Specifies the percentage margin of error allowed in the audit estimate. Enter the tolerance value as a decimal number, between 0 and 100. The default value is 5, for a 5% margin of error.</p> <p>Setting this value to 0 results in a full database audit, which is very resource intensive, as AUDIT analyzes the entire database. A full database audit significantly impacts performance, so Vertica does not recommend it for a production database</p> <p>Due to the iterative sampling that the auditing process uses, making the error tolerance a small fraction of a percent (for example, 0.00001) can cause AUDIT to run for a longer period than a full database audit. The lower you specify this value, the more resources the audit uses, as it performs more data sampling.</p>
<p><i>confidence-level</i></p>	<p>Specifies the statistical confidence level percentage of the estimate. Enter the confidence value as a decimal number, between 0 and 100. The default value is 99, indicating a confidence level of 99%.</p>

The higher the confidence value, the more resources the function uses, since it performs more data sampling. Setting this value to 100 results in a full audit of the database, which is very resource intensive, as the function analyzes all of the database. A full database audit significantly impacts performance, so Vertica does not recommend it for a production database.

Privileges

Non-superuser:

- Table: SELECT privilege
- Schema: USAGE privilege
- Database: Only audits the size of data that the user has permission to access

Examples

Audit the entire database:

```
=> SELECT AUDIT('');  
AUDIT  
-----  
76376696  
(1 row)
```

Audit the database with 25% error tolerance:

```
=> SELECT AUDIT('',25);  
AUDIT  
-----  
75797126  
(1 row)
```

Audit the database with a 25% level of tolerance and a 0% confidence level:

```
=> SELECT AUDIT('',25,90);  
AUDIT  
-----  
76402672  
(1 row)
```

Audit schema `online_sales`:

```
=> SELECT AUDIT('online_sales');  
AUDIT
```

```
-----
35716504
(1 row)
```

Audit schema `online_sales` and report the results by table:

```
=> SELECT AUDIT('online_sales','table');
          AUDIT
-----
See table sizes in v_catalog.user_audits for schema
online_sales
(1 row)
=> \x
Expanded display is on.
=> SELECT * FROM user_audits WHERE object_schema =
'online_sales';
-[ RECORD 1 ]-----+-----

cell_count            | 9000000
```

AUDIT_FLEX

Estimates the ROS size of one or more flexible tables contained in a database, schema, or projection.

The `audit_flex()` function measures the export size of the flex data values (does not include flex keys) for the `__raw__` column of one or more flexible tables. The function does not audit other flex table columns that are created as, or promoted to, real columns. Temporary flex tables are not included in the audit.

Each time a user calls `audit_flex()`, Vertica stores the results in the `V_CATALOG.USER_AUDITS` system table.

Syntax

```
AUDIT_FLEX (name)
```

Parameters

<i>name</i>	<p>Specifies what database entity to audit. Enter the entity name as a string in single quotes (' '), as follows:</p> <ul style="list-style-type: none">• Empty string (' ') — Return the size of the ROS containers for all flexible tables in the database. You cannot enter the database name.• Schema name (' schema_name ') — Return the size of all <code>__raw__</code> columns of flexible tables in <code>schema_name</code>.• A projection name (' proj_name ') — Return the ROS size of a projection for a <code>__raw__</code> column.• A flex table name (' flex_table_name ') — Return the ROS size of a flex table's <code>__raw__</code> column.
-------------	---

Privileges

- SELECT privilege on table
- USAGE privilege on schema

Note: AUDIT_FLEX() works only on the flexible tables, projections, schemas, and databases to which the user has permissions.

Examples

To audit the flex tables in the database:

```
dbs=> select audit_flex('');
audit_flex
-----
8567679
(1 row)
```

To audit the flex tables in a specific schema, such as public:

```
dbs=> select audit_flex('public');
audit_flex
-----
8567679
(1 row)
```

To audit the flex tables in a specific projection, such as bakery_b0:

```
dbs=> select audit_flex('bakery_b0');
audit_flex
-----
8566723
(1 row)
```

To audit a flex table, such as bakery:

```
dbs=> select audit_flex('bakery');
audit_flex
-----
8566723
(1 row)
```

To report the results of all audits saved in the USER_AUDITS, the following shows part of an extended display from the system table showing an audit run on a schema called test, and the entire database, dbs:

```
db>=> \x
Expanded display is on.

db>=> select * from user_audits;
-[ RECORD 1 ]-----+-----

-[ RECORD 3 ]-----+-----
.
.
.
```

AUDIT_LICENSE_SIZE

Triggers an immediate audit of the database size to determine if it is in compliance with the raw data storage allowance included in your Vertica licenses.

Syntax

```
AUDIT_LICENSE_SIZE()
```

Privileges

Superuser

Example

```
=> SELECT audit_license_size();
  audit_license_size
-----
Raw Data Size: 0.00TB +/- 0.00TB
License Size : 10.00TB
Utilization  : 0%
Audit Time   : 2015-09-24 12:19:15.425486-04
Compliance Status : The database is in compliance with respect to raw data size.

License End Date: 2015-11-23 00:00:00 Days Remaining: 60.53
(1 row)
```

AUDIT_LICENSE_TERM

Triggers an immediate audit to determine if the Vertica license has expired.

Syntax

```
AUDIT_LICENSE_TERM()
```

Privileges

Superuser

Example

```
=> SELECT audit_license_term();
  audit_license_term
-----
Raw Data Size: 0.00TB +/- 0.00TB
License Size : 10.00TB
Utilization  : 0%
Audit Time   : 2015-09-24 12:19:15.425486-04
Compliance Status : The database is in compliance with respect to raw data size.

License End Date: 2015-11-23 00:00:00 Days Remaining: 60.53
(1 row)
```

GET_AUDIT_TIME

Reports the time when the automatic audit of database size occurs. Vertica performs this audit if your Vertica license includes a data size allowance. For details of this audit, see [Managing Licenses](#) in the Administrator's Guide. To change the time the audit runs, use the [SET_AUDIT_TIME](#) function.

Syntax

```
GET_AUDIT_TIME()
```

Privileges

None

Example

```
=> SELECT get_audit_time();
get_audit_time
-----
The audit is scheduled to run at 11:59 PM each day.
(1 row)
```

GET_COMPLIANCE_STATUS

Displays whether your database is in compliance with your Vertica license agreement. This information includes the results of Vertica's most recent audit of the database size (if your license has a data allowance as part of its terms), and the license term (if your license has an end date).

GET_COMPLIANCE_STATUS measures data allowance by TBs (where a TB equals 1024⁴ bytes).

The information displayed by GET_COMPLIANCE_STATUS includes:

- The estimated size of the database (see [How Vertica Calculates Database Size](#) in the Administrator's Guide for an explanation of the size estimate).
- The raw data size allowed by your Vertica license.
- The percentage of your allowance that your database is currently using.

- The date and time of the last audit.
- Whether your database complies with the data allowance terms of your license agreement.
- The end date of your license.
- How many days remain until your license expires.

Note: If your license does not have a data allowance or end date, some of the values may not appear in the output for `GET_COMPLIANCE_STATUS`.

If the audit shows your license is not in compliance with your data allowance, you should either delete data to bring the size of the database under the licensed amount, or upgrade your license. If your license term has expired, you should contact Micro Focus immediately to renew your license. See [Managing Licenses](#) in the Administrator's Guide for further details.

Syntax

```
GET_COMPLIANCE_STATUS()
```

Privileges

None

Example

```
=> SELECT get_compliance_status();
  get_compliance_status
-----
Raw Data Size: 0.00TB +/- 0.00TB
License Size : 10.00TB
Utilization  : 0%
Audit Time   : 2015-09-24 12:19:15.425486-04
Compliance Status : The database is in compliance with respect to raw data size.

License End Date: 2015-11-23 00:00:00 Days Remaining: 60.53
(1 row)
```

DISPLAY_LICENSE

Returns the terms of your Vertica license. The information this function displays is:

- The start and end dates for which the license is valid (or "Perpetual" if the license has no expiration).
- The number of days you are allowed to use Vertica after your license term expires (the grace period)
- The amount of data your database can store, if your license includes a data allowance.

Syntax

```
DISPLAY_LICENSE()
```

Privileges

None

Examples

```
=> SELECT DISPLAY_LICENSE();
          DISPLAY_LICENSE
-----
Vertica Systems, Inc.
1/1/2011
12/31/2011
30
50TB
(1 row)
```

SET_AUDIT_TIME

Sets the time that Vertica performs automatic database size audit to determine if the size of the database is compliant with the raw data allowance in your Vertica license. Use this function if the audits are currently scheduled to occur during your database's peak activity time. This is normally not a concern, since the automatic audit has little impact on database performance.

Audits are scheduled by the preceding audit, so changing the audit time does not affect the next scheduled audit. For example, if your next audit is scheduled to take place at 11:59PM and you use `SET_AUDIT_TIME` to change the audit schedule 3AM, the previously scheduled 11:59PM audit still runs. As that audit finishes, it schedules the next audit to occur at 3AM.

Vertica always performs the next scheduled audit even where you have changed the audit time using `SET_AUDIT_TIME` and then triggered an automatic audit by issuing the statement, `SELECT AUDIT_LICENSE_SIZE`. Only after the next scheduled audit does Vertica begin auditing at the new time you set using `SET_AUDIT_TIME`. Thereafter, Vertica audits at the new time.

Syntax

`SET_AUDIT_TIME(time)`

<i>time</i>	A string containing the time in 'HH:MM AM/PM' format (for example, '1:00 AM') when the audit should run daily.
-------------	--

Privileges

Superuser

Example

```
=> SELECT SET_AUDIT_TIME('3:00 AM');
          SET_AUDIT_TIME
-----
The scheduled audit time will be set to 3:00 AM after the next audit.
(1 row)
```

Multiple Active Result Sets Functions

This section contains the functions associated with the Vertica library for Multiple Active Result Sets (MARS).

CLOSE_ALL_RESULTSETS

Closes all result set sessions within Multiple Active Result Sets (MARS) and frees the MARS storage for other result sets.

Syntax

```
SELECT CLOSE_ALL_RESULTSETS ('session_id')
```

Parameters

<i>session_id</i>	A string that specifies the Multiple Active Result Sets session.
-------------------	--

Privileges

None; however, without superuser privileges, you can only close your own session's results.

Examples

This example shows how you can view a MARS result set, then close the result set, and then confirm that the result set has been closed.

Query the MARS storage table. One session ID is open and three result sets appear in the output.

```
SELECT * FROM SESSION_MARS_STORE;
```

node_name	session_id	user_name	resultset_id	row_count	remaining_row_count	bytes_used
v_vmart_node0001	server1.company.-83046:1y28gu9	dbadmin	7	777460	776460	89692848
v_vmart_node0001	server1.company.-83046:1y28gu9	dbadmin	8	324349	323349	81862010
v_vmart_node0001	server1.company.-83046:1y28gu9	dbadmin	9	277947	276947	32978280

(1 row)

Close all result sets for session server1.company.-83046:1y28gu9:

```
SELECT CLOSE_ALL_RESULTSETS('server1.company.-83046:1y28gu9');
```

close_all_resultsets

Closing all result sets from server1.company.-83046:1y28gu9

(1 row)

Query the MARS storage table again for the current status. You can see that the session and result sets have been closed:

```
SELECT * FROM SESSION_MARS_STORE;
```

node_name	session_id	user_name	resultset_id	row_count	remaining_row_count	bytes_used
-----------	------------	-----------	--------------	-----------	---------------------	------------

(0 rows)

CLOSE_RESULTSET

Closes a specific result set within Multiple Active Result Sets (MARS) and frees the MARS storage for other result sets.

Syntax

```
SELECT CLOSE_RESULTSET ('session_id', ResultSetID)
```

Parameters

session_id	A string that specifies the Multiple Active Result Sets session containing the ResultSetID to close.
ResultSetID	An integer that specifies which result set to close.

Privileges

None; however, without superuser privileges, you can only close your own session's results.

Examples

This example shows a MARS storage table opened. One session_id is currently open, and one result set appears in the output.

```
SELECT * FROM SESSION_MARS_STORE;
   node_name      | session_id          | user_name | resultset_id | row_count |
remaining_row_count | bytes_used
-----+-----+-----+-----+-----+-----
v_vmart_node0001 | server1.company.-83046:1y28gu9 | dbadmin  |             1 |      318718 |
      312718 |      80441904
(1 row)
```

Close user session server1.company.-83046:1y28gu9 and result set 1:

```
SELECT CLOSE_RESULTSET('server1.company.-83046:1y28gu9', 1);
      close_resultset
-----
Closing result set 1 from server1.company.-83046:1y28gu9
(1 row)
```

Query the MARS storage table again for current status. You can see that result set 1 is now closed:

```
SELECT * FROM SESSION_MARS_STORE;
```

```
node_name      | session_id      | user_name | resultset_id | row_count |
remaining_row_count | bytes_used
-----+-----+-----+-----+-----+-----
(0 rows)
```

Partition Management Functions

This section contains partition management functions specific to Vertica.

COPY_PARTITIONS_TO_TABLE

Copies partitions from one table to another. This lightweight partition copy increases performance by initially sharing the same storage between two tables. After the copy operation is complete, the tables are independent of each other. Users can perform operations on one table without impacting the other. These operations can increase the overall storage required for both tables.

Note: Although they share storage space, Vertica considers the partitions as discrete objects for license capacity purposes. For example, copying a one TB partition would only consume one TB of space. Your Vertica license, however, considers them as separate objects consuming two TB of space.

Syntax

```
COPY_PARTITIONS_TO_TABLE (  
    '[schema.]source-table',  
    'min-range-value',  
    'max-range-value',  
    '[schema.]target-table'  
)
```

Parameters

<i>schema</i>	Specifies a schema. If multiple schemas are defined in the database, include the schema name. For example: <pre>myschema.thisDBObject</pre>
<i>source-table</i>	The source table of the partitions to copy.
<i>min-range-value</i>	The minimum value of the partition to copy. To copy one partition, the minimum and maximum values must be the same.
<i>max-range-value</i>	The maximum value of the partition to be copied. To copy one partition, the minimum and maximum values must be the same.

<i>target-table</i>	The target table of the partitions to copy. If the table does not exist, Vertica creates a table from the source table's definition, by calling CREATE TABLE with LIKE and INCLUDING PROJECTIONS clause. The new table inherits ownership from the source table. For details, see Replicating a Table ..
---------------------	--

Privileges

- Ownership or USAGE privileges on the source table.
- CREATE privileges on the target table, if COPY_PARTITIONS_TO_TABLE creates it.

Table Attribute Requirements

The following attributes of both tables must be identical:

- Column definitions, including NULL/NOT NULL constraints
- Segmentation
- Partitioning expression
- Number of projections
- Projection sort order
- Primary and unique key constraints. However, the key constraints do not have to be identically enabled. For more information on constraints, refer to [Enforcing Primary Key and Foreign Key Constraints](#).

Note: If the target table has primary or unique key constraints enabled and copying or moving the partitions will insert duplicate key values into the target table, Vertica rolls back the operation.

- Check constraints. For [MOVE_PARTITIONS_TO_TABLE](#) and [COPY_PARTITIONS_TO_TABLE](#), Vertica enforces enabled check constraints on the target table only. For [SWAP_PARTITIONS_BETWEEN_TABLES](#), Vertica enforces enabled check constraints on both tables. If there is a violation of an enabled check constraint, Vertica rolls back the operation.
- Number and definitions of text indices.

Table Restrictions

The following restrictions apply to the source and target tables:

- If the source and target partitions are in different storage tiers, Vertica returns a warning but the operation proceeds. The partitions remain in their existing storage tier.
- The following tables cannot be used as sources or targets:
 - Temporary tables
 - Virtual tables
 - System tables
 - External tables

Examples

If you call `COPY_PARTITIONS_TO_TABLE` and the target table does not exist, the function creates the table automatically. In the following example, the target table `partn_backup.tradfes_200801` does not exist. `COPY_PARTITIONS_TO_TABLE` creates the table and replicates the partition. Vertica also copies all the constraints associated with the source table except foreign key constraints.

```
=> SELECT COPY_PARTITIONS_TO_TABLE (  
        'prod_trades',  
        '200801',  
        '200801',  
        'partn_backup.tradfes_200801');  
COPY_PARTITIONS_TO_TABLE  
-----  
 1 distinct partition values copied at epoch 15.  
(1 row)
```

See Also

[Archiving Partitions](#)

DROP_PARTITION

Drops the specified partition. If the WOS contains table data, `DROP_PARTITION` forces a moveout before it executes the drop operation.

Syntax

```
DROP_PARTITION (
  '[schema.]table-name',
  partition-value
  [, ignore-moveout-errors]
  [, reorganize-data ]
)
```

Parameters

<i>schema</i>	<p>Specifies a schema. If multiple schemas are defined in the database, include the schema name. For example:</p> <pre>myschema.thisDBObject</pre>
<i>table-name</i>	The target table. The table cannot be used as a dimension table in a pre-join projection and cannot have out-of-date (unrefreshed) projections.
<i>partition-value</i>	The key of the partition to drop.
<i>ignore-moveout-errors</i>	<p>Optional Boolean argument:</p> <ul style="list-style-type: none"> <code>true</code>: Ignores any WOS moveout errors and forces the operation to continue. Set this parameter to <code>true</code> only if there is no WOS data for the partition. <code>false</code> (default): Displays any moveout errors and aborts the operation on error. <p>Note: If you set this parameter to <code>true</code> and the WOS includes data for the partition in WOS, partition data in WOS is not dropped.</p>
<i>reorganize-data</i>	<p>Optional Boolean argument:</p> <ul style="list-style-type: none"> <code>true</code>: Reorganizes the data if it is not organized, and then drops the partition. <code>false</code>: Does not attempt to reorganize the data before dropping the partition. If this parameter is <code>false</code> and the function encounters a ROS without partition keys, an

	error occurs.
--	---------------

Privileges

One of the following:

- DBADMIN
- Table owner
- USAGE privileges on the table schema and TRUNCATE privileges on the table

Examples

See [Dropping Partitions](#) in the Administrator's Guide.

See Also

- [DUMP_PARTITION_KEYS](#)
- [DUMP_PROJECTION_PARTITION_KEYS](#)
- [DUMP_TABLE_PARTITION_KEYS](#)
- [PARTITION_TABLE](#)

DUMP_PROJECTION_PARTITION_KEYS

Dumps the partition keys of the specified projection.

Syntax

```
DUMP_PROJECTION_PARTITION_KEYS( '[schema.]projection-name'
```

Parameters

<i>schema</i>	Specifies a schema . If multiple schemas are defined in the database, include the schema name. For example: <pre>myschema.thisDBObject</pre>
---------------	---

<i>projection-name</i>	The projection name.
------------------------	----------------------

Privileges

- SELECT privilege on table
- USAGE privileges on schema

Example

The following statements create the table and projection `online_sales.online_sales_fact` and `online_sales.online_sales_fact_unseg_p`, respectively, and partitions table data by the column `call_center_key`:

```
=> CREATE TABLE online_sales.online_sales_fact
(
  sale_date_key int NOT NULL,
  ship_date_key int NOT NULL,
  product_key int NOT NULL,
  product_version int NOT NULL,
  customer_key int NOT NULL,
  call_center_key int NOT NULL,
  online_page_key int NOT NULL,
  shipping_key int NOT NULL,
  warehouse_key int NOT NULL,
  promotion_key int NOT NULL,
  pos_transaction_number int NOT NULL,
  sales_quantity int,
  sales_dollar_amount float,
  ship_dollar_amount float,
  net_dollar_amount float,
  cost_dollar_amount float,
  gross_profit_dollar_amount float,
  transaction_type varchar(16)
)
PARTITION BY (online_sales_fact.call_center_key);

=> CREATE PROJECTION online_sales.online_sales_fact_unseg_p AS SELECT * from online_sales.online_sales_fact unsegmented all nodes;
```

The following `DUMP_PROJECTION_PARTITION_KEYS` statement dumps the partition key from the projection `online_sales.online_sales_fact_unseg_p`:

```
=> SELECT DUMP_PROJECTION_PARTITION_KEYS('online_sales.online_sales_fact_unseg_p');

Partition keys on node v_vmart_node0001
Projection 'online_sales_fact_unseg_p'
Storage [ROS container]
  No of partition keys: 1
  Partition keys: 200
Storage [ROS container]
```

```
No of partition keys: 1
Partition keys: 199
...
Storage [ROS container]
  No of partition keys: 1
  Partition keys: 2
Storage [ROS container]
  No of partition keys: 1
  Partition keys: 1

Partition keys on node v_vmart_node0002
Projection 'online_sales_fact_unseg_p'
Storage [ROS container]
  No of partition keys: 1
  Partition keys: 200
Storage [ROS container]
  No of partition keys: 1
  Partition keys: 199
...
(1 row)
```

DUMP_TABLE_PARTITION_KEYS

Dumps the partition keys of all projections for the specified table.

Syntax

```
DUMP_TABLE_PARTITION_KEYS ( 'table-name' )
```

Parameters

<i>table-name</i>	The name of the table.
-------------------	------------------------

Privilege

- SELECT privilege on table
- USAGE privileges on schema

Examples

The following example creates a simple table called `states` and partitions the data by state:

```
=> CREATE TABLE states (year INTEGER NOT NULL,  
    state VARCHAR NOT NULL)  
    PARTITION BY state;  
=> CREATE PROJECTION states_p (state, year) AS  
    SELECT * FROM states  
    ORDER BY state, year UNSEGMENTED ALL NODES;
```

Now dump the partition keys of all projections anchored on table `states`:

```
=> SELECT DUMP_TABLE_PARTITION_KEYS( 'states' );  
    DUMP_TABLE_PARTITION_KEYS  
-----  
Partition keys on node v_vmart_node0001  
Projection 'states_p'  
Storage [ROS container]  
  No of partition keys: 1  
  Partition keys: VT  
Storage [ROS container]  
  No of partition keys: 1  
  Partition keys: PA  
Storage [ROS container]  
  No of partition keys: 1  
  Partition keys: NY  
Storage [ROS container]  
  No of partition keys: 1  
  Partition keys: MA  
  
Partition keys on node v_vmart_node0002  
...  
(1 row)
```

MOVE_PARTITIONS_TO_TABLE

Moves partitions from one table to another.

Syntax

```
MOVE_PARTITIONS_TO_TABLE (  
  '[schema.]source-table',  
  'min-range-value',  
  'max-range-value',  
  '[schema.]target-table'  
)
```

Parameters

<i>schema</i>	Specifies a schema . If multiple schemas are defined in the database, include the schema name. For example: <pre>myschema.thisDBObject</pre>
<i>source-table</i>	The source table of the partitions to move.
<i>min-range-value</i>	The minimum value of the partition to move. To move one partition, the minimum and maximum values must be the same.
<i>max-range-value</i>	The maximum value of the partition to be moved. To move one partition, the minimum and maximum values must be the same.

<i>target-table</i>	The target table of the partitions to move. If the table does not exist, Vertica creates a table from the source table's definition, by calling <code>CREATE TABLE</code> with <code>LIKE</code> and <code>INCLUDING PROJECTIONS</code> clause. The new table inherits ownership from the source table. For details, see Replicating a Table .
---------------------	--

Privileges

If the target table does not exist, you must have `CREATE` privileges on the target schema, to enable table creation. One of the following conditions is also required:

- `DBADMIN` role
- Owner of the source and target tables
- `USAGE` privileges on source and target schemas, `TRUNCATE` privileges on the source table, and `INSERT` privileges on the target table

Table Attribute Requirements

The following attributes of both tables must be identical:

- Column definitions, including `NULL/NOT NULL` constraints
- Segmentation
- Partitioning expression
- Number of projections
- Projection sort order
- Primary and unique key constraints. However, the key constraints do not have to be identically enabled. For more information on constraints, refer to [Enforcing Primary Key and Foreign Key Constraints](#).

Note: If the target table has primary or unique key constraints enabled and copying or moving the partitions will insert duplicate key values into the target table, Vertica rolls back the operation.

- Check constraints. For `MOVE_PARTITIONS_TO_TABLE` and `COPY_PARTITIONS_TO_TABLE`, Vertica enforces enabled check constraints on the target table only. For `SWAP_`

[PARTITIONS_BETWEEN_TABLES](#), Vertica enforces enabled check constraints on both tables. If there is a violation of an enabled check constraint, Vertica rolls back the operation.

- Number and definitions of text indices.

Table Restrictions

The following restrictions apply to the source and target tables:

- If the source and target partitions are in different storage tiers, Vertica returns a warning but the operation proceeds. The partitions remain in their existing storage tier.
- The following tables cannot be used as sources or targets:
 - Temporary tables
 - Virtual tables
 - System tables
 - External tables

Examples

See [Archiving Partitions](#).

- [SWAP_PARTITIONS_BETWEEN_TABLES](#)

PARTITION_PROJECTION

Splits ROS containers for a specified projection. `PARTITION_PROJECTION` also purges data while partitioning ROS containers if deletes were applied before the AHM epoch.

Syntax

```
PARTITION_PROJECTION ( '[schema.]projection-name'
```

Parameters

<i>schema</i>	Specifies a schema . If multiple schemas are defined in the database, include the schema name. For example: <pre>myschema.thisDBObject</pre>
<i>projection-name</i>	The projection to partition.

Privileges

- Table owner
- USAGE privilege on schema

Examples

In this example, PARTITION_PROJECTION forces a split of ROS containers on the states_p projection:

```
=> SELECT PARTITION_PROJECTION ('states_p');
PARTITION_PROJECTION
-----
Projection partitioned
(1 row)
```
